General preparation 401
Create a resource location 401
Connect your AWS account 402
Create AssumeRole for Amazon WorkSpaces Core integration 404
(Optional) Set up BYOL for your account 407
Create a directory connection 409
Import an image 410
Requirements for Dedicated Tenancy Images 411
Requirements for Default or Shared Tenancy Images 412
OS, Directory Type, and Session Support Compatibility 413
Integrate Microsoft Office 2019 Image when importing an image 413
Create a custom image from an existing WorkSpaces instance 414
Create a deployment 417
Integrate Microsoft 365 Windows apps 419
Manage machines in a deployment 419
Add applications to a deployment 419
Use persistent desktops with a non-persistent user profile 420
Reference 420
AWS account programmatic access permissions 420
Citrix DaaS™ for Google Cloud 424
Quick Deploy for Google Cloud 425
Launch Quick Deploy for Google Cloud 425
Manage user access rights 426
Convert a deployment 427
Use DaaS get-started guide 428
Benefits 428
Supported deployment scenarios 428

Prepare a master image on the hypervisor or cloud service 930
Volume licensing activation 932
Key Management Service (KMS) 932
Active Directory-based activation (ADBA) 932
Multiple Activation Key (MAK) 932
Create a machine catalog using Studio 934
Launch the catalog creation wizard 935
Select a machine type 935
Select machine management options 936
Select a desktop experience 937
Select an image and a machine profile 938
Configure the machines 940
Security 945
Configure NICs for the machines 945
Add machine accounts 945
Configure identities for machines in the catalog 946
Add domain credentials 950
Select a WEM configuration set for Experience Optimization 951
Upgrade VDA (optional) 952
Review the settings 953
Create an MCS machine catalog using PowerShell commands 954
Assign a specific drive letter to an MCS I/O write-back cache disk 954
Important consideration about setting custom properties 956
Important consideration about setting ProvScheme parameters 956
Add SIDs while creating virtual machines 957
Validate configuration before creating an MCS machine catalog 958
Onboard VMs to Azure Arc 959
Prerequisites 960

Overview

Introduction

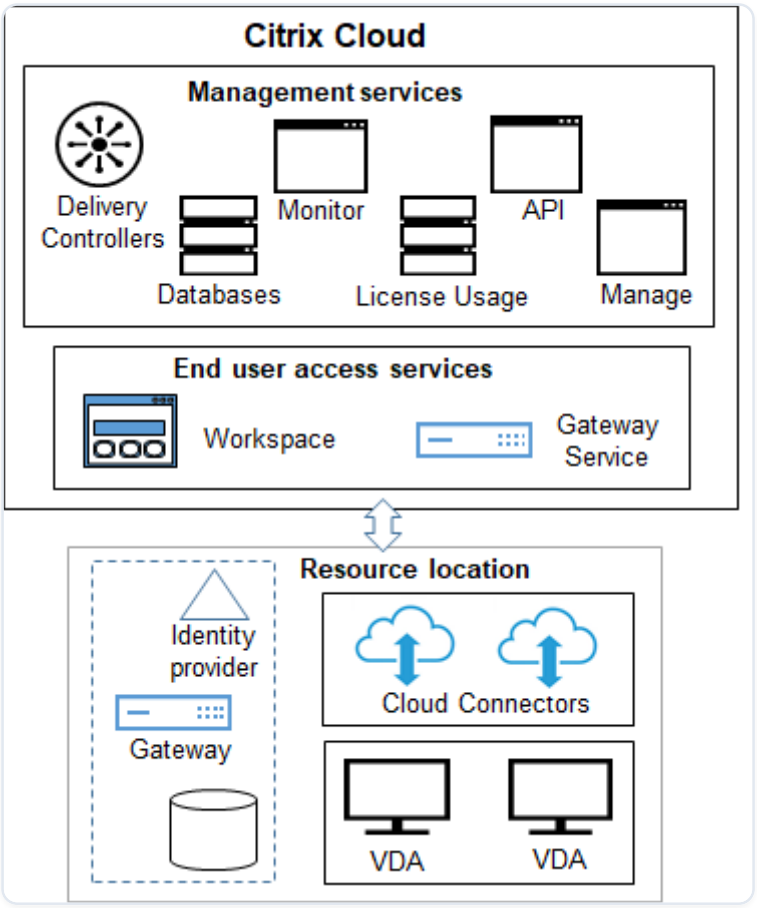
Citrix DaaS™ is a service that provides app and desktop virtualization, giving IT control of on-prem or cloud-hosted virtual machines, applications, and security while providing anywhere access for any device. End users can use applications and desktops independently of the device's operating system and interface.

Using Citrix DaaS, you can deliver secure virtual apps and desktops to any device, leaving most of the installation, setup, and upgrades to Citrix. You maintain complete control over applications, policies, and users while delivering the best user experience on any device.

Citrix DaaS allows you to manage on-premises data center and public cloud workloads together in a hybrid deployment. You can connect to public clouds Microsoft Azure, Amazon Web Services (AWS), and Google Cloud, plus on-premises hypervisors such as XenServer®, Microsoft Hyper-V, Nutanix AHV, and VMware vSphere. The hybrid, multi-cloud approach gives you the flexibility to deploy different applications in different resource locations worldwide.

Citrix DaaS offers several ways to deliver apps and desktops.

- Delivery methods describes the primary ways, with use-cases and pros/cons.
- Delivery models lists more choices, and also offers VDI model comparisons.



Citrix Managed Azure further simplifies the deployment of virtual apps and desktops. With Citrix Managed Azure, Citrix also manages the hosting of Azure workloads.

Learn more about the advantages of using this service.

Site overview

The following graphic shows the services and components that Citrix administrators work with in a Citrix DaaS production deployment (also known as a site).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

As shown in the graphic, Citrix manages the user access and management services and components in Citrix Cloud. The applications and desktops that you deliver to users reside on machines in one or more resource locations. In a Citrix DaaS deployment, a resource location contains components from the access layer and resource layers. Each resource location is considered a zone.

If you recently migrated from Citrix Virtual Apps and Desktops™, you'll see that Citrix DaaS eliminates most of the component setup work required in an on-premises deployment.

Components and services managed by Citrix

- **Delivery Controllers:** Citrix DaaS provides the functionality to load balance applications and desktops, authenticate users, and broker or prioritize connections directly from the cloud, without the need to manage Delivery Controllers, as with Citrix Virtual Apps and Desktops.
- **Databases:** Site configuration, monitoring, and configuration logging data is stored by the cloud service, eliminating the SQL database requirement of the on-premises Citrix Virtual Apps and Desktops product.
- **Licensing:** Manages licenses and provides usage statistics.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Studio:** A web-based, central console that lets you configure, manage, and monitor your DaaS deployments for delivering virtual apps and desktops. For more information, see Plan and build a deployment and Manage your deployments.

  You can also use service APIs and PowerShell commands to configure and manage your DaaS deployments.

- **Monitor:** The Monitor console enables IT support and help desk teams to monitor an environment, troubleshoot issues before they become critical, and perform support tasks for end users. Displays include:

  - Real-time session data from the Broker Service in the Controller, which includes data from the broker agent in the Virtual Deliver Agent (VDA).
  - Historical data from the Monitor Service in the Controller.
  - Data about HDX™ traffic (also known as ICA traffic).

- **Cloud Connectors:** A Cloud Connector is the communications channel between the components in the Citrix Cloud and components in the resource location. In the resource location, the Cloud Connector acts as a proxy for the Delivery Controller™ in Citrix Cloud.

  Every resource location contains at least one Cloud Connector. Two or more Cloud Connectors are recommended for redundancy.

  - When using Studio to provision machines, you first install Cloud Connectors from the Citrix Cloud™ console. For details, see Cloud Connectors.
  - When using Quick Deploy to provision Azure machines, Citrix creates the resource location and Cloud Connectors for you when you create a catalog.

  After Cloud Connectors are installed, Citrix manages and updates them. The only tasks handled by the customer are Cloud Connector Windows updates and patching.

Studio

Studio is a web-based, central portal that lets you configure, manage, and monitor your DaaS deployments for delivering virtual apps and desktops.

CALLOUT	AREA	DESCRIPTION	
		indicate its progress.	
		• Task Center displays a comprehensive list of all tasks, organized by category. The UI provides Filter, Search, and other controls consistent with the main view. You can perform actions on any listed task, including common actions like **Delete** and **View details**, and task-specific actions such as Rerun task and Export sub-task status.	

Components and technologies managed by the customer

- **Citrix Gateway:** When users connect from outside the corporate firewall, Citrix DaaS can use Citrix Gateway technology to secure these connections with TLS. The Citrix Gateway or VPX virtual appliance is an SSL VPN appliance deployed in the DMZ. It provides a single secure point of access through the corporate firewall.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Citrix installs and manages the Citrix Gateway service in Citrix Cloud. You can also optionally install Citrix Gateway in resource locations.

- **Active Directory:** Active Directory is used for authentication and authorization. It authenticates users and ensures that they are getting access to appropriate resources. A subscriber's identity defines the services to which they have access in Citrix Cloud. This identity comes from Active Directory domain accounts provided from the domains within the resource location.
- **Identity Provider (IdP):** The IdP is the final authority for the user's identity. Supported IdPs include: on-premises Active Directory, Active Directory plus token, Microsoft Entra ID, Citrix Gateway, and Okta. For more information, see:
  - Tech Brief: Workspace Identity
  - Identity and access management
- **Virtual Delivery Agents (VDAs):** Each physical or virtual machine that delivers resources (applications and desktops) must have a Citrix VDA installed on it. VDAs establish and manage the connection between the machine on which it's installed and the user device, and apply policies that are configured for the session.

  The VDA registers with a Delivery Controller, using a Cloud Connector in the resource location as a proxy.

  Several VDA types are available:

  - VDAs for Windows multi-session operating systems allow multiple users to connect to the machine at one time. This VDA type is usually installed on Windows servers.
  - VDAs for Windows single-session operating systems allow one user to connect to a machine at a time. This VDA type is usually used for VDI.

    A core version of this VDA type is available for use with the Remote PC Access feature. It contains a subset of the features in the full single-session VDA.
  - Linux VDAs support virtual apps and desktops based on an RHEL, CentOS, SUSE, or Ubuntu distribution.

  Throughout this service's documentation, "VDA" often refers to the agent and the machine on which it is installed.
- **Hypervisors and cloud services:** In most production sites, the app and desktop instances (workloads) that you make available (publish) to your users are "hosted" by a supported

© 1997–2026 Citrix Systems, Inc. All rights reserved.

hypervisor or cloud service. (The Remote PC Access feature is usually used with physical machines. Therefore, it does not use hypervisors or cloud services for machine provisioning.)

  - When using Studio, you first create a connection to a supported host hypervisor or cloud service. Next, you use an image (created through that host) to create a catalog of machines that contain the app and desktop instances. Finally, you create a delivery group. Citrix provides various tools to simplify and facilitate how these session hosts are built and maintained.
  - When using Quick Deploy to deliver Azure workloads, you only need to create the catalog. Although you can use your own Azure subscription when creating the catalog, using a Citrix Managed Azure subscription eliminates your need to manage the host, too.

  The app and desktop instances that you publish can be on-premises, hosted in public clouds, or in a hybrid mixture of both.

- **Citrix StoreFront™:** Citrix StoreFront is the customer hosted access tier, as an alternative to Citrix® StoreFront Cloud. For more information, see StoreFront and Citrix® StoreFront Cloud).

Objects you configure to deliver desktops and applications

You configure the following items to deliver apps and desktops in a production environment.

- **Host connection:** A host connection (mentioned earlier) helps enable communication between components in the control plane (Citrix Cloud) and VDAs in a resource location. Connection specifications include:

  - The address and credentials to access the host
  - The storage method to use, and the machines to use for storage
  - Which network the VMs can use

  Remember: When using Quick Deploy, you don't have to create a connection. And if you use Citrix Managed Azure, Citrix manages the hosting, as well.

- **Catalog:** In the Studio and Monitor interfaces, catalogs are called "machine catalogs." A catalog is a collection of virtual or physical machines that have the same operating system type (for example, Windows multi-session, Ubuntu single-session).

  When creating a catalog, you usually use an image, which is also known as a template. (Remote PC Access catalogs usually contain physical machines, so no image is needed.)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - When using Quick Deploy, Citrix provides several Citrix prepared images you can use to create your own customized images. Or, you can import images from your own Azure subscription.
  - When using Studio to create VMs using a supported host type, the image usually must be created and reside on a host machine. When creating the catalog, you provide the path to that image.

  Regardless of where the image resides, you can install applications on the image, if you want those apps on all machines created from that image (and don't want to virtualize those apps).

  After the image is ready, you create the catalog.

  - For VMs, MCS creates the machines and the catalog.
  - For Remote PC Access, MCS simply creates the catalog, because the physical machines already exist.

  For more information about MCS, see Image management.

- **Delivery group:** A delivery group specifies:

  - One or more machines from a catalog.
  - Users who are allowed to access those machines.
  - The applications and desktops that users can access through their store.

  When using Quick Deploy, a delivery group is created automatically. (It appears only in the Studio interface.)

- **Application group:** Application groups let you manage collections of applications. You can create application groups for applications shared across different delivery groups or used by a subset of users within delivery groups. Application groups are optional.

Citrix Managed Azure

Citrix Managed Azure is an option available in several Citrix DaaS editions. Using Citrix Managed Azure simplifies the deployment of virtual apps and desktops from Azure. Citrix manages the infrastructure for hosting Azure workloads.

With Citrix Managed Azure, you get a dedicated Citrix-managed Azure subscription and resource location. In that Azure subscription, you create a catalog of VMs. You can:

- Deploy single-session and multi-session Windows OS machines or Linux OS machines, from various supported versions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Choose from a curated list of compute types and storage options in select regions.
- Provision persistent or non-persistent workloads on those machines.
- Choose from several Citrix provided images that have the latest VDA installed. Then, from the Citrix interface, you build your own image from that template, and customize it. You can also import and use images from your own Azure subscriptions.

Even though Citrix manages Azure capacity, if you want to communicate with existing resources on your own Azure subscription, you can use Azure VNet peering to connect resources. You can also use Azure VPN gateway to connect to your on-premises resources directly.

For information about security and responsibilities when using Citrix Managed Azure, see Technical security overview for Citrix Managed Azure.

Ordering Citrix Managed Azure

To get a Citrix Managed Azure subscription, you must subscribe to a supported Citrix service offering, and then order Citrix Managed Azure Consumption Funds. You can order Citrix DaaS and consumption funds through Citrix or from Azure Marketplace. Citrix Managed Azure is supported on the following service offerings:

- Citrix DaaS, Advanced, Advanced Plus, and Premium editions
- Citrix DaaS Standard for Azure edition

For details, see Sign up for Citrix DaaS.

Citrix Managed Azure benefits summary

Using Citrix Managed Azure offers several benefits:

- Fastest path to hybrid-cloud benefits.
- Offloads IT management of infrastructure. Provides an administration experience that puts IT in control without the management and maintenance challenges.
- Enables you to rapidly scale work solutions.
- Provides a separate Azure subscription that is managed and maintained by Citrix. This Isolates activity from your other Azure subscriptions.
- You retain the flexibility to create and manage workloads using your own Azure subscriptions. Your deployment can include workloads that use the Citrix Managed Azure subscription, and workloads that use your own (customer-managed) Azure subscriptions.
- Uses a true consumption-based Infrastructure as a Service (IaaS) model.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Several technologies are available to create connections to your own on-premises networks (such as Azure VNet peering and Azure VPN gateway). This allows your users to access your network's resources, such as file servers.

Deploying and managing Citrix Managed Azure from this service uses the Quick Deploymanagement interface.

For more information, contact your Citrix representative.

Delivering applications and desktops to users

Citrix® StoreFront and Citrix® StoreFront Cloud

StoreFront and Citrix® StoreFront Cloud are the access tiers, providing a user interface for end users to view and launch apps and desktops. Within StoreFront and Citrix® StoreFront Cloud you can define one or more stores, each with a URL. End users can access these stores using Citrix Workspace app or a web browser.

- Citrix® StoreFront Cloud is the Citrix managed access tier. Once you have provisioned DaaS, **Citrix® StoreFront Cloud** is available on the main menu. You must configure the URL, authentication and other configuration. For more information, see Get started with Citrix® StoreFront Cloud.
- StoreFront is the customer managed access tier. You can install StoreFront on servers on your corporate network. End users can connect directly to stores hosted by StoreFront over the network. You can provide remote access using a Citrix Gateway. StoreFront can use Local Host Cache to provide access to resources when DaaS is not reachable. For more information, see Get started. See User access for considerations for using StoreFront in a service environment.

You can use both access tiers. For example you could use Citrix® StoreFront Cloud for remote access, while deploying on-premises StoreFront for areas of your corporate network that need increased resiliency against network outages.

Citrix Workspace app

From the user side, Citrix Workspace app is installed on user devices and other endpoints, such as virtual desktops. Citrix Workspace app provides users with secure, self-service access to documents, applications, and desktops from any device, including smartphones, tablets, and PCs. Citrix Workspace app provides on-demand access to Windows, web, and Software as a Service (SaaS) applications.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For devices that cannot install Citrix Workspace app software, Citrix Workspace app for HTML5 provides a connection through a HTML5-compatible web browser.

Citrix Workspace app is available for various operating systems. For details, see Citrix Workspace app.

Service Level Agreement

Citrix DaaS is designed using industry best practices to achieve cloud scale and a high degree of service availability.

For complete details about Citrix's commitment for availability of Citrix Cloud services, see the Service Level Agreement.

Performance against this goal can be monitored on an ongoing basis at `<https://status.cloud.com>`.

Limitations

The calculation of this Service Level Goal will not include loss of availability from the following causes:

- Customer failure to follow configuration requirements for Citrix DaaS documented in the product documentation on `<https://docs.citrix.com>`.
- Caused by any component not managed by Citrix including, but not limited to, customer controlled physical and virtual machines, customer installed and maintained operating systems, customer installed and controlled networking equipment or other hardware; customer defined and controlled security settings, group policies and other configuration policies; public cloud provider failures, Internet Service Provider failures or other external to Citrix control.
- Service disruption due to reasons beyond Citrix control, including natural disaster, war or acts of terrorism, government action.

- System requirements
- Features
  - An introduction to HDX technologies, plus details about Devices, Graphics, and Multimedia.
  - Remote PC Access: Allow users to log on remotely from anywhere to a physical PC in the office. You can configure Remote PC Access using Studio.
  - Publish content: Publish an application that is simply a URL or UNC path to a resource.
  - Server VDI: Deliver a desktop from a server operating system for a single user.
- For Citrix DaaS Standard for Azure, see its dedicated product documentation.
- To learn about feature availability in the Citrix DaaS products and editions, see the Citrix DaaS feature matrix.
- The Citrix Cloud Learning Series offers education course to get you up and running with Citrix Cloud and its services. You can sequentially view all of the modules, from introductions through planning and building services. You can also choose individual modules or task-specific segments within a module. See Cloud Learning Series.

Get started

To learn how to set up your deployment, start with Plan and build a deployment. That summary guides you through the major steps in the process, and provides links to more information and detailed procedures.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

What's new

A goal of Citrix® is to deliver new features and product updates to Citrix DaaS™ customers when they are available. New releases provide more value, so there's no reason to delay updates. Rolling updates to Citrix DaaS are released approximately every three weeks.

This process is transparent to you. Initial updates are applied to Citrix internal sites only and are then applied to customer environments gradually. Delivering updates incrementally in waves helps ensure product quality and maximize availability.

It is possible that the updates mentioned in this documentation are being rolled out and are not accessible to all customers at the same time.

For details about the Service Level Agreement for cloud scale and service availability, see Service Level Agreement. To monitor service interruptions and scheduled maintenance, see the Service Health Dashboard.

Use these articles to learn about release updates, known issues, deprecations and removals, and features in preview:

- What's new lists new and enhanced features in recent releases.
- Known issues lists issues that might affect deployments.
- Deprecations and removals gives advance notice about features that are deprecated, removed, or planned for removal.
- Features in preview lists preview features available for non-production or limited production environments and provides a way to submit feedback.

What's new

This article lists new and enhanced features for Citrix DaaS™. Updates are organized by release month.

Virtual Delivery Agents (VDAs)

VDAs for Windows machines generally are released at the same time as the Citrix Virtual Apps and Desktops™ product.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For information about new VDA and HDX features, see the What's new and Known issues articles for the current Citrix Virtual Apps and Desktops release.
- For information about VDA platforms and features that are no longer supported, see Deprecation. That article also includes platforms and features that will not be supported in a future release (such as which operating systems support VDA installation).

IMPORTANT:

If the Personal vDisk (PvD) component was ever installed on a VDA, that VDA cannot be upgraded to version 1912 LTSR or later. To use the new VDA, you must uninstall the current VDA and then install the new VDA. (This instruction applies even if you installed PvD but never used it.) For details, see If the VDA has Personal vDisk installed.

August 2026

New and enhanced features

Thresholds. Monitor now supports configurable thresholds for system metrics. Define Critical, Warning, and Healthy states for metrics such as CPU usage, memory usage, ICA RTT, network latency, and logon duration across data sources including Machines, Sessions, Cloud Connectors, Provisioning Services, and StoreFront. Color-coded indicators appear on the Dashboard, Infrastructure, Filters, and User/Machine Details pages. Create custom thresholds for specific workloads, or use predefined thresholds with dynamic defaults that automatically adapt to your environment.

For more information, see Thresholds

Citrix Advisor: Scheduled runs and Home page widget. Advisor now runs site checks automatically on a recurring weekly schedule. Each run generates a report retained for up to 90 days.

Also, a new **Advisor** widget on the **Home** page displays a summary of recommendations grouped by impact level and filterable by category, so you can quickly identify and act on critical items.

For more information, see Check for recommendations and Advisor widget.

Microsoft Entra single sign-on. Starting with VDA version 2607, you can use the Microsoft Entra single sign-on machine policy setting to enable or disable this capability on your session hosts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Web sign-in (Preview). You can enable web-based sign-in to log in or unlock your Entra joined or Entra hybrid joined virtual desktop. See Web sign-in for details.

Connector Appliance to backend application latency in the Application Topology. The Secure Private Access Application Topology now shows a **Connection Latency** value on the link between the Connector Appliance and the backend application, completing the hop-by-hop latency view. The value is a synthetic P90 round-trip time that the Connector Appliance measures over the past hour. Currently, this covers cloud deployments.

For more information, see Connector Appliance to backend application latency.

July 2026

New and enhanced features

Machine catalog experience enhancements in Studio. We enhanced the machine catalog experience in Studio by displaying the configured naming scheme in the machine catalog details and optimizing the action bar based on usage frequency. **View Machines** is now a top-level action while **Delete Machine Catalog** has been moved to the **More** menu due to its infrequent use.

For more information, see Manage machine catalogs.

Citrix Advisor: New checks for reliability, performance, and operational excellence. Citrix Advisor now includes the following new environment checks that provide actionable recommendations to help improve reliability, performance, and operational excellence:

- Reliability
  - Check Cloud Connector communication with StoreFront
- Performance
  - Place StoreFront servers in a low-latency network
- Operational excellence
  - Review machines in maintenance mode for extended periods
  - Reduce troubleshooting time with Always On Tracing

These enhancements help you proactively identify issues and take corrective actions. For more information, see Citrix Advisor.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Extend configuration log search to include low-level operation details. You can now extend the search scope in the **Logging** section of **Web Studio** to include low-level operation details. By selecting **Extend search scope to include details**, you can search low-level details, such as machine name, VDI name, and so on.

For more information, see View configuration log content.

Exclude draining machines from Autoscale capacity buffer. You can now exclude machines that are draining due to scheduled restarts from the Autoscale capacity buffer calculation for multi-session OS delivery groups. When this option is enabled, only machines that are fully available to accept new sessions are counted when determining required capacity. This helps prevent over-provisioning that can occur when draining machines are included in the buffer.

For more information about configuring the option using Web Studio, see Schedule-based and load-based settings.

Alternatively, for configuring using PowerShell, see Exclude draining machines from autoscale calculations.

Deep links from Citrix Aidrien to DaaS. When you ask Citrix Aidrien about machines or sessions, responses now include deep links to the corresponding DaaS console view with search filters applied automatically. This lets you jump directly from a chat response to the relevant interface without manually navigating or rebuilding filters.

Scope support for zones. You can now apply scope control to zones (known as resource locations in Citrix Cloud). This enhancement extends existing scope control capabilities in Citrix DaaS to the zone objects, allowing you to grant custom administrators scoped access to specific zones. With this support, you can align administrative access more closely with your organization's operational and security requirements. For more information, see Assign scopes to a zone.

Set up BYOL separately after connecting your AWS account. You can now connect an Amazon Web Services (AWS) account to Web Studio without configuring Bring Your Own License (BYOL) support during the account connection process. Previously, BYOL setup was a required step in the **Connect AWS account** wizard when connecting to a BYOL-enabled region. Now you can connect your account first, then configure BYOL support at any time by selecting **Set up BYOL** from the **Accounts** list or from the account detail panel. The **Set up BYOL** wizard guides you through enabling BYOL in the AWS WorkSpaces Console and importing a Windows 10 or 11 desktop image for your Citrix on Amazon WorkSpaces Core deployment.

For more information, see Set up BYOL for your account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Faster domain selection with search. Finding Active Directory domains and organizational units (OUs) is now faster in Web Studio. During machine catalog creation, when you select **Create new Active Directory accounts**, you can search for a specific domain directly from the **Location (domain)** drop-down list instead of browsing the full list of trusted domains.

For more information, see Identity pool of on-premises Active Directory joined machine identity.

Task Center: Recurring tab and enhanced task management. Task Center now includes a **Recurring** tab that shows tasks scheduled to run periodically or in the future. In addition to the existing **Recent tasks** tab, which shows individual task runs from the past 90 days, you can now:

- Search and filter both recent and recurring tasks.
- Track real-time task status and recurring schedule state.
- Perform actions on recent tasks, such as cancel or rerun.
- Perform actions on recurring schedules, such as edit or delete.

For more information, see Monitor and manage tasks in Task Center.

Restrict VDA upgrades to tagged machines. You can now limit catalog-level VDA upgrades to a specific subset of machines by using machine tags in Web Studio. When scheduling an upgrade, select **Upgrade machines that match the tag**, choose a tag, and only machines with that tag are included.

This helps support ring-based upgrade strategies where administrators validate a new VDA version with a pilot group before rolling it out to the full catalog.

For more information, see Upgrade VDAs using VUS.

Select Azure replication regions when creating an image version. Studio now includes an **Image Share** page during image version creation, where you can select one or more Azure regions to automatically replicate the prepared image to. You can select resources from different hosting connections and optionally assign a regional disk encryption key. This page appears only when **Store image versions in Azure Compute Gallery** is enabled on the image definition. For more information, see Create image versions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

June 2026

New and enhanced features

Access Citrix DaaS data in Aidrien. Aidrien can retrieve and display Citrix DaaS environment data directly within the chat, allowing you to investigate issues and manage resources without leaving the conversation. Using natural language, you can search for and view information about:

- Machines and sessions
- Machine catalogs
- Delivery groups

Aidrien presents the retrieved data directly in the chat UI, making it easier to explore your environment, identify issues, and gather information during troubleshooting workflows.

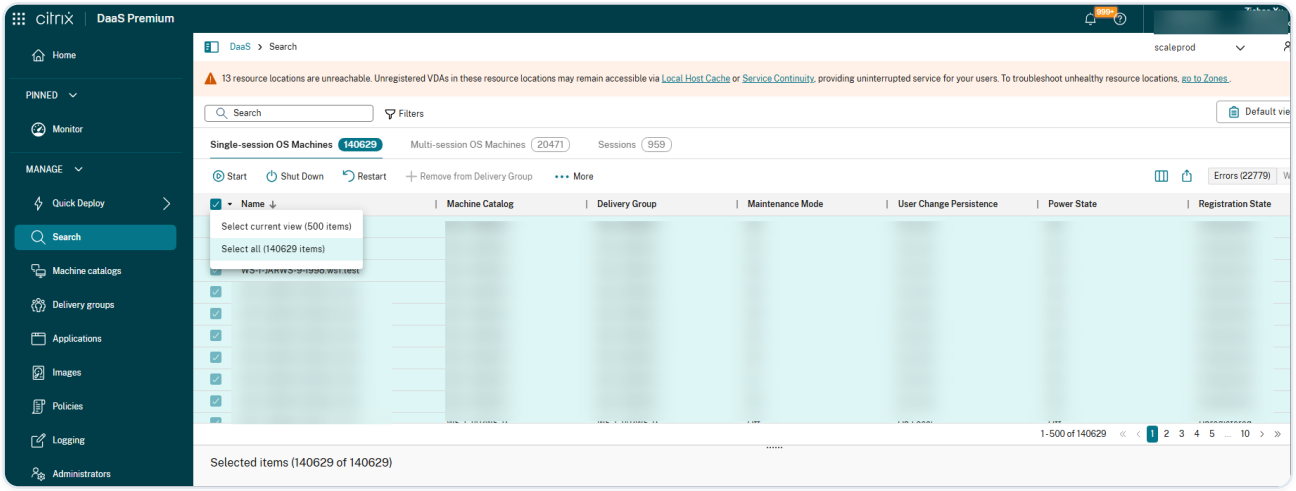
For more information, see Access Citrix DaaS data in Aidrien.

App protection reporting in Citrix Monitor. Real-time reporting of protection policy activations and security risk detections is available in Citrix Director and Monitor. The reporting enables you to quickly assess the risk and configure your protection policies to ensure a safer environment. By proactive risk management and policy reconfiguration, you can strengthen endpoint security in your environment and reduce exposure to emerging threats. For more information, see Endpoint Security policy activation & threat detection reporting

Azure SSD Storage Types for Ephemeral OS Disks. Studio now allows Azure Machine Catalogs that use Azure Ephemeral OS Disks to select the base OS managed disk storage type (Premium SSD, Standard SSD, or Standard HDD) during catalog creation and subsequent catalog/scheme updates, with UI validation and preflight checks to prevent unsupported configurations. For more information, see Use Azure ephemeral OS disk.

Endpoint OS Version Visibility. You can now more effectively manage and track user sessions and connections through enhancements to the Session and Connection pages. These pages now include an Endpoint OS Version column and a corresponding filter for Windows and Linux devices.

This helps you to:



- View the endpoint operating system version directly on the Session and Connection pages.
- Filter sessions or connections based on specific Windows or Linux operating system versions.

For more information, see Endpoint OS Version Visibility

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Improved bulk actions in Web Studio. You can now select all items across all pages or only within the current page. This enhancement removes the previous 500-item limit for bulk operations on matched search results, improving administrative efficiency in large environments with thousands of VDAs or sessions.

Performance optimizations have also been implemented to ensure bulk actions remain smooth and responsive at scale.

Topology view expanded for Chrome Enterprise Premium and improved policy-evaluation data quality. Citrix Monitor now shows six Chrome Enterprise Premium topology variants spanning cloud and hybrid deployments across internal, external, and external fixed-IP application routes. The **Policy Evaluation** pane can also carry **Application Name**, **Application Type**, **Policies**, and **Security Controls** values over from enumeration events when an app launch event omits them; the **Data path** field can render empty when the source event does not specify it.

For more information, see Chrome Enterprise Premium topology variants.

Image management support prepared image searching

You can now use a search bar in the **Images** node to filter and find image versions by criteria including image definition name, image version number, image version description, OS type, hypervisor type, host connection name, host unit name, host connection type, master image name, provisioning scheme count, and version creation time. This enhancement helps administrators efficiently manage images across large deployments.

For more information, see Image management.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for creating Citrix Provisioning catalogs in OpenShift virtualization environments using Studio

With Studio, you can now create Citrix Provisioning catalogs in OpenShift virtualization environments. Previously, you had to switch between different consoles to provision and manage those catalogs. This feature simplifies the process, letting you perform provisioning and power management tasks entirely within Studio.

For more information see, Create Citrix Provisioning™ catalogs in Citrix Studio.

Support for creating Citrix Provisioning catalogs in Citrix Web Studio for Nutanix AHV Prism Central

You can now create a Citrix Provisioning catalog using Web Studio with the Nutanix AHV Prism Central host connection type.

This implementation offers the following advantages:

- A single console to manage both MCS and Citrix Provisioning catalogs.
- New features for Citrix Provisioning catalogs, such as identity management.

For more information see, Create Citrix Provisioning™ catalogs in Citrix Studio.

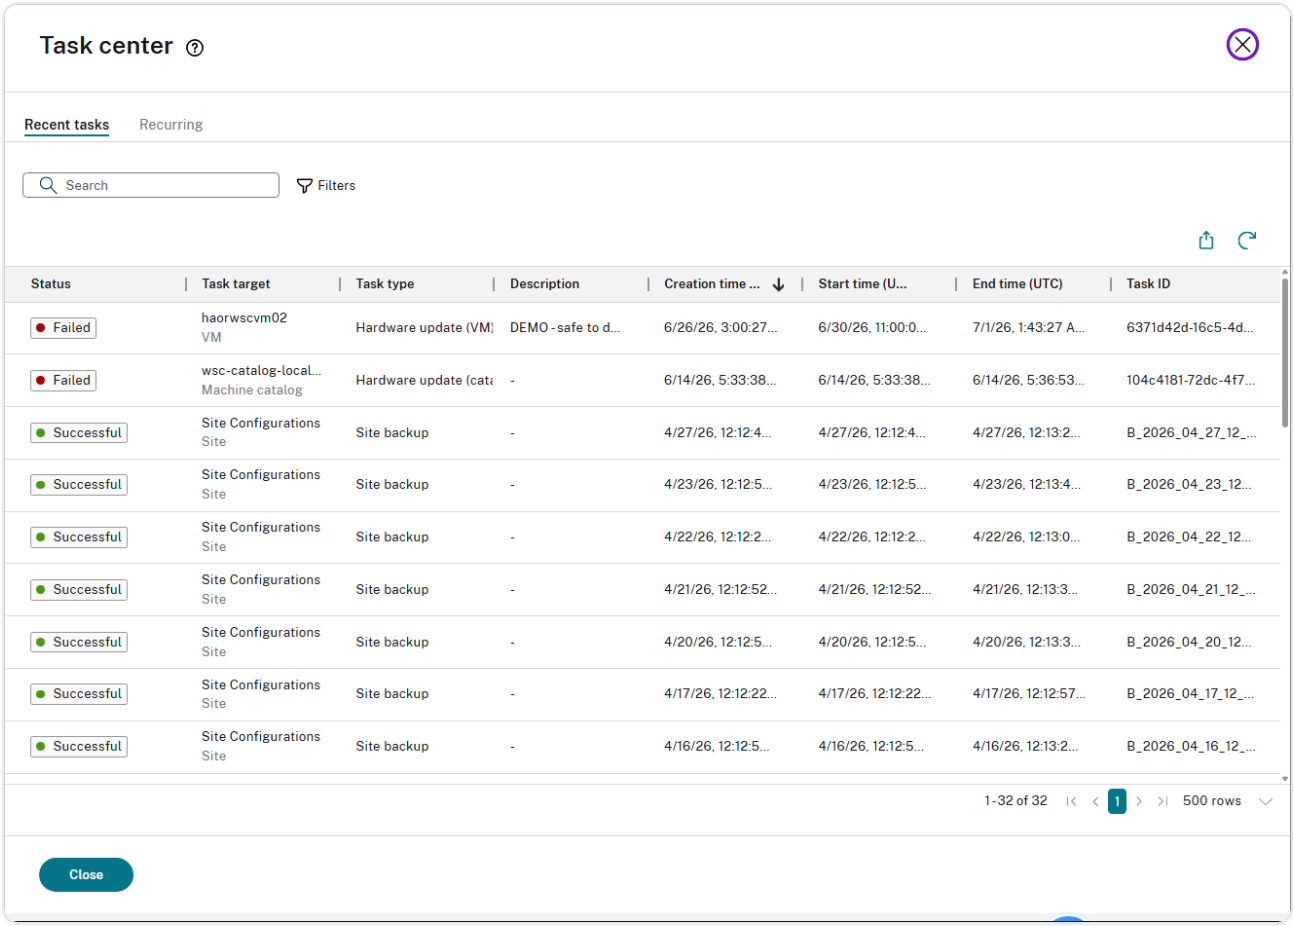
May 2026

New and enhanced features

Studio support for controlling the visibility of packaged applications. With Studio, you can now control the visibility of a packaged application—on a desktop, on **Citrix Workspace > Apps**, or both. To change visibility for a specific packaged app, go to the **Applications** node, select the application, and choose **Properties > Delivery**.

By default, packaged applications are delivered only on **Citrix Workspace > Apps**. For more information, see Change application properties.

Ability to see sessions and component score and correlate with session performance. Session experience overview is now available on Monitor dashboard. The experience summary provides insights into the number of sessions analysed over a given time-period and the categorisation of the analysed sessions into Good, Medium, and Bad. Session categorisation is done based on the session scores. For the quick snapshot of the overall environment health, the summary also includes the average session score and average component score of the analysed



© 1997–2026 Citrix Systems, Inc. All rights reserved.

sessions. Component score can be utilised for troubleshooting session performance, as it provides an additional layer of details for the analysis. For more information, see Session Score

Support for Numecent Cloudpaging applications. You can now discover and publish Numecent Cloudpaging apps using the **App packages** node in Web Studio. You can also store Numecent Cloudpaging application containers on a network file share of your choice and discover and deliver them to end users in Studio by specifying the file share path. This capability simplifies application discovery and expands your options for moving away from App-V infrastructure. For more information, see Cloudpaging applications.

Task Center now available. Task Center provides a centralized view of scheduled and recurring tasks in Studio, helping you track these task statuses: Scheduled, Completed, Failed, or About to run. You can access Task Center by selecting the calendar icon in the upper-right corner of the Studio console.

For more information, see Monitor and manage tasks in Task Center.

Resource filtering. The resource filtering feature lets you configure rules to control user access to resources across delivery groups. You can define the resource type (application, desktop, or both), apply tag restrictions, and set conditions for rule enforcement based on factors like network location and store connection context. To access the feature, go to **Delivery groups > Settings >**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Resource filter. For more information, see Restrict user access to resources across all delivery groups.

Amazon WorkSpaces Core Managed Instances: Studio support for MCS I/O (MCSIO) write-back cache. You can now configure MCS Storage Optimization (MCSIO) write-back cache (WBC) settings directly in Citrix Studio when creating or editing machine catalogs for Amazon WorkSpaces Core Managed Instances. Previously, configuring write-back cache was only avialable through PowerShell commands. Studio now exposes write-back cache options on the Disk Settings page of the Machine Catalog Setup wizard, including cache disk size, memory allocation, EBS storage type (e.g., gp2, gp3, io1, io2), disk persistence across power cycles, and OS disk retention for faster boot times. For more information, see MCSIO enabled catalog.

April 2026

New and enhanced features

Microsoft Entra single sign-on. The **Disconnect remote session on lock for Microsoft identity platform authentication** is now supported on the single-session VDA. See session lock behavior for details.

Update BDM disks for Citrix Provisioning catalogs. You can now update Boot Device Management (BDM) disks for your Machine Creation Services (MCS)-provisioned Citrix Provisioning catalogs. The BDM disk update helps update the Citrix Provisioning server addresses, and UEFI firmware using Studio or PowerShell. This feature saves administrative effort and keeps your environment current. It simplifies catalog management without recreating virtual machines. It supports Azure, Nutanix AHV Prism Central, VMware, and XenServer environments. For more information, see Update BDM disks.

Update vDisk assignments for MCS-provisioned Citrix Provisioning catalogs. You can now update vDisk assignments for existing MCS-provisioned Citrix Provisioning catalogs using Studio or PowerShell. Previously, you had to recreate catalogs to change vDisks. This enhancement saves you time and effort by letting you manage assignments. You can list available vDisks and assign existing vDisks at the catalog level. This feature applies to Azure, Nutanix AHV Prism Central, VMware, and XenServer environments. Note that the vDisk lifecycle management remains within the Citrix Provisioning console. For more information, see Update vDisk assignment.

Reset OS disk for persistent VMs in Nutanix AHV Prism Central. With this feature, you can now reset OS disk for persistent VMs using the `Reset-ProvVMDisk` PowerShell command in

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Nutanix AHV Prism Central environments. For more information, see Reset OS Disk for Persistent VMs.

Citrix Advisor: New checks for security, reliability, performance, and operational excellence. Citrix Advisor now includes the following new environment checks that provide actionable recommendations to help improve security, reliability, performance, and operational excellence for StoreFront, VDAs, and Active Directory:

- Security
  - Address VDA security vulnerabilities
  - Address Citrix Workspace app security vulnerabilities
  - Upgrade StoreFront server versions that reached End of Life
  - Use HTTPS for StoreFront base URL
  - Use HTTPS for communication between StoreFront and Cloud Connectors
  - Review StoreFront stores with anonymous access enabled
- Reliability
  - Ensure StoreFront server redundancy
- Performance
  - Enable socket pooling for StoreFront stores
- Operational excellence
  - Reset tainted Active Directory accounts
  - Replace deprecated beacon point for StoreFront
  - Disable XenApp Services URL for StoreFront stores
  - Deprecate unsupported StoreFront sites
  - Disable Kerberos delegation for StoreFront stores

These enhancements help you proactively identify issues and take corrective actions. For more information, see Citrix Advisor.

Granular dismissal for Citrix Advisor recommendations. Citrix Advisor now supports granular dismissal, allowing you to dismiss specific affected items within a recommendation rather than having to dismiss the entire recommendation. This enhancement is useful for environments where

© 1997–2026 Citrix Systems, Inc. All rights reserved.

some resources, such as test, validation, or temporary resources, are expected to deviate from best practices.

By dismissing only intentionally non-compliant items, you can reduce noise while maintaining visibility into genuine issues and continuing to receive best-practice guidance for your production resources.

This feature is available for the following resource types:

- Machine catalogs
- Delivery groups
- Application groups
- Zones

For more information, see Dismiss specific affected items in a recommendation.

Customize Advisor check rules. You can now customize Advisor check rules for three key recommendations:

- **Enhance Cloud Connector hardware:** Adjust thresholds for CPU, memory, and disk usage, and exclude specific disks.
- **Release unused resources:** Set custom unused time thresholds for machines and applications.
- **Optimize GPO configuration for VDAs:** Modify GPO processing time duration.

Customized recommendations are labeled with **Customized** for easy identification. You can revert to default settings anytime. For more information, see Customize Advisor check rules.

Control application package update behavior with Preferences. You can now control how application packages are updated in the **Studio > Application Packages** workflow by using new **Preferences** settings. These settings let you preserve user favorites during upgrades, prevent unintended downgrades, and automatically remove obsolete packages during update checks. This helps you maintain a clean and consistent application environment with less manual effort.

For more information, see Upload application packages into your environment.

Cloud Connector visibility for VDAs. You can now see which Cloud Connectors your VDAs are proxied through in **Web Studio > Search**. Use the new **Cloud Connector** column and filter to quickly view and filter VDAs by Cloud Connector. To display the **Cloud Connector** column in the main Search view, select **Columns to display** in the top-right corner.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add notes for power actions. You can now add optional notes when you perform power actions on machines and sessions. These notes help you and other administrators understand the reason for the action. They are recorded in logs for auditing purposes. Notes are supported for the following actions:

- **Machine Actions**:
  - Start
  - Shut down
  - Restart
  - Force restart
  - Force shut down
- **Session Actions**:
  - Log off
  - Restart (single-session)
  - Shut down (single-session)

Support for creating Citrix Provisioning catalogs in Red Hat OpenShift and Nutanix AHV Prism Central virtualization environments using Studio. With Studio, you can now create Citrix Provisioning catalogs in Red Hat OpenShift and Nutanix AHV Prism Central virtualization environments. Previously, you had to switch between different consoles to provision and manage those catalogs. This feature simplifies the process, letting you perform provisioning and power management tasks entirely within Studio. For more information see, Create Citrix Provisioning™ catalogs in Citrix Studio.

Azure ZRS disk types for prepared images. MCS in Azure now enables you to select Zone Redundant Storage (`ZRS`) disk types for prepared images with MCS image management. This enhancement provides greater flexibility in disk type selection and improves the resiliency of your MCS machine catalogs in Azure by ensuring higher availability for prepared image disks.

This helps you to:

- Have prepared image disks with higher availability.
- Avoid the risk of losing prepared images due to zone outages.
- Maintain ongoing operations without impact from storage-side disk failures.

For more information, see Create a prepared image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for image management in Nutanix AHV Prism Central environments. Image management functionality is now generally available for OpenShift virtualization environments. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process. Currently, you can also PowerShell commands to achieve this goal. For information, see Create catalogs using prepared images in Nutanix AHV Prism Central.

Support for Amulet Hotkey CoreStation plug-in (Preview). With this feature, Citrix manages your Amulet Hotkey CoreStation workloads through a Amulet Hotkey CoreStation plugin. With this plug-in, you can create hosting connections to your Amulet Hotkey CoreStation enclosure, create catalogs, and power manage machines in the catalog using PowerShell commands.

For more information, see:

- Amulet Hotkey CoreStation virtualization environments
- Connection to Amulet Hotkey CoreStation
- Create an Amulet Hotkey CoreStation machine catalog
- Power manage Amulet Hotkey CoreStation VMs

Support for creating MCSIO-enabled MCS machine catalogs of Amazon WorkSpaces Core Managed Instances. You can now create MCSIO-enabled MCS catalogs to create MCSIO-enabled MCS machine catalogs of Amazon WorkSpaces Core Managed Instances to improve write IOPS by directing write operations to the write-back cache and to reduce the startup time when the persisting OS disk is enabled. For more information, see MCSIO enabled catalog.

Manage on-premises image replication. This enhancement introduces an explicit image replication workflow for on-premises hypervisors. Previously, you were not able to replicate image version instances to newly added or superseded storage locations, making it difficult to manage image availability across all necessary storage. With this enhancement, you can run PowerShell commands and replicate the image version instance to storage locations. This feature applies to on-premises hypervisors, including VMware, XenServer, and Nutanix AHV Prism Central environments.

For more information, see Image Replication of additional storage for supported on-premises hypervisors.

Azure SSD storage for ephemeral OS disks. This feature enhances ephemeral OS disk performance in Azure by allowing you to select higher-tier SSD storage types. Previously, only `Standard_LRS` was supported. Now, you can use `StandardSSD_LRS` or `Premium_LRS` by setting the `StorageType` custom property when creating an MCS catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This helps you to:

- Achieve a higher SLA with improved reliability.
- Experience significantly higher IOPS compared to `Standard_LRS`.

For more information, see Configure storage type used by ephemeral disks.

Enhance Azure backup SKU mix. This enhancement removes previous limitations in Azure's `BackupVmConfiguration` feature. Previously, you can't mix VM SKUs that support hibernation with those that do not support it within the same backup list. This update allows you to include both hibernate-capable and non-hibernate-capable SKUs in your backup configurations.

This helps you to:

- Use a broader range of VM SKUs in your backup configurations.
- Improve VM provisioning and start success rates on Azure.
- Increase the resilience of your deployments.

For more information, see Configure backup VM sizes.

Ability to bypass Cloud Connectors for Amazon WorkSpaces Core API requests. When using Amazon WorkSpaces Core Managed Instances, you can now configure host connections to bypass Citrix Cloud Connectors for AWS API requests. This allows MCS to communicate directly from the Delivery Controller to AWS services for provisioning and power management operations instead of routing through a proxy.

This enhancement provides greater operational flexibility, reduces the compute load on Cloud Connector VMs, and removes MCS dependency on Cloud Connectors for AWS API requests. For more information, see Bypass Cloud Connectors for AWS API requests.

Change Azure VM availability zones. This enhancement allows you to modify the availability zone property for existing MCS provisioned VMs in Azure. Previously, this required recreation of the VM. This feature provides greater flexibility, especially for persistent virtual machines.

This helps you to:

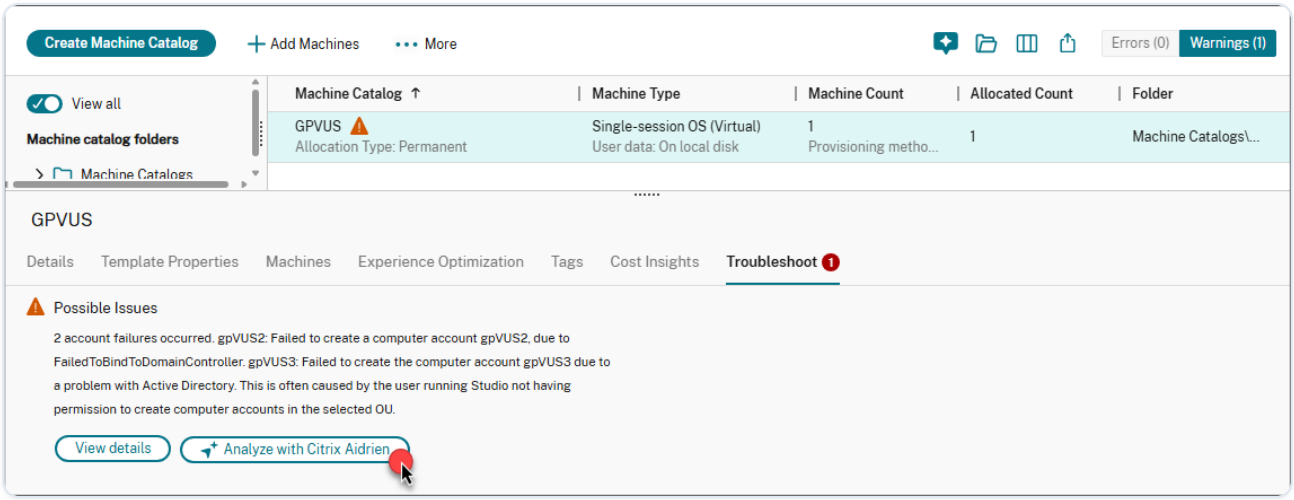
- Adjust existing Azure VMs to have no availability zone affinity.
- Assign a specific availability zone to Azure VMs that currently lack one.
- Move an existing Azure VM from one availability zone to another.

For more information, see Update provisioned machines to current provisioning scheme state.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

GPU Support in OpenShift MCS. OpenShift MCS currently supports GPU configuration through passthrough behavior. The GPU settings defined on the master VM or in the Machine Profile are read and applied to the VMs provisioned through the MCS catalog. Currently, you can't modify GPU parameters during catalog creation. The GPU configuration is inherited directly from the source configuration and applied to the provisioned VMs as configured.

Flexible billing for Amazon WorkSpaces Core Managed Instances. You can now choose between Monthly (flat-rate) and Hourly (pay-as-you-go) billing models when provisioning Amazon WorkSpaces Core Managed instances using Citrix MCS.



This flexibility allows you to optimize compute costs based on your specific workload requirements and usage patterns.

Use the Monthly billing mode for persistent desktops to benefit from predictable, flat-rate pricing, or use Hourly billing for on-demand or intermittent workloads.

This feature requires your AWS account to be configured for the Amazon WorkSpaces billing service.

For more information, see Flexible billing.

Troubleshoot with Citrix Aidrien. You can now troubleshoot warnings and errors in Citrix DaaS using Citrix Aidrien. When warnings or errors occur, Aidrien is available directly from the **Troubleshoot** tab, warning and error popups, and the Notifications center. Aidrien analyzes issues in context and provides guided insights to help you diagnose and resolve problems faster. For more information, see Citrix DaaS use cases.

AWS EC2: Share AWS prepared images across regions. You can now share a prepared image from one region to one or more different regions within the same AWS account. This feature is available for AWS EC2 environments. When you share an image, the underlying AMI is copied

© 1997–2026 Citrix Systems, Inc. All rights reserved.

along with its properties, such as encryption, hibernation, tags, and trusted launch. This helps you to:

- Deploy and manage prepared images across different regions efficiently.
- Create or update machine catalogs in multiple regions using the shared prepared images.
- Maintain consistent image configurations across your AWS deployment.

For more information, see Share prepared images across availability zones and regions.

AWS EC2: Provision workloads in AWS local zones. You can now provision AWS EC2 workloads directly in AWS local zones. This new feature helps you to:

- Provide low-latency access for end-users by deploying Citrix workloads closer to them.
- Improve regional coverage for your Citrix infrastructure in areas not served by full AWS Regions.

You can create a host connection with a hosting unit in a desired local zone and then provision VMs in that local zone.

For more information, see:

- Create a connection using Studio
- Create a machine catalog from the Machine Catalogs node

Support for creating Citrix Provisioning (PVS) catalogs using MCS PowerShell commands with Nutanix AHV Prism Central connection. You can now create Citrix Provisioning catalogs using MCS PowerShell commands in Nutanix AHV Prism Central host connection. This implementation provides you the following advantages:

- A single unified API to manage both MCS and Citrix Provisioning catalogs.
- Have new features for Citrix Provisioning catalogs, such as, identity management solution, on-demand provisioning, and others.

For more information, see PVS documentation.

March 2026

New and enhanced features

Microsoft Entra single sign-on for DaaS. The following enhancements are available:

- Support for hybrid access on Linux is now available with Citrix Workspace app for Linux 2601.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You can now register the Citrix Resource and Client applications through the Citrix Cloud portal.
- You can now perform the Azure configuration through Azure portal.

For more information, see Microsoft Entra single sign-on.

Support for Entra ID extension attributes in MCS. You can now integrate Entra ID extension attributes into your MCS environment. These attributes allow you to store unique, custom data directly on your Entra ID device objects. You can thus apply precise conditional access policies by filtering devices with extension attributes. See Supported operators and device properties for filters for creating more filters based on device attributes. The feature is supported for both Microsoft Entra joined and Microsoft Entra hybrid joined identity types.

You can manage your MCS machine catalogs using Entra ID extension attributes (ExtensionAttribute1-15). For this, prepare a Service Principal with `Device.ReadWrite.All` permission. You can create and update an MCS machine catalog with Entra ID extension attributes using both Studio and PowerShell commands.

Extension attributes are assigned to devices (both persistent and non-persistent VMs) when they are registered.

For more information, see:

- Identity pool of Microsoft Entra joined machine identity
- Identity pool of Microsoft Entra hybrid joined machine identity
- Create Microsoft Entra catalogs enrolled in Microsoft Intune
- Create Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

Nutanix AHV Prism Central: Improve network configuration. This enhancement improves network configuration for MCS catalogs on Nutanix AHV Prism Central host connections. You can now configure network settings by clearly distinguishing between Basic VLANs, Advanced VLANs, and Overlay networks, preventing errors that occurred when mixed types were previously listed together.

This helps you to:

- Reduce errors during machine catalog creation and editing processes.
- Ensure consistent and valid network configurations through new preflight checks.

For more information, see Create a machine catalog using Studio.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Share prepared image versions across hosts in the same resource pool in XenServer. You can now use the **Images** node to share image versions across hosts in the same resource pool in XenServer. This implementation ensures consistency and uniformity of images across different hosts, enhancing deployment flexibility and operational efficiency. You can also use PowerShell commands to achieve this goal. For more information, see Create a prepared image machine catalog in XenServer.

Citrix Advisor: New reliability check. Citrix Advisor now includes a new environment check with the recommendation **Enable service continuity for Citrix Workspace**. This check identifies when service continuity isn't enabled and provides guidance to help you enable it. For more information, see Reliability recommendations.

Customize column layout in Search main views. You can now reorder columns in Web Studio to better organize and group related information. Web Studio retains your column order and width preferences, so your customized layout persists across sessions. Currently, this capability is supported in the main views in **Search**.

Service Window. The Service Window feature provides a capability to schedule and automate operations on MCS-provisioned VMs. This feature currently supports various operations such as Reset OS disk and hardware configuration changes using PowerShell. For information, see Service Window.

February 2026

New and enhanced features

Monitor now supports running Scripted Tasks. This includes the ability to execute Citrix built-in scripts and custom scripts, as well as upload custom scripts for execution. This enhancement enables administrators to perform troubleshooting and automate operational tasks directly from Monitor.

Citrix Always on Tracing. Citrix Cloud expands Always On Tracing (AOT) to simplify centralized log collection for Citrix Virtual Apps and Desktops. Configuration is managed through DaaS Settings, where administrators define Log Server details, logging scope, and access controls, with settings applied across the environment.

Citrix Monitor adds a dedicated AOT Logs view with near real-time visibility, search, and filtering by time range, log type, and machine to speed up troubleshooting.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

AOT logs are sent to the AOT Log Server from supported components deployed in customer resource locations, including Windows, Linux, and Mac VDAs, StoreFront, Federated Authentication Service (FAS), and Session Recording Server.

For more information, see Always On Tracing.

NOTE:

AOT logs from Citrix Cloud control plane components continue to be sent to Citrix-managed monitoring systems, such as Splunk. Only components deployed in customer resource locations send logs to the AOT Log Server.

Microsoft Entra single sign-on for DaaS. Support for hybrid access on Windows and Mac is now available. See Microsoft Entra single sign-on for details.

Backup VM configuration in AWS EC2. Studio now enables you to define a list of backup EC2 instance types ("Backup SKUs" that can be On-demand or Spot instances) in AWS environments that Machine Creation Services (MCS) can fall back to in case of capacity-related issues. MCS tries to fall back on the backup EC2 instance types in the order that is provided by you in the list. For more information, see Create a catalog using Studio.

Support for Azure Extended Zones. You can now provision workloads in Azure Extended Zones using MCS provisioning. Azure Extended Zones are small footprint extensions of major Azure regions. They provide lower latency and data residency for customers that are further from the main region location. For more information, see Azure Extended Zones.

Red Hat OpenShift: Citrix Provisioning catalog using MCS. This enhancement adds support to the OpenShift Plug-in to provision Citrix Provisioning (PVS) catalogs using MCS.

With this capability:

- The OpenShift Plug-in can be used as a hosting connection for Citrix Provisioning machine catalogs provisioned by MCS.
- Citrix Provisioning target devices can boot using Citrix Provisioning BDM boot, with the BDM disk stored in OpenShift.

For more information, see the Citrix Provisioning document Create Citrix Provisioning™ catalogs in Citrix Studio.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enroll HPE Moonshot machines to machine catalogs using WebSocket. You can now register your non-domain joined or Microsoft Entra joined VDAs on HPE Moonshot to machine catalogs using WebSocket. For more information, see Enroll machines to catalogs using the WebSocket VDA enrollment tool.

Support for VMware vVols in MCS. You can now use VMware vVols with MCS on vSphere environments. Previously, creating MCS catalogs on vVols resulted in PBM errors. This update resolves that issue. This integration provides granular control over your MCS virtual machine storage. For information, see Storage Profile.

Use WinHttp (netsh) proxy server settings for hosting connection. This feature allows hosting connections to use the WinHttp (netsh) proxy server settings configured on the Citrix Cloud Connectors to be used with the hosting connection. For more information, see Use WinHttp (netsh) proxy server settings for hosting connection.

Amazon Workspaces Core Managed Instances: Cross-account provisioning using PowerShell. There are use-cases where the Cloud Connectors would like to be placed in a separate AWS account (shared services account or site components account) with IAM roles that have cross-account access (cross-account IAM role) and MCS-provisioned machine catalogs in separate secondary AWS account (workloads accounts), without the need for additional Cloud Connectors in the separate accounts. To support such scenarios, this feature uses VPC peering and cross-account access using IAM roles to make provisioning across different AWS accounts possible for enterprises managing multiple AWS accounts.

With VPC peering, you can have your Cloud Connector, and provisioned VMs in different regions or accounts be able to communicate among each other.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

For detailed information, see Cross account provisioning.

Amazon Workspaces Core Managed Instances: Provision workloads in AWS local zones. You can now provision Amazon Workspaces Core Managed Instances workloads directly in AWS local zones. This new feature helps you to:

- Provide low-latency access for end-users by deploying Citrix workloads closer to them.
- Improve regional coverage for your Citrix infrastructure in areas not served by full AWS Regions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You can create a host connection with a hosting unit in a desired local zone and then provision VMs in that local zone.

For more information, see:

- Create a connection using Studio
- Create a machine catalog from the Machine Catalogs node

Amazon WorkSpaces Core Managed Instances: Share AWS prepared images across regions. You can now share a prepared image from one region to one or more different regions within the same AWS account. This feature is available for Amazon Workspaces Core Managed Instances environments. When you share an image, the underlying AMI is copied along with its properties, such as encryption, tags, and trusted launch. This helps you to:

- Deploy and manage prepared images across different regions efficiently.
- Create or update machine catalogs in multiple regions using the locally shared prepared images.
- Maintain consistent image configurations across your AWS deployment.

For more information, see Share prepared images across availability zones and regions.

Expanded icon support. When customizing icons for desktops and applications in Studio, you can now extract and use icons from `.exe` files, in addition to the previously supported `.ico` format.

You can browse and select those icons from either your local machine or a VDA machine. The maximum supported icon file size is 500 KB. For more information, see Create delivery groups and Manage delivery groups.

Citrix Advisor: New checks for reliability, performance, security, and cost effiency. Citrix Advisor now includes the following new environment checks that provide actionable recommendations to help improve security, reliability, performance, and operational excellence:

- Security
  - Use HTTPS for host connections
  - Upgrade operating systems that reached End of Life
  - Upgrade hypervisor versions that reached End of Life
- Reliability

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Enable advanced health check for StoreFront stores
    - Add all Cloud Connectors as STA servers on StoreFront and NetScaler Gateway
- Performance
    - Optimize GPO configuration for VDAs
    - Evaluate write cache disk size for PVS target devices
- Operational excellence
    - Simplify catalog configuration with a machine profile

These enhancements enable you to proactively identify issues and take corrective actions to maintain a secure, reliable, high-performance, and operationally efficient deployment. For more information, see Citrix Advisor.

Forward Always-on Tracing (AOT) logs to your log server. In Web Studio, you can now forward Always-on Tracing (AOT) logs from Citrix components to a designated log server. This feature enables centralized troubleshooting and more effective monitoring of your Citrix environment. For more information, see Configure the log server settings.

Migrate machine catalogs to Citrix-managed Nutanix AHV Prism Central host connection. With this feature, you can migrate your Citrix machine catalogs, and their associated VMs from existing Nutanix AHV (for Prism Element) and Nutanix AHV PC (for NC2 on Azure) host connections to the Citrix-managed Nutanix AHV Prism Central host connection. For migration, use PowerShell commands, which also include fast rollback options in case of issues, and commands to clean up source resources post-migration. For information, see Migrate machine catalogs to Citrix-managed Nutanix AHV Prism Central host connection.

Use machine profiles for Nutanix AHV Prism Central host connections. You can now use machine profiles to define hardware configurations for VMs provisioned through your Nutanix AHV Prism Central host connection. This new workflow captures properties like CPU, memory, cores per socket, GPU, and categories from the machine profile. You can overwrite CPU, memory, and core per socket configurations during catalog creation or editing. The master image's template version defaults as the machine profile for new catalogs. You can create a new catalog with a machine profile, update an existing catalog, and convert a non-machine profile based machine catalog to a machine profile based machine catalog using Studio and PowerShell. For more information, see:

- Studio

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Create a machine catalog using Studio
    - Add or change the machine profile.

- Powershell

    - Create a machine catalog using PowerShell commands
    - Add or change machine profile

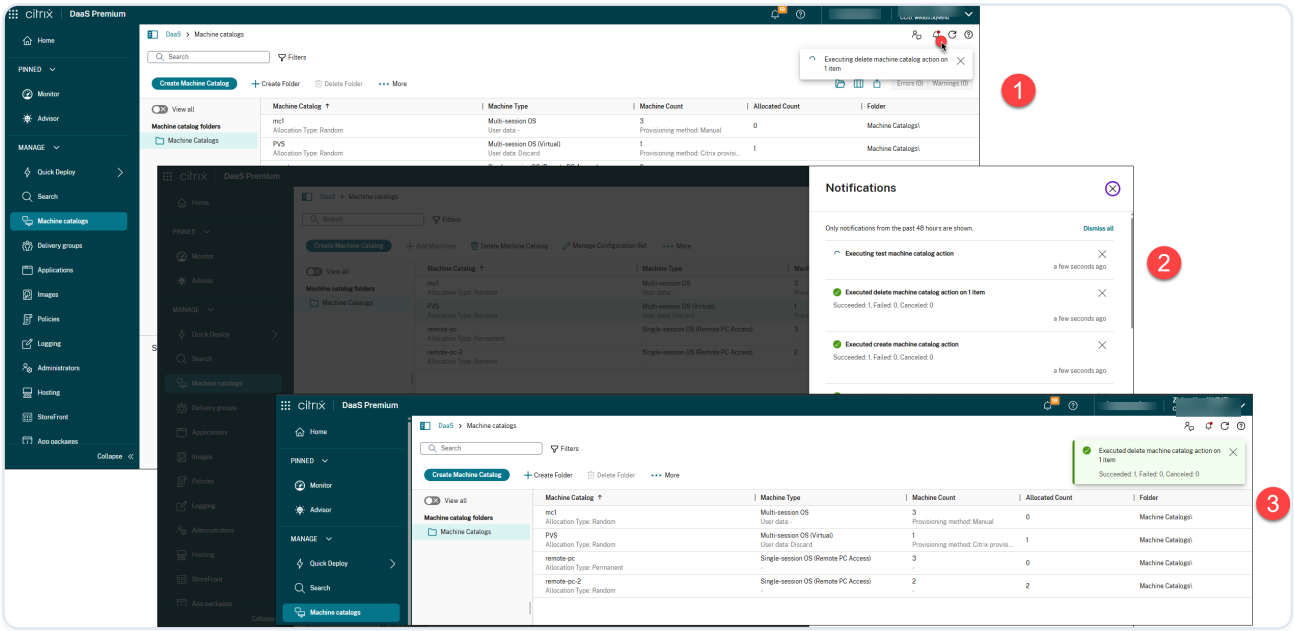
Single-use pooled desktops during LHC events. Power-managed, single-session, pooled desktops are now available for a single use by default during a Local Host Cache (LHC) event. This change ensures that users can access these machines without the concerns about desktop reuse. The existing functionality to configure these desktops for reuse remains unchanged. For more information, see Enable using Studio.

January 2026

New and enhanced features

Discover and deliver Citrix elastic app layers in Studio. You can now discover and publish elastic app layers using the **App packages** node in Studio, including:

- Discover and enumerate a library of elastic app layers authored using Citrix App Layering.
- Create assignment policies to deliver apps elastically to users on non-persistent machine catalogs.
- Deliver portable elastic app layers to any non-persistent Windows machine, regardless of whether the image was published from an App Layering appliance.



For more information, see Manage app packages.

In-session notifications for background operations. Web Studio now includes a notification center that gives you real-time visibility into background operations and reports on operation results.

When you start a time-consuming operation, a notification appears in the upper-right corner to let you know it's in progress. Operations that previously blocked the UI now run in the background, so you can continue working without interruption. Once the operation completes, a real-time status notification appears, and the result is also saved in the notification center. The notification center maintains a 48-hour history, making it easy to track recent activity.

For more information, see Studio overview.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Microsoft Entra single sign-on for DaaS. Support with new Workspace app platforms and Windows Server 2025 is now available. See Microsoft Entra single sign-on for details.

Follow-me tagging. Follow-me tagging enables tracking of individual end-user VM usage by applying hypervisor-level tags. These tags, labeled with the specific user and/or organization (using `citrix-user-upn` as the key and the User Principal Name (UPN) as the value), are added when a user is assigned to a VM and removed when the user is unassigned.

This feature offers several advantages:

- **IT chargeback**: Facilitates filtering resource usage (Azure: NICs, OS, ID, WBC, Data disks, and VMs) (AWS EC2: EC2 instance, EBS volumes (OS, ID, WBC, and Data disks), Network Interfaces) by tags, allowing for accurate chargeback to individual users or business units.
- **Efficient user management**: Automates the removal of tags from resources when end-users are unassigned due to employment changes like termination or reorganization.
- **Enhanced security monitoring**: Helps identify VMs assigned to specific end-users for targeted security scans.

Currently, follow-me tagging is applicable to:

- AWS EC2 and Azure environments
- Statically assigned machines running single-session OS
- Persistent and non-Persistent catalogs
- All supported machine identity joined catalogs
- Only MCS provisioned VMs

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Managed disks only

For more information, see Follow-Me Tagging.

Support for provisioning data disk in AWS. A data disk allows storage of persistent data like event logs, security traces, and application data.

With this feature, you can now create and assign a persistent data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in AWS. The source of the data disk must be the master image (AMI's secondary volume). You can provision the data disk using both Studio and PowerShell commands. However, you can provision data disks using Studio UI only when the master image (AMI) has two volumes, OS disk (root volume) and data disk (secondary volume).

For information on creating an MCS machine catalog with a data disk, see Provision a data disk on MCS created VM.

December 2025

New and enhanced features

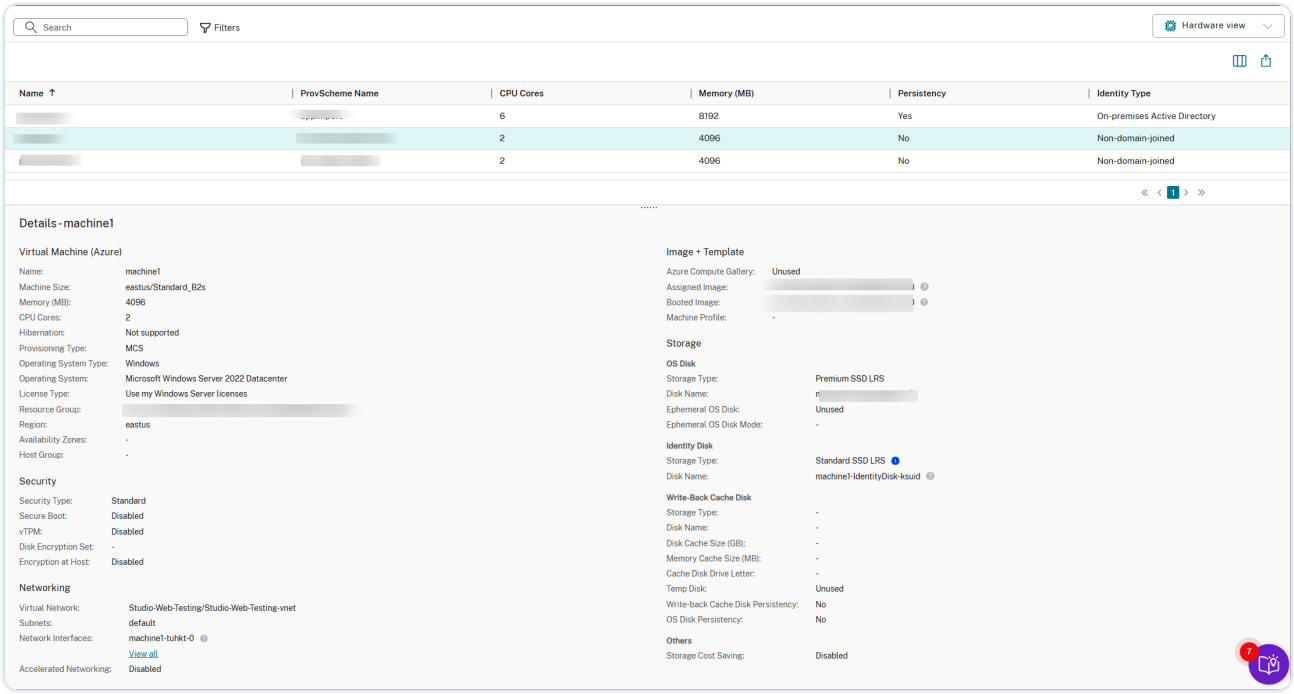
Azure: Clone MCS catalogs. You can now use the `Copy-ProvScheme` PowerShell command to clone an existing persistent and non-persistent MCS machine catalog in the Azure virtualization environment. This feature creates a new provisioning scheme by copying the details of an existing scheme, including associated configurations, network mappings, and security groups. This helps you to:

- Split an existing single catalog into multiple catalogs to apply different catalog-level policies and configurations.
- Isolate specific virtual machines within a large catalog for quick testing or to treat them separately based on functional roles.

For more information, see Clone an MCS catalog.

Enhanced experience optimization settings for Citrix DaaS. We've enhanced **Experience Optimization** settings to help you easily fine-tune resource allocation and boost performance across machine catalogs. You can now create or select configuration sets for tailored optimization, or quickly apply default settings like automatic CPU spike protection and intelligent CPU optimization.

For more information, see Select a configuration set for experience optimization.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Machine hardware view in the Search node. You can now access a dedicated hardware view in the Search node for machines provisioned using Machine Creation Services (MCS). This view gives better visibility into machine hardware details and makes managing MCS-provisioned machines easier.

Key benefits include:

- View detailed hardware configurations, including machine size, operation system, license type, security settings, networking, image, template, and disk settings.
- Easily locate machines using hardware filters and search options.

Currently, Hardware view is available for MCS-provisioned machines in VMware, XenServer, SCVMM/Hyper-V, Nutanix PC, Azure, Azure Arc, Azure Local, AWS EC2, and GCP. OpenShift and Amazon WorkSpaces Core currently show basic hardware information as columns only. For more information, see Monitor MCS-provisioned machines in Search > Hardware view.

Improved scope control for Default Policy Set. Scope control has been available for policy sets. To maintain compatibility, **Default Policy Set** is now assigned to *any* scope, with **Bypass scope control** enabled by default. Review your **Default Policy Set** assignments and adjust them if you want to limit access based on scope.

You can update scope assignments in two ways:

- From the policies: Edit the **Default Policy Set** and change its associated scopes.
- From the scope: Go to the scope in **Administrators > Scopes** and assign or remove **Default Policy Set** from it.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Create and manage scopes and Create and manage policy sets.

StoreFront node relocation. The **StoreFront** node has been removed from Web Studio. All settings and configuration options previously available in the **StoreFront** node are now available on the **Settings** tab of the **Delivery groups** node. This consolidation simplifies navigation and keeps related configuration options in one place.

AWS EC2: Share prepared images across availability zones. Previously, to create MCS machine catalogs across multiple availability zones, you needed a separate prepared image for each availability zone. This increased your operational complexity to have to manage several prepared images and could lead to potential inconsistencies in image management.

With this feature, you can share a single prepared image across different availability zones within the same AWS region for AWS EC2. This simplifies catalog creation and image updates, reducing management overhead significantly. Currently, use PowerShell commands to manage image sharing. For more information, see Share prepared images across availability zones.

Create MCS provisioned VMs with vTPM enabled in XenServer 8. With this feature in XenServer 8, you can create an MCS machine catalog with vTPM. If machine profile-based configuration is used and vTPM is enabled, then VMs in the catalog inherit the same vTPM content from the VM template. If the machine profile is not used and the master image is vTPM enabled, then VMs in the catalog will inherit the same vTPM content as the master image. For information, see Create a machine profile-based machine catalog using PowerShell.

November 2025

New and enhanced features

Microsoft Entra single sign-on for DaaS. You can now leverage single sign-on (SSO) when using Microsoft Entra ID credentials to access virtual applications and desktops on Microsoft Entra joined or Microsoft Entra hybrid joined session hosts. For more information, see Microsoft Entra single sign-on.

Amazon WorkSpaces Core Managed Instances: Share prepared images across availability zones using Studio UI. With this feature, you can share a single prepared image across different availability zones within the same AWS region for Amazon WorkSpaces Core Managed Instances using Studio UI. Alternatively, you can also use PowerShell commands to manage image sharing. For more information, see Share Prepared Images Across Availability Zones.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

One-time use pooled desktops in Local Host Cache. You can now configure one-time use of pooled desktops during Local Host Cache (LHC) outage mode. It leverages a hygiene blob distributed only to VDAs version 2407 and later. Capable machines are automatically scheduled for reboot after a single outage session to guarantee a clean state. This feature improves customer sentiment during outages by making availability more seamless. For more information, see One-time use pooled desktops in Local Host Cache.

Managing prepared image versions in AWS EC2. Image management functionality is now generally available for AWS EC2 virtualization environments. You can use **Images** node to create multiple image versions and apply or update multiple machine catalogs. This implementation significantly reduces the storage and time costs and simplifies the VM deployment and image update process. You can also use PowerShell commands to achieve this goal. For more information, see Create a prepared image machine catalog in AWS EC2.

Amazon WorkSpaces Core Managed Instances non-domain join support in Studio UI. Previously, the Studio UI supported on-premises Active Directory and Microsoft Entra hybrid joined for Amazon WorkSpaces Core Managed Instances, but it did not support provisioning non-domain joined configurations.

With this enhancement, you can provision Amazon WorkSpaces Core Managed Instances that are non-domain joined directly within the Studio UI using MCS. This functionality is supported during both the creation and editing phases of MCS machine catalogs in the Studio UI. For information, see Create a machine catalog from the Machine Catalogs node.

Azure: Support cross-family backup VM sizes for Hibernated VMs. MCS on Azure now supports using cross-family VM sizes for backup configurations in hibernation-enabled machine catalogs, improving resiliency. This feature removes the prior restriction that blocked cross-family fallback to prevent blue screen errors upon resume. When an allocation failure occurs while resuming a hibernated VM, MCS automatically handles the size change, ensuring you still get a working VM. Note that switching the VM size requires clearing the hibernated state, resulting in the loss of the VM's memory state (RAM data). This functionality is available for both persistent and non-persistent MCS catalogs. For more information, see Configure backup VM sizes.

Enhanced workload rightsizing. The enhanced workload rightsizing page helps you analyze the usage and sizing aspects of your delivery groups. Hereby, delivery groups can be analyzed based on machine or user activity.

The machine-based analysis enables you to:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Categorize virtual desktops based on usage to identify machines with no or low activity and reduce spending on unused resources. For more information, see Usage Analysis
- Analyze resource utilization on virtual desktops to identify machines that needs to be right sized to reduce cost or improve user experience.For more information, see Sizing Analysis

The user-based analysis enables you to:

- Categorize the users based on their activity. Consider removing the access entitlement of users with no activity for IT hygiene reasons. Users with low usage could be moved to shared resources for a more efficient use of resources.
- Analyze the resource consumption of users to identify cohorts with higher or lower than average resource consumption, and to distribute users more effectively.

Machine analysis is ideal for scenarios with virtual desktops statically assigned to users, such as Windows 365 Enterprise or Frontline dedicated. User analysis is useful for the analysis of delivery groups with randomly assigned virtual desktops. Both analyses are currently limited to single session machines.

NOTE:

The classic rightsizing analysis, accessible through the “All Workloads” button at the top of the page, will be deprecated in an upcoming release.

View users blocked by session launch failures. Administrators now have **visibility into users blocked by session launch failures**. This new summary is available within the **Filters** under the **Connections** view, enabling improved prioritization and analysis of failures.

Session performance trends are now available with customization. The Session Performance trends in Citrix Director supports historical data. Administrators can now customize the metrics to correlate from an enriched list of performance metrics.

Diagnostic insights on machines and sessions for Proactive monitoring. Citrix Director now features an Insights panel to help administrators proactively identify and resolve session failures and performance issues. This powerful tool provides diagnostic insights, refreshed every 15 minutes, to highlight problematic machines and sessions impacting your site.

Key insights include:

- Black Hole machines: Detects machines that fail to service consecutive session requests

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Zombie sessions: Identifies single-session OS machines with abandoned sessions that block new session launches.
- Overloaded machines: Flags machines with sustained CPU or memory spikes that are degrading user experience.
- Connection failures: Highlights client and server failures, providing details on failure patterns and user impact.

The insights are customizable, with alert policies that can be configured for notification. Insights empower administrators to be proactive, take timely action, and improve session availability and performance across their environment. For more information, see Insights

October 2025

New and enhanced features

Citrix Advisor: New checks for reliability, performance, security, and cost efficiency. Citrix Advisor now includes the following new environment checks that provide actionable recommendations to help improve reliability, performance, security, and cost efficiency:

- **Reliability**
  - Enable communication between Cloud Connectors for reliable LHC performance
  - Place Cloud Connectors in the same domain
  - Check resiliency configurations
- **Performance**
  - Rightsize high resource-consuming machines
  - Reduce the number of host connections in your zones
  - Reduce the number of VDAs in your zones
  - Evaluate resource allocation for PVS servers
  - Increase resource allocation for PVS servers
  - Optimize Cloud Connectors for LHC mode
- **Security**
  - Upgrade Citrix Workspace app versions that reached End of Life
  - Assign resources to security groups

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Cost optimization**
  - Release unused resources

These enhancements help you proactively identify issues and take corrective actions to maintain a reliable, secure, and cost-effective environment. For more information, see Citrix Advisor.

Provision persistent workloads of Amazon WorkSpaces Core Managed Instances. Previously, you could only use MCS to provision non-persistent workloads of Amazon WorkSpaces Core Managed Instances. With this new capability, you can create a persistent catalog of Amazon WorkSpaces Core Managed Instances using MCS. User writes and changes to their desktops are persisted on the OS disk (root volume) between different boots of their persistent WorkSpaces Core Managed Instance provisioned by MCS.

Note that this workflow differs from using Quick Deploy to provision Amazon WorkSpaces Core Bundles.

For more information, see Create a catalog of Amazon WorkSpaces Core Managed Instances.

Amazon WorkSpaces Core Managed Instances: Share prepared images across availability zones. Previously, to create MCS machine catalogs across multiple availability zones, you needed a separate prepared image for each availability zone. This increased your operational complexity to have to manage several prepared images and could lead to potential inconsistencies in image management.

With this feature, you can share a single prepared image across different availability zones within the same AWS region for Amazon WorkSpaces Core Managed Instances. This simplifies catalog creation and image updates, reducing management overhead significantly. Currently, use PowerShell commands to manage image sharing. For more information, see Share Prepared Images Across Availability Zones.

Share prepared image versions across clusters and vCenters. You can now use the **Images** node to share image versions across hosting connections in VMware. This implementation ensures consistency and uniformity of images across different clusters or vCenters, enhancing deployment flexibility and operational efficiency. Alternatively, you can use PowerShell commands to achieve this goal. For more information, see Image Management and Share prepared images.

Create a secure environment for AWS-managed traffic in Amazon WorkSpaces Core environment. If you have a proxy configured on the Cloud Connectors, then you must create the host connection to use the proxy so that API calls made by MCS are properly routed through the proxy. MCS enables network traffic (API calls from Citrix Cloud to AWS hypervisor) to be routed

© 1997–2026 Citrix Systems, Inc. All rights reserved.

through Cloud Connectors in your Amazon WorkSpaces Core environment using Studio. For more information, see Create a connection using Studio.

Exclude maintenance mode VMs from the autoscale pool. Previously, VMs in maintenance mode were included in the autoscale pool depending on the delivery group. For example, single-session delivery groups included VMs in maintenance mode in the autoscale pool, while multi-session delivery groups excluded them.

With the new desktop group property `PoolSizeExcludesMaintenanceMode`, you can now exclude VMs in maintenance mode from the autoscale pool irrespective of the delivery group. If you set the property to `true`, VMs in maintenance mode are excluded from the autoscale pool. Conversely, if set to `false`, they are included. For more information, see Set-BrokerDesktopGroup.

Enhanced user assignment default for improved security. We've updated the default behavior when assigning users within a delivery group. Restricted control is now the default, ensuring better security and more granular access control. The alternative option, **Allow any authenticated users to use resources**, is now clearly marked as **Not recommended**, and should be used only for specific scenarios like shared or pooled desktops for broad access, kiosk environments, or testing purposes. This change helps reduce risk while giving you flexibility when needed.

For more information, see Configure user scope for an access policy.

Two new service health alerts. Two new site-level alerts are available to help you monitor deployment health:

- Resources are located in the initial zone.
- Advanced health check is not enabled on StoreFront.

To view these alerts, click the flag icon in the upper-right corner of the Home page. For more information, see Studio home page.

Improved application package management. In Studio, you can now choose to automatically remove packages that no longer exist in the source (now called *profile*) location when checking for updates. This new **Remove absent packages** option in the **Preferences** field helps you easily clean up the application packages UI by removing outdated entries from the **Packages** tab.

In addition, several tabs and sections in the App packages node have been renamed to better align with the wider suite of package types now supported in Studio:

- **Add Source** is now **Create discovery profile**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Check for package updates** is now **Check for updates**
- **Remove source** is now **Delete profile**

For more information, see Manage app packages.

Cross-account provisioning in AWS EC2 using Studio UI. There are use-cases where the Cloud Connectors would like to be placed in a separate AWS account (shared services account or site components account) with IAM roles that have cross-account access (cross-account IAM role) and MCS-provisioned machine catalogs in separate secondary AWS account (workloads accounts), without the need for additional Cloud Connectors in the separate accounts. Such a deployment model is already supported using Powershell SDK, and is now also supported using the Studio UI.

Enhanced proxy configuration for AWS EC2 host connections. Previously, MCS was unable to read the system proxy value configured by you on the Cloud Connector to configure a system proxy for an AWS host connection. With this enhancement, AWS host connection can now read the WinHTTP system proxy value that is configured during Cloud Connector installation if you set the custom property `UseSystemProxyForHypervisorTrafficOnConnectors` to `true` when creating or updating a host connection using PowerShell. This enhancement therefore:

- Allows AWS client to read proxy values, enabling proper API calls through the proxy, which is essential for internet communication.
- Reduces the need to manually configure proxy server and port values through CLI.

For more information, see Enhanced Proxy Configuration for AWS host connection.

Multi-select support for key entities using “IN” operator. This enhancement introduces the ability to select multiple values for key filter fields such as users, machines, and delivery groups, utilizing an "IN" operator.

September 2025

New and enhanced features

Support for using AWS EC2 Spot instances. With this feature, you can create an MCS machine catalog of Spot instances (persistent request only) in AWS virtualization environment using machine profile workflow.

Compared to On-demand instances, Spot instances offer cost savings of up to 90%. However, Spot instances may be interrupted by Amazon EC2 if capacity becomes unavailable, making them suitable for non-critical applications and desktops only.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Additionally, with this feature, you can use Spot instances as backup SKUs.

For more information, see Create a catalog using AWS Spot instance.

Scoped Studio access for CSP tenant admins (Preview). As a Citrix Service Provider (CSP), you can now grant your tenant admins access to a lightweight version of the DaaS Studio console directly from their Citrix Cloud console.

Instead of being blocked when selecting Manage DaaS, tenant admins are now taken to a scoped Studio view where they can manage their own objects—such as catalogs and delivery groups—based on federated domain and role-based permissions. Unscoped or global objects like Zones and Tags are hidden to maintain tenant isolation and provide a secure, streamlined self-service experience.

For more information, see Tenant service administration.

Citrix Troubleshoot Connection. The Citrix Troubleshoot Connection feature is designed to empower end-users to effectively self-troubleshoot potential desktop or application launch failures. This enhancement aims to provide users with clear diagnostics, potential recommendations, and the ability to run fixes with a simple click. For more information, see Citrix Troubleshoot Connection.

Improved multi-selection in the Search node. We've updated the **Search** node with a more intuitive table layout. This change enables you to:

- Select multiple items using checkboxes in each row, making the experience more intuitive.
- Select all items on the current page using the checkbox in the column header.

While multi-selection and page-level selection aren't new (previously done using keyboard shortcuts), this enhancement greatly improves affordance and usability, and lays the groundwork for future support of multi-selection across pages.

Session auto reconnect details in Filters view and Session Performance tab. You can now view session auto reconnect details in both the **Filters** > **Sessions** tab and the **Session Performance** tab. This enhancement allows you to quickly access and analyze the number of auto reconnects in a session.

Filters view:

To display the new Session Auto Reconnect column, go to **Choose Columns** and then select **Session Auto Reconnect** in the **Filters** > **Sessions** tab.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

A drilldown provides additional information such as Session Reliability or Auto Client Reconnect, timestamps, Endpoint IP, and Endpoint Name of the machine where Citrix Workspace app is installed. This information was previously available in the Trends tab. For more information, see the Historical trends page.

Session Performance Tab:

You can now view session auto reconnect details in the **Last 48 hr** tab of the **Session Performance** tab.

The graph displays the number of Total Session Reconnects, Auto Client Reconnects, and Session Reliability Reconnects.

The auto reconnect information helps you to view and troubleshoot network connections with interruptions and analyze networks for a seamless experience.

Enhanced definitions of ICA RTT and Network latency measurements in Monitor. The definitions and measurement methods for ICA Round Trip Time (RTT) and Network Latency in Director are now enhanced. This update changes the underlying counters and the sampling interval for these metrics. These improvements address previous limitations in how the metrics were reported. You now get more accurate and reliable insights for monitoring user experience in Citrix environments.

Support for image management in Red Hat OpenShift environments. Image management functionality is now generally available for OpenShift virtualization environments. You can use **Images** node to create image definitions, versions, and MCS machine catalogs. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process. You can also use PowerShell commands to achieve this goal. For information, see Create a prepared image machine catalog in Red Hat OpenShift.

Support for creating Red Hat OpenShift catalogs using machine profile. With this feature, using Studio, you can now create a Red Hat OpenShift catalog in MCS using a machine profile. The input of the machine profile is an existing VM. Creating a catalog using a machine profile allows VMs in the catalog to inherit hardware properties such as CPU count and memory size. For information, see Create a Red Hat OpenShift catalog.

Managing prepared image versions in XenServer. Image management functionality is now generally available for XenServer virtualization environments. You can use **Images** node to create multiple image versions, and apply or update to multiple machine catalogs. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image

© 1997–2026 Citrix Systems, Inc. All rights reserved.

update process.You can also use PowerShell commands to achieve this goal. For more information, see Create a prepared image machine catalog in XenServer .

Improve upgrade reliability with a pre-upgrade VDA restart. The VDA Upgrade Service now offers the ability to restart VDAs before the upgrade begins. This helps improve upgrade success rates by starting from a stable system state and avoiding issues caused by pending restarts. For more information, see Upgrade VDAs.

Secure Private Access integration in Web Studio The integration of Secure Private Access (SPA) with Web Studio is enhanced. Administrators in your organization can now open the SPA console directly from the left navigation in Web Studio.

August 2025

New and enhanced features

Multi-select support for delivery groups. The **Delivery Group** drop-downs in the **Sessions** and **Logon Performance** pages under the **Trends** tab are enhanced with:

- Search for delivery group names using text input
- Multi-select up to 15 delivery groups for comprehensive analysis

This enhancement improves usability and allows for more efficient monitoring and comparison across multiple delivery groups simultaneously.

Share prepared image versions across subscriptions and tenants in Azure. You can now use the **Images** node to share image versions across hosting connections in Azure. This implementation ensures consistency and uniformity of images across different subscriptions or tenants, enhancing deployment flexibility and operational efficiency. You can also use PowerShell commands to achieve this goal. For more information, see Image Management.

Improved handling of vertical and horizontal load balancing alerts. Previously, when you set `UseVerticalScalingForRdsLaunches` to true and configured the “Maximum number of sessions” policy in Studio, machines moved to the “Maximum capacity” state. Director triggered alerts for “Maximum capacity” whether the limit was reached due to vertical or horizontal load balancing. There was no way to distinguish between vertical and horizontal load balancing when encountering specific errors, such as "Max Load Reached." This caused unnecessary alerts for expected behavior in vertical scaling scenarios, wasting your time, and creating confusion.

Now, when vertical load balancing is active and a machine reaches its session limit, it moves to a new state: “Maximum capacity for vertical scaling.” Director no longer generates alerts for this new

© 1997–2026 Citrix Systems, Inc. All rights reserved.

state. Alerts only trigger for “Maximum capacity” in horizontal scaling scenarios. You can view the new state in the **Filters** and **Custom reports** pages, making it easier to distinguish between expected and exceptional conditions. This enhancement helps you avoid unnecessary alerts and focus on real issues, streamlining monitoring and troubleshooting. It applies when you configure `UseVerticalScalingForRdsLaunches` using Set-BrokerSite and set the “Maximum number of sessions” policy in Studio.

Connector Appliance health alerts. Previously, creating and managing alerts for Connector Appliance was not available. With this release, you can create and manage alerts for Connector Appliance. This feature enables administrators to monitor the health of Connector Appliances using a single dashboard view and proactively configure alerts.

You can configure alerts under Advanced Alert Policies for the health/connectivity and resource utilization of Connector Appliances. Define severity and scopes for administrators to receive detailed alerts according to the alert configuration. For more information, see Connector Appliance health metrics.

Enhanced network metrics collection for session troubleshooting. Network metrics are critical for Citrix session troubleshooting because session performance and stability depend heavily on underlying network conditions. Unlike local applications, Citrix sessions stream interactive desktop or application experiences over a network, meaning any network instability directly impacts user performance.

Use the policies in Citrix Studio to enable or disable collection of specific network metrics based on your requirements. The policies provide Citrix administrators with granular controls to report metrics in adherence to compliance requirements. For more information, see Network metrics documentation.

Observability for multi-session VDA. The observability for multi-session VDA feature enhances the monitoring and troubleshooting capabilities for Secure Private Access sessions within a multi-user VDA environment. This feature empowers Citrix Helpdesk Administrators to monitor Secure Private Access sessions, troubleshoot issues, and gain insights into app launches and user transactions in case of a multi-session VDA.

Key features:

- Enhanced observability: Administrators can monitor Secure Private Access sessions, including app launches and enumerations, within the Citrix Director interface. This includes detailed views of enumeration and app launch issues.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- User context tracking: The feature maintains user context for apps accessed in a shared VDA environment, ensuring accurate session data visibility for each user.
- Error insights: Captures and displays Single Sign-On (SSO) failures, error codes (e.g., 6003, 6007), and troubleshooting steps to resolve issues.
- Session search: Administrators can search for sessions, apps, and user transactions using the same workflow as for VDI sessions and apps.
- Cross-session navigation: Enables navigation between Secure Private Access sessions and VDA sessions for streamlined troubleshooting.

For more information, see Observability for multi-session VDA.

Custom schedule for holidays. Autoscale™ now allows you to create custom schedules to turn off unused VMs in a delivery group on specific days, like holidays, to reduce unnecessary resource consumption.

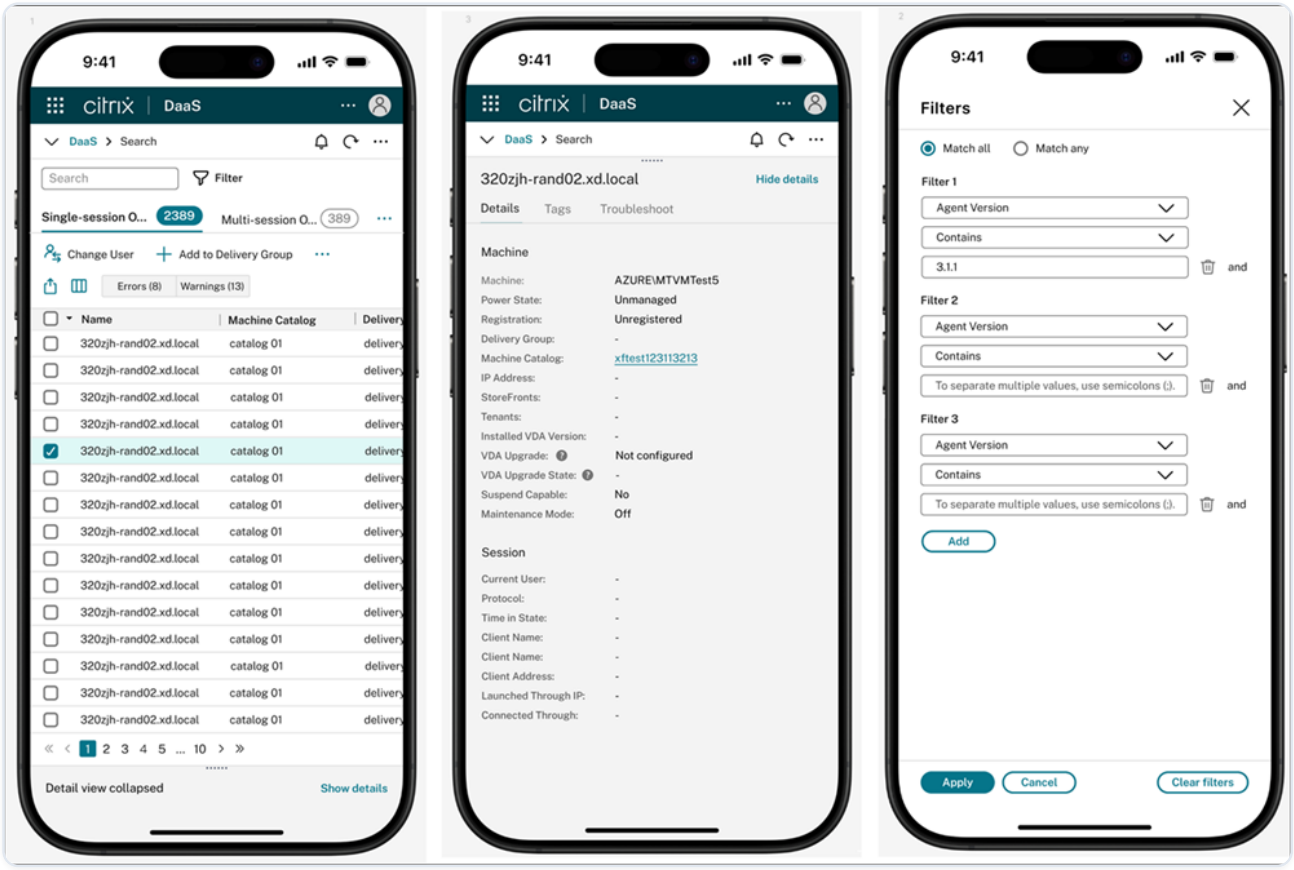
To create custom schedules:

1. In Studio, go to **Delivery Groups**. Right click a delivery group and select **Manage Autoscale**.
2. On the **Schedule** page, click **Create schedule**.

For more information on creating custom schedules for holidays, see Create custom holiday schedules using Studio.

Support for Image Management with Azure Confidential VMs using Studio UI. You can now use the **Images** node to prepare and manage images that are compatible with Azure Confidential VMs. You can also use PowerShell commands to achieve this goal. For more information, see:

- Azure confidential VMs
- Create an image definition and initial image version



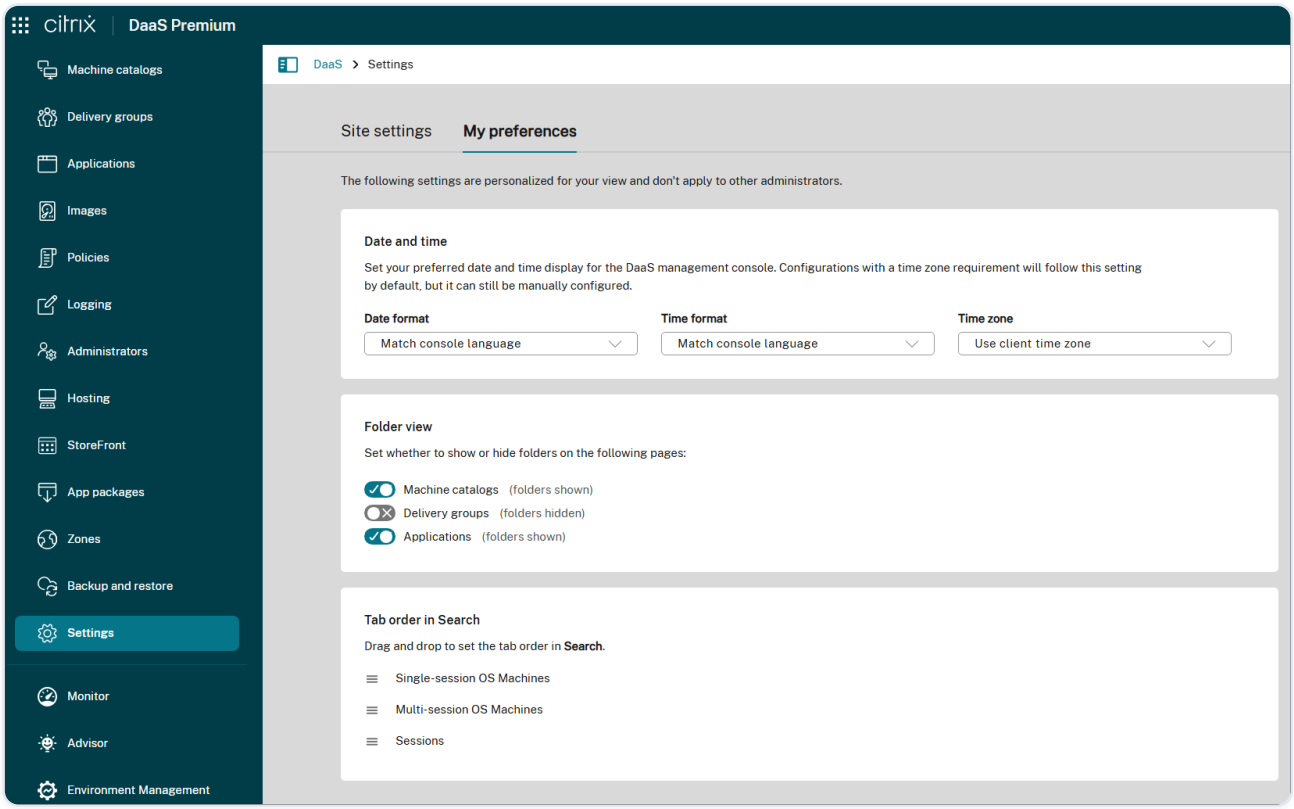
Enhanced mobile experience for critical on-the-go DaaS tasks. You can now manage Citrix DaaS more easily from your mobile device. The updated experience is optimized for smaller screens, making it easier to access Studio from a mobile device when a desktop isn't available. Whether you're responding to an alert or quickly checking a misconfiguration, you can take action right away—no need to wait until you're back at your desk.

The mobile interface offers improved accessibility and is designed for touch-friendly interactions. Layouts and functionality might differ slightly from the desktop experience to better suit mobile workflows.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

With a responsive layout and streamlined navigation, you can:

- Monitor DaaS health at a glance
- View details for machine catalogs and delivery groups
- Take key actions, such as restarting machines or disabling delivery groups



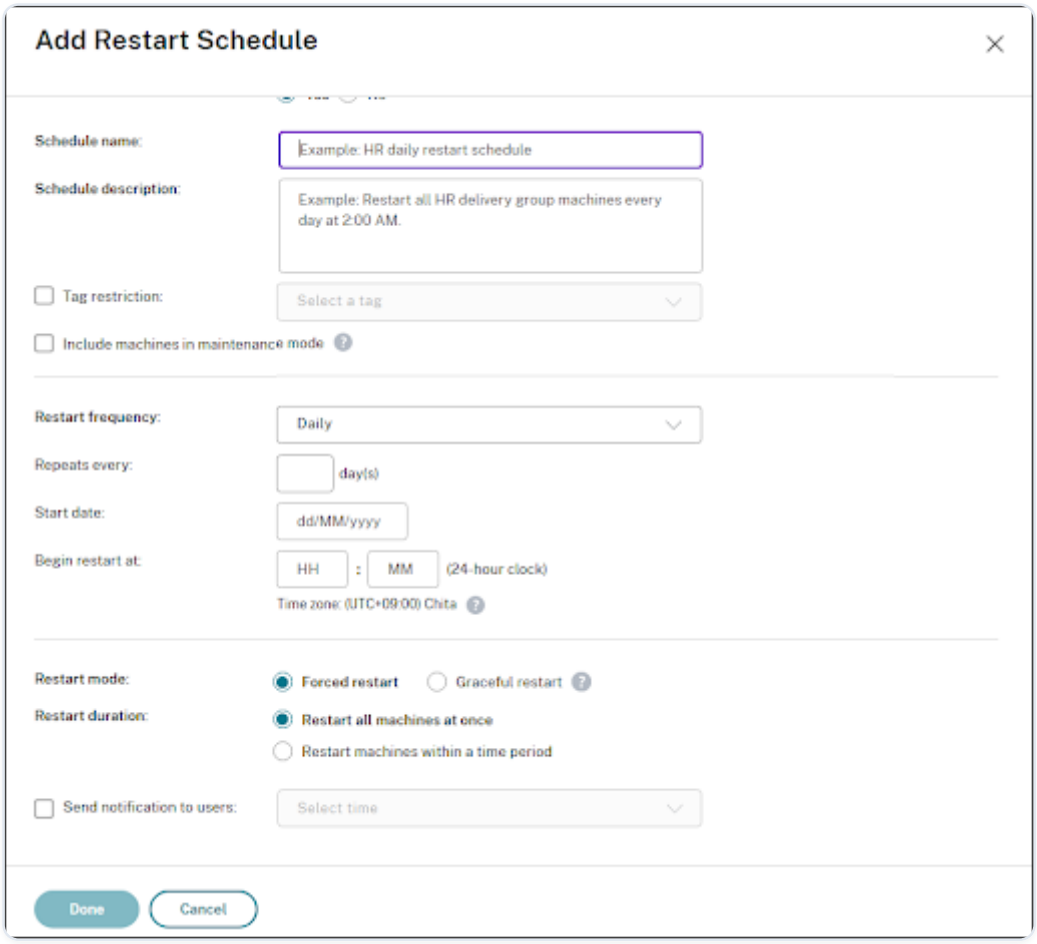
Customize your Studio view with My preferences settings. A new **My preferences** tab is now available under the **Settings** node. Settings on this tab let you tailor your Studio interface to suit your preferences. These settings apply only to your account and don't affect other administrators.

You can configure the following options:

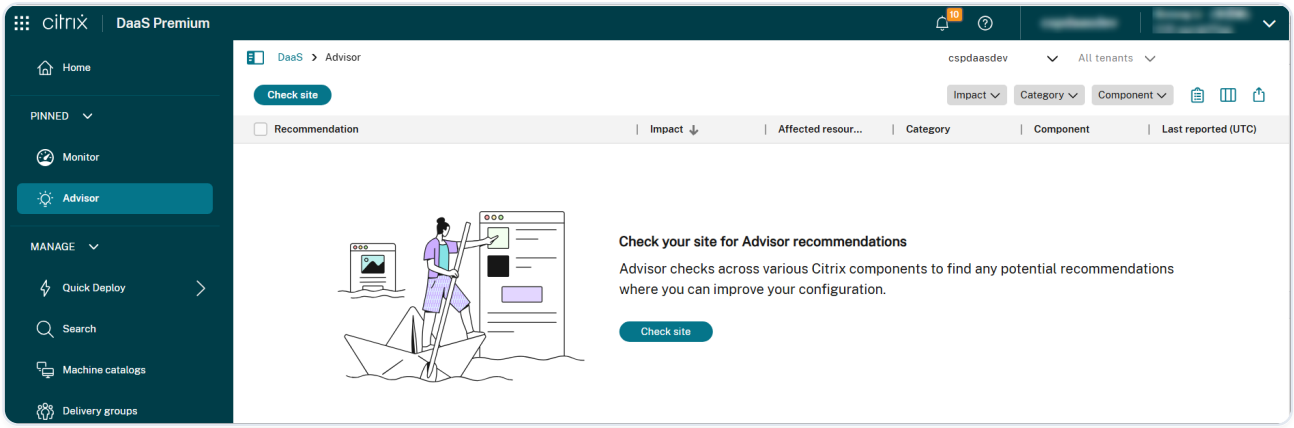
- **Date and time**: Set your default time zone, date format, and time format. These settings are used throughout Studio for time-related displays, such as scheduled restarts and autoscaling.
- **Folder view:** Choose whether to show or hide the folder view in the **Machine Catalogs**, **Delivery Groups**, and **Applications** nodes.
- **Tab order in Search**: Customize the tab order within the **Search** node.

For more information, see Manage personal preferences in Studio

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Improved restart UI for clearer control and customization. We've enhanced the restart schedule UI to make restart modes clearer and more customizable. You can now easily distinguish between *graceful restart* and *forced restart*, and configure custom restart durations to suit your needs.



To help you make informed choices, we've also added tooltips that explain key options—such as how forced restart can forcibly restart machines, even if sessions are unresponsive.

For more information, see Manage delivery groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Citrix Advisor: Proactive insights and optimization for your DaaS deployment. Citrix Advisor is a service that helps you optimize DaaS deployment and enhance its overall health and readiness. It automates environment checks and delivers actionable recommendations, empowering you to proactively identify configuration issues, inefficiencies, resource wastes, deviations from best practices, and more.

With Advisor, you can:

- **Proactively identify and resolve issues:** Detect potential problems, configuration drift, and deviations from best practices before they impact users, disrupt business operations, or compromise security.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Optimize environment performance and stability:** Fine-tune configurations, optimize resource allocation, and implement best practices to enhance the stability, security, and performance of your Citrix deployments.
- **Streamline operations and reduce overhead:** Automate routine checks, simplify complex remediation tasks, and receive guided assistance, thus reducing operational overhead and freeing up administrative resources.
- **Optimize costs and resource utilization:** Identify areas of overspending, uncover opportunities for resource optimization, and ensure efficient utilization of Citrix technologies to minimize total cost of ownership.
- **Maintain compliance and adherence to best practices:** Ensure that Citrix deployments adhere to Citrix best practices, security standards, and industry regulations, reducing risk and improving overall governance.
- **Simplify complex tasks:** Simplify administrative tasks to support a healthy, optimized environment.

For more information, see Citrix Advisor.

July 2025

New and enhanced features

Cost summary. The **Cost summary** page provides a comprehensive summary of the expenses associated with running the Citrix environment. With this enhancement, you gain visibility into the following:

- The overall cost per user
- Cost of delivering virtualization by the chosen Workload providers, desktop types, and VM series sets

This page offers:

- Insight into the cost of delivering a virtualized app or desktop to a user The amount saved
- Information on costs and savings categorized by
  - Platform provider
  - OS type
  - Desktop type
  - VM series

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The **Cost summary** page is available only if the site has been running for at least 15 days in a month.

For more information, see the Cost summary page.

Cross-account provisioning in AWS EC2 using PowerShell. There are use-cases where the Cloud Connectors would like to be placed in a separate AWS account (shared services account or site components account) with IAM roles that have cross-account access (cross-account IAM role) and MCS-provisioned machine catalogs in separate secondary AWS account (workloads accounts), without the need for additional Cloud Connectors in the separate accounts. To support such scenarios, this feature uses VPC peering and cross-account access using IAM roles to make provisioning across different AWS accounts possible for enterprises managing multiple AWS accounts.

With VPC peering, you can have your Cloud Connector, and provisioned VMs in different regions or accounts be able to communicate among each other.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

For detailed information, see Cross account provisioning.

Support for backup SKU list for VMs in AWS EC2. Public clouds can sometimes run out of capacity for a specific EC2 instance type (**Primary SKU**). If the primary VM configuration is not available, then the VM cannot start resulting in loss of time and business disruption.

With this feature, in the AWS virtualization environment, you can provide a list of backup EC2 instance types (**Backup SKUs** that can be **On-demand** instances) using PowerShell that MCS can fall back to in case of capacity-related issues. MCS tries to fall back on the backup EC2 instance types in the order that is provided by you in the list. In case MCS fails to fall back on all backup EC2 instance types provided, you get an error message. This feature is applicable to both persistent and non-persistent MCS machine catalogs.

For more information, see Backup SKU list for VMs.

Enhanced session launch diagnostics with recommended actions. The updated **Session Launch Failure Diagnostics** page offers a more thorough understanding of session launch issues. You can find the visualization of involved components with error analysis and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

recommended actions. Previously, only a **Transaction Details** panel was available, which listed involved components and indicated error locations.

The enhanced page now includes:

- Components overview: This section displays all components involved in the session launch process, adapting to the specific scenario and failure stage. Examples of components include Endpoint, Citrix Workspace™, Citrix DaaS, Cloud Connector, Gateway Service, VDA, and StoreFront. The root cause component is clearly highlighted.
- Error details: Specific error messages and context are provided for quick identification of the root cause.
- Transaction logs: Raw session launch event data is accessible for in-depth troubleshooting and analysis.

These enhancements enable IT administrators to resolve session launch issues more quickly and efficiently. For more information, see the Session Launch Diagnostics documentation.

Integration with Nutanix Prism Central on AHV. You can now connect Citrix DaaS to Nutanix AHV clusters through Nutanix Prism Central using a new host connection, Nutanix AHV Prism Central.

The benefits of using Nutanix AHV Prism Central host connection are:

- Supports machine catalogs with both power managed only and MCS provisioned VDAs.
- Enables MCS master VM sharing across AHV clusters using template version.
- Simplifies certificate trust on host connection.
- Eliminates the need to separately install the plug-in on Cloud Connectors.

For more information, see:

- Nutanix virtualization environments
- Nutanix cloud and partner solutions
- Connection to Nutanix
- Connection to Nutanix cloud and partner solutions
- Create a Nutanix catalog
- Manage a Nutanix catalog

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for creating non-persistent MCS machine catalogs in Amazon Workspaces Core. MCS has now integrated with Amazon Workspaces Core to provision non-persistent MCS machine catalogs in the customer's AWS account. For a comparison of how this new integration compares with MCS for AWS EC2 and Quick Deploy for Amazon WorkSpaces Core Bundles and how to set up the resource location, see AWS virtualization environments.

With this feature:

- You can create a host connection to Amazon WorkSpaces Core Managed Instances.
- Create a prepared image and use the prepared image and machine profile to create a non-persistent MCS machine catalog.

Customize desktop icons across platforms using Studio. Studio now allows you to customize desktop icons for any desktop of your choice. Previously, all desktops used the default icon, and you couldn't change it in Studio. You can now:

- Upload icons and use them for desktops or apps
- Change the icon for individual desktops
- Select from built-in icons for the desktops of your choice

For more information, see Create delivery groups and Manage delivery groups.

Studio: Support for more granular control over access policies in delivery groups. Previously, you could apply access policies to specific users only using PowerShell or REST APIs. Now, you can achieve this goal directly in Studio. This enhancement gives you more flexibility in defining different access conditions for various users or user groups, achieving more granular access control. For more information, see Configure user scope for an access policy.

Additionally, we've improved compatibility between Studio and the PowerShell or REST API approach. Previously, if you configured access policies with user scopes using PowerShell or REST APIs, the Users and Access Policies pages in Studio were blocked. Studio now fully supports these scenarios, offering clear information or UI guidance where necessary.

Option to use system proxy on Citrix Cloud™ Connectors for redirected Azure and GCP API traffic. With this feature, you can redirect Azure and GCP API internet traffic on Citrix Cloud Connectors through the system proxy. This helps you to route all external traffic through a non-transparent proxy.

For information on enabling the proxy, see:

- For Azure:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - Studio: Create a service principal and connection using Studio
  - PowerShell: Option to use system proxy on Citrix Cloud Connectors for redirected Azure API traffic

- For GCP:
  - Studio: Add a connection
  - PowerShell: Option to use system proxy on Citrix Cloud Connectors for redirected GCP traffic

Share encrypted prepared image across subscriptions and tenants for Azure. Azure Compute Gallery (ACG) images can be encrypted with a Disk Encryption Set (DES). With this feature, you can share an encrypted prepared image across subscriptions and tenants. You can thereafter create a machine catalog in the resource where the encrypted prepared image is shared. For more information, see Share encrypted prepared images across regions, subscriptions, tenants.

Add notes while assigning prepared images. With this feature, you can now add custom notes using Studio and PowerShell while creating or updating an MCS catalog with a prepared image. MCS keeps a record of all prepared image assignments. This helps you to:

- Retrieve the image assignments history of all the prepared images assigned to a catalog.
- Quickly roll back a machine catalog to a previously assigned prepared image using the **Use previous image assignment for quick rollback** action. Simply select a version from the history list for a quick and informed rollback. For information on rolling back, see Update a machine catalog with a different prepared image.

This feature is applicable to both Azure and VMware environments

For information on creating a catalog with prepared images, see:

- Create a prepared image machine catalog in Azure
- Create a prepared image machine catalog in VMware

For information on updating a catalog with prepared images, see Manage prepared image machine catalogs.

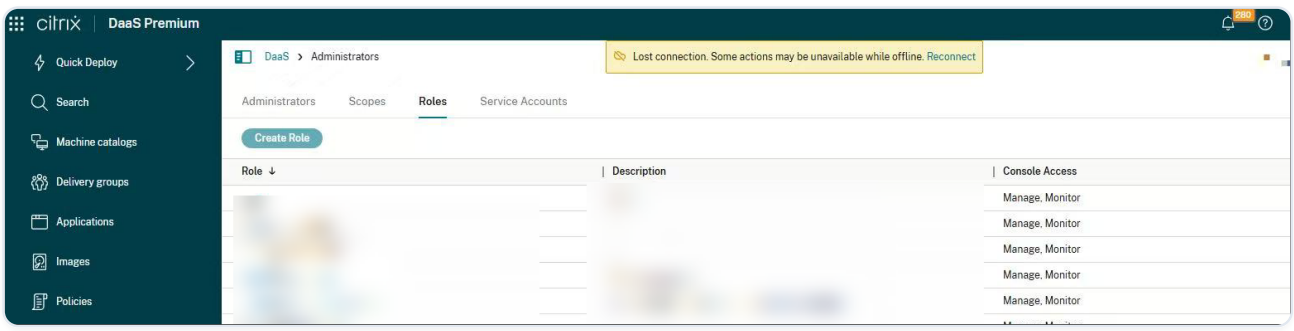
Support for Azure Arc onboarding across all on-premises hypervisor. Azure Arc enables organizations to manage resources such as VMs hosted anywhere as if they are running in Azure.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

With Azure Arc, you can use Azure services such as Azure Monitor for comprehensive visibility and proactive management of the resources.

With this feature, you can now enable Azure Arc Onboarding for an MCS machine catalog using PowerShell commands. Once onboarded, the VMs can be managed from the Azure portal to perform operations such as power management, add or remove extensions, assign policies, and enable Azure Monitor on the Arc-enabled VMs through built-in Azure policy.

Currently, this feature is applicable to all Citrix on-premises hypervisors Vmware, Nutanix and SCVMM.



For more information, see Onboard VMs to Azure Arc.

Migration from unmanaged to managed disks in Azure. On September 30, 2025, Azure will officially retire unmanaged disks (that is, VHDs). After this date, you will no longer be able to start Azure VMs that use unmanaged disks. With this feature, you can migrate your MCS-provisioned Azure VMs from unmanaged to managed disks through Citrix.

The migration applies to both persistent and non-persistent machine catalogs, supporting both on-demand and legacy VMs. This ensures seamless integration with Azure's updated disk management standards and prevents any service disruptions due to the retirement of unmanaged disks. For more information, see Migrate from unmanaged to managed disks.

Support for Image Management with Azure Confidential VMs. You can now prepare and manage images that are compatible with Azure Confidential VMs. These images ensure that VMs provisioned from such MCS machine catalogs are encrypted in memory and protected while in use. For more information on Image Management, see Image management.

Studio always-on mode. Web Studio now introduces always-on mode to enhance resiliency and reduce downtime during infrastructure failures. In this read-only mode, you can securely view and monitor your Citrix DaaS environment even during service disruptions, helping maintain operational continuity. Always-on mode is available on all MANAGE nodes, except Quick Deploy. For more information, see this blog post.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Studio: Support for managing Azure AD security groups using service accounts. In Studio, you can now use Azure AD service accounts to configure and manage dynamic security groups for VMs. Previously, configuring Azure AD security groups required manually entering credentials. This update allows you to use a pre-configured service account to perform security group management without user interaction, simplifying the process and enhancing security.

For more information, see Azure AD service accounts and Create a Microsoft Azure catalog.

Migrate existing MCS provisioned catalogs to prepared image machine catalog. With this feature, you can convert an existing MCS catalog provisioned from master image to a catalog using a prepared image. For information on prepared image, see Image management.

However, you cannot revert to the legacy catalog after migration. Currently, this feature is applicable to Azure and VMware virtualization environments. For information on the steps to migrate, see Migrate existing MCS provisioned catalogs to prepared image machine catalog.

Display NVMe v6 SKUs for ephemeral OSDisk usage. You now have the option to store an ephemeral OS disk on a NVMe Disk using Studio. For information see, Azure ephemeral disks.

Updated duration of Pending HA state. The Pending HA state duration when Cloud Connectors determine if there is a need to enter LHC mode has been extended from 60 to 90 seconds. For information on LHC states, see Local Host Cache states.

June 2025

New and enhanced features

Support for assigning Citrix Group Policies to Microsoft Entra ID users. You can now assign Citrix Group Policies to Microsoft Entra ID (Azure AD) users from multiple IDPs in Studio. This enhancement gives you more flexibility when applying policies to specific user groups and simplifies deployments using Citrix DaaS with Windows 365. For more information, see Specify policy assignments.

Monitoring VDA logon duration details. Citrix Monitor now includes detailed information on VDA logon duration to provide visibility into the time taken to log on to the VDA. The following items are added to view the details of VDA logon duration:

- The following metrics are added to the tooltip as breakdown metrics:
  - **AppX file associations**: The time taken to associate AppX files during the new VDA session.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - **AppX load packages**: The time taken to load the AppX packages during the new VDA session.

  These metrics are exported in PDF and CSV formats, and the chart is also included in the exported files.

- Breakdown of **Shell** step on the **Session Logon** tab: AppX file associations and AppX load packages are added as a breakdown of interactive session step on the graph on the **Session Logon** graph tab.

Benefits:

- Accurate troubleshooting: Helps administrators accurately determine the causes of slow logons, which might be often due to deployment type, GPOs, profiles, and user interaction.
- Corrective actions: Enables administrators to take corrective actions in the right areas, improving the overall user experience.

This feature is designed to improve the session logon breakdown, providing a more accurate representation of logon performance and session logon triage for the Director help desk.

For more information, see Logon process phases.

Endpoint metrics available on the Filters tab and Custom Reports. Previously, endpoint metrics were available only in the Endpoint view at the **User Details** > **Session Performance** > **Session Topology** section.

With this enhancement, you can now view the following more endpoint metrics in the Monitor Connection or Session filters and Custom Reports:

- Public IP address
- ISP
- Location (Country or City)
- Workspace type - Citrix Workspace app (app or browser)
- Access type (through Workspace or StoreFront)

This enhancement helps you to do the following:

- You can select the endpoint metrics as part of column selection in the **Filters** tab.
- You can create custom reports using the **Custom Query** option by selecting output columns as endpoint metrics.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bulk alert dismissal. This feature aims to optimize the alert management process for administrators by providing more flexibility and reducing alert fatigue. It allows administrators to bulk dismiss alerts by time, type or category, making it easier to manage alerts, especially during maintenance modes or when dealing with alerts from hypervisors and other environments.

By allowing bulk dismissal of alerts, administrators can manage their workload more efficiently and avoid being overwhelmed by a high volume of alerts.

For more information, see Bulk alert dismissal.

Enhanced network metrics monitoring in Citrix Monitor. Citrix Monitor now provides administrators with unparalleled visibility into session performance. This enhancement empowers them to proactively identify and address bottlenecks, optimize applications, and ensure a superior user experience.

Key enhancements:

- **L7 latency monitoring**: Pinpoint and resolve performance issues by monitoring application-level processing time (L7 latency).
- **New network metrics**: Gain a comprehensive understanding of network performance through insights into throughput and client-side retransmits.
- **Historical data**: Identify patterns and potential issues by viewing latency trends for the past 15 minutes and 24 hours.
- **Filtering**: Perform targeted analysis and troubleshooting by filtering latency data in the **Filters** page.
- **Session connection path visualization**: Quickly identify and resolve latency issues by visualizing the end user's connection path to VDA machines, including network hops and components.

Benefits:

- **Enhanced visibility**: Rapidly identify the root causes of poor in-session experiences.
- **Efficient troubleshooting**: Streamline latency troubleshooting with a clear visualization of the session connection path.

Metrics collected:

- Throughput
- L7 Server Latency

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- L7 Client Latency
- Client-Side Retransmits

NOTE:

- To view the new metrics, enable the **Network Telemetry** policy in Citrix Web Studio. After enabling the policy, users must launch a new session for the changes to take effect.
- L7 latency is measured for HDX™ sessions established with Citrix Workspace app for Windows and Windows VDA through the Gatxeway service.
- After launching a session:
- New metrics are available in the **Session Topology** and **Last 15 Minutes** sections after a 2-minute wait.
- Historical data (from the last 48 hours) is available after approximately 5 minutes due to the 5-minute aggregation window.

With these enhancements, Citrix Monitor equips administrators with the tools to proactively optimize application performance and deliver a seamless user experience.

For more information, see End-to-end Network Hop view documentation.

Support for Citrix-managed OpenShift plug-in. With this feature, Citrix manages your Red Hat OpenShift workloads through a Citrix-managed OpenShift plug-in. With this plug-in, you can create hosting connections and hosting units to your OpenShift cluster, create catalogs, and power manage machines in the catalog. For more information, see:

- Red Hat OpenShift virtualization environments
- Connection to Red Hat OpenShift
- Create a Red Hat OpenShift catalog

Improved UI performance for importing VMs from AWS. We've enhanced Studio UI performance by optimizing the process of importing VMs into Citrix DaaS from AWS. To prevent timeouts caused by fetching a large number of AMIs, Studio no longer retrieves AMIs during this process.

Service account for routing Azure AD Identity traffic. Using this feature, you can create and modify an Azure AD service account to route Azure AD identity traffic from Delivery Controller to

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure AD through Citrix Cloud Connector to enhance security. For more information, see Route Azure AD device management and security group management traffic.

Support for assigning security groups per network interface to VMs using the machine profile in AWS. In the AWS virtualization environment, you can now create an MCS machine catalog where the provisioned VMs are assigned security groups per ENI (Network Interface). To do this, use a machine profile input (EC2 instance or launch template) that has different security groups mapped to distinct ENIs. For example, if machine profile input has ENI A with SG 1 and ENI B with SG 2, then provisioned VMs will also have ENI A with SG 1 and ENI B with SG 2.

This feature applies to:

- Persistent and non-persistent catalogs
- New machine catalogs
- New VMs provisioned to an existing catalog

For information, see Create a machine profile-based machine catalog using PowerShell.

Support for creating host connections using Azure Managed Identity using Studio. Using Studio, you can now create host connections to Microsoft Azure Resource Manager using Azure Managed Identity. This method offers a secure and scalable alternative to using a service principal, eliminating the need to manage credentials manually. Managed identities support automatic token refresh and reduce the risks associated with storing and rotating secrets. Alternatively, you can use PowerShell. For more information, see Create a host connection using Azure Managed Identity and Manage Azure Managed Identity of an existing hosting connection.

Cost modeling for Azure workloads. The new cost modeling feature supports Azure workloads and provides recommendations based on usage patterns. Customers receive recommendations on whether Azure Reservations or Savings Plan is more suitable to provide maximum cost savings. Azure Reservations customers reserve a specific number of machines upfront at a discounted flat cost, while savings plans allow them to commit to a dollar amount for discounted rates. The feature analyzes the last 28 days of data to provide estimated recommendations. This feature helps customers save costs by making informed decisions on resource allocation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

For optimal estimates, it is recommended to use data from a stable environment over the last 28 days. Avoid using data from periods of unusual activity, such as vacations or sudden spikes in usage. Wait until your usage returns to baseline levels before taking these recommendations.

Benefits:

- Provides tailored cost-saving recommendations.
- Supports both reservation and savings plans.
- Analyzes recent usage data for accurate insights.
- Helps optimize resource allocation and reduce expenses.
- Offers flexibility in selecting delivery groups, tags, VM series, and regions.

For more information, see the Cost modeling page.

View and filter machines by VDA upgrade state in Studio. Studio now includes **VDA Upgrade State** as a column in the **Search** and **Machine Catalogs** nodes. This column shows the status of scheduled VDA upgrades—for example, whether an upgrade was successful. You can also filter machines based on their VDA upgrade state, making it easier to track and manage VDA upgrades across your deployment.

For more information about this column, see Machine actions and columns.

Option to extend monitoring of HDX optimization beyond Microsoft Teams. Citrix Monitor now adds an option to extend the monitoring of HDX optimization beyond Microsoft Teams. Previously, only Microsoft Teams was available for monitoring HDX optimization, showing whether it was optimized or not in the **Session Topology** screen. With this new feature, instead of **Microsoft Teams**, a new parameter called **Real-time communications** is added on the **Session Topology** screen. Currently, only Microsoft Teams is monitored for HDX optimization status. However, this feature provides the possibility of adding more software for monitoring beyond just Microsoft Teams in the future. This feature allows administrators to monitor and troubleshoot applications with and without HDX optimizations, providing a better user experience.

You can click **View details** next to the application to view additional information, such as categorization under Third-Party Optimization and HDX Optimization. For Microsoft Teams Slims

© 1997–2026 Citrix Systems, Inc. All rights reserved.

core, it is part of third-party optimization. If not part of third-party optimization, then it is HDX optimized.

Key features and benefits:

- **Comprehensive monitoring**: Monitor and troubleshoot both HDX optimized and non-optimized applications.
- **Detailed insights**: View detailed information about the optimization status of applications.

NOTE:

- To use this new feature, ensure that you are using the Citrix Workspace app for Windows version 2503 and VDA version 2503.
- For using Microsoft Teams Slims core, you must install the Plug-in manager on the endpoint, configure the allow list for the virtual channel, and ensure that the virtual channel is open. This feature is only for HDX sessions.

For more information, see HDX optimization details.

New metrics in the Monitor dashboard. Citrix Monitor dashboard is enriched with the following two metrics to provide valuable insights for administrators:

- **Total connected users**: Shows the number of users who had at least one connection in the last 24 hours and the last 7 days. Helps the admins to showcase adoption trends to their executives.
- **Citrix Workspace app versions found in your environment**: Provides an overview of the Citrix Workspace app versions used across the organization. It helps in unifying the versions by showing how many devices are using different versions. You can select the **All** or specific OS from the **Platform** drop-down list.

This feature provides essential data points for administrators to monitor and manage their environments effectively.

Fore more information, see Site Analytics page.

Enhancements to Cost savings page. The following enhancements have been made to the Cost saving page to provide you greater flexibility and insight when managing costs:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Service provider filter supportability option**: You can now filter by service providers. If a site has both cloud and on-premises workloads, you can now filter by all cloud providers, all on-premises providers, or individual providers.

  NOTE:

  The filter is applied immediately upon selection without an apply button.

- **Multiple delivery group selection**: Previously, you can only select a single delivery group (DG) or all DGs. Now, you can select up to 15 DGs at once. If a site has fewer than 15 DGs, you can select all available DGs. You can also exclude specific DGs from the selection to view data for the remaining DGs.
- **Insight into failed machines**: The **Cost savings** page now provides visibility into machines in a failed or unregistered state. The following two new fields are included:
  - **Failed state with no sessions**: This field displays the count of machines that are in a failed state and have no active sessions.
  - **Unregistered with sessions**: This field displays the count of machines that are in an unregistered state but still have active sessions.

You can see the count of machines in the preceding states and act based on the failure reason, time, and delivery group. The counts are clickable links that navigate to the **Filters** page for further actions. The count includes both single-session and multi-session machines.

NOTE:

Filters are preserved across page navigation.

For more information, see the Cost savings page.

May 2025

New and enhanced features

Share encrypted prepared image across regions in Azure. Azure Compute Gallery (ACG) images can be encrypted with a Disk Encryption Set (DES). With this feature, you can share an encrypted prepared ACG image across multiple regions in the same subscription and tenant using

© 1997–2026 Citrix Systems, Inc. All rights reserved.

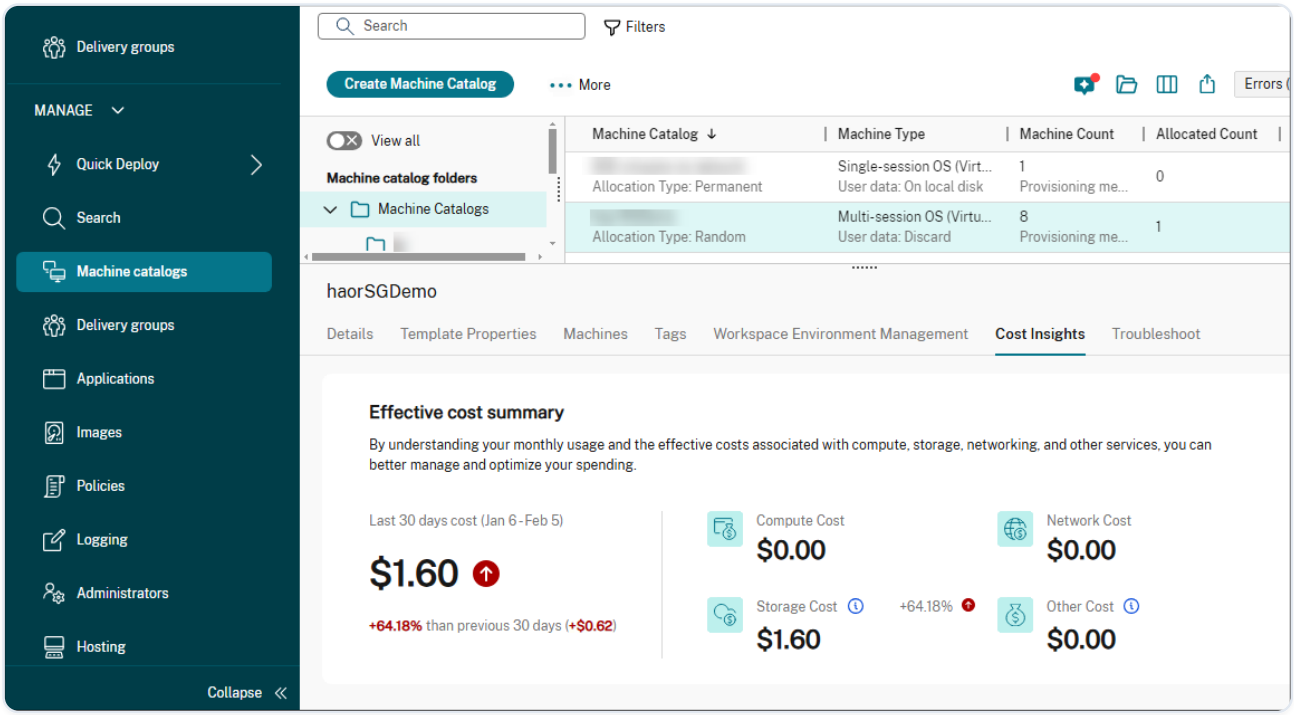
DES. You can thereafter create a machine catalog in the region where the encrypted prepared image is shared. For more information, see Share encrypted prepared image across regions.

Update properties of individual VMs in VMware. You can now update properties of individual VMs in a persistent MCS machine catalog using a PowerShell command. This implementation helps you to manage individual VMs efficiently without updating the entire machine catalog. Currently, this feature is applicable only to the Azure and VMware virtualization environments. For more information, see Update properties of individual VMs.

Support for updating MCS provisioned machines in VMware environments. In VMware environments, `Set-ProvScheme` changes the provisioning scheme and does not affect existing machines of an MCS machine catalog. Using the PowerShell command `Set-ProvVMUpdateTimeWindow`, you can now apply the current provisioning scheme to an existing persistent or non-persistent machine or set of machines. This feature is applicable to machine profile and non-machine profile-based machine catalog. For more information, see Update provisioned VMs to current provisioning scheme state.

Estimate Azure VM costs during catalog creation. When creating a machine catalog, you can now estimate the monthly cost of Azure virtual machines, including VM size and disk costs. You can also refine the estimate by adjusting settings such as daily power-on hours, workdays, savings plans, reserved instances, and shutdown storage. This feature helps you plan deployments more efficiently and optimize costs early on.

For more information, see View monthly estimate details.



Visualization of provisioning cost insights. You can now view detailed cost information for machine catalogs. The visualization provides an overview of provisioning costs and trends for the last 30 days.

The report breaks down provisioning costs based on individual catalogs, allowing for a clear understanding of how each category contributes to the overall cost. The report:

- Displays the total cost incurred over the past 30 days.
- Compares the current 30-day total cost with the previous 30-day period.
- Displays cost details of:
  - Compute cost
  - Storage cost
  - Network cost

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Other cost

For more information, see View catalog details.

Support for converting machine catalogs from using master images to using prepared images. With a new action, **Convert to Prepared Image**, in Studio, you can now convert MCS-provisioned machine catalogs using master images to catalogs using prepared images. The converted catalogs cannot be reversed. This feature is available for Azure and VMware virtualization environments.

For more information, see Convert MCS-provisioned catalogs from using master images to using prepared images.

Proxy configuration for service accounts. Service accounts creation now supports proxy configuration through NGS Proxy for Azure AD Identity management. With this feature, you can:

- Delete Azure AD devices for Azure AD joined catalogs
- Delete Intune devices for Azure AD joined and Intune enrolled catalogs
- Create, edit, and delete Azure AD security groups

For more information, see Create an Azure AD service account.

Connector Appliance health metrics. The **Connector Appliance** component is added by default as part of Infrastructure monitoring. The **Connector Appliance** component that is connected to the Citrix DaaS site is auto onboarded for monitoring.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This feature enables customers to monitor Connector Appliance's health under the Infrastructure monitoring dashboard.

You can select the required **Component** type and the details are displayed according to the selected site name. You can also select the **Resource location**. For more information, see Connector Appliance health metrics.

April 2025

New and enhanced features

Use Autoscale to hibernate VMs. The power management is now enhanced to support hibernation of VMs through Autoscale configurable settings. Use the PowerShell commands `Get-BrokerDesktopGroups`, `New-BrokerDesktopGroups`, or `Set-BrokerDesktopGroups` to set the following positive value to the parameter `AutoscaleScaleDownActionDuringPeak` (during peak) or `AutoscaleScaleDownActionDuringOffPeak` (during off peak) to define the power actions:

- 0: Shut down the VMs when scaling down
- 1: Suspend (hibernate the VMs) when scaling down

VMs not capable of hibernation are shut down.

Intelligent Autoscale. Intelligent Autoscale is a data driven Autoscale feature with minimum administrative settings that allows you to configure the performance target of a delivery group. The performance target value ranges from 1 to 99 and the value specifies a target balance between user experience and cost:

- A low value prioritizes cost savings.
- A high value prioritizes user experience.

The performance target, combined with historical usage data, calculates an optimal buffer capacity (the number of VMs to be powered on) for each 30-minute block of a day. Therefore, 48 optimal buffer capacities are computed at the start of each day.

The optimal buffer capacity replaces peak and off-peak buffer capacity and pool size to manage available machines.

For more information, see Intelligent Autoscale schedules plugin.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Studio: Support for exercising access control over apps at the delivery group level. Previously, within Studio, you could only exercise access control over apps at the individual app level, not at the delivery group level. Now, you can perform access control over apps at the delivery group level. Currently, this ability is limited to controlling access to all apps within a delivery group. For more information, see Restrict application access to specific users.

Client Platform filter for policy assignments. You can now control policy assignments more precisely with a new filter, Client Platform. This filter lets you assign (Allow) or exclude (Deny) policies based on the operating system of users' devices, including Windows, macOS, Linux, iOS, Android, or HTML5. This enhancement offers greater flexibility and precision in policy assignment, ensuring a customized and uniform experience across managed and unmanaged devices. For more information, see Policy assignments.

Option to reset In-Use Active Directory (AD) accounts. With Studio you can now reset machine Active Directory (AD) accounts even when the status of the machine is In Use. This enhancement is necessary because sometimes the system doesn't correctly detect when a machine is in a *tainted* state.

Support for provisioning Data disk in VMware. A Data disk allows storage of persistent data like event logs, security traces, and application data. With this feature, you can now create and assign a persistent and non-persistent Data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in VMware.

The Data disk must be provisioned from the master image. The provisioned VM's Data disk derives properties like storage policy, size, and so on from the master image. For machine profile based catalog, it can optionally use the VM template’s Data disk for deriving the properties. If the VM template doesn't have a data disk, then Storage's default policy is used. For information on creating an MCS machine catalog with a Data disk, see Provision a Data disk on MCS created VM.

Enable trusted launch of existing persistent and non-persistent catalogs. With this feature, you can update an existing non-Trusted Launch persistent and non-persistent machine catalog to a catalog enabled with Trusted Launch.

To successfully create or update a machine catalog with Trusted Launch, you must use a machine profile. However, if you use a master image enabled with Trusted Launch and a machine profile not enabled with Trusted Launch, you get a warning message because of the mismatched Trusted Launch configuration between master image and machine profile.

For more information, see Machine catalogs with trusted launch.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Simplified Azure AD security group management using service accounts. Previously, managing the Azure AD security group required you to log in to Azure AD and get the access token.

With this enhancement, MCS now supports using a pre-created service account to manage Azure AD security groups for Azure AD joined machines. However, to use a service account with Azure AD security group management capability, you need some permissions. For information, see Permissions required for an Azure AD service principal.

You can use the service account to do the following without the requirement to get the access token.

- Create a machine catalog with Azure AD dynamic security group
- Enable security group feature for an Azure AD catalog
- Delete a machine catalog with Azure AD joined device security group
- Create an Azure AD dynamic security group under an existing Azure AD assigned security group

For information, see:

- Azure Active Directory dynamic security group
- Create an Azure AD dynamic security group under an existing Azure AD assigned security group

Support for creating Hybrid Azure AD joined catalogs and Hybrid Azure AD joined catalogs enrolled in Microsoft Intune with prepared images. With this feature, you can now use prepared images to create Hybrid Azure AD joined catalogs and Hybrid Azure AD joined catalogs enrolled in Microsoft Intune using Studio and PowerShell commands. This feature is applicable to single and multi-session persistent and non-persistent type MCS catalogs. However, currently, you can create catalogs for Hybrid Azure AD joined catalogs enrolled in Microsoft Intune for only persistent single and multi-session VMs. Enrollment of Hybrid Azure AD joined non-persistent VMs into Microsoft Intune is currently under preview.

This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process. For the complete set of Powershell commands to create image definition, image version, and prepared image version spec, see Use PowerShell. For information on creating a Hybrid Azure AD joined catalog and Hybrid Azure AD joined catalogs enrolled in Microsoft Intune, see Identity pool of Hybrid Azure Active Directory joined machine identity and Create Hybrid Azure AD joined catalogs enrolled in Microsoft Intune.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for SCVMM 2025. Citrix DaaS now supports Microsoft's System Center Virtual Machine Manager (SCVMM) 2025. SCVMM provides a range of services to include maintaining the resources you need to deploy VMs. For more information about the new features supported in SCVMM 2025, see What's new in System Center Virtual Machine Manager.

Support for automatically using Azure Temporary Disk for write-back cache disk. When you edit an MCS-provisioned catalog in Studio, the catalog now automatically uses Azure Temporary Disk for the write-back cache (WBC) disk if the required criteria are met. As a result, new VMs added to the catalog uses Azure Temporary Disk for the WBC disk.

Previously, if a catalog didn't qualify at creation, Azure Temp Disk wasn't used for WBC disk—even if the catalog was later updated to meet the criteria.

Benefits:

- Reduce costs. Temp Disks don't incur storage costs when the VM is powered off.
- Improve flexibility. Use Temp Disks for WBC without recreating the catalog.

An MCS-provisioned catalog automatically uses Azure Temp Disk for WBC disk when the catalog meets all the following criteria:

- MCSIO is enabled.
- The WBC disk is non-persistent.
- The VM size includes a Temp Disk large enough for the WBC disk.
- No drive letter is specified for the WBC disk.

For more information, see Create a Microsoft Azure catalog.

App visibility control support for Azure AD users. Previously available only for Active Directory users, the ability to restrict app visibility is now extended to Azure AD users. With Studio, you can now control which Azure AD users and groups can see a specific app in the Workspace app.

This function requires VDA version 2411 or later. For more information about detailed steps, see Change application properties > Limit visibility.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

March 2025

New and enhanced features

Re-trust option for untrusted host connection certificates. If a host connection outage occurs due to an untrusted certificate, you can re-trust the certificate for that host connection in Studio. For more information, see Test TLS Certificate Trust.

Re-sync deployments in AWS UI. A new option to re-sync deployments in AWS is added. Re-sync a deployment that is in Pending state or if the number of machines listed in a deployment does not match with the number of machines listed in AWS.

NOTE:

- When a deployment of Active or Error state is re-syncing, the status of that deployment changes to **Syncing machines**.
- When a deployment of Pending state is re-syncing, the status continues to show as **Pending** until completed.

For more informantion, see Create a deployment.

Centralized site management is generally available. As a Cloud Administrator of multiple sites, you can now designate one site as the primary and link other sites to it for streamlined, centralized management. This feature helps improve operational efficiency by reducing the need to switch between sites for daily tasks.

Key benefits:

- **Efficient site management**: Administrators can manage multiple sites from a single interface, switching between them using the drop-down menu in the upper-right corner, eliminating the need to change accounts.
- **Seamless navigation**: Administrators can seamlessly switch between Studio and Monitor without needing to reselect the site. When a site is selected in Studio, it's automatically selected in Monitor, streamlining your workflow.
- **Simplified help desk operations**: Help desk administrators can view information for all sites in one Monitor console.
- **Aggregated end-user experience**: End users sign in to a single Citrix Workspace URL (for example, customer.cloud.com) to access resources from linked sites.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Centralized site management.

UI Enhancements in Studio. Web Studio introduces the following improvements to enhance your administration efficiency:

- Copying data from tables

  You can now copy data directly from table components, such as "Machine name" on the Machine Allocation table. This enhancement reduces the need for manual data entry, minimizing the risk of errors.

- Pagination for tables

  Table components now support pagination, boosting performance and usability.

What's new widget enhancement. A new feature has been introduced to the What's new widget on the Studio **Home** page. You can now seamlessly switch between two content sources:

- **Featured**: Curated, handpicked content for quick product insights and highlights.
- **General**: A comprehensive list of content sourced directly from the DaaS documentation for in-depth, extensive feature updates. This update ensures that you have the flexibility to access both curated and extensive content, enhancing your experience and keeping you well-informed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Token usage limit in token-based enrollment increased to 5000. We've increased the token usage limit in token-based enrollment from 100 to 5000, allowing for greater flexibility when enrolling machines in large-capacity machine catalogs.

For more information, see Generate and manage enrollment tokens.

Migration of non-persistent VMs in VMware. Previously, in the VMware environment, you could migrate only the persistent VM disks from one storage to another storage. With this feature, you can migrate the non-persistent VM disks from one storage to another storage using the `Move-ProvVMDisk` PowerShell command. You can migrate: OS Disk, Identity Disk, and Write-back Cache (WBC) disk.

For more information, see Storage migration of VMs.

Migration of persistent and non-persistent VMs in XenServer®. With this feature, in the XenServer environment, you can migrate the following VM disks from one storage to another storage using the `Move-ProvVMDisk` PowerShell command.

- For persistent full clone VMs: OS Disk, Identity Disk, and non-MCS provisioned disks.
- For non-persistent VMs: OS Disk, Identity Disk, and Write-back Cache (WBC) disk.

For more information, see Storage migration of VMs.

Enhanced Autoscale features for improved power management. We've enhanced Autoscale to improve your experiences. You can now:

- Receive notifications if machines in a delivery group don't support hibernation, along with recommendations for alternative actions, such as shutting down those machines.
- Choose to suspend machines over stopping them, wherever supported.
- Set restart schedules for suspended machines to prevent them from remaining suspended indefinitely.

For more information, see Schedule-based settings and Load-based settings.

Improvement to Workload rightsizing. The **Workload rightsizing** (formerly Infrastructure Rightsizing) tab now includes an option to identify power users. This feature allows you to export the details of power users.

NOTE:

This feature is available only for single-session OS delivery groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The **Export** data includes **User Name**, **Total Session Count**, **Average Session Duration (Mins)**, **Peak CPU Usage (%)**, and **Peak Memory Usage (%)**.

This enhancement provides valuable insights into resource utilization and helps in optimizing infrastructure costs by ensuring efficient resource allocation based on user behavior. For more information, see Workload rightsizing page.

Enhancement to Session Performance tab. The **Session Topology** section of the **Session Performance** tab is enhanced to include the following:

- **Protocol**: Displays the MTU value for EDT protocol. For example:
  - Single-stream: EDT (MTU = 1500)
  - Multi-stream: EDT (MTU stream IDs 0=1500, 1=1500)
- **MS Teams**: Displays whether HDX optimized or not HDX optimized.
- **HDX Connection Type**: Displays the HDX connection type. For example: HDX, HDX Direct, and Rendezvous.
- **Frames Per Second** provides information on:
  - Input Frames Per Second
  - Output Frames Per Second

Security groups configurations are inherited from machine profiles. You can now create an MCS machine catalog and select a machine profile that has security groups assigned. This avoids the security group configuration as it is inherited from the machine profile. Alternatively, if you do not select a machine profile, at the time of MCS machine catalog creation then configure the security groups in the Security page in Studio. For more information, see Security.

Autoscale holiday plug-in. With this feature, you can deviate from the standard Autoscale settings related to the power management of VMs and allow VMs to be powered off on specified holiday dates. For example, for weekdays you want most of the VMs to be powered on and by default, on public holidays, the weekday schedule is applied. To manage such scenarios, use the Autoscale holiday plug-in to power off the VMs on specified holiday dates.

For more information, see Autoscale holiday plugin.

Match UEFI boot program to Citrix Provisioning version for MCS created Citrix Provisioning catalogs. The Citrix Provisioning server uses a BDM disk, which contains a UEFI boot program. This feature allows generation of `BOOTX64.EFI` file alongside the `PVSBOOT.INI` file when

© 1997–2026 Citrix Systems, Inc. All rights reserved.

creating a Citrix Provisioning catalog using MCS. As a result, target devices can boot from the latest boot settings file, ensuring that target devices align with the Citrix Provisioning version.

Support for creating Azure AD joined and Microsoft Intune enrolled catalogs with prepared images. With this feature, you can now use prepared images to create Azure Active Directory joined and Microsoft Intune enrolled catalogs using Studio and PowerShell commands. This feature is applicable to single and multi-session persistent and non-persistent type MCS catalogs. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process. For the complete set of Powershell commands to create image definition, image version, and prepared image version spec, see Use PowerShell. For information on creating an Azure AD joined catalog and Azure AD catalog enrolled in Microsoft Intune, see Identity pool of Azure Active Directory joined machine identity and Create Azure AD catalogs enrolled in Microsoft Intune.

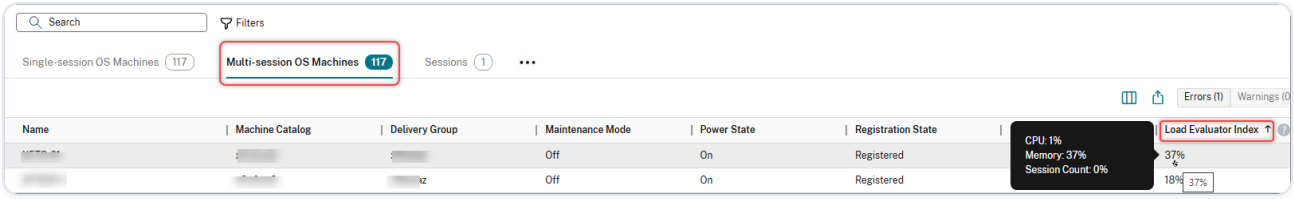
Flexible storage location option for VMs. Previously, VM allocation began from a fixed Storage Service (SR), such as SR1, and progressed sequentially through SR2, SR3, and so on. And, for some cases, the storage load is not evenly distributed across storages.

This feature gives you the ability to balance VM allocation across different storage service using the following methods:

- **Enhanced current round robin allocation method**: Instead of always starting from the same fixed SR, MCS now begins the allocation from the SR right after the last used SR.
- **Least load-based allocation method**: Places the VMs on the least current load, determined by comparing the total number of VMs on each SR within the same machine catalog. For example, if a machine catalog contains 100 VMs distributed as follows: 20 VMs on SR1, 30 VMs on SR2, and 50 VMs on SR3, the new VMs are allocated to SR1 first. This method ensures that the load across SR1, SR2, and SR3 is balanced. You can use this method by adding a custom property Name=`"StorageBalanceType"` Value=`"VMCountBasedLeastLoad` while creating or updating a host connection.

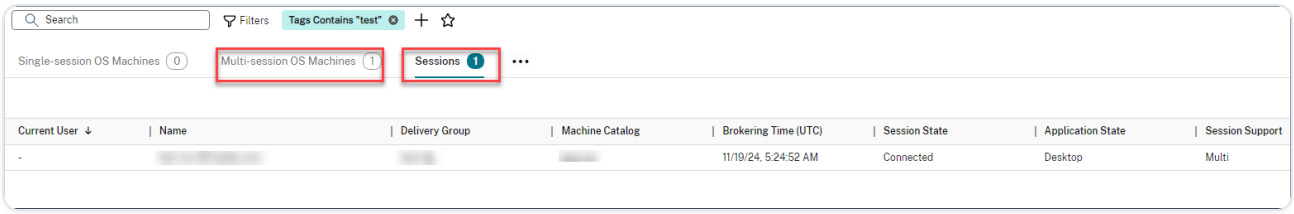
This feature is:

- Applicable to all on-premises hypervisors (VMware, XenServer, and Hyper-V).
- Applicable to only OS disk storage.
- Not applicable to the existing VMs.



For information on creating or updating an existing host connection with the load-based allocation option, see Flexible storage location option for VMs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Enhanced resource monitoring for multi-session VDAs in Studio. Studio now provides detailed resource utilization and capability insights for multi-session VDAs.

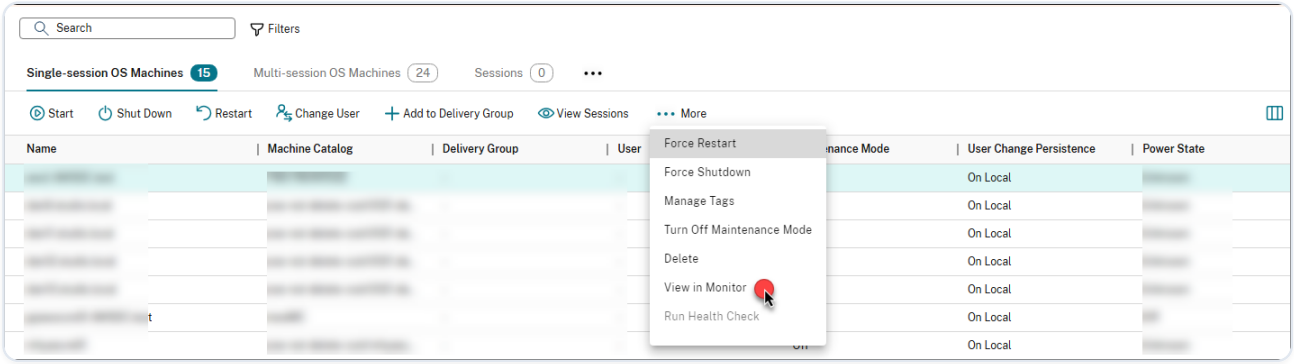
Hover over the **Load Evaluator Index** column of a multi-session VDA in the **Search** node to view detailed metrics, including CPU, memory, disk usage, maximum number of sessions allowed, and more. The specific metrics displayed depend on the enabled policy settings.

This enhancement eliminates the need to run PowerShell cmdlets or navigate through multiple steps to switch to Monitor to gather this data, providing the same capabilities directly within Studio. For more information, see Machine actions.

Improved session visibility in tag-based searches. When you search for *machines* by tag in **Studio > Search**, active user *sessions* on the matching machines now appear on the **Sessions** tab. This enhancement helps prevent accidental shutdowns of machines with active sessions by providing clear visibility of those sessions, improving your management efficiency.

February 2025

New and enhanced features



Support for provisioning data disk on Azure. You can now create and assign a persistent data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in Azure. The data disk is used for storage of persistent data like event logs, security traces, and application data.

The data disk must be provisioned from the master image. The properties such as storage type, encryption settings, zones are derived from custom properties or from the OS disk template if the properties are not specified in the custom properties. For information on creating an MCS machine catalog with a data disk, see Provision data disk.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Navigate seamlessly from Studio to Monitor for machines and sessions. A new option, **View in Monitor**, is now available in **Studio > Search**, providing quicker access to detailed session and machine information in **Monitor**.

After selecting a machine or session, simply click **View in Monitor** to open its detailed view in **Monitor**. This enhancement simplifies your workflow and saves time when analyzing workload performance or troubleshooting issues. For more information, see Machine actions and Session actions.

Cost Savings by optimizing storage usage. The **Cost Savings** page now provides visibility into the amount of savings achieved through storage optimization when machines are powered Off. Previously, only compute-related cost savings were displayed. This enhancement includes the following two types of storage savings:

- **Write-back Disk**: Savings from deleting the write-back disk when a non-persistent machine is powered Off.
- **OS Disk**: Savings from downgrading the OS disk from Premium to Standard HDD when any machine is shut down.

Prerequisite:

- Autoscale must be enabled to optimize compute costs. For more information, see Get started with Autoscale.
- Change the storage type to a lower tier when a VM is shut down to optimize storage costs. For more information, see Change the storage type to a lower tier when a VM is shut down documentation.
- This feature is currently applicable only to Azure machines.

The enhancement includes:

- A report detailing storage savings from machine power-offs (autoscale or user-initiated) is now available in the **Estimated infrastructure savings** section.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Total savings calculations now incorporate both compute and storage savings, broken down by source (autoscale or user action). The historical trend graph now visually distinguishes between compute and storage savings, and a tooltip provides further details on hover.
- The **Catalog details** section now includes **Compute Cost Per Hour** and **Storage Cost Per Hour**.

For more information, see Cost summary page.

NitroTPM and UEFI secure boot capability for MCS created AWS VM instances. With this feature, when creating a catalog in AWS environments, you can now select a master image (AMI) with NitroTPM and/or UEFI secure boot enabled. Accordingly, the provisioned VMs in the catalog are also enabled with NitroTPM and/or UEFI secure boot. This implementation ensures that the VMs are secured and trusted. For more information on NitroTPM and UEFI Secure Boot, see the AWS documentation. For creating a catalog enabled with NitroTPM and UEFI secure boot, see Enable NitroTPM and UEFI secure boot for VM instances.

Monitor action enhancements Citrix Monitor now provides the progress of bulk actions performed along with improvements to role based accesses on bulk actions enhancing user experience and control.

Action Progress Bar:

With this enhancement, when any action is in progress, such as a power control function (for example, restart), you can see a status of the action and a dialog box when the action is completed. This feature is applicable to all actions in the **Filters** tab. However, note that the status bar is not be available for single actions.

The progress bar shows the outcomes of bulk actions performed. Currently, customers do not know whether their action succeeded or failed and on how many sessions. This enhancement provides clarity on actions performed.

Custom role to limit bulk action option for user actions:

This enhancement allows the addition of custom roles to limit what the admin can see and control. The new custom role limits the ability to select bulk actions such as log off, disconnect, or message. This control is necessary to prevent unintentional or malicious mass actions on users.

With these enhancements, you can effectively manage and control actions within Citrix Monitor, ensuring a more secure and efficient environment. For more information, see Custom role to limit bulk action option for user actions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Option to view and troubleshoot Secure Private Access Sessions for hybrid deployments. Citrix Monitor now supports viewing and troubleshooting Secure Private Access sessions for hybrid deployments. This enhancement allows DaaS customers using Gateway, StoreFront, and Secure Private Access on-premises to monitor and troubleshoot their session data directly in the DaaS Monitor.

Previously, only cloud and on-premises deployments were visible in the Monitor. With this update, hybrid Secure Private Access sessions can now be monitored and analyzed, providing a unified view across all deployment types.

This improvement ensures better visibility, faster issue resolution, and a seamless monitoring experience for customers managing hybrid environments.For more information, see Secure Private Access integration with Monitor (Preview).

Share prepared image versions across hosting units in VMware. You can now use the **Images node** to share image versions across hosting units within the same hosting connection in VMware. This implementation ensures consistency and uniformity of images across different host units, enhancing deployment flexibility and operational efficiency. You can also use PowerShell commands to achieve this goal. For more information, see Image Management

January 2025

New and enhanced features

Support for creating MCSIO-enabled MCS machine catalogs in AWS. You can now create MCSIO-enabled MCS catalogs to create MCSIO-enabled MCS machine catalogs in AWS to improve write IOPS by directing write operations to the write-back cache and to reduce the startup time when the persisting OS disk is enabled. For more information, see Machine Creation Services (MCS) storage optimization.

Integration with Webhook Citrix Monitor now integrates with Webhook. Using this feature, you can select the required tool from the **Alerting and ITSM** section on the **Integrations and data exports** page and then click **Get Started**. This gives you reference links to create the tool specific channel and webhook URL, which is the first step. Once the first step is completed, you can create webhook profiles.

You can also create webhook profiles in the **Integrations and data exports** > **Developer tools** page of Citrix Monitor. You can find steps and resources to integrate the following alerting and ITSM tools with Citrix Monitor:

- Slack

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Microsoft Teams
- ServiceNow

This feature helps you to send alert notifications to the preceding third-party applications that have incoming webhook URLs configured.

Key features:

- New integration tiles for Slack, Teams, ServiceNow, and other supported platforms
- Navigation to the FTU page for each integration
- Create or edit webhook configuration page with a UI workflow to provide webhook URL, headers, body, and test the webhook configuration and save it
- List the webhook profiles created and provide the capability to edit or delete the webhook profiles
- Map created webhook profiles with the advanced alert policies

For more information, see Integrations and data exports page.

Add applications to existing AWS deployments in Quick deploy node. You can now add applications to existing AWS deployments thus simplifying the overall deployment process. For more information, see Create a deployment.

Option to reset In-Use Active Directory (AD) accounts. With Studio you can now reset machine Active Directory (AD) accounts even when the status of the machine is In Use. This is necessary because sometimes the system does not correctly detect when a machine is in a tainted state.

Alerting admins that power policies remain effective when disabling Autoscale. The enhancement is to remind the admins that disabling Autoscale does not affect the power policy settings for a delivery group. This ensures that admins are aware of the scope of Autoscale disabling and clarifies that power policies remain effective when Autoscale is turned off.

Filter master images based on hosting unit regions. During machine catalog creation for the Azure platform, Studio can now filter out and exclude master images that belong to different regions other than the hosting unit's region. This ensures that only images from the same region as the hosting unit are available for selection. For more information, see Create a machine catalog from the Machine Catalogs node.

MCSIO with only disk cache is no longer supported. The option to configure MCSIO with only disk cache (without memory cache) has been removed across all hypervisor and cloud service environments. When creating machine catalogs with the MCSIO enabled, you must now set a non-

© 1997–2026 Citrix Systems, Inc. All rights reserved.

zero memory cache size. In addition, you can't edit catalogs configured with only a disk cache until you set a memory cache size. For more information, see Configure cache for temporary data.

Creating AWS VMs using machine template properties is no longer supported. Support for creating AWS VMs by capturing machine template properties has been removed as part of the transition to creating VMs using machine profiles. The **Apply machine template properties to virtual machines** option has been removed from the **Machine Template** page. Instead, you can create AWS VMs using machine profiles for a similar and more streamlined experience. For more information, see Create a machine profile-based machine catalog using Studio and Create a machine profile-based machine catalog using PowerShell.

Support for creating MCSIO enabled MCS machine catalog in AWS. In the AWS environment, you can now create MCS Storage Optimization (MCSIO) enabled non-persistent catalog using PowerShell commands. To create such a catalog, you must install the MCSIO driver while installing or upgrading the VDA. By default, that driver is not installed. For more information on creating the MCSIO enabled catalog, see MCSIO enabled catalog. The option to configure MCSIO with only disk cache (without memory cache) using Studio has been removed across all hypervisors and cloud service environments.

Least used and unused published apps report. The **Applications** page now offers detailed usage information for published apps accessed through the Citrix Workspace app, empowering administrators to optimize app management and resource allocation.

This feature helps in understanding the application usage patterns within the organization and enables customers to make data-driven decisions to help make their Citrix deployments more efficient.

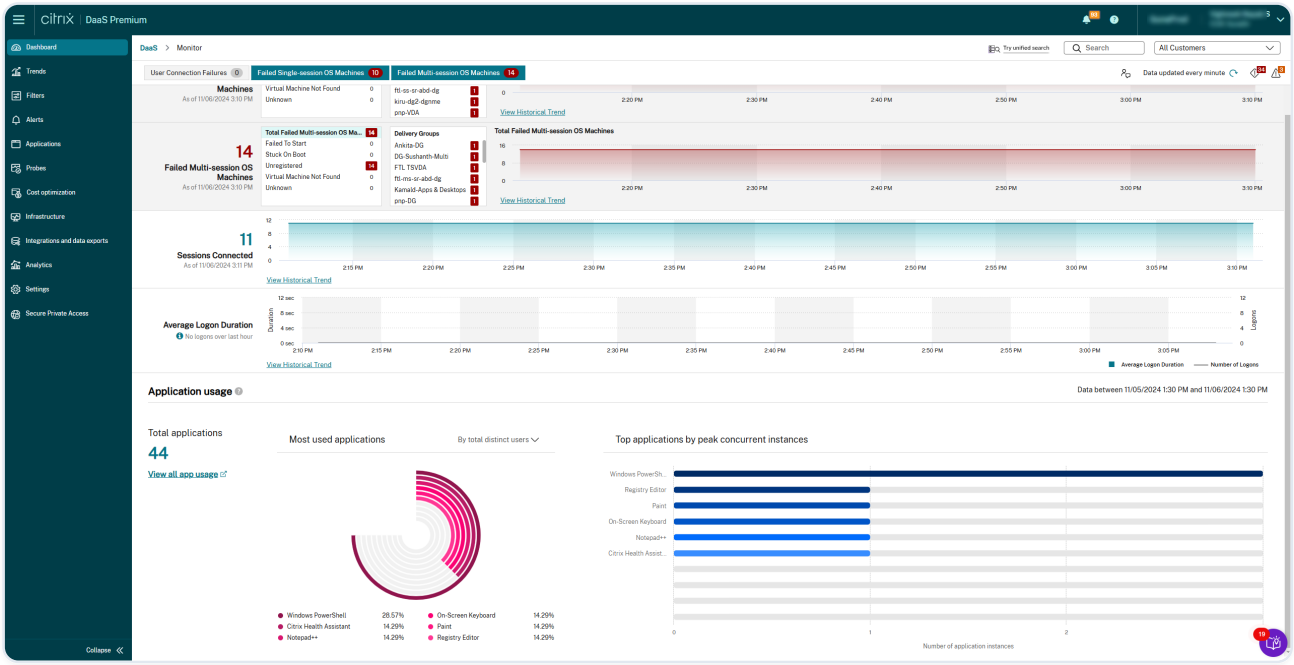
NOTE:

This feature is available only for the platinum-licensed sites.

The enhanced **Applications** page includes a usage section that shows the following:

- **Total published apps:** Identifies the total number of published apps.
- **Least used apps:** Helps to make informed decisions about retaining or removing rarely used apps, optimizing resource allocation, and license management. This section lists the following:
  - **Distinct users in the last 30 days**
  - **Total launches**

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- **Peak concurrent instances**
- **Trend chart:** View a graph showing distinct users over time.

- **Not used apps:** Helps to identify unused apps to free up memory, configuration resources, and potentially save on licensing costs. This section lists the name of the apps, the corresponding delivery group, and the state of the app.

You can also use the **Export** option to export the data in the **Least used** and **Not used** sections.

NOTE:

Currently, only published apps (desktop apps in Citrix Workspace app) are included in this enhancement.

For more information, see the Least used and unused published apps report documentation.

Secure Private Access integration with Monitor (Preview). The Secure Private Access integration with Monitor allows admin to monitor and troubleshoot all Secure Private Access sessions in Monitor.

Available actions include viewing the details of the following:

- Secure Private Access active sessions for a user under the Select a Session popup > Active Sessions tab
- Secure Private Access failed or blocked enumerations and failed app launches under the Select a Session popup > Denied Access tab

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Session and application details view for active and failed app launches, as well as for failed and blocked enumerations

For more information, see Secure Private Access integration with Monitor (Preview) page.

December 2024

New and enhanced features

Automated configuration tool commands for backup and restore. With this feature, you can use PowerShell commands supported by Automated configuration tool to trigger the backup and restore APIs that Studio uses. For more information, see Automated configuration tool cmdlets for backup and restore.

New permission for orphaned resource detection in Citrix DaaS. Previously, only **Full Administrator** or **Cloud Administrator** roles could perform orphaned resource detection. With the introduction of a **Use Host Connection to Detect Orphaned Resources in Hypervisor** permission to the **Hosts** category, any roles assigned with this permission can now detect orphaned resources. For more information, see Detect Orphaned Azure resources and Retrieve a list of orphaned resources.

Get started with Citrix DaaS on Google Cloud. Integrating Google Cloud Platform (GCP) with Citrix DaaS and deploying the first set of virtual desktops involves a series of sequential steps, making it a relatively intricate process. To simplify this process for administrators, a streamlined deployment experience, similar to AWS WorkSpaces Core's Quick Deploy feature, has been introduced. This streamlined onboarding process aims to increase GCP adoption, prompting Google's sales teams to collaborate with Citrix in customer engagements. Also, it opens avenues for Citrix sales teams to engage with customers who prioritize Google-centric solutions. For more information, see Quick Deploy for Google Cloud.

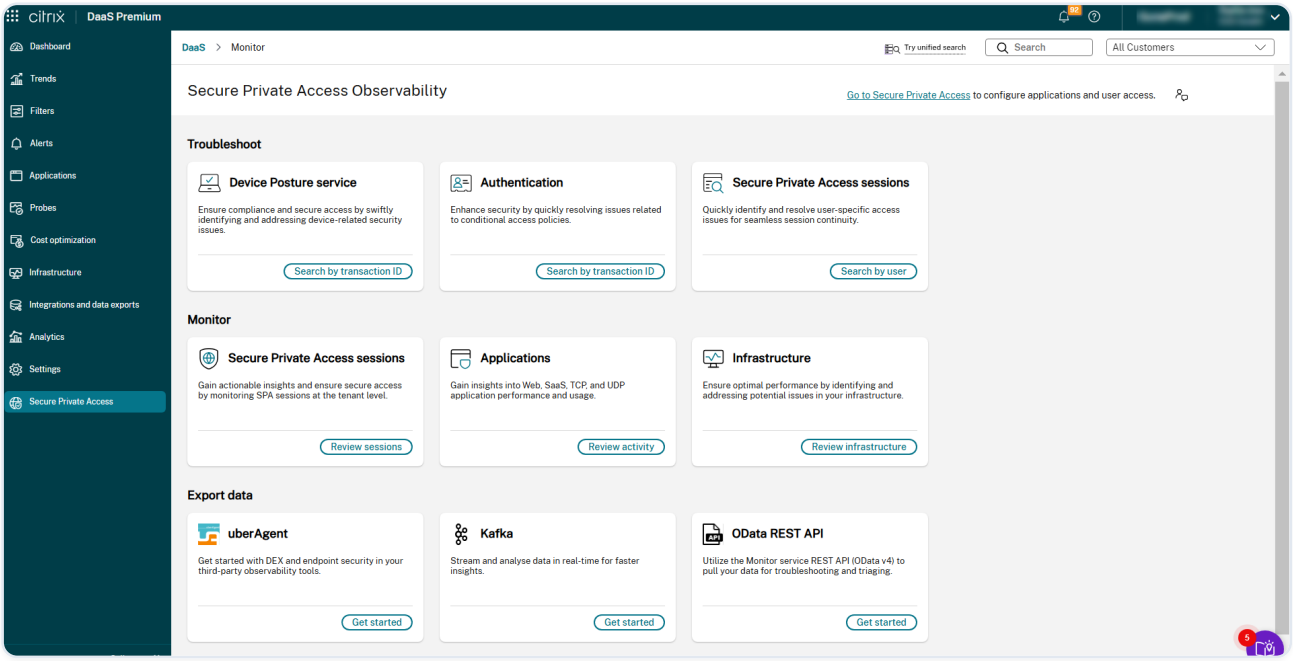
Full Configuration: Support for selecting launch template as machine profile for AWS. When provisioning AWS VMs using MCS, you can now select a launch template as the machine profile. For more information, see Select an image and a machine profile.

Multi-select policies. You can now select multiple policies and checkout the following enhancements:

- Click a policy row: If you click a policy row, the actions bar at the top shows actions of a single policy. The details pane at the bottom provides information about the policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Select the check boxes of multiple policies: If you select the check boxes of multiple policies whose statuses are either enabled or disabled, then the actions bar at the top shows actions of multiple policies. The details pane at the bottom displays the number of policies selected.



NOTE:

After you select multiple policies, you can view the details of another single policy by clicking the row of that policy. This action does not clear the previously selected policies. However, the right-click action does not display the actions for that policy row.

GCP catalogs support inheriting the machine type settings from machine profiles. When creating MCS-provisioned machine catalogs in GCP environments, the machine type now defaults to the size specified in the selected machine profile. If necessary, you can manually adjust this setting. For more information, see Create a machine catalog using Full Configuration interface.

Clarity on dependent policies. Some settings are dependent on other settings. For example, a child setting might be configured, but if its parent setting is not enabled, the child setting configured does not take effect. The dependencies were not clear before. Starting with this release, clarity is provided on which are the parent policies that must be configured first before you can configure the child policies. For more information, see Policy settings.

Secure Private Access tab on Monitor. The **Secure Private Access** tab on Monitor provides a dedicated place for all new features related to Secure Private Access. This tab offers details on the supported functions for Secure Private Access, giving administrators a central location to access and manage these features.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Key benefits:

- Centralized information: Administrators can easily see all supported troubleshooting features for Secure Private Access in one place.
- Enhanced observability: The new left navigation bar in the Monitor UI lists all Secure Private Access services, including Secure Private Access sessions, applications, and device posture, providing better observability.
- Improved navigation: The Secure Private Access tab includes hyperlinks to different pages, making it easier for administrators to navigate to various features and functions.

For more information, see Secure Private Access tab on Monitor.

Visibility for Secure Private Access Service. To provide detailed monitoring and visibility for Secure Private Access applications and users, Monitor is now enhanced to include Secure Private Access session visibility. The **Filters** tab and **Dashboard** provide detailed Secure Private Access session information.

Key features:

- **Filter Secure Private Access Sessions**: You can now filter Secure Private Access sessions in the **Filters** > **Sessions (Web, SaaS, and TCP/UDP)** tab.
- **Filter Secure Private Access Applications**: You can also filter Secure Private Access applications in the **Filters** > **Applications (Web, SaaS, and TCP/UDP)** tab.
- **App Failures and Active Sessions**: Monitor app failures for web/SaaS and TCP/UDP apps, and view active sessions for web/SaaS apps in the Dashboard.

For more information, see Visibility for Secure Private Access Service.

Unified platform experience for Citrix Monitor. Citrix Monitor is now aligned with all other components within Citrix Cloud, providing a unified platform experience. The user interface has been refreshed with a modern look and feel, offering easier navigation and better data representation. The enhanced interface is intuitive and designed to help users easily comprehend the data needed to monitor and troubleshoot Citrix sessions.

Enhancement to Connections tab. The **Connections** tab now offers streamlined navigation for quicker troubleshooting. From the **Filters** tab > **Connections** page, you can directly access:

- **Activity Manager**: Click the **Associated User** or **Endpoint name** to view the respective Activity Manager details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Machine Details page**: Click **Machine Names** to see comprehensive machine information, including machine details, utilization details, infrastructure details, and applied hotfixes. For more information, see Troubleshoot Machines. This enhancement simplifies navigation, enabling faster resolution of connection-related issues.

For more information, see Filter data to troubleshoot failures.

Filter resource location details. You can now view the resource location for single-session or multi-session OS machines in the **Filters** > **Machines** tab. This enhancement allows you to quickly identify and address issues related to specific resource locations, leading to a smoother user experience.

To display the new **Resource Location** column, go to **Choose Columns** and select **Resource Location** in the **Filters** > **Machines** tab.

Enhancement to Session Performance tab. The **Session Topology** section of the **Session Performance** tab is enhanced to include the following endpoint metrics which exist in the Citrix Workspace app for Windows, Mac, Linux, HTML5, or Chrome:

- Public IP address
- Internet Service Provider
- Location such as country or city
- Whether the Citrix Workspace app session is opened in native app or browser (HTML5)
- Accessed using Workspace or StoreFront
- Resource utilization such as CPU %, Memory %, and GPU (Overall %)
- Network latency

This enhancement helps to troubleshoot issues regarding sessions quickly. For more information, see Session Performance metrics.

Machine net active usage. The **Workload rightsizing** page now includes detailed insights into machine net active usage, providing the following details:

- Percentage of net active usage
- Average machine uptime
- No session time
- Idle time
- Disconnected time

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This feature allows you to see detailed machine usage information, enabling you to optimize costs accordingly.

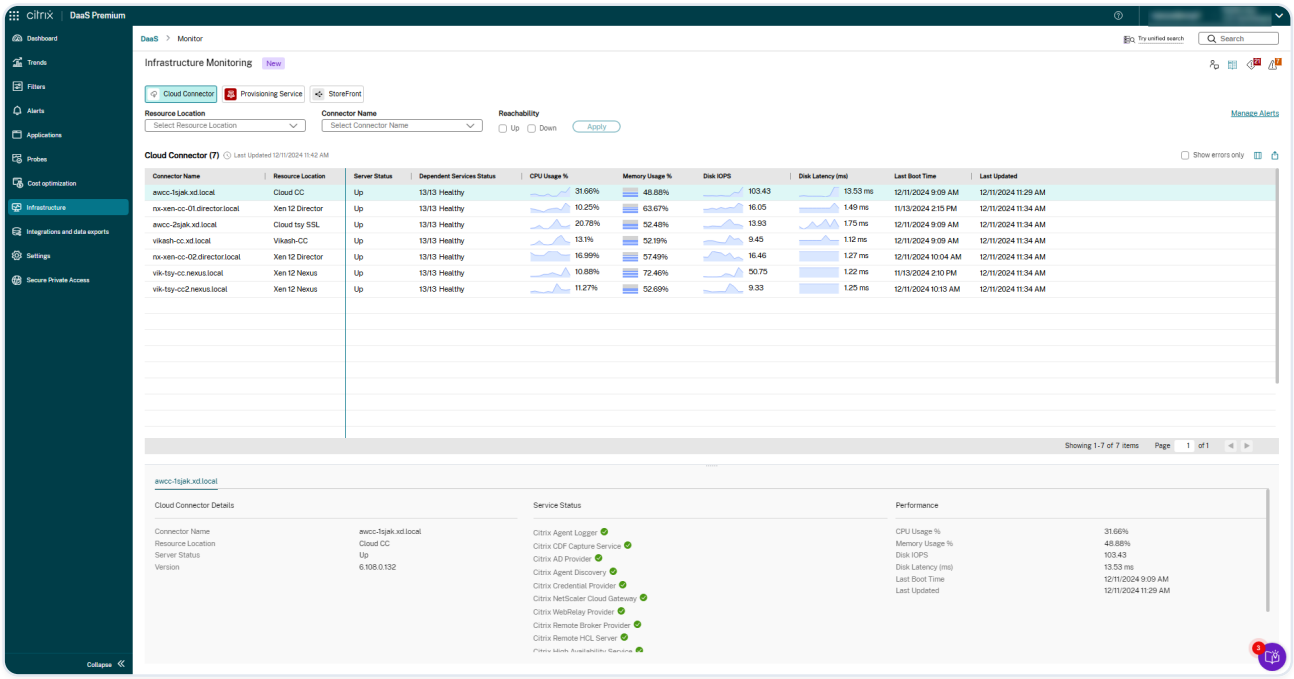
For more information, see Workload rightsizing.

Cloud Connector health monitoring. The Cloud Connector component is now added to the **Infrastructure Monitoring** dashboard. Cloud Connectors are automatically onboarded when a connection between Citrix Cloud and your resource locations is established.

This feature enables administrators to monitor the health of Cloud Connectors using a single dashboard view and proactively configure alerts.

NOTE

.



The `citrixinframonitor.msi` is not required to be installed for monitoring Cloud Connectors.

Benefits:

- **Comprehensive monitoring**: Visibility into critical health indicators for the Cloud Connector such as high availability, connection lease exchange, and AD provider, and so on
- **Configurable alerts**: You can configure alerts on health metrics of interest, define severity, and scopes for admins to receive detailed alerts according to the alert configuration.

To monitor the Cloud Connector, click the **Infrastructure** tab on Monitor. The **Infrastructure Monitoring** page opens.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

You can also view the details of all the services status in the **Cloud Connector Details** section.For more information, see Cloud Connector health metrics.

Support for creating Citrix Provisioning catalogs in VMware environments using Studio. With Studio, you can now create Citrix Provisioning catalogs in VMware environments. Previously, you had to switch between different consoles to provision and manage those catalogs. This feature simplifies the process, letting you perform provisioning and power management tasks entirely within Studio. For more information see, Create a Citrix Provisioning catalog in VMware environment using Studio.

Delivery of app attach disks as CimFS. Previously, only delivery of app attach disks as virtual disks (VHD and VHDX) was supported. With this feature, delivery of app attach disks as Composite Image File System (CimFS) is also supported. For information, see Store application packages on network shares.

Optimize storage load balancing with the least load method. Previously, Machine Creation Services™ (MCS) used a round-robin method to distribute VMs across storage repositories, often leading to uneven storage utilization.

Studio now introduces the **Optimize storage load balancing with least load method** option. If you select two or more OS data storage locations during catalog creation, this option becomes available, enabling disks to be allocated to the least loaded storage repository.

This feature enhances load balancing and improves system stability, and it's supported in XenServer, VMware, and SCVMM virtualization environments. For more information, see Step 3. Storage selection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Autoscale powers on hibernated VMs. With this feature, in Azure, autoscale can power on hibernated multi-session Remote Desktop Services (RDS) and shared single session VMs with no sessions on it during peak time. The VMs can be of MCS and non-MCS machine catalogs.

Support for NVMe-only SKUs in Azure. Previously, MCS supported only SCSI storage controller type. With this feature, MCS also supports the NVMe storage controller type to support the new VM SKUs on Azure. For information on NVMe, see the Microsoft documentation General FAQ for NVMe. For information on creating an MCS machine catalog using a service offering that:

- supports both SCSI and NVMe, see Create a catalog using a service offering that supports both SCSI and NVMe
- supports only NVMe, see Create a catalog using a service offering that supports only NVMe

Set a default time zone for your Citrix DaaS site. With Studio, you can now set a default time zone for your Citrix DaaS site. To complete this task, go to **Settings > Date and Time**. Studio uses this time zone for all time displays and scheduling such as scheduled restart and autoscaling. This setting makes it easier to manage time and ensure time consistency across your site. For more information, see Time zone setup.

If needed, you can change the time zone for individual resources. For example, you can set a different time zone for a delivery group that serves machines in a different region. For more information, see Change user settings in a delivery group.

Studio aligns with Citrix Cloud's unified navigation experience. As part of the shift towards a unified navigation experience across the Citrix Cloud platform, we've updated Studio to align with this platform-wide initiative. Key changes include a green background for the navigation pane and breadcrumb navigation for easier access. These updates enhance usability and drive feature adoption, making it easier to discover and manage resources. For more information, see Studio.

Support for AWS on-demand provisioning. Previously, when you would shut down a non-persistent VM in AWS, the OS disk did not get deleted. Now, with on-demand provisioning, the OS disk gets deleted when you shut down a non-persistent VM. This implementation of AWS on-demand provisioning saves cost when the VM is not in use. For more information, see AWS on-demand provisioning.

Show Secure Default Settings. This feature shows the secure default setting along with the default setting for a policy. The default setting might be overwritten by the secure default setting. If the secure default setting is enabled, during VDA installation, the priority of the policy settings is affected as follows:

- Customized setting takes the highest priority

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Secure default setting takes the second priority
- Default setting takes the least priority

For more information, see Policy settings.

Displaying policy details in Device Posture Events. You can now view Device Posture policy evaluation details as part of Device Posture events on Citrix DaaS Monitor. The different states of the policy evaluation and error codes are displayed. This feature simplifies the triage and troubleshooting of user issues. For more information, see the Diagnose Device Posture events failure page.

November 2024

New and enhanced features

Image management is now Generally Available. Image management functionality is now generally available for Azure and VMware virtualization environments. Also, the **Images** node now allows you to share image versions across hosting units within the same hosting connection in Azure. This implementation ensures consistency and uniformity of images across different host units, enhancing deployment flexibility and operational efficiency. You can also use PowerShell commands to achieve this goal. For more information, see Image Management.

WebSocket communication. With this feature, you can set up a WebSocket connection for communication between VDAs and Delivery controllers as an alternative to using WCF communication. For more information, see WebSocket communication between VDA and Delivery Controller.

Studio support for a snapshot of the disk or an OS image of the disk as a master image in the GCP. In the GCP virtualization environment, you can now select a snapshot of the disk or an image of the disk as a master image while using Studio to create an MCS machine catalog. The snapshot of the disk or an image of the disk can be regional and multi-regional as compared to the VM instance which is only regional. This feature significantly simplifies image management workflow and reduces the time and effort required for image management in GCP. For information on creating an MCS catalog in GCP using Studio, see Create a machine catalog.

Connecting Citrix Components from the UI. Admins can use the Monitor UI to register their Citrix components for Infrastructure Monitoring. After installing `Citrixinframonitor.msi`, the UI-based workflow can be used to complete the registration process without needing to use PowerShell commands. This enhancement simplifies the process of registering, deregistering, and updating Citrix components.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The new **Connect Citrix components** page allows you to manage connections between Citrix components and the Citrix DaaS site. You can also view the available connections from Provisioning Service and StoreFront on this page.

These updates streamline the management and integration of Citrix components, making it easier to maintain and monitor your infrastructure.

For more information, see Step 2: Register Citrix Infrastructure Monitor on Monitor UI.

Enhancement to Advanced Alert Policies. Alerts related to Infrastructure Monitoring, previously known as Infrastructure policies, are now part of Advanced alert policies.

You can select the dependent services based on the selected data source and create alerts for Cloud Connectors as well.

NOTE:

The existing Infrastructure policies created for Provisioning Service and StoreFront are migrated to the Advanced alert policies section.

For more information, see Advanced alert policies.

Support to configure secondary VMs scale up or scale down list for MCS-created catalogs on Azure. Web Studio now enables the administrators to define secondary VMs to scale up and scale down the MCS-created catalogs on Azure. Based on the usage of CPU and memory resources, if the CPU or memory usage exceeds a certain threshold, the system will automatically use the secondary VMs to handle the load. Alternatively, if the usage falls below a certain level, the system will automatically shut down some VMs to conserve resources. For more information, see Create a machine catalog using an Azure Resource Manager image in Studio.

Delivery group details enhanced with policy information. We've enhanced the **Details** view for Delivery Groups by adding a dedicated tab that shows policies assigned to the selected group. This improvement simplifies policy management, configuration, and troubleshooting for delivery groups by providing quick access to relevant policy information.

Support for multi-region snapshot of the disk or an image of the disk as master image in GCP. A snapshot or an image of a disk in GCP can be regional or multi-regional. Regional snapshots and disk images are tied to a particular region, example, `us-central1`, whereas multi-regional snapshots and disk images are tied to a geo-location, example, `US`. With this feature, you can use a multi-region snapshot of the OS disk or an image of the disk as master

© 1997–2026 Citrix Systems, Inc. All rights reserved.

image input when creating MCS machine catalogs in GCP. You can see the list of all snapshots (both regional and multi-regional) under `snapshots.folder` location and disk images (both regional and multi-regional) under `images.folder` under hosting unit inventory path.

Support for converting a non-machine profile-based machine catalog to machine profile-based machine catalog in VMware environment. In the VMware environment, you can now use a VMware template as a machine profile input to convert a non-machine profile-based machine catalog to a machine profile-based machine catalog. New VMs added to the catalog take property values from the machine profile. For more information, see Convert a non-machine profile-based machine catalog to machine profile-based machine catalog.

Support for Windows Server 2025. Citrix Virtual Apps and Desktops now supports Windows Server 2025. For more information on Windows Server 2025, see the Microsoft documentation What's new in Windows Server 2025.

Studio: Support for provisioning persistent VMs on Windows Server OS using Full Copy Clone. Studio now supports provisioning persistent VMs on Windows Server OS using the Full Copy Clone approach. This approach improves data recovery and migration capabilities and can help reduce IOPS after machines are created. For more information, see Select a desktop experience and Virtual machine copy mode.

Studio AWS Quick Deploy: Support for adding non-BYOL-enabled AWS accounts. Studio now allows you to connect an AWS account without enabling BYOL feature for a region. You can configure the BYOL feature for a region later. The account without BYOL enabled for a region has a restriction of selecting only default tenancy images and shared directory connection to continue to setup the account. For more information, see Connect your AWS account.

Backup and restore using Studio is now Generally Available. You can now use the Backup and Restore node available in the left pane of your Manage DaaS console. This feature enables you to create on-demand and scheduled backups and restore deleted applications, policies, and more. For more information, see Backup and Restore using Studio.

Configuration guides widget on the Studio Home Page. We've updated the Studio **Home** page by renaming the **Get started** widget to **Configuration guides**. This widget now includes the original **Get Started with DaaS** guide and a new **Check resiliency configurations** guide.

Check resiliency configurations guide. We've introduced a new **Check resiliency configurations** guide in the **Configuration guides** widget on the Studio **Home** page. This guide provides checklists for verifying resiliency settings across various types of StoreFront deployments:

- Checklist for on-premises StoreFront deployments

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Checklist for Citrix® StoreFront Cloud deployments
- Checklist for mixed StoreFront deployments

Following this guide, you can verify Local Host Cache and Service Continuity are properly configured in your deployment, ensuring uninterrupted access to apps and desktops during service disruptions.

DaaS get-started guide now generally available. The **Get-started with DaaS guide** streamlines and simplifies the DaaS deployment process for both new and experienced administrators. This guide walks you through setting up your DaaS deployment by asking a series of questions to guide the configuration. For more information, see Use DaaS get-started guide.

Enhanced domain selection. A new option in the UI now allows you to enter a domain name for an exact match wherever domain selection is needed. This enhancement offers these benefits:

- Faster searches: You can skip browsing large directories, getting results directly and instantly.
- Time savings: Eliminates full-directory loading, speeding up workflows.
- Enhanced experience: Improves admin management efficiency, especially in environments with large directories.

Validate configuration before creating an MCS machine catalog in AWS environments. With this feature, you can now validate configuration settings before creating an MCS machine catalog in AWS environments using the parameter `-validate` in `New-ProvScheme` command. After you run this PowerShell command with the parameter, you get an appropriate error message if there's an incorrect parameter used or a parameter has conflict with another parameter. You can then use the error message to resolve the issue and successfully create an MCS machine catalog using PowerShell. This feature is applicable to AWS, Azure, GCP, and VMware virtualization environments. For more information, see Validate configuration before creating an MCS machine catalog.

Update to Performance Metrics panel. The **Performance Metrics** panel has an enhanced visualization of the historical data metrics. When you click the **Session Performance** tab, along with the last 15-minutes data, you can view the last 48 hours data for ICARTT and ICA® Latency. This enhancement helps to reduce mean time for resolution by enabling admins to triage issues even though the session was terminated in the last 48 hours.

For more information, see the Performance metrics section.

Enhancement to Filters tab. With this release, the following extra filters are added to the **Sessions** tab.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **All** - Displays all sessions
- **Active, Connected, and Disconnected** - Displays only the active, connected, and disconnected sessions.
- **Ended** - Displays only the sessions that have ended within the last 48 hours. The default filter is **Active, Connected, and Disconnected**.

Enhancement to ended session . In the ended session (formerly historical session), the **Session Performance** tab shows data for the last 48 hours. Also, you can view the **Session Logon** tab for the ended session.

For more information, see the Diagnose ended user sessions [Preview] page.

October 2024

New and enhanced features

Policy sets now generally available. Policy sets are collections of rules and guidelines that allow simplified, role-based, and easy management operations. Policy sets allow you to create logical divisions within your administrator team, organizations, or machines. You can assign scopes and delivery groups so that authorized administrators can manage the relevant policies for users and machines. For more information, see Policy sets.

Enroll persistent machines of hybrid Azure AD joined type into Microsoft Intune for co-management. During machine catalog creation, you can now enroll persistent machines of the hybrid Azure AD joined type into Microsoft Intune (with Configuration Manager) for co-management. This feature applies to single and multi-session, persistent VMs and on all hypervisors and cloud services, ensuring uniform device management across your infrastructure. This feature is applicable only to VDA version 2407 and later.

For more information, see Hybrid Azure AD joined catalogs enrolled in Microsoft Intune and Create Hybrid Azure AD joined catalogs enrolled in Microsoft Intune.

Diagnose conditional authentication failures. Whenever any conditional authentication fails, you can use the transaction ID available in the failure message and search in the Monitor for the failure details. Monitor helps you to troubleshoot conditional authentication failure events by displaying failure reasons and conditional policies on the Monitor UI. For more information, see Diagnose conditional authentication failures.

Service accounts for machine identity management. MCS has developed a new mechanism for managing on-premises Active Directory and Azure Active Directory (Azure AD) identity service

© 1997–2026 Citrix Systems, Inc. All rights reserved.

accounts to simplify and enhance the management of machine identities including computer accounts in on-premises Active Directory, Azure AD joined devices and Intune enrolled devices. Firstly, we have introduced on-premises Active Directory service account support which allows administrators to manage computer accounts in on-premises Active Directory without having to enter domain credentials every time. Secondly, we have introduced Azure AD identity Service Principal Names (SPN) support which allows administrators to manage Azure AD joined or Intune enrolled devices in the Azure AD tenant, in a secure and streamlined manner. Lastly, we have implemented a new mechanism for service account management in our Studio, simplifying the process and making it easier to maintain security and compliance. For more information, see Service accounts for machine identity management.

Support to select an Instance template as a machine profile. When creating MCS machine catalogs in GCP environments using Studio, you can now select Instance Templates as the inputs for machine profiles. Also, the Customer-Managed Encryption Key (CMEK) settings follow a priority sequence. For more information, see Create a machine catalog using Studio

Export a machine profile to an ARM template spec. Studio now supports exporting the machine profile used by a catalog into an ARM template spec. With this feature you can easily reuse an existing machine profile as a template and modify it for future provisioning needs. For more details, see Export a machine profile as an ARM template spec.

MCS catalogs: AWS launch templates support. You can now use AWS launch templates as machine profiles when creating or editing MCS catalogs in your AWS environment. AWS launch templates are available in the machine profile list for selection.

Retrieve Connector Appliance information. With this feature, you can use the PowerShell command `Get-ConfigEdgeServer` to retrieve the Connector Appliance information.

- `Get-ConfigEdgeServer -ConnectorType 'Unified'`: Returns Connector Appliance information
- `Get-ConfigEdgeServer -ConnectorType 'Windows'`: Returns only edge servers information
- `Get-ConfigEdgeServer`: Returns only edge servers information.

Reboot schedules for hibernated VMs. With this feature, you can configure reboot schedules for hibernated VMs if the Delivery Group is hibernation enabled. In the reboot cycle, the VMs are resumed and, then shut down. The reboot schedule can be set as weekly, daily, monthly, and once. You can configure multiple schedules. Note that VMs resuming from hibernation can take few mins.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Data caching for the Images node. We've introduced data caching for the **Images** node to improve the overall user experience. This enhancement significantly reduces the page load time when you navigate to the **Image definition** and **Image versions** lists, as well as the **Details** and **Image Scheme** tabs.

Configuration logs labeling. You can now label configuration logs on the **Logs > Events** tab, facilitating the identifying and exporting of logs. In addition, the **Logging** node now offers enhanced features, including exporting logs to CSV files, advanced search, and table-style display for the **Events** tab. For more information, see View configuration log content.

Support for creating a host connection using Azure Managed Identity. Previously, you could create an Azure hosting connection using a service principal. This required providing and storing of the application ID and secret of the service principal. The Azure Managed Identities offers a secure and scalable way to access Azure services without the need to manage credentials. This approach eliminates the risks associated with storing, rotating, and managing secrets. Managed identities also support automatic token refresh, ensuring that applications always use valid credentials without any additional code for token lifecycle management.

With this feature, you can create a host connection to Microsoft Azure Resource Manager using Azure Managed Identity. Currently, you can create the host connection using only PowerShell commands. For information on creating a host connection using Azure Managed Identity, see Create a host connection using Azure Managed Identity.

Support for Boot Integrity Monitoring in Azure. With this feature, in Azure virtualization environments, you can enable Boot Integrity Monitoring for MCS machine catalog VMs (persistent and non-persistent VMs) using a machine profile (VM or template spec) that has GuestAttenstation extension installed. Boot Integrity Monitoring is only supported for Trusted Launch and Confidential VMs that use Secure Boot and virtual Trusted Platform Module(vTPM).

If your VM has Secure Boot and vTPM enabled, and GuestAttestation extension installed, Microsoft Defender for Cloud can remotely validate that your VM boots correctly. This monitoring is called Boot Integrity Monitoring. For more information on boot integrity monitoring, see Boot integrity monitoring overview.

For information on creating a catalog enabled with boot integrity monitoring, see Boot Integrity Monitoring.

Filter empty resource groups. With this feature, you can filter out empty resource groups while selecting a master image, machine profile, or prepared image during the machine catalog creation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

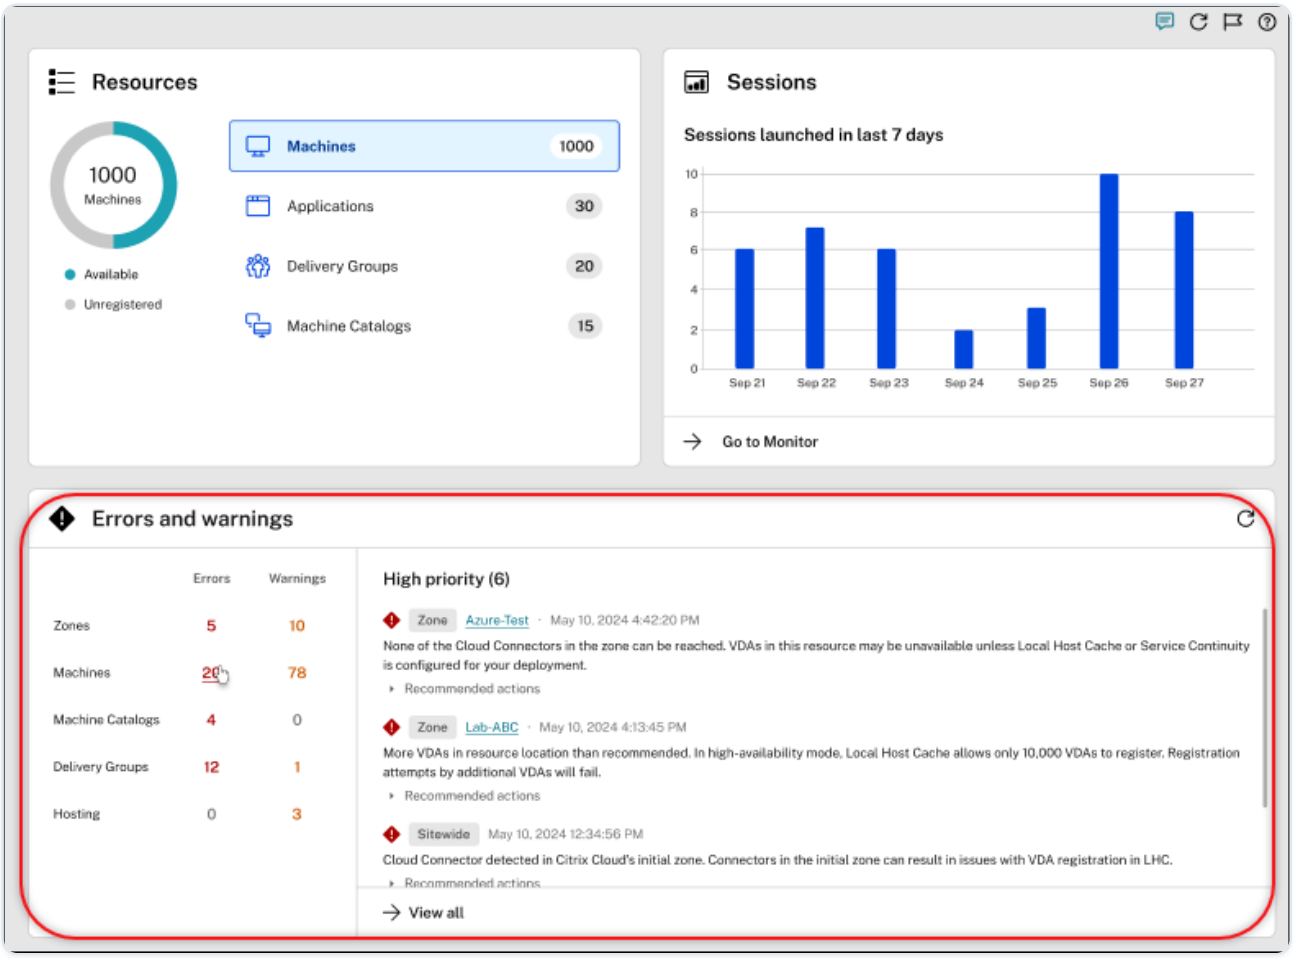
You can do this using a PowerShell command `Get-HypInventoryItem`. For more information, see Filter empty resource groups.

Support for creating preformatted WBC disk catalogs in Azure. With this feature, in Azure virtualization environments, you are able to utilize a preformatted WBC disk for newly created catalogs. This action significantly reduces the time required to start each VM of an MCS or MCS provisioned Citrix Provisioning™ machine catalog. To implement this functionality, create an Azure catalog with WBC enabled and include an additional custom property `PreformatWriteBackCache` as `True`.

You can update an existing catalog using the `Set-ProvScheme` command to update the WBC disk size.

This feature is compatible with the Image management workflow where MCS separates the mastering phase from the overall provisioning workflow. For more information, see Create a preformatted WBC disk catalog.

Delete WBC disk at shutdown for MCS provisioned Citrix Provisioning catalogs. With this feature, you have the option to delete the write-back cache (WBC) disk after you shut down the VM for MCS provisioned Citrix Provisioning catalogs in Azure. This implementation helps to save cost when you do not need a persistent WBC disk. This feature is also applicable to an existing catalog. For more information, see Delete WBC disk at shutdown for MCS provisioned Citrix Provisioning catalogs.



Support for creating a network security group. With this feature, you can now create a Deny-All network security group for image preparation instead of requesting Citrix to create and modify a network security group automatically. Edit the custom properties of the hosting unit using a PowerShell command `Set-Item` to include the parameter `NsgForPreparation` to provide the Deny-All network security group. For more information on using the PowerShell command, see Use a pre-created network security group.

Support for using Azure temporary disk as a WBC disk for existing MCS machine catalogs. With this feature, you can now use Azure Temporary disk as a write-back cache (WBC) disk for existing MCS machine catalogs and existing VMs. Use the `Set-ProvScheme` PowerShell command to update existing catalogs. This implementation saves storage cost because Azure temporary disk is free of charge. For information on the steps, see Use temporary disk as WBC disk for existing catalogs.

Errors and warnings center. With a new widget, **Errors and warnings**, on the Studio **Home** page, you can now view all errors and warnings from your DaaS deployments in one place. This

© 1997–2026 Citrix Systems, Inc. All rights reserved.

widget streamlines issue resolution by consolidating scattered alerts, enhancing visibility, and reducing troubleshooting time. For more information, see Home page.

Enhancement to Trends page. The **Trends** page now features two new banners linking to the **Cost optimization** page, providing quicker access to cost-saving information and reports. The **Machine Usage** tab now includes links to **Estimated Savings** and **Savings report**, while the **Resource Utilization** tab offers a link to **Workload rightsizing** (formerly known as **Infrastructure rightsizing**). These enhancements streamline navigation and improve visibility, enabling users to make data-driven decisions for cost optimization. For more information, see the Trends page.

September 2024

New and enhanced features

Backup and restore using Studio (Preview). You can now use the **Backup and Restore** node available in the left pane of your Manage DaaS console. This feature enables you to create on-demand and scheduled backups and restore deleted applications, policies, and more. For more information, see Backup and Restore using Studio (Preview).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Validate permissions on host connection in Azure. Previously, in Azure environments, you could validate only the host connection credentials (client id or application id) used to create a connection to Azure.

With this feature, you can:

- Get the list of permissions assigned to your host connection credential
- Get the list of operations that can be performed with the permissions assigned
- Information on the permissions required
- Information on how to add the desired permissions

This helps you to troubleshoot and get necessary permissions ahead of time so that you can perform the tasks without being blocked. For more information, see Validate permissions on host connection.

Create Citrix Provisioning catalogs using MCS PowerShell commands in XenServer. You can now create Citrix Provisioning catalogs using MCS PowerShell commands in XenServer environments. You can create both machine-profile based and non-machine profile based Citrix Provisioning catalogs. For more information, see Create Citrix Provisioning catalogs in Citrix Studio.

Repair the identity information of active computer accounts in GCP, SCVMM, and XenServer. In GCP, SCVMM, and XenServer environments, you can now reset the identity information of active computer accounts that have identity-related problems. You can choose to reset only the machine password and trust keys, or reset all configuration of the identity disk. This implementation is applicable to both persistent and non-persistent MCS machine catalogs. Currently, the feature is supported for AWS, Azure, GCP, SCVMM, VMware, and XenServer virtualization environments. For more information, see Repair the identity information of active computer accounts.

Support for creating Azure AD joined catalogs enrolled in Microsoft Intune for non-persistent VMs. You can now create Azure AD joined catalogs enrolled in Microsoft Intune for non-persistent single-session and multi-session. This feature is applicable only to VDA version 2407 and later.

For information on requirements, limitations, and considerations on Microsoft Intune enabled catalogs using Citrix DaaS, see Microsoft Intune.

For information on creating Microsoft Intune enabled catalogs, see Identity pool of Microsoft Intune enabled machine identity.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

New application publishing option for associating file types with applications. We've added an option, **File Type Association**, for publishing applications in Studio. This feature enables you to specify and manage extensions for applications when publishing them:

- When you add Local App Access applications, this option appears in the left pane.
- When you add an application for delivery or application groups, this option is accessible through the **Properties** menu of the application.

This enhancement ensures a more comprehensive and streamlined application publishing experience.

Enhancements to the Preview widget. We've enhanced the **Preview** widget in Citrix DaaS, providing a more streamlined and user-friendly preview experience. The enhancements include:

- **Preview activity logging.** Enabling or disabling preview features are now recorded in the Logging node. This feature ensures visibility into the activation and deactivation of preview features for audit and troubleshooting purposes.
- **Contextual information.** Supplementary content for preview features is now available to improve your understanding of each preview feature. The information includes links to installation packages, demo videos, Podio forms, preview articles, blogs, and other relevant documentation.
- **Feedback option.** With a new icon, **Submit Feedback**, you can now directly provide feedback, comments, and suggestions for preview features. This feature helps us gather valuable insights and improve our services based on your input.

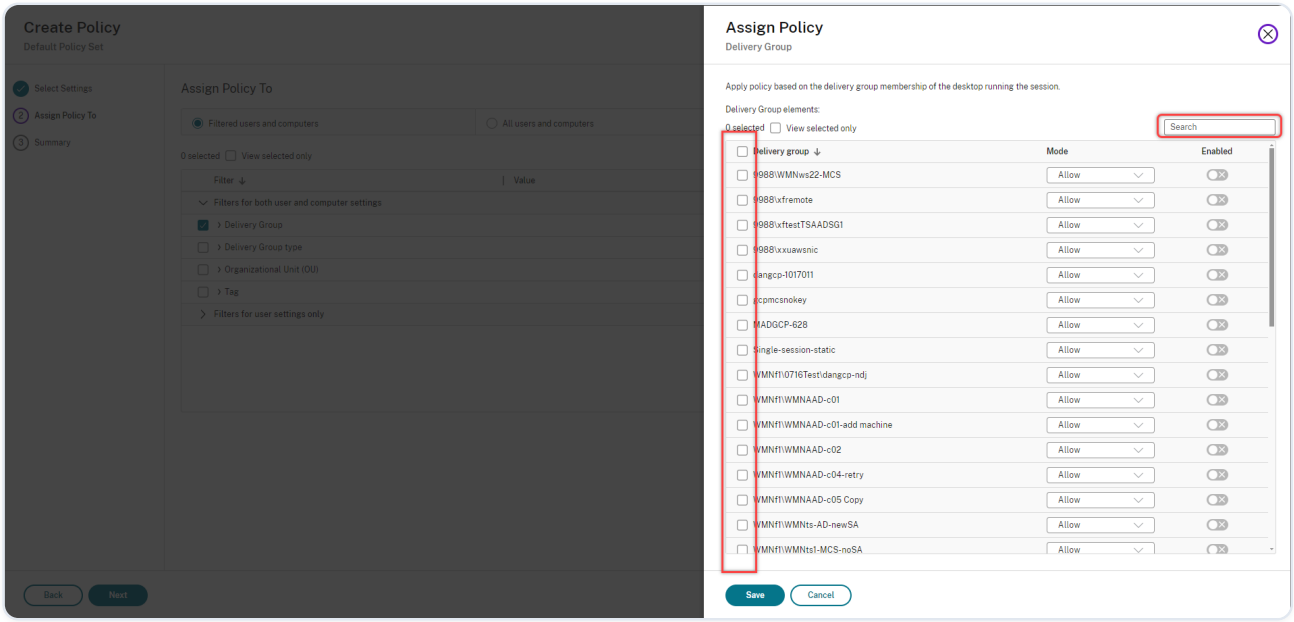
Option to export data from the Cost optimization page. You can export the data in the **Cost optimization** page using data integration and ODATA queries. To export data, you can use on of the following options:

- Setup data integration - You can integrate Cost optimization data with Monitor Service API using which you can collect the data for troubleshooting and triaging the issues. For more information, see Integrations and data exports page.
- ODATA queries for cost optimization - You can use the available sample ODATA queries on the **Cost optimization** page to export data.

For more information, see Export data.

Webhook configuration using PowerShell SDK. The Webhook Configuration feature using PowerShell SDK allows administrators to create, modify, delete, and list webhook profiles. This

© 1997–2026 Citrix Systems, Inc. All rights reserved.



feature provides flexibility in configuring webhooks by allowing the specification of headers, authentication types, content types, payloads, and webhook URLs.

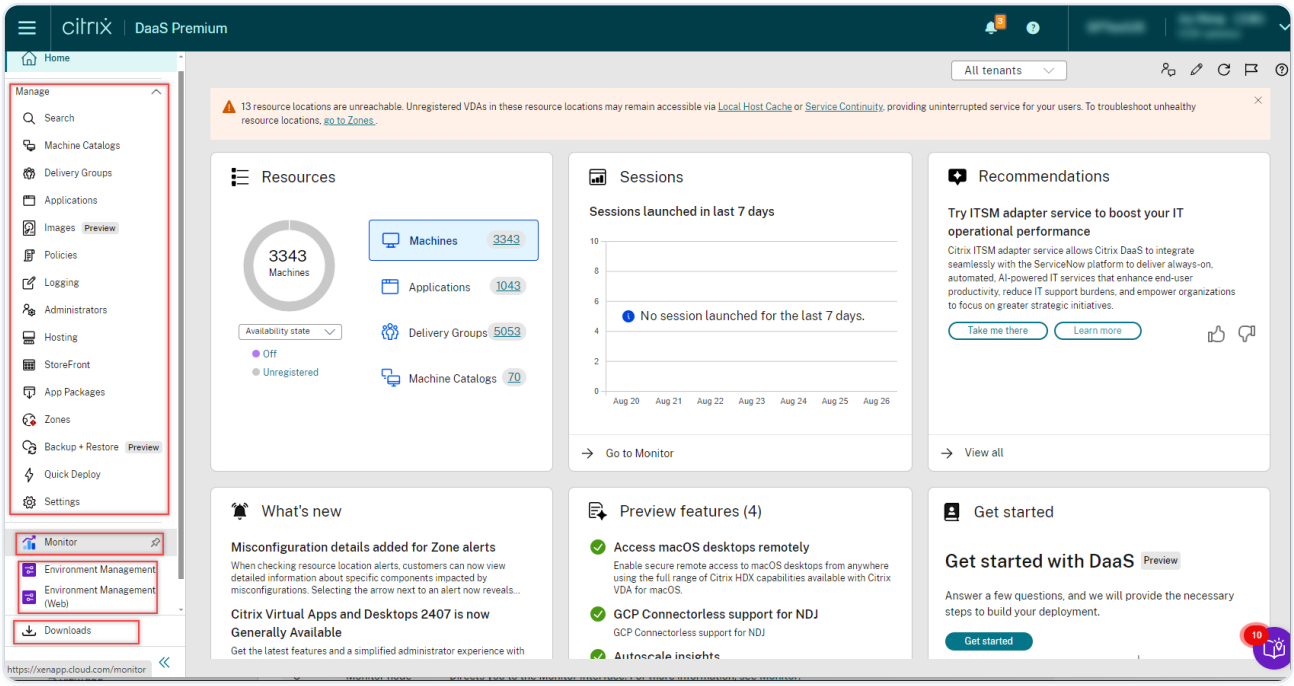
NOTE:

The supported payload format is text and the end user must enable text in their webhook.

For more information, see the Webhook configuration using PowerShell SDK documentation.

Enhanced policy assignment experience. You can now simplify your policy assignments in the **Policies** node with the new multi-selection and search functions. With those functions, you can view all objects of a selected type on the **Assign Policy** page and assign policy settings to multiple targets in fewer clicks. You can also use the search function to quickly filter and find specific objects, saving your time and reducing errors.

August 2024



New and enhanced features

Redesigned DaaS navigation pane. We've revamped the DaaS navigation pane to streamline your management tasks:

- **Simplified navigation:** Reduced from two layers to one by moving the **Manage** and **Monitor** menus and the **Downloads** link from the top menu bar to the left navigation pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Centralized configuration:** All configuration-related nodes and menus are now located in the Manage section on the left navigation pane, consolidating items from the previous **Full Configuration** and **Quick Deploy** menus.
- **Reorganized Cloud services for machine management:** The **Environment Management**, **Environment Management (Web)**, and **Session Recording services**, previously under the **Manage** menu, are now at the same level as the **Manage** menu in the navigation pane.
- **Pin menus for quick access:** The newly added **Pin** function allows you to pin frequently used menus at the top of the navigation pane for quick access. You can reorder pinned menus by dragging them to desired places.

MCS creates ID Disks with GP3 volume type in AWS environment. Previously, in AWS environments, the Identity disks (ID) of VMs were of GP2 volume type. With this feature, MCS can now provision VMs with Identity disks of GP3 volume type. As GP3 volume type is the cheapest option offered by AWS, this feature minimizes cost.

The feature is applicable only to the VMs added to a new catalog and new VMs added to an existing catalog. Existing VMs created before this feature continues to have ID disks with GP2 volume type, unless the ID disk is reset.

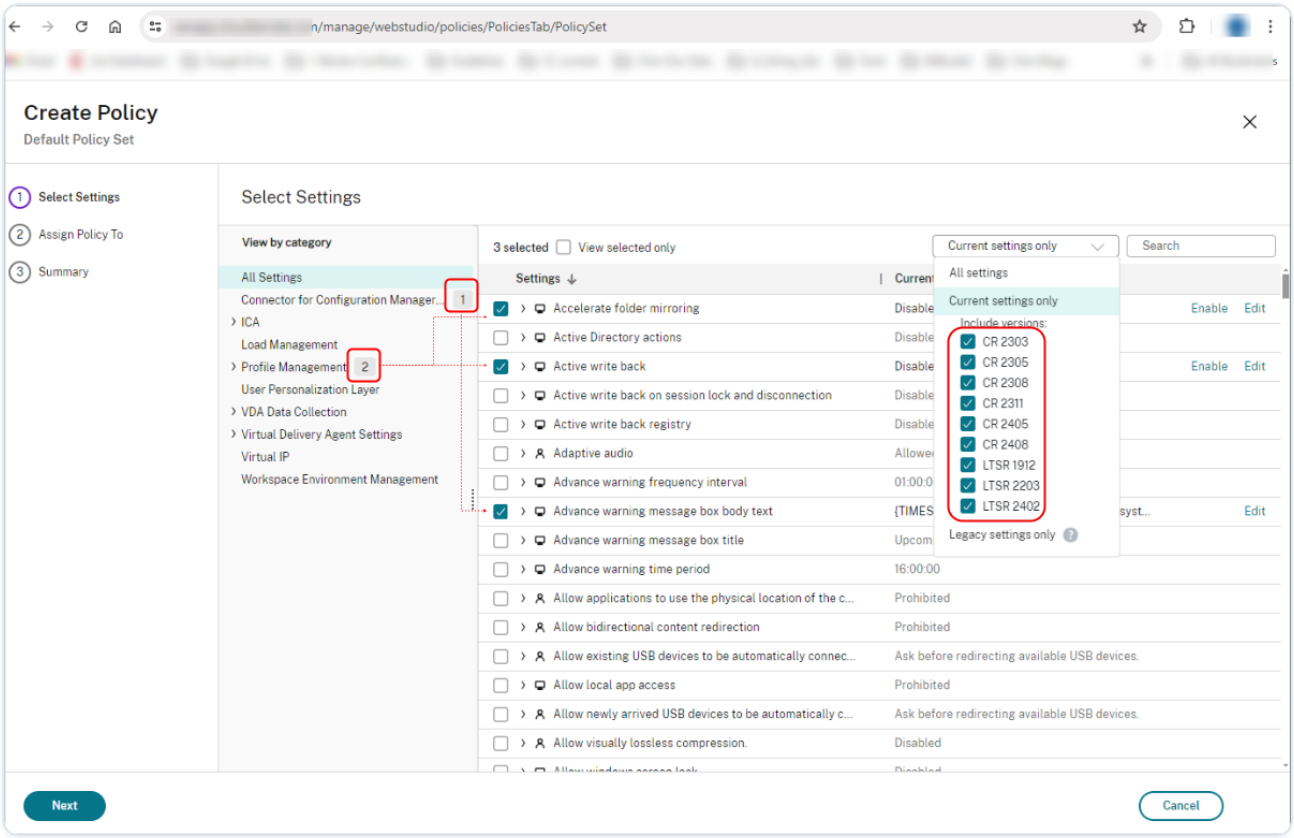
Validate permissions on host connection in AWS. In AWS environments, you can now validate permissions on a host connection to do tasks related to creating and managing MCS machine catalogs. This implementation helps you to find out the missing permissions required for different scenarios such as creating, deleting, and updating VMs, power management of VMs, and EBS

© 1997–2026 Citrix Systems, Inc. All rights reserved.

encryption, ahead of time so that you can avoid being blocked at critical times. For more information, see Validate permissions on host connection.

Create Custom Image from an existing Workspace Instance. This enhancement allows you to create a custom image from an already existing workspace instance. For more information, see Create Custom Image from an existing Workspace Instance.

Persist BDM storage type as standard SSD in Azure. Going forward, for Citrix Provisioning catalogs that are created using MCS in Azure, the BDM storage type is configured as standard SSD by default. This option is considered as a cost-saving measure and cannot be modified.



Customize the Home Page. You can now personalize the DaaS **Home** page by adding, removing, and repositioning its widgets to suit your needs better. This customization is specific to each administrator, ensuring a personalized dashboard experience. For more information, see Home page for the Full Configuration interface.

Misconfiguration details added for Zone alerts. When checking resource location alerts, you can now view detailed information about specific components impacted by misconfigurations. Previously, only general information was available on the **Troubleshoot** tab of the **Zones** node, making it difficult to address precise problems. With this enhancement, clicking the right direction arrow next to an alert reveals more specific details, enabling you to take targeted actions on misconfigurations. For more information, see Troubleshooting.

Policies UI improved for better user experience. We've enhanced the UI design for the **Policies** node to improve its overall usability and functionality. Detailed improvements include:

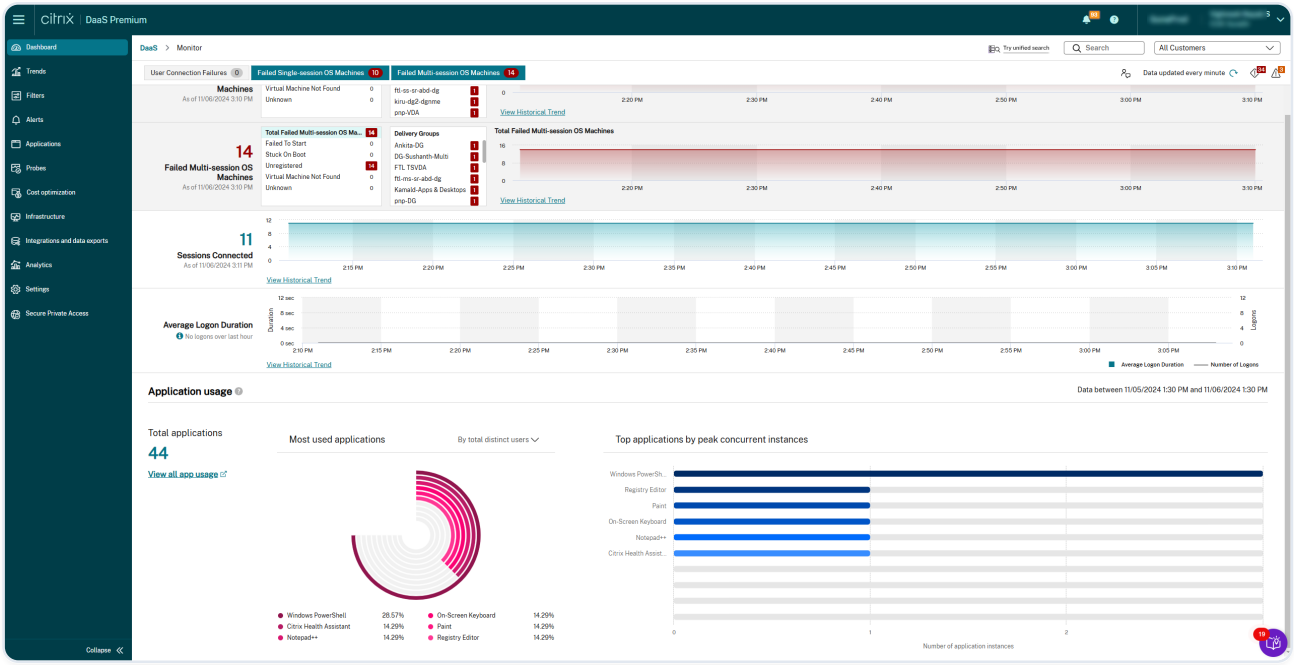
- **Full screen for creation and editing UIs.** Full-screen mode is now used for an improved and more efficient creation and editing experience on the **Policies** node.
- **Simplified setting filtering.** A dropdown list for supported VDA versions is now available under the **Current settings only** filter, allowing you to filter settings based on VDA versions.
- **Enhanced setting categorization.** When you select multiple settings, the number of settings chosen now appears next to the relevant categories and sub-categories in the left pane. This improvement helps you quickly identify the category and sub-categories to which each selected setting belongs, streamlining your policy management.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Data caching for the Details tab on Full Configuration nodes. We've introduced data caching for the **Details** tab on all Full Configuration nodes. This enhancement significantly reduces the data load time for the **Details** tabs, improving the overall user experience.

Application usage monitoring charts on Dashboard. Now, Citrix Monitor helps you to monitor the usage of published applications. This feature is present on the Dashboard and contains curated charts to help the IT admins or application admins to gain insight into which applications are heavily used and the extent of their usage.

These charts comprise of the following data points for the last 24 hours:



- Total number of applications in use
- Most used applications (limit 10) by total number of distinct users
- Most used applications (limit 10) by total number of application launches
- Top peak concurrent application instances

Through this visualization, customers can get visibility into the popular published applications to perform a Consumption versus Entitlement analysis to optimize on cost incurred on purchasing software licenses.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

This feature is available only for the platinum-licensed sites.

For more information, see Application usage monitoring charts on Dashboard.

Option to view and filter session type and last boot time. Citrix Monitor now offers an option to add **Session Type** as a new column. The different session types available are desktop and application. You can also add **Session Type** as a new column by adding it at **Filters** > **Sessions** > **Choose Columns.** This is also added at **Trends > Sessions.**

Similarly, a new option to find out the **Last Boot Time** is added on the **Filters** > **Machines** section. You can also add **Last Boot Time** as a new column by adding it at **Filters** > **Machines** > **Choose Columns**.

Convert legacy MCS catalogs to machine profile-based catalogs in Azure and AWS. You can now convert non-machine profile-based machine catalogs to machine profile-based machine catalogs in Full Configuration for both Azure and AWS environments. This new capability allows you to upgrade legacy MCS catalogs to the recommended machine profile-based catalogs.

For more information, see:

- Convert legacy MCS catalogs in Azure to machine profile-based catalog
- Convert legacy MCS catalogs in AWS to machine profile-based catalog

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for backup VM sizes configuration. Public clouds can sometimes run out of capacity for a specific VM size. Also, if you use Azure Spot VMs, then the VMs are evicted at any time based on Azure's capacity needs. In such a case of insufficient capacity on Azure or a Spot VM power-on failure, MCS now falls back on the backup VM sizes.

You can provide a list of backup VM sizes using a custom property `BackupVmConfiguration`. MCS tries to fall back on the backup VM sizes in the order that is provided by you in the list. In case, MCS fails to fall back on all backup VM sizes provided, you get an error message. This feature is supported only for a catalog that uses a machine profile and is applicable to both persistent and non-persistent MCS machine catalogs. This feature is currently supported only for Azure environments. For more information, see Configure backup VM sizes.

July 2024

New and enhanced features

Configure required Azure host connection permissions. Previously, the host connection test validated whether the credential is good to connect to the hypervisor. The test did not perform validation on actual permissions that you might need to perform relevant MCS operations such as power management, VM creation, and many more.

With this feature, you can now easily configure all the minimum permissions required for a service principal or user account in Azure tied to a host connection to perform all MCS operations using an ARM template. This ARM template automates the following:

- Creation of an Azure Role with minimal permissions necessary for operations.
- Assignment of this role to an existing Azure Service Principal at the subscription level.

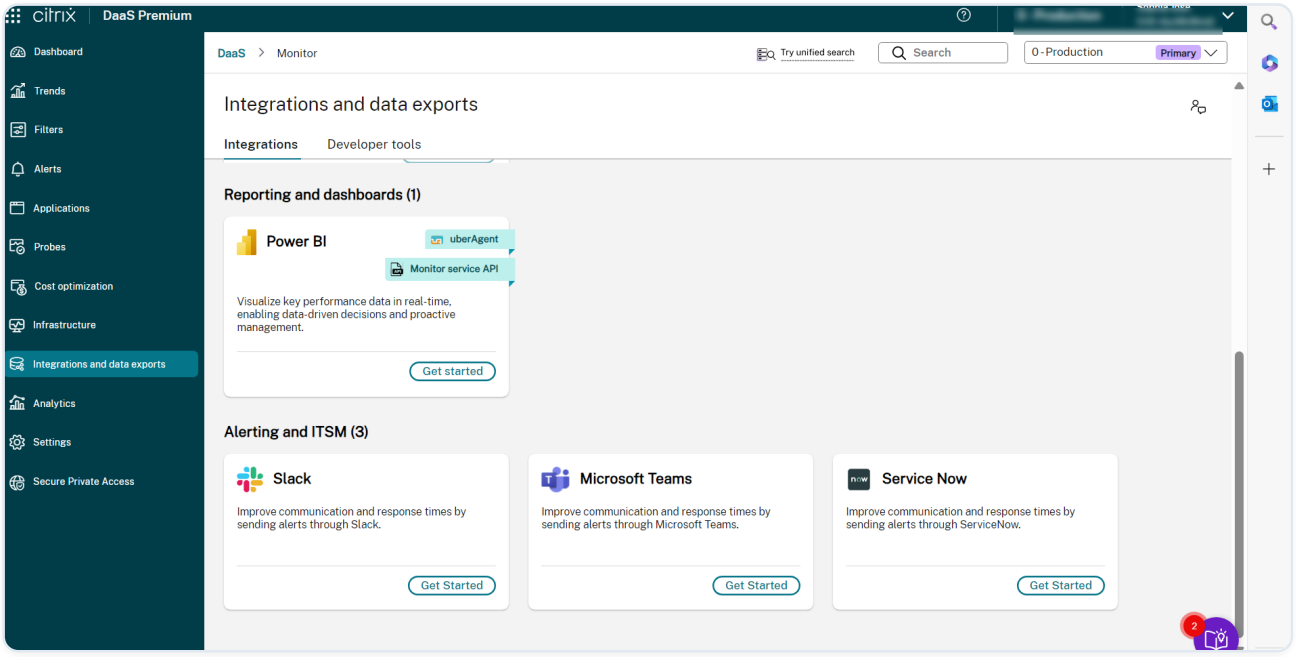
You can deploy this ARM template using the Azure Portal or PowerShell commands. For more information, see ARM Template for CVAD Operations.

Enhanced Performance Metrics panel. The **Performance Metrics** panel has an enhanced visualization of the historical data metrics. When you click the **Session Performance** tab, along with the last 15-minutes data, you can view the last 24 hours data for ICARTT and ICA Latency. This enhancement helps to reduce mean time for resolution by enabling admins to triage issues even though the session was terminated in the last 24 hours.

For more information, see Performance Metrics.

Integrations and data exports. Citrix Monitor now provides a new UI for integrations and data exports. This feature helps to improve the awareness of the various interfaces and third-party

© 1997–2026 Citrix Systems, Inc. All rights reserved.



integrations available in Citrix Monitor. The newly introduced Integrations and Data exports page lists the following:

- Available integrations
- Supported developer tools

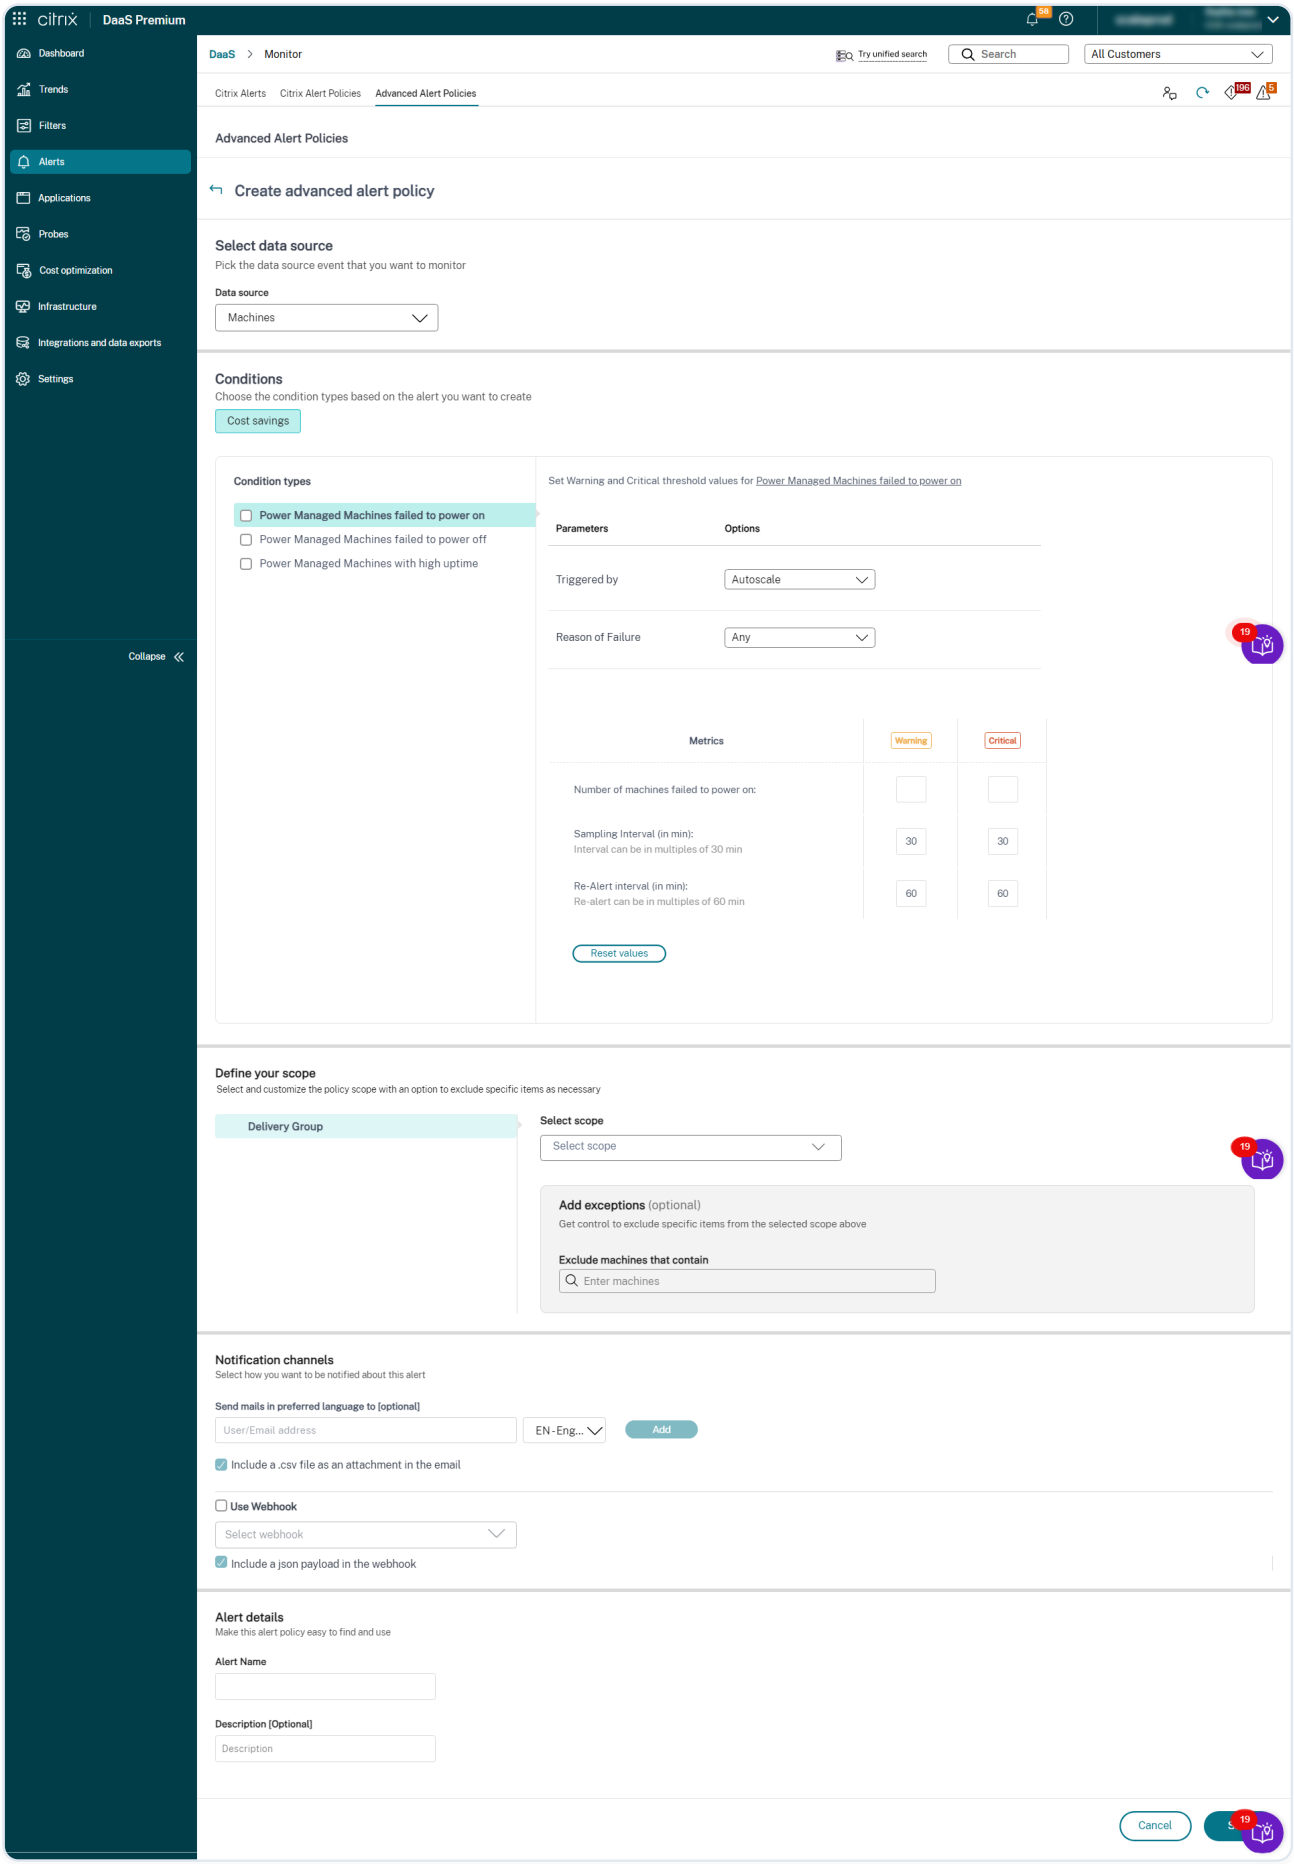
This page also describes the REST API set up for data exports and provides reference links to the guides and documents to get started with the integrations and developer tools.

Currently, Citrix Monitor is integrated with the Power BI observability. You can use this feature to export performance data and events from Citrix Monitor to Power BI using the REST APIs.

Click **Integrations and Data exports** from the left navigation menu. The **Integrations and Data exports** page appears.

For more information, see Integrations and data exports.

Enhancement on triaging user profile load issues. Citrix Monitor now supports the Profile Load duration and container metrics collection from Citrix Profile Management container and FSLogix container. This enhancement assists admin to receive comprehensive profile usage and performance data in user session reports. With this data you can identify and resolve issues with greater efficiency. For more information, see Profile load.



Advanced alert policies. The Proactive Notification and Alerting feature of the Monitor is enhanced to include a new alerting framework named **Advanced Alert Policies**. With this feature, you can create alerts by including granular details for each element or condition, thereby

© 1997–2026 Citrix Systems, Inc. All rights reserved.

enhancing the control over the alerts scope. Currently, these policies include alerts for cost savings and infrastructure.

This feature helps you to reduce excessive alerts which might lead to reduced responsiveness or effectiveness in addressing important issues. This policy helps to measure effectiveness of alert policies and engagement from admins.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Advanced alert policies.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enhancements on alert content. The alerting feature of the Monitor is enhanced to include a CSV attachment and a JSON payload. With this enhancement, you can get alert details in a CSV attachment over email or as a JSON payload in case of a webhook. Using this CSV attachment and JSON payload, you can receive enriched content at a detailed level, aiding in the quick identification and resolution of issues.

Currently, this enhancement is available only on the following alerts:

- Machine uptime
- Failed power on actions
- Failed power of actions
- Unregistered machines (%)

For more information, see Enhancements on alert content.

Local Host Cache config sync failure alert monitoring. Local Host Cache allows user sessions to continue even if Cloud Connectors lose connectivity with Citrix Cloud. The cache used by Local Host Cache is regularly synchronized with the primary database to ensure up-to-date configurations when Local Host Cache mode is activated. You can learn more information about Local Host Cache and the config sync process at Local Host Cache. If the configuration sync fails more than three times consecutively, Citrix Monitor sends a warning alert to the administrator.

A predefined alert policy named **Local Host Cache - Config Sync Failure** has been introduced in Citrix Monitor to notify administrators about configuration sync failures. You can find the newly introduced policy on **Monitor** > **Citrix Alerts**. For more information, see Local Host Cache config sync failure alert monitoring.

Failed power on action and Failed Power off action alert. The Proactive Notification and Alerting feature of the Monitor is enhanced to include two new alerts, **Failed power on action** and **Failed Power off action** alerts based on the number of power-managed machines failed to power on or off in a delivery group. The new alert condition allows you to configure alert thresholds as the number of power-managed machines failed to power on or off in a delivery group.

For more information, see Failed power on action and Failed Power off action.

Infrastructure monitoring (Preview). Citrix Monitor now offers visibility into the operational health of Citrix Virtual Apps and Desktops components. This feature helps you to easily identify, troubleshoot, and resolve issues related to your infrastructure. Currently, the health of the Citrix Provisioning (PVS) and StoreFront components are monitored.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To support this feature, a new Windows executable named Citrix Infrastructure Monitor is introduced. This helps with the collection and transmission of relevant health metrics from PVS or StoreFront servers to Monitor.

This feature helps you to get critical monitoring data sets and proactive alerts with respect to PVS and StoreFront servers system metrics on a single console in Monitor. Data is collected every five minutes from the monitoring components to ensure the latest information.

This feature aims to enhance operational efficiency by offering proactive monitoring, detailed metrics, and automated alerts, ensuring your Citrix infrastructure runs smoothly and efficiently. For more information, see Infrastructure monitoring [Preview].

Infrastructure policy (Preview). This policy is introduced to create alerts related to the health of supported Citrix Virtual Apps and Desktops components.

Once the Infrastructure monitoring setup is completed, you can use the health data available in Monitor to configure alerts for any required component. Admins can set conditions, scopes, and notification mediums to receive important alerts through emails or a json payload through webhooks. The alerts raised are also available in the **Citrix Alerts** section for analysis and management.

As part if this policy, the following four new categories are introduced:

- Reachability
- Dependent services
- Impact
- Resource utilization

You can set different conditions and can modify the severity of the preceding categories as required in the **Critical** and **Warning** section. You can also schedule re-alert intervals for these alerts.

Conditions within each category can be set with the severity of Critical and Warning based on your organizational priorities. You can also schedule re-alert intervals for these alerts.

For more information, see Infrastructure policies (Preview).

Increased limit of replicas per image version in Azure. Azure has increased the maximum count of replicas for a gallery image single version to 100. With the increase in limit, you can now set the property `SharedImageGalleryReplicaMaximum` to a maximum value of 100 while

© 1997–2026 Citrix Systems, Inc. All rights reserved.

creating an MCS machine catalog using the Azure Compute Gallery image. For more information, see Configure Azure Compute Gallery.

Managing prepared images with the Images node. An **Images** node is now available in Full Configuration interface, that lets you prepare an MCS image (prepared image) from a single source image and deploy it across various MCS machine catalogs. This node facilitates complete image lifecycle management, enabling you to create image definitions, versions, and catalogs.

Images prepared using this node can only be used in Azure and VMware environments. For detailed information on image management, see Image management (Preview).

Alternatively, you can also create catalogs with prepared images using the **Machine Catalogs** node. For more information, see Creating machine catalogs.

Detailed misconfiguration report. The misconfiguration alerts that are exposed in the **Zones** node of the Full Configuration interface provide general information about a misconfiguration in the resource location.

With this enhancement, a new PowerShell cmdlet, `Get-ConfigMisconfigurationReport`, provides a detailed misconfigurations report in the zone. Added details include information such as which Connector is misconfigured, what is the current misconfiguration, and what is the recommended configuration. See Troubleshooting for the documentation on misconfigurations.

Introducing user and desktop display names in the Search node. To improve your troubleshooting efficiency, we've introduced two new columns on the Search node:

- **User Display Name** column on the **Sessions** tab. With this column, you can quickly identify sessions associated with a specific user.
- **Desktop Display Name** column on both the **Single-session OS Machines** tab and the **Sessions** tab. With this column, you can quickly identify the machine associated with a specific desktop.

Additionally, we've added corresponding filters for efficient searching. For more information about these two columns, see Machine actions and columns and Session actions and columns.

Modify desktop display names using Full Configuration. We've enhanced the **Machine Allocation** page for single-session OS static delivery groups by introducing a new column, **Display name**. With this addition, you can now modify desktop display names for machines assigned to users. For more information, see Manage user assignments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Options to troubleshoot when ICA RTT or Session Logon Duration data fails to populate. Previously, when EUEM service or UPM service failed to run, the reason for failure in getting the data related to ICA RTT or Session Logon Duration wasn't displayed. With this new feature, you can get the reason for failure and the corresponding solution for the failure. For more information, see Troubleshoot when ICA RTT or Session Logon Duration data fails to populate.

Support for Azure's nested virtualization. With this feature, if you configure the master VM with nested virtualization enabled, then all VMs in the MCS machine catalog created using that master VM have nested virtualization enabled. This feature is applicable to both persistent and non-persistent VMs. You can update an existing MCS machine catalog and existing VMs to have nested virtualization through image update.

Currently, only Dv3 and Ev3 VM sizes support nested virtualization.

For information on nested virtualization, see the Microsoft blog Nested Virtualization in Azure.

Support for inheriting labels from a machine profile source to the VMs and disks in GCP. With this feature, MCS machine catalog VMs and disks (Identity Disk, Write-cache Back Disk, and OS disk) can now inherit the labels of a machine profile source (GCP VM instance or instance template). You can use the labels to distinguish instances owned by different teams (for example, **team:research** and **team:analytics**), and further use it for cost accounting or budgeting.

For more information on labels, see the GCP document Organize resources using labels.

This feature is applicable to persistent and non-persistent MCS machine catalogs.

You can create a new MCS machine catalog, update an existing catalog, and update existing VMs to inherit the labels from a machine profile source.

For information on creating an MCS machine catalog, see VMs and disks with inherited labels.

Support for inheriting custom tags from machine profile to the provisioned VMs. You can now add the custom tags of an SCVMM VM to the MCS provisioned VMs along with the default `CitrixProvisioningSchemeId` tag. To add the custom tags to the provisioned VMs, you must use the SCVMM VM as a machine profile while creating or updating an MCS machine catalog. If you remove a VM from a catalog, then only the `CitrixProvisioningSchemeId` is removed from the tag. The custom tags are not deleted from the VM. This feature applies to a new MCS machine catalog and new VMs added to an existing catalog. For more information, see Create a catalog with a machine profile.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for on-demand capacity reservation in Azure. With this feature, you can create an MCS machine catalog of Azure VMs with on-demand capacity reservation using a machine profile (VM or template spec). This feature is applicable to persistent and non-persistent machine catalogs. You can update an existing machine catalog and existing VMs to have or remove on-demand capacity reservation.

For more information on Azure on-demand capacity reservation, see the Microsoft documentation On-demand Capacity Reservation. For information on creating and updating an MCS machine catalog with on-demand capacity reservation, see Create a catalog of on-demand capacity reservation VMs.

Support for placing WBC disk on the same storage location as OS disk. In XenServer, VMware, and SCVMM virtualization environments, MCS now places Write-back cache (WBC) disk on the same storage location as OS disk if you configure the available OS storage list the same as the available temporary storage list while creating a host connection.

This implementation helps to reduce the complexity in managing the OS and WBC disks. For creating a host connection, see Create a connection and resources.

Enhancement to Cost savings page. Cost savings page is enhanced with the following:

- **Estimated Savings** - The Estimated savings chart now includes additional filter options to view data for last 7 days and 30 days. It also shows savings in relation to the customer's account-specific pricing.
- **Filter by Tags** - Displays the tag of the machines that is configured in the Autoscale settings in a WebStudio. You can also filter the data based on the tagged machines. In this case, you will get only the tagged machines summary.
- **Average logon duration** - Displays the average time for a user to log on over the selected time duration.
- **Power managed machines** - The power managed machine chart now includes the hibernate state of the machine, which helps you to analyze how many machines are in hibernate state.

For more information, see Cost savings[Preview] section.

Get warnings messages for hibernation failure. You can now get warning messages using a PowerShell command `Get-ProvOperationEvent` in case of hibernation failure of MCS-provisioned and existing hibernation-capable VMs. For more information, see Get warnings messages for hibernation failure.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Option to update write-back cache settings post creation for Machine Creation Service (MCS) catalogs in the hypervisors. You now have the option to update the memory and disk cache size of the write-back cache, when Machine Creation Service (MCS) Storage Optimization (MCSIO) is enabled, after the catalog is created for MCS catalogs in the hypervisors.

For more information, see:

- Create a machine catalog using a machine profile
- Create a catalog with a machine profile
- Create a machine profile-based machine catalog using PowerShell

Enhancement to Session Performance tab. The **Session Topology** section of the **Session Performance** tab is enhanced to include the following endpoint metrics which exists in the Citrix Workspace app for Windows:

- WIFI signal strength
- Throughput incoming and outgoing
- Network interface type
- Link speed

This enhancement helps to troubleshoot issues with respect to sessions quickly.

Diagnose historical user sessions . Citrix Monitor now displays the details of sessions in active, disconnected, or in terminated state. Previously, you could see the details of active sessions only. With this feature, helpdesk admins can troubleshoot issues with a session that was ended or in terminated state. The session details are available for last 24 hours and last 2 days. You can view the following details of an ended or terminated session:

- Machine Details panel - Displays the available details of the machine where the selected session was launched.
- Session Details panel - Displays the available details of the selected session.
- Session logon duration - Displays the information on the logon duration taken for the selected session. You can view the chart on time taken for brokering, machine start-up, hdx connection, authentication, GPOs, logon scripts, profile load on disk, and interactive session.

For more information, see Diagnose historical user sessions.

Machine uptime alert. The Proactive Notification and Alerting feature of the Monitor is enhanced to include a new alert, Machine uptime alert based on the uptime of a power managed machine in

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a delivery group. For every delivery group, for which the machines crossed the threshold, you will get an attachment or webhook alert for that delivery group alone.

The new alert condition allows you to configure alert thresholds as the number of hours per day, hours per week, or hours per month for a machine is turned on in a delivery group.

For more information, see Machine uptime alert.

Published desktop name. Citrix Monitor now displays the published desktop name in the UI. This new field allows you differentiate among user groups within the same delivery group. You can also generate custom reports for these user groups. This new field is added to **Filters**, **Custom Reports**, or to **Machine Details** section of Citrix Monitor UI.

Infrastructure rightsizing. The **Infrastructure Rightsizing** page helps you to analyze the provisioning and sizing aspects of your delivery group based on the resources utilization. Based on this analysis, you can optimize the machine provisioning and sizing to match the utilization pattern. You can optimize your infrastructure cost by reducing spending on the unused resources. You can also choose to opt for lower CPU and memory specifications machines if the resource utilization is consistently lower than provisioned. You can optimize for performance by opting for a higher CPU and memory specifications machines if the resource utilization is consistency higher and see evidence of it impacting the session experience such as *Logon and ICARTT* metrics.

You can filter the Infrastructure rightsizing using the following:

- Delivery Group - You can filter for single session OS or multi session OS delivery groups
- Tags - Tags are the tag names applied to the machine. So, you can filter machines with the same tags. You can select multiple tags up to five tags. When you select multiple tags, you can filter for all the machines which have at least one of those selected machine tags applied.
- Time period - You can filter the data for last 24 hours, 7 days, and 30 days.

The Infrastructure rightsizing page offers:

- Insight in to the utilization details
- Summary of the resource utilization
- Trends on the resource utilization

Click the **Cost Optimization** tab from the left menu on the Home page. And then, click the **Infrastructure rightsizing** tab to access the **Infrastructure rightsizing** page.

You can also click the **Rightsize this delivery group link** from the **Infrastructure details** section in the **Cost Optimization** tab > **Cost savings** to access the **Infrastructure rightsizing** page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Infrastructure rightsizing.

Local Host Cache activity dashboard. The new Local Host Cache dashboard under the **Trends tab** provides detailed information on user sessions and machines available during an outage on any Resource location or Zone. Administrators can use the details around number of machine registrations, reconnected sessions, and new sessions brokered to evaluate and audit activities while in Local Host Cache mode. The default selected data is for last 24 hours and for all zone and cloud connectors, with the ability to filter on time period, zone, and cloud connector. The Local Host Cache data is available for last 2 hours, 24 hours, 7 days, 1 month, and up to 90 days. For more information, see Available trends.

Specify CMEK global and regional keys from all projects. In Google Cloud environments, previously, you could only use customer-managed encryption key (CMEK) from within the same GCP project and the same region in which the hosting connection is created.

With this feature, you can now browse and use global or regional CMEK from all projects that are accessible to the service account. This feature enhances the flexibility to manage encryption keys. This feature requires extra permission for the following two service accounts:

- The service account of the current project with which the hosting connection is created.
- The Compute Engine Service Agent of the current project.

For more information, see Specify CMEK global and regional keys.

Decoupled Workspaces, allow userGroup assignment. Decoupled Workspaces now allows for a more flexible and independent management of users and their associated workspaces. It simply means, you can create deployments without associating any users to it and instead assign the users to a deployment later. For more information, see Create a deployment.

Support to import Workspace images type. You can now import Workspace images type to create a desktop experience for users. For more information, see Import an image.

Export function extended to all nodes in Full Configuration. You can now export records from the main view of any node in Full Configuration to a CSV file. Note the following:

- The **Export** icon is disabled while data is loading, except for the **Search** and **Applications** nodes.
- For nodes with the **Columns to Display** function, exported data includes only selected columns.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for adding notes for maintenance mode. You can now add notes when placing a machine, delivery group, or connection into maintenance mode. Those notes are visible in the **Maintenance reason field** of the Details pane, helping you and other administrators understand the reason for maintenance.

Data caching for the Zones and Policies nodes. We've introduced data caching for the **Zones** and **Policies** nodes. This enhancement significantly reduces the page load time when you navigate to a node, improving the overall user experience.

Option to update Write-back cache setting post creation for Machine Creation Service (MCS) catalogs in the Google Cloud Platform.

You now have the option to update the memory and disk cache size of the Write-back cache, when Machine Creation Service (MCS) Storage Optimization (MCSIO) is enabled, after the catalog is created for MCS catalogs in the Google Cloud Platform.

For more information, see Create a machine catalog using the Full Configuration interface.

Option for manually managing the service principal's role for Azure AD joined device management.

We've enhanced the **Enable Azure AD joined device management** option for greater flexibility. Previously, you had to sign in to Azure and allow Citrix to assign the **Cloud Device Administrator** role to the connection's service principal on your behalf. This design worked only when your Azure account had permission to grant this role.

With this enhancement, if your Azure account doesn't have the required permission, you can now choose Don't sign in to Azure when enabling Azure AD joined device management. This allows you to manually assign the role to the connection's service principal in the Azure portal.

For more information, see Enable Azure AD joined device management.

Install the FlexApp One agent. Liquidware has a package called FlexApp One. FlexApp One agent bundles the software applications along with their configurations and dependencies for easy distribution and deployment in a shareable file.

To support the discovery and publishing of Liquidware FlexApp One packages, install the FlexApp One agent on any VDA used for package discovery or launching. For more information, see Install the FlexApp One Agent.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

June 2024

New and enhanced features

Full Configuration: Support for provisioning VMWare VMs using machine profile. When provisioning VMWare VMs using Machine Creation Services (MCS), you can now select an existing template as the machine profile, letting the VMs within the catalog inherit settings from the selected template.

The inherited settings include:

- Tags placed on the template
- Custom attributes
- vSAN Storage policies
- Virtual hardware version
- vSphere Virtual TPM (vTPM)
- CPU count and core per socket
- NIC count

Create delivery groups exclusively for suspend-capable VMs using Full Configuration. We've introduced a new option in **Full Configuration > Create Delivery Group**, **Make suspend capability required for this delivery group**. This option enables you to create delivery groups that contain only suspend-capable VMs, facilitating your machine power management at the delivery group level. Note that this feature applies only to single-session OS VMs.

For more information, see Create delivery groups.

Enhanced Performance Metrics panel. The **Performance Metrics** panel has an enhanced visualization of the historical data metrics. When you click the **Session Performance** tab, along with the real time data, you can view the last 15 minutes data without waiting for the page load time. This enhancement helps to reduce mean time for resolution by enabling admins to be able to correlate multiple component performance metrics in a single view. For more information, see Performance Metrics.

Improved Session Logon view. - The new **Machine Start-up** option with the following sub-sections on the **Session Logon** tab on the **Filters** -> **User Details** page provides breakdown of the time taken to start a virtual machine during different phases:

- **Power on** - Displays the time taken to power on a virtual machine
- **Boot-up and registration** - Displays the time taken to boot up and register a virtual machine

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The newly introduced collapsible button on the **Session Logon** page helps to collapse or expand the options on the **Machine Start-up** and the **Interactive Session**.

Along with the default **Logon Duration Phases** table options, which are **Session Logon Phase** and **Duration**, you can also choose the following columns on the **Session Logon** page:

- Start time
- End time
- Delivery Group's 7 Day Avg (sec)
- User's 7 Day Avg (sec)

You can also export the preceding data to a .CSV file.

The newly added columns **Power on** and **Boot up and registration** can be added to the **Logon Duration by User Session** table in the **Trends** -> **Logon Performance** > **Choose Columns**. You can also export the reports on the **Logon Performance** screen.

This enhancement helps to understand and easily troubleshoot issues related to logon duration. For more information, see Diagnose user logon issues.

Unregistered machines alert. The Proactive Notification and Alerting feature of the Monitor is enhanced to include a new alert, **Unregistered Machines (in %)** based on the percentage of unregistered machines in a delivery group. The new alert condition allows you to configure warning and critical threshold values as a percentage of unregistered machines in a delivery group. For more information, see Unregistered Machines (in %) section in the Alerts article.

Shared or Dedicated directory connections. You can now create directory connections using dedicated or shared tenancies. If dedicated tenancy is selected while adding a directory connection then the workspaces created are for single session desktops. If shared tenancy is selected while adding a directory connection then the workspaces created are shared. For more information, see: **Shared or Dedicated directory connections.** You can now create directory connections using dedicated or shared tenancies:

- If you select dedicated tenancy while adding a directory connection then the workspaces created are for single session desktops.
- If you select shared tenancy while adding a directory connection then the workspaces created are shared. For more information, see:
    - Create a directory connection
    - Import an image

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create a deployment

Contextual App Protection. With this feature, the administrators can apply **App Protection Anti-Screen Capture** and **Anti-keylogging** control on devices and users contextually instead of having the controls always enabled or always disabled. This implementation helps you to enforce **App Protection Anti-Screen Capture** and **Anti-keylogging** only when required. For more information, see Step 7. App Protection and Manage app protection.

Enhanced default view settings for machine catalogs, delivery groups, and applications. We've introduced new default view options for Machine Catalogs, Delivery Groups, and Applications, offering greater flexibility and customization:

- **Default view selection.** Previously, those nodes defaulted to a folder view, which was suitable for organizations using folder-based management structures. With the introduction of a **Folder** icon on the action bar, you can now switch between folder view and list view as your preferred default view.
- **Improved folder view.** The **View all** toggle now retains your last selection when you sign back in. If previously turned off, it will remain off, with the root folder selected and the first-level sub-folders expanded.

Data caching for the StoreFront node. We've introduced data caching for the **StoreFront** node. This enhancement significantly reduces the page load time when you navigate to the **StoreFront** node, improving the overall user experience.

Improved user name search in machine catalog creation. We've enhanced the functionality for searching for administrators by user names during machine catalog creation. Key enhancements to the **Machine Catalog Setup > Enter Credentials** page include:

- **Domain specification:** A new option, **Domain**, is now available on that page, enabling you to narrow the search by entering the domain name or SID.
- **SamName search optimization:** Searches using SamName are now confined to the specified domain.

These enhancements make user searches faster and more efficient.

Simplified subnet updates for machine catalogs. Previously, to change the subnet settings of a machine catalog, you had to delete and recreate it. With this feature, you can now achieve the same functionality by editing the catalog. Note that only new virtual machines created under the catalog will be on the newly associated subnets. This enhancement reduces the need for catalog deletion and associated tasks. For more information, see Edit a catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for creating resource groups during Azure catalog creation (for PVS). Previously, when creating Azure catalogs using Full Configuration, you had to create the resource groups using PowerShell commands. With this feature, you can now seamlessly create a resource group as part of catalog creation in Web Studio. This enhancement simplifies the overall creation workflow. For more information, see Create a Citrix Provisioning catalog using the Full Configuration Interface.

May 2024

New and enhanced features

Secure HDX (Preview). You can now use this feature to prevent any network elements in the traffic path from being able to inspect the HDX traffic. For more information, see Secure HDX.

Azure GPU hibernation support (Preview). You now have the option to support hibernation for Azure machine SKUs that support GPU. For more information on supported VM sizes, see the Microsoft documentation.

Citrix Provisioning catalogs support for hybrid Azure AD join extended to Full Configuration. When you create a Citrix Provisioning catalog, the **Hybrid Azure Active Directory joined** identity type is now available on the **Machine Catalog Setup > Machine Identities** page. With this new option, you can create hybrid Azure AD joined machines through Citrix Provisioning. For more information, see this Citrix Provisioning article.

Enhancements to Full Configuration contextual help. We've redesigned the help panel to provide a more informative experience, offering targeted information for each node within Full Configuration. By clicking the Help icon on any node, you can now access a comprehensive set of resources aimed at providing a one-stop learning experience, helping you better understand related features:

- Access key documents specifically related to the selected node.
- Stay informed about service updates including Citrix Roadmap, Known issues, Limits, System requirements, and What's new features.
- Access expanded resources such as Citrix Blogs, Citrix Community, Citrix Feature Explained, Citrix Product Documentation, Citrix Support, and Developer Documentation.

Enhanced configuration logging: tracking membership changes for delivery groups. With this enhancement, configuration logging now captures and displays user and group IDs added to

© 1997–2026 Citrix Systems, Inc. All rights reserved.

or removed from delivery groups. To view configuration logs, go to **Full Configuration > Logging > Events**.

Customize the tab order on the Search node. You can now customize the order of tabs on the **Search** node according to your usage patterns, enhancing the browsing experience. To do so, click the three-dot icon next to the tabs, drag the tabs to your preferred order, and then click **Apply**.

Data caching for the Machine Catalogs node. We've introduced data caching for the Citrix DaaS **Machine Catalogs** node. This enhancement significantly reduces the page load times when you navigate to the **Machine Catalogs** node, improving the overall user experience.

Support for creating Citrix Provisioning catalogs using MCS PowerShell commands in VMware. You can now create Citrix Provisioning catalogs using MCS PowerShell commands in VMware.

This implementation provides you the following advantages:

- A single unified API to manage both MCS and Citrix Provisioning catalogs.
- Have new features for Citrix Provisioning catalogs, such as, identity management solution, on-demand provisioning, and so on.

For more information, see Create Citrix Provisioning catalogs in Citrix Studio.

Failure Detection and Mitigation in VDA Upgrade Service During the VDA upgrade process (Preview). Our service now incorporates advanced detection mechanisms. If any issues are detected that could potentially lead to the failure of the VDA IPU, rendering the VDA unusable, the service will take proactive measures. It will cease to update additional machines and gracefully exit the current workflow. This proactive approach aims to minimize the impact and ensure a smooth experience, even in the event of unexpected challenges, reducing the potential blast radius of any issues encountered. For more information, see Failure Detection and Mitigation in VDA Upgrade Service

Support VDA Updates from a local file share that VDAs have access (Preview). With Enhanced VDA Installer Access Control, you can now have greater flexibility and control over which VDAs can connect and retrieve necessary download MSIs without worrying about granting network access for VDAs to fetch updates from the Citrix Managed Azure CDN. This allows you to enforce stricter network rules while ensuring seamless access to essential updates. For more information, see Support VDA Updates from a local file share that VDAs have access

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Full Configuration support for delivering packaged applications to single-session static desktops and office PCs. With this enhancement, you can now deliver packaged applications to all types of desktops using Full Configuration. Benefits of delivering packaged applications to *single-session static* desktops include:

- Applications are available on the VDA at sign-in and not staged on demand through Workspace or StoreFront.
- Improved launch time when accessing the packaged applications.
- Facilitates maintenance of the packaged applications independently, separate from the VDA's base image.

To deliver packaged applications to desktops, add those applications to the delivery groups using these ways:

- Add applications during delivery group creation.
- Add applications to an existing delivery group using one of these entries: **Delivery Groups > Add Applications > Applications**, **Applications > Properties > Groups**, or **App Packages > Packages > Add Delivery Groups**.

For more information, see Create delivery groups, Manage delivery groups, and Add applications to delivery groups.

Full Configuration support for delivering packaged applications in FlexApp format. In **Full Configuration > App Packages**, you can now upload FlexApp packaged applications to Citrix Cloud, and deliver them to your users. For more information, see App packages.

OData pagination. Monitor enhances the limit of OData pagination. All OData v4 endpoints return a maximum of 1000 records per page with a link to the next 1000 records in the response. Because every page returns large data sets, you can get the same amount of total data with lesser OData queries. Thus this feature reduces time to get total data and thus improves the user experience. For more information, see Accessing Monitor Service data using the OData v4 endpoint in Citrix Cloud documentation.

Support for creating and managing Azure confidential VMs using Full Configuration. Azure confidential VMs provide a strong, hardware-enforced boundary to help meet your security needs. With the Full Configuration user interface, you can now create and manage confidential VMs on Azure. For more information, see Azure confidential VMs (Preview).

Support for displaying client IPs in configuration logs. In **Full Configuration > Logging > Events**, you can now view IP address details in logs, facilitating tracking of action origins. To show

© 1997–2026 Citrix Systems, Inc. All rights reserved.

the IP address column in the main view, click the **Columns to Display** icon in the top right of the logs, and then select **Client IP**. For more information, see View configuration log content.

Support for capturing additional properties using machine profile source in AWS. In AWS environments, with this enhancement, you can now create or update a machine profile-based catalog to include the following:

- Capture CPU options, tenancy type, and hibernation capability from the machine profile source while creating an MCS machine catalog.
- Change the tenancy type of the machine profile source while editing an MCS machine catalog. This functionality is applicable only to the new VMs added to the catalog.
- Change the hibernation capability of the machine profile source while editing an MCS machine catalog. This functionality is applicable only to the new VMs added to the catalog.

The machine profile source can be a VM or launch template version. This feature is applicable to both persistent and non-persistent catalogs.

For more information, see Create a machine profile-based machine catalog using PowerShell.

Repair the identity information of active computer accounts in AWS. In AWS environments, you can now reset the identity information of active computer accounts that have identity-related problems. You can choose to reset only the machine password and trust keys, or reset all configuration of the identity disk. This implementation is applicable to both persistent and non-persistent MCS machine catalogs. Currently, the feature is supported only for AWS, Azure and VMware virtualization environments. For more information, see Repair the identity information of active computer accounts.

Support for encrypting ID disk of an MCS machine catalog VMs in AWS. Previously, in AWS environments, MCS allowed the encryption of only the OS disk of the provisioned VMs. With this feature, you can now encrypt the ID disk in addition to the OS disk. This functionality allows you to use AWS KMS keys (Customer managed key and AWS managed key) to perform cryptographic operations on the disks attached to a VM.

For encryption of OS and ID disks, configure one of the following:

- Use a master image that is encrypted (for example, an AMI created from an instance or snapshot that contains a root volume encrypted with KMS key)
- Use a machine profile source (VM or launch template) that contains an encrypted root volume.

For more information, see Encrypt OS and ID disks.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure security groups per network interface in AWS. When editing a host connection for AWS environments, you can now configure the maximum number of security groups allowed per elastic network interface (ENI) using a PowerShell command. Therefore, if you increase your security groups per network interface quota, you can configure the same value for the hosting connection. For information on configuration, see Configure security groups per network interface.

Cost optimization . The **Cost Optimization** page provides a visual representation of infrastructure savings accrued over a selected period and forecasts expected savings for the remaining days. By analyzing machine usage and sessions, this page helps you to identify achieved savings and opportunities for cost reduction. This page offers:

- Insight into the optimization of infrastructure costs
- The amount saved
- Information on a range of scenarios that might result in exceeding projected costs
- Potential opportunities for identification and strategic planning to realize infrastructure cost savings

The **Cost Optimization page** includes **Estimated savings** and **Autoscale savings report**.

The **Estimated savings** helps to evaluate the efficient utilization of infrastructure resources. The cost savings are displayed in either US dollars or as a percentage of the cost incurred. You can view the results for the last 3, 6, and 12 months. The **Estimated savings** graph displays the following:

- Estimated savings - Displays the amount of savings achieved in infrastructure for the selected duration
- Power managed machines - Displays the total number of power-managed machines.
- Projected savings - Displays how much infrastructure savings can be done for the remaining duration

The **Autoscale savings report** displays information about the delivery group for which the Autoscale is configured and enabled. This report is applicable only for power-managed machines. For more information, see the Cost Optimization page.

Inspect machines with recent power actions. You can now inspect machines with the status of the success and failed power actions. This feature helps you to analyze the following:

- Power on failure which causes user issues
- Power off failure which increases cost

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Data is available only for the power-managed machine. Data is not available for the power actions taken before the feature was supported.

You can view the power action status of the machines using the following ways:

- From **Filters** -> **Machines** tab. In this case, by default the **Power Action Time** and the **Power Action Result** columns are visible. You can also select the columns that you want to visible.
- From **Cost Optimization** tab. In this case, the default filter is **Power Action Triggered By** is set to *Autoscale* and the **Power Action Result** is set to *Failed*.

With this feature, you can view the details of the power action controls. For example, you can view who triggered the action, which action changed the power state, the reason for failure, and the time when the action is completed. You can also export these details.

For more information, see Inspect machines with recent power actions.

April 2024

New and enhanced features

Support for newer version of Microsoft Teams. Citrix Monitor now supports Microsoft Teams version 2.1 or earlier.

Change disk encryption in Azure. With this feature, you can now change the disk encryption in Azure virtualization environments. You can do the following:

- Create an MCS machine catalog with a disk encryption set (DES) that is different from the master image DES.
- Change the disk encryption type from one DES key to another DES key of an existing MCS machine catalog and existing VMs.
- Update an MCS machine catalog and VM that was not previously CMEK enabled to have customer-managed encryption key (CMEK) encryption (DES), disk encryption at host, or double encryption.
- Update an existing MCS machine catalog and VM to be non-encrypted that was previously encrypted.
- Enable disk encryption with private endpoint (an MCS machine catalog that used a host connection enabled with `ProxyHypervisorTrafficThroughConnector`).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Change disk encryption.

Support for modifying the page file settings. With this feature, you can modify the page file settings of the newly added VMs to an existing catalog without updating the master image. Currently, this feature is applicable to only Azure environments.

To modify the page file settings, you need VDA version 2311 or later. You can modify the page file settings using the PowerShell commands. For more information on modifying the page file settings, see Modify page file settings.

Check for multiple NICs in VMware. In VMware environments, we have introduced various pre-flight checks when the hosting unit and machine profile template have multiple networks, and the `-NetworkMapping` parameter is used in the `New-ProvScheme` and `Set-ProvScheme` commands. For more information on the pre-flight checklist for multiple NICs, see Check for multiple NICs.

Support for creating Windows 11 VMs in GCP. You can now create Windows 11 VMs in GCP. If you install Windows 11 on the master image, then you must enable vTPM during the master image creation process. Also, you must enable vTPM on the machine profile source (VM or instance template).

This feature is applicable to:

- Persistent and Non-persistent MCS machine catalogs.
- Only sole-tenant node group.

For information on creating Windows 11 VMs on the sole-tenant node, see Create Windows 11 VMs on the sole-tenant node.

Virtual channel allow list support for environment variables. You can now use system environment variables in the trusted processes' path. For more information, see Using system environment variables.

Deprecated features in Full Configuration. The following features and settings have been deprecated in Full Configuration:

- Azure environments:

  Provisioning VMs using a master image from a different region has been deprecated. We recommend using Azure Compute Gallery to replicate the master image to the region where the VMs will be created.

- AWS environments:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The option **Apply machine template properties to virtual machines**, on the **Machine Catalog Setup > Machine Template** page, has been deprecated. We recommend using machine profiles to specify machine properties for VMs instead.

- All hypervisor and cloud service environments:

  Configuring the write-back cache with only a disk cache and no memory cache has been deprecated. We recommend setting the memory cache size to a value greater than zero.

Enhanced service disruption experience in Full Configuration. To enhance your experience during service disruptions, we've improved the notification content on the Full Configuration page. With this enhancement, you can now gain a clearer understanding of service disruptions, such as the causes, steps to enable service, and estimated enablement times. This enhancement covers the following service disruptions:

- Service enablement requests for first-time use
- Service pauses caused by prolonged inactivity
- Service outages caused by DaaS unavailability

Data caching for the Hosting node. We've introduced data caching for the Citrix DaaS **Hosting** node. This enhancement significantly reduces the page load times when you navigate to the Hosting node, improving the overall user experience.

Support for HDX Plus for Windows 365 Cloud PCs and Azure Virtual Desktops. Monitor now supports HDX Plus for Windows 365 Cloud PCs and Azure Virtual Desktops (AVD). For more information, see Troubleshoot Machines.

VDA environments with proxies for internet and URL filtering (Preview). You can now use the VDA Upgrade Service to update VDAs when you have proxies for internet connectivity and web filtering. The proxy configured in policy takes precedence over the proxy configured in registry. For more information, see Install VDAs. Also, refer to the list of urls that need to be white listed in the proxy.

Cloud Build Service Account Change. GCP is introducing changes to Cloud Build Services's default behavior and use of service accounts in new projects created after April 29, 2024. For more information, see Cloud Build Service Account Change. However, your existing Google projects and Citrix catalogs are not affected by this change. For more information, see:

- Configure and update service accounts
- Required GCP permissions

© 1997–2026 Citrix Systems, Inc. All rights reserved.

March 2024

New and enhanced features

Dynamic Session Recording. You can now record the current active session using the Session Recording controls from the **User Details** screen without the need to re-establish the session. This feature enables quicker and effective troubleshooting of session experience-related issues faced by users. This is useful to debug issues that are difficult to reproduce.

For more information about Dynamic Session Recording, see the Session Recording service article.

Enrollment tool to register VDAs using WebSockets to machine catalogs. You can now use this enrollment tool to securely register your non-domain joined VDAs to machine catalogs. This feature provides the benefits of using only the TLS port 443 for communication from VDA to the Delivery Controller and removing port 80 traffic. For more information, see Enroll machines to catalogs using the WebSocket VDA enrollment tool.

Full Configuration: Support for updating more Azure VM settings using machine profiles. With Full Configuration, you can now update a wider range of settings for MCS-provisioned Azure VMs through machine profiles, which include:

- Machine size
- License type
- Availability Zone
- Dedicated Host Group ID

After you update the machine profile, Full Configuration compares the current settings with the new ones. If differences exist, you'll be prompted to confirm which to apply. This design ensures transparent and efficient VM setting updates.

Full Configuration: Support for Changing write-back cache properties for MCS-provisioned Azure VMs. For Azure VMs provisioned using Machine Creation Services (MCS), you can now change their write-back cache (WBC) properties using Full Configuration, such as **Disk cache size**, **Memory cache size**, and **Enable storage cost saving**. In addition, when you select a new machine size or machine profile for those VMs, Full Configuration validates WBC settings to prevent conflicts, such as exceeding the memory limit of the new selection. If conflicts occur, you'll be prompted to re-configure WBC settings.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

February 2024

New and enhanced features

Suspend VMs from the Workspace interface. You can now suspend persistent VMs with active sessions from the Workspace user interface. This enhancement offers the following benefits:

- Resume the system from where you left off.
- Faster launch time compared to a stopped deallocated machine.
- Cost-effective and energy efficient.
- Efficient resource allocation using the Autoscale feature.

New Machine Creation Services (MCS) Storage Optimization (MCSIO) support: You now have the option for the Image Portability Service to add or remove MCSIO when you prepare an image for the MCS provisioning. For more information, see Automate VDA configuration.

Probes Overview enhancements: A summary of the Probe Metrics and the Probe Failure Stages in now available in the **Probe** > **Overview** page. The Probe Metrics shows the count of Scheduled, Failed, Skipped, and Successful runs. The graphical representation of the failure stages helps analyze the stages in which most failures have occurred. This information helps to quickly troubleshoot the probe results. For more information, see the Application and Desktop Probing article.

Image information on the Machine Catalogs page. You can now view the following image information through the **Template Properties** of the machine catalog:

- Operating system
- Machine identity service
- Machine Creation Service storage
- Filepath for `pagefile.sys` for Azure deployments

This enhancement provides better clarity on the image information and ensures that the administrators have all the information about the machine catalog in one place.

Full Configuration support for VDA enrollment token management. Token-based VDA enrollment reduces the load on Cloud Connectors and decreases potential failure points, ideal for the use cases where you prepare the machines using non-Citrix Provisioning technology. With Full Configuration, you can now generate and manage enrollment tokens for non-Citrix-provisioned

© 1997–2026 Citrix Systems, Inc. All rights reserved.

VDAs, streamlining enrollment token-based deployments. For more information, see Generate and manage enrollment tokens.

PowerShell logging. In Full Configuration, you can now view the PowerShell commands corresponding to your daily UI actions. This feature helps you gain insights into the underlying PowerShell commands for learning purposes. To view the PowerShell logs, go to **Logging > PowerShell**. For more information, see Configuration logging.

Enable Local Host Cache (LHC) for single-session pooled VDAs using Full Configuration. By default, single-session pooled VDAs provisioned using MCS or Citrix Provisioning are unavailable when in LHC mode. With Full Configuration, you can now override this default behavior on a per delivery group basis, making those VDAs available for new connections during LHC. For more information, see Create delivery groups and Manage delivery groups.

Citrix Hypervisor™ rebranded to XenServer in Full Configuration. In line with our rebranding strategy, we've updated all instances of Citrix Hypervisor within Full Configuration to XenServer.

End-to-end Network Hop view. End-to-end network hop view is the next step towards enhancing troubleshooting workflows in Citrix Monitor. The **User Details** > **Session Performance** > **Session Topology** section provides a visual representation of the end-to-end network hop view for connected HDX sessions. The in-session path helps understand the components involved in the session path with their metadata, the link between the components, and the applications published on the VDA. The Session Topology helps the data flows and to identify the specific hop that might be bringing in performance issues.

In addition, ICA Latency and ICA RTT measurements are displayed for the session when it is in a connected state. For more information, see End-to-end Network Hop view.

Use Disk Encryption Set ID (DES ID) of the master image to encrypt all the disks of catalog VMs. In Azure environments, previously, the Disk Encryption Set ID (DES ID) of an MCS machine catalog was derived from a machine profile or custom properties. With this feature, a machine catalog can also derive the DES ID from the master image to encrypt all the disks of the VMS in a catalog.

Update MCS tags to detect orphaned resources after migration. When you migrate from on-premises configuration to a cloud site, or from your cloud configuration to another cloud site, the orphaned resources aren't detected correctly because of the old site id tag. With this feature, using a PowerShell command, you can update the MCS site id tags of a persistent catalog, after migration so that orphaned resources can be detected correctly. Currently, this feature is applicable

© 1997–2026 Citrix Systems, Inc. All rights reserved.

to Azure. For more information, see Update MCS tags to detect orphaned resources after migration.

Validate configuration before creating an MCS machine catalog. With this feature, you can now validate configuration settings before creating an MCS machine catalog using the parameter `-validate` in `New-ProvScheme` command. After you run this PowerShell command with the parameter, you get an appropriate error message if there's an incorrect parameter used or a parameter has conflict with another parameter. You can then use the error message to resolve the issue and successfully create an MCS machine catalog using PowerShell.

Currently, this feature is applicable to Azure, GCP, and VMware virtualization environments. For more information, see Validate configuration before creating an MCS machine catalog.

Support for copying tags from a machine profile source to a VM in AWS. With this feature, in AWS virtualization environments, you can copy tags on NICs, and disks (Identity disk, write back cache disk, and OS disk) that are specified in the machine profile to newly created VMs in an MCS machine catalog. You can specify these tags in any of the machine profile sources (AWS EC2 instance or AWS launch template version). This feature is applicable to persistent and non-persistent machine catalogs and VMs. For more information, see Copy tags on VMs.

SCVMM support for machine profile. With this feature, you can now use a machine profile to create and update an MCS machine catalog in System Center Virtual Machine Manager (SCVMM) environments. You can also enable nested virtualization and vTPM. For more information, see Create a catalog with a machine profile.

Azure support for using spot VMs with MCS. Azure Spot VMs allow you to take advantage of Azure's unused computing capacity at a significant cost savings. However, due to its eviction policy, Azure Spot VMs are good for only some non-critical applications and desktops.

With this feature, you can create an MCS machine catalog of Azure Spot VMs using a machine profile (VM or template spec). You can update an existing catalog to have Azure Spot VMs as the newly created VMs or switch to have standard Azure VMs. You can also update existing VMs to be Azure Spot VMs. For more information, see Create a catalog using Azure Spot VMs.

Support for capturing diagnostic settings from a machine profile. In Azure environments, MCS now supports capturing of diagnostic settings on VMs and NICs from a machine profile while creating or updating an MCS machine catalog, or updating existing VMs. Therefore, with this implementation, the diagnostic data can be seamlessly transmitted to designated Azure destination endpoints, such as Log Analytics workspaces or Event Hubs, for in-depth analysis and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

visualization. For more information, see Capture diagnostic settings on VMs and NICs from a machine profile.

MCS support for managing different versions of a machine catalog. With this feature, you can manage the configuration versions of a machine catalog using PowerShell commands. Each configuration change using the `Set-ProvScheme` results in a new configuration version. You can:

- See the list of versions.
- Use any previous version to update a machine catalog.
- Manually delete a version if it isn't used by a VM.
- Change the number of maximum versions to be retained by a machine catalog.

For more information, see Manage versions of a machine catalog.

Publish App-V, MSIX and MSIX app attach packaged applications on single-session and shared desktop VDAs. You can now access packaged applications, for example, App-V, MSIX, and MSIX app attach on the single-session and shared desktop VDAs. This enhancement ensures that the packaged applications are readily available to use when you sign in. This feature facilitates faster launch of packaged applications and improves your experience significantly by bringing it closer to accessing a locally installed application. For more information, see Publish packaged applications on single-session or shared desktop VDAs.

Play back live and recorded sessions: Citrix Monitor now supports playing back recorded and live user sessions that are recorded using the Session Recording service. You can quickly understand the session-related issues encountered by the user from the replay. With this feature, you get ready access to recordings along with session-related metrics within the Monitor console. It helps corelate the issues discovered in the recordings with the performance metrics. It eliminates the requirement of searching for recordings across multiple session recording servers or looking for third-party apps to view the recordings.

This feature requires VDA and the Session Recording server version 2308 or later.

Monitor stores the recordings in a centralized repository and displays them on the **Session Selector** modal. The **Sessions with recordings** link displays the recordings of sessions that were active during the last 24 hours or the last 2 days. The recording is played back on a new tab using the Citrix Session Recording playback server.

For more information, see Record sessions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Microsoft Teams Optimization: Monitor displays the status of HDX optimization available for Microsoft Teams. The new **Microsoft Teams Optimization** can be viewed in the **User Details** page > **Session Details** panel. Monitor displays the status of the Microsoft Teams optimization only if Microsoft Teams is run as a published app or inside a published desktop. This enhancement provides administrators with visibility to enable troubleshooting of session performance issues on Microsoft Teams reported by users. For more information, see Troubleshoot user issues.

User interface improvements: The Citrix Monitor user interface is now refreshed with a modern look and feel. The new and improved user interface provides easier navigation and better data representation. The improved experience is intuitive and designed to easily comprehend the data required to monitor and troubleshoot a Citrix session.

Optimal screen resolution: The recommended optimal screen resolution for viewing the Citrix Monitor is updated to 1440 x 1024.

January 2024

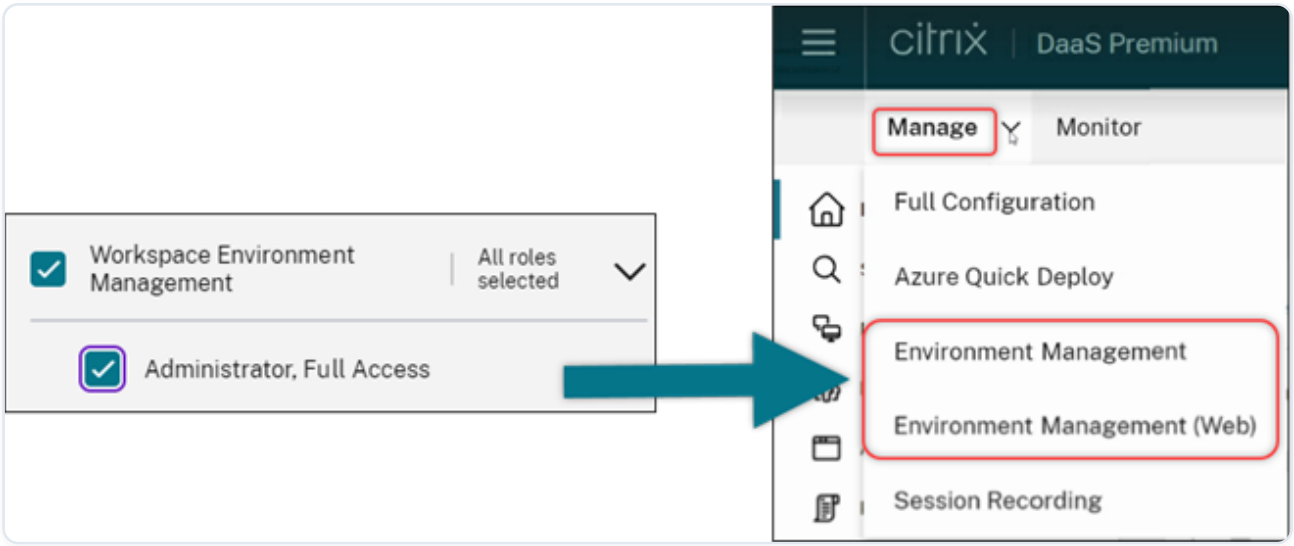
New and enhanced features

Enhanced bidirectional content redirection configuration Previously, configuring bidirectional content redirection involved managing three distinct policies: Allow bidirectional content redirection, Allow redirection of URLs to VDA, and Allow redirection of URLs to the Client. These policies require configurations on both the server side (configured in **DaaS > Full Configuration**) and the client side (configured through Group Policies). Starting with this release, we have consolidated all three policies into a single, unified policy. It not only simplifies and enhances the configuration process but also eliminates the requirement for client-side configurations. For more information, see Bidirectional content redirection configuration.

Support for restarting and shutting down single-session machines from the Search node's Sessions tab. On the **Sessions** tab of the **Search** node, you can now search for user sessions in an unhealthy state and seamlessly restart or shut down the associated single-session machines within the same tab. This feature enhances efficiency, enabling prompt action on identified session issues within a single interface.

Support for accessing Global App Configuration Service from Full Configuration. We've provided action items in the Full Configuration interface to link you to the Global App Configuration Service. With this integration, you can easily access Global App Configuration for managing end-user settings through Full Configuration.

To access this service from Full Configuration, you have two options:



© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Select the **StoreFront** node, click a server record, and then select **Configure Client Settings** in the action bar.
- Select the **Policies** node and then select **Configure Client Settings** in the action bar.

Support for managing user assignments for Citrix Cloud-managed delivery groups using Full Configuration. As part of our plan to migrate user assignment management from Cloud Library to Full Configuration, you can now manage user assignments for Citrix Cloud-managed delivery groups through Full Configuration. To accomplish this task, edit a target delivery group in **Full Configuration > Delivery Groups** and designate users permitted to use desktops or applications through one of these menus: **Desktops** (or **Desktop Assignment Rules**) or **Application Assignment Rule**. For more information, see Manage delivery groups.

Updates made in one portal seamlessly synchronize with the other, ensuring consistent updates across both portals.

Limit WEM console access to the WEM Full Access Administrator role. We've enabled access control for the Workspace Environment Management™ (WEM) consoles to prevent unauthorized entry. Only users with the **Workspace Environment Management Full Access Administrator** role can now use **DaaS > Manage** to access the WEM consoles.

Full Configuration: Azure catalogs support for inheriting DES settings from master images. Previously, Full Configuration set the Azure catalogs' default DES settings only based on machine profiles. We've now expanded this capability. With this enhancement, in the following cases, Full Configuration sets an Azure catalog's default DES settings directly based on the master image:

- If a machine profile isn't selected
- If the profile specifies a Platform Managed Key (PMK)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Create a machine catalog using an Azure Resource Manager image in the Full Configuration interface.

Enhanced search: More filters for enhanced precision. We've enhanced the search on the Search node to include two new filters, Zone and Provisioning Type, for enhanced precision and improved usability.

Full Configuration: Support for selecting Google Cloud machine type for GCP machine catalogs. With this feature, administrators have the flexibility to select the required memory and processor configurations for provisioned GCP VMs, tailoring them to meet specific operational requirements. For more information, see Create a machine catalog using the Full Configuration interface.

Support for global and regional customer-managed encryption keys (CMEK) for provisioning GCP VMs. You can now use global and regional CMEK keys for provisioning VMs from any provisioning project. This enhancement provides greater flexibility in key selection for provisioning VMs and improving VM security.

December 2023

New and enhanced features

Send Message progress. You can now view the progress of the **Send Message** operation available in **Monitor** > **Filters**. This operation helps send bulk messages to all connected sessions on your Site. The progress of the operation is displayed in percentage. Once the operation is completed, the system displays the number of messages that were sent and the number that have failed. Send message status is helpful when you are administering large sites. It helps understand if the message needs to be resent to certain users. Sending messages can fail if the machines are unregistered or if the sessions are faulty. For more information about Send Message, see Send messages to users.

Citrix Probe Agent authentication support via Citrix Gateway with domain credentials and Multi-factor authentication.

Citrix Probe Agent for application and desktop probing now supports authentication via Citrix Gateway with domain credentials and Multi-factor authentication. This feature helps to run the Probe Agent on machines that are connected to StoreFront via Citrix Gateway. The comprehensive probe results available on Monitor help troubleshoot issues related to the applications, hosting machine, or connection before the users experience them. Support for Citrix Gateway with Multi-

© 1997–2026 Citrix Systems, Inc. All rights reserved.

factor authentication is available only for Citrix Gateway that is configured with LDAP and Native OTP using Single Login Schema. For more information, see Application and Desktop Probing

Redesigned Access Policy UI for more flexible resource access control. We've redesigned the **Edit Delivery group > Access Policy** UI to give you more flexibility in managing resource access for delivery groups. The following are the key features available with the new design:

- **Support for adding policies.** You can now add access policies to restrict resource access based on attributes of user connections. A policy can consist of two types of criteria:
  - **Inclusion criteria.** Let you specify user connections that are allowed to access the delivery group.
  - **Exclusion criteria.** Let you specify user connections that are prohibited from accessing the delivery group.
- **Expanded filter support.** You can now define inclusion and exclusion criteria using a range of SmartAccess filters. Those filters include Workspace filters such as `Citrix.Workspace.UsingDomain` and `Citrix-Via-Workspace`, as well as filters for network location-based adaptive access.
- **Match All logic support for included criteria.** The new logic enables you to achieve a high level of precision and control when specifying allowed user connections for delivery groups.

For more information, see Restrict access to resources in a delivery group.

November 2023

New and enhanced features

Support for creating Citrix Provisioning catalogs using Full Configuration interface. To create a Citrix Provisioning catalog, you had to use the Citrix Virtual Apps and Desktops Setup Wizard. With this feature, you can now create a Citrix Provisioning catalog using the Full Configuration interface and PowerShell.

This implementation provides you the following advantages:

- A single unified console to manage both MCS and Citrix Provisioning catalogs.
- Have new features for Citrix Provisioning catalogs, such as, identity management solution, on-demand provisioning and so on.

Currently, this feature is available only for Azure workloads. For more information, see Create Citrix Provisioning catalogs in Citrix Studio.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Introducing search for Application Groups. We have introduced the search functionality for application groups in the **Applications** node. With this enhancement, you can now directly search for an application group inside any application folder. For more information, see Search for Application Groups.

Modified configuration limits. The following table describes the modifications made to the DaaS configuration limits to improve the performance and provide cost-effectiveness.

RESOURCE	OLD LIMIT	NEW LIMIT
Active Directory domains	85	100
Catalogs	1000	2000
Delivery Groups	1000	2000
Resource location	85	100
Resource location -> Total sessions	20,000	25,000

For more information, see Limits.

A single option to retain VM and system disk during power cycles. Starting an existing VM on Azure is now faster than launching a new one, making it a more efficient choice to retain VMs across power cycles. In response to this change, we've combined the options **Retain VMs across power cycles** and **Retain system disk during power cycles** into a single option **Retain VM and system disk during power cycles**. This means that when you select this option to reduce VM restart times by retaining system disks, your VMs are retained as well.

New capability in Full Configuration to filter machine sizes based on *Encryption at Host property* in machine profiles (Azure VMs specific). Once you choose a machine profile with *Encryption at Host* enabled during Azure machine catalog creation or management, only machine sizes that support this feature are displayed.

Restrict backup and restore actions to Full Administrator role. We've enhanced access control for the backup and restore actions. Only users with the Full Administrator role can now access the **Backup + Restore** node, preventing unauthorized actions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Data caching for the Search node. We have introduced data caching for the Citrix DaaS **Search** node. This enhancement improves the performance of the search and the following lists the use cases that ease your regular tasks:

- Quick display of search results after they are retrieved for the first time.
- Retains pagination results after navigating out and back to the **Search** node.

Image information on the Machine Catalogs page. You can now view the following image information through the **Template Properties** of the machine catalog:

- Operating system
- Machine identity service
- Machine Creation Service storage
- Filepath for `pagefile.sys` for Azure deployments.

This enhancement provides better clarity on the image information and ensures that the administrators have all the information about the machine catalog in one place.

Support for pinning search filters. To provide a quick search experience, Full Configuration enables a facility to pin your search filters. Filter pins allow you to keep the frequently used search filters accessible on the page. This enhancement is available in the search panels of the following nodes:

- **Search**
- **Machine Catalogs**
- **Delivery Groups**
- **Applications**

For more information, Use Search in the Full Configuration management interface.

Support for associating metadata with configuration logs. Using this enhancement, you can now attach metadata with the configuration logs by associating a `name-value` pair on the high-level operations. For more information, see Associate metadata with configuration logs.

Ignore orphaned resources with specific tag. In Azure environments, a customer-managed resource tagged with all Citrix tags is detected as an orphaned resource. With this feature, if you add another tag `CitrixDetectIgnore` with value as true to that resource, then the resource is ignored while detecting orphaned resources.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Solution for SCCM duplicated GUID issue. After creating multiple VMs using MCS, the System Center Configuration Manager (SCCM) displayed only one VM on its console because of duplicated GUIDs. This issue is now resolved by adding a step in the image preparation. This step deletes the existing certificates and GUID information within the master image. The step is enabled by default.

Repair the identity information of active computer accounts. With this feature, you can reset the identity information of active computer accounts that have identity-related problems. You can choose to reset only the machine password and trust keys, or reset all configuration of the identity disk. This implementation is applicable to both persistent and non-persistent machine catalogs. Currently, the feature is supported only for Azure and VMware virtualization environments. For more information, see Repair the identity information of active computer accounts.

Get encryption at host information associated with a machine profile. In Azure environments, with this feature, you can now know whether encryption at host is enabled for a machine profile input (VM or template spec) using PowerShell commands. For more information, see Retrieve encryption at host information from a machine profile.

Repair the user certificates of hybrid Azure AD joined machine identities. With this feature, you can use Powershell command to repair the user certificates of hybrid Azure AD joined machine identities if they corrupt or expire. For more information, see Identity pool of Hybrid Azure Active Directory joined machine identity.

Certificate expiry warning support for Hybrid Azure AD joined machine catalogs. Full Configuration now provides one-month advance warnings for user certificate expiration on Hybrid Azure AD joined machine catalogs. This enhancement aims to reduce the risk of service interruptions resulting from certificate expiration. To view the details and recommended actions, go to the **Machine Catalogs** node, select the machine catalog, and then click the **Troubleshoot** tab.

You can run the `Get-ProvScheme` command to get information about the user certificate expiration date of a hybrid Azure AD joined machine catalog.

Support for Azure confidential VMs (Preview). Azure confidential computing VMs ensure that your virtual desktop is encrypted in memory and protected in use. With this feature, you can now use MCS to create a catalog with Azure confidential VMs. You must use the machine profile workflow to create such a catalog. You can use both VM and ARM template spec as a machine profile input. For more information, see Azure confidential VMs (Preview).

Support for converting a non-machine profile-based machine catalog to machine profile-based machine catalog in AWS environment. In an AWS environment, you can now use a VM or

© 1997–2026 Citrix Systems, Inc. All rights reserved.

launch template as a machine profile input to convert a non-machine profile-based machine catalog to machine profile-based machine catalog. New VMs added to the catalog take property values from the machine profile. For more information, see Convert a non-machine profile-based machine catalog to machine profile-based machine catalog.

Support for Citrix-managed HPE Moonshot plug-in (Preview). Previously, you used HPE-managed Moonshot plug-in (HPE Moonshot Machine Manager) maintained by Hewlett Packard Enterprise (HPE) to perform the power management actions on HPE Moonshot chassis. The plug-in was based on legacy APIs that made MCS infrastructure projects difficult. With this feature, a Citrix-managed HPE Moonshot plug-in (HPE Moonshot) is introduced. With this plug-in, you can create connections to your HPE Moonshot chassis, create catalogs, and power manage machines in the catalog using Full Configuration interface and PowerShell commands. For more information, see:

- HPE Moonshot virtualization environments (Preview)
- Connection to HPE Moonshot (Preview)
- Create an HPE Moonshot machine catalog (Preview)
- Manage an HPE Moonshot catalog (Preview)

Ability to change memory and disk cache size. With this feature, you can now change the memory and disk cache size of the Write-back cache (when MCSIO is enabled) using a PowerShell command without creating a new machine catalog. This implementation helps you to have the optimized cache configuration that is suitable for your business needs. This feature is applicable to:

- GCP and Microsoft Azure environments, and
- a non-persistent catalog with MCSIO enabled

For more information, see Change cache configuration on an existing machine catalog.

Support for creating a customer-managed encryption key enabled catalog. In Azure environments, you can now create a Citrix Provisioning catalog enabled with customer-managed encryption key (CMEK) using the Full Configuration interface and PowerShell commands. For more information, see Create a customer-managed encryption key enabled catalog.

Ability to copy tags on all resources in Azure. With this feature, in Azure environment, you can now copy tags specified in a machine profile to all the resources such as, multiple NICs and disks (OS disk, Identity disk, and write-back cache disk) of a new VM or an existing VM in a machine catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The machine profile source can be a VM or an ARM template spec. For more information, see Copy tags on all resources.

Session state updated to disconnected after the machine is suspended. Previously, after you suspended a VM, the session was still shown as **Active**. With this enhancement, after you suspend a VM, the associated session's state is now shown as **Disconnected**.

Support for creating AWS VMs that support hibernation. You can now create machine catalogs that support VM hibernation in your AWS environments, enhancing the overall cost-effectiveness of your deployment. You can also edit a catalog to include hibernation-capable VMs if the associated machine profile supports this capability. For more information, see Power Manage AWS VMs.

Support for configuring load-balancing methods at the delivery group level (Preview). This feature allows you to choose the **Vertical Load Balancing** method at a delivery group level. With this feature, each machine is aligned to the maximum load index before the next machine is powered on. Autoscale and Vertical Load Balancing determine when the next machine is powered on. This feature achieves maximum utilization for each machine and cost savings in public clouds. This feature offers more flexibility in managing the load balancing strategies for machines.

You can configure a delivery group to either inherit the load balancing method from the site-level settings or override the site-level load balancing method and instead choose one of the vertical or horizontal load balancing methods. For more information, see Step 2. Load balancing.

Support for hibernation-capable VMs in Azure (Preview). In Azure environments, you can create an MCS machine catalog that supports hibernation. Using this feature, you can suspend a VM, and then reconnect to the previous state of the VM when a user signs in again. For more information, see Create hibernation-capable VMs (Preview).

DaaS get-started guide. We've launched a new guide to streamline and simplify DaaS deployment and configuration for both new and experienced administrators. It offers these key benefits:

- **Easy to get started.** Using a step-by-step questionnaire-based approach, this guide helps new administrators set up their deployments quickly. Contextual help info throughout the guide aids in understanding essential concepts and terminology.
- **Simplify complex configurations.** This guide includes pre-configured settings where applicable and provides access to the Full Configuration UI for advanced setup. Experienced admins can use it as a foundation for more complex configurations.

For more information, see Use DaaS get-started guide.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Assign drive letters to write-back cache disks using Full Configuration. Previously, you could assign a specific drive letter to the write-back cache disk only by using a PowerShell cmdlet. You can now accomplish the same task using Full Configuration. For more information, see Create machine catalogs.

Support for changing various Azure machine properties using Full Configuration. For Machine Creation Services-provisioned Azure machines, you can now change the following property settings using Full Configuration:

- Storage type
- Dedicated host group
- Azure Compute Gallery settings

When you change any of these settings, Full Configuration automatically identifies related settings and provides automatic synchronization or prompt messages requesting you to reselect related settings. This capability ensures consistent changes across associated settings, preventing potential configuration errors. For more information, see Edit a catalog.

Use existing identity pools to create identities for MCS-provisioned machines. When creating AD-joined catalogs or adding machines to them using Full Configuration, you can now use an existing identity pool to allocate machine identities. This feature allows you to apply a consistent machine account naming scheme across multiple catalogs. For more information, see Machine identities.

Session Topology. The Session Topology view is the next step towards enhancing troubleshooting workflows in Monitor. The Session Topology view provides a visual representation of the in-session path for connected HDX sessions. You can access the topology view from the **User Details > Session Performance**.

The Session Topology view for an HDX connected session shows the components involved in the session path with their metadata, the link between the components, and the applications published on the VDA. In addition, ICA Latency and ICA RTT measurements are displayed for the session when it is in a connected state.

Use the Session Topology view to understand the components through which the session data flows and to identify the specific hop that might be bringing in performance issues. For more information see Session Topology.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

October 2023

New and enhanced features

Refine your Autoscale settings using historical usage. A new Autoscale settings tab called **Autoscale Insights**, offers a comprehensive graph that visually compares your Autoscale settings and machine usage data from the previous week. With this graph, you can gain insights into the effectiveness of Autoscale settings:

- **Not cost-effective**. Financial waste exists due to the over-provisioning of capacity.
- **Poor user experience**. User experience is negatively impacted due to the under-provisioning of capacity.
- **Good balance between user experience and cost**. The capacity provisioned is aligned with the historical usage.

For more information, see Analyze the effectiveness of Autoscale settings.

Multiple NICs support for Azure VMs. With Full Configuration, you can now create Azure VMs with multiple NICs. A VM's maximum NIC count is determined by the machine size setting while its actual NIC count allowed is defined by the machine profile setting. For more information, see Create machine catalogs.

For creating or updating a catalog with multiple NICs per VM using PowerShell commands, see Create or update a catalog with multiple NICs per VM.

Trends for Session Performance metrics. Monitor is introducing a new **User Details > Session Performance** tab with enhanced troubleshooting workflows starting with the ability to correlate real-time metrics in identifying issues within user sessions. Session Experience now contains trends of session metrics like ICARTT, ICA Latency, Frames Per Second, Output Bandwidth Available, and Output Bandwidth Consumed. This feature helps reduce the mean time for resolution by enabling you to correlate multiple performance metrics in a single view. For more information see the User Issues article.

Support VDA version on settings page of create/edit policy. As part of creating a policy, when configuring the settings, the system provides an option to view the settings type. You can view the following settings type:

- All settings - View all settings for all VDA versions
- Current settings only - View settings for only the current VDA versions
- Legacy settings only - View settings for only the deprecated VDA versions

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Create policies

Limit application visibility only supported for Active Directory accounts. The capability to limit the application visibility is available only for the Active Directory user accounts, and not for Azure Active Directory and Okta accounts. Note that to aid this feature, on the application setting workflow, on the Select Users or Groups page, **Azure Active Directory**, and **Okta** options in the **Select Identity type** field are disabled.

New UI option to delete VM records only from the Citrix site database. When catalog and VM deletion fails due to an unreachable hypervisor, you can now opt to only delete VM records from the Citrix site database, leaving the VMs intact on the host. For more information, see Delete a catalog.

Support for creating empty machine catalogs for non-MCS-provisioned machines. Creating empty machine catalogs now extends to non-MCS-provisioned machines, including:

- Virtual or blade machines provisioned using technologies other than Machine Creation Services.
- Physical machines not power managed by Citrix DaaS
- Remote PC Access machines

With this feature, you can now create machine catalogs without the need to add machines to them during catalog creation.

Image Refresh enhancements. Previously, when refreshing images, all images in the image tree were updated, irrespective of whether a specific node in the tree was selected. With the latest enhancement, if you've selected a node, only images in this node are refreshed. This enhancement ensures a more targeted refresh process, significantly improving the image refresh speed. Additionally, you can now clear a selected node in the image tree by holding CTRL and clicking the node. For more information, see Master image.

Peak Autoscale Assigned PowerOn. When persistent desktops are powered on but remain unused or if no user logs on, the administrators can define the wait time to take actions like, no action, suspend, or shutdown.

For assigned machines, where it is powered on but a session has not been connected to it within the set time after the start of peak time, then you can add a policy to the delivery group level to turn off the machine.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For assigned machines, where it is in resumed state but a session has not been connected to it within the set time after the start of peak time, then you can add a policy to the delivery group level to suspend the machine.

This feature is helpful if there is an end user who is on PTO, or has not logged on, or if a company has a long weekend, then you can set the wait time and machine disconnection actions to take to help reduce the Azure consumption cost. For more information, see Single-session OS random delivery groups and Single-session OS static delivery groups.

Monitor multiple Citrix DaaS instances (Preview). You can now use Citrix Monitor to monitor and troubleshoot issues across multiple Citrix DaaS instances. Citrix DaaS allows customers to aggregate multiple service instances using a hub and spoke model. With this configuration, administrators can perform helpdesk search on all configured DaaS instances from a single Monitor console. For more information regarding the configuration required to aggregate the spoke service instances to a hub, see Aggregate multiple Citrix Virtual Apps and Desktops service instances. Monitor supports the aggregation of up to four DaaS tenants (spokes) under a single DaaS tenant (hub). To have unified monitoring across all DaaS tenants, use bi-directional enumeration of the hub and spoke instances. For more information, see Aggregated Search across multiple DaaS instances (Preview).

Support for vSAN 8.0. You can now use MCS to provision VMs in the vSAN 8.0 environment.

Preserve NIC settings on provisioned VMs. Previously, the NIC settings of the master image were not retained in the provisioned VMs. For example, if you configured the DNS settings on the master image, the provisioned VMs did not retain the configured DNS settings of the master image. With this feature, the provisioned VMs can now retain the NIC settings of the master image. The settings are retained even after a Windows update. The filter driver is automatically installed if you do a fresh installation of VDA version 2308 or later on a Hyper-V deployed machine through the MCS master image installations. However, currently, if you upgrade from an older version of VDA (version less than 2308) and want to install the filter driver, then you must select the checkbox **Citrix HyperV Filter Driver** on the **Additional Components** page while upgrading the VDA. For more information, see Install additional components.

This feature is applicable to:

- Hyper-V VMs (including Azure and SCVMM)
- Persistent and non-persistent MCS machine catalogs
- Non-persistent MCS machine catalogs with MCSIO
- Master image with multiple NICs

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Detect Orphaned Azure resources. With this feature, you can now detect the orphaned resources in your Azure deployment, enabling efficient resource management. After the orphaned resources are identified, you can take further action, bringing in more productivity and cost reduction. For more information, see Detect Orphaned Azure resources in your deployment.

New image update status. When monitoring image update statuses for catalogs in Full Configuration, you can now view a new status **Preparing image**, in addition to the existing ones **Fully updated**, **Partially updated**, and **Pending update**. For more information, see Change the master image.

PowerShell commands to create Auto-tags (Preview). With this feature you can now create tags automatically by using the PowerShell command. For more information, see Auto Tags.

Notification sign is shown to user or delivery group. While creating or modifying a policy and configuring the settings, if all delivery groups are disabled, the system displays a warning that - None of the elements in this filter is enabled. If at least one delivery group is enabled, the system does not display the warning sign. For more information, see Policy settings

September 2023

New and enhanced features

PowerShell commands to manage Local Host Cache (LHC). You can now use PowerShell commands to manage LHC on Citrix Cloud Connectors. For more information, see Local Host Cache PowerShell commands.

Support for creating empty machine catalogs. In Full Configuration, you can now create a machine catalog without immediate VM creation. With this feature, you can postpone VM creation until back-end hosts are fully prepared or VM provisioning is completed, gaining more flexibility in creating catalogs. Currently, this feature applies only to Machine Creation Services-provisioned catalogs. For more information, see Create machine catalogs.

Data caching for the Home node. We've introduced data caching for the Citrix DaaS **Home** node. This enhancement improves the user experience by reducing the page load times when you navigate to the **Home** node.

Search enhancements for applications. We've revamped the search functionality in the **Applications** node to align with the new design introduced in the **Search** node. This new feature improves your application search experience and maintains a consistent search experience across DaaS. The keyword **Application Name** in the filter expression is renamed to **Name**, while retaining

© 1997–2026 Citrix Systems, Inc. All rights reserved.

its original meaning. For more information, see Use Search in the Full Configuration management interface.

Enhanced scope management: showing objects in folder view. On the scope creation and management pages, machine catalogs, delivery groups, and application groups are now displayed in folder structures that align with their management in DaaS. This folder view simplifies the process of selecting objects for scope creation and management, making your choices more intuitive and straightforward. For more information, see Create and manage scopes.

Removed the Leave user management to Citrix Cloud option. When creating a delivery group in Manage > Full Configuration, on the Users page, the support for this option is removed. For delivery groups where user assignments were handled through Citrix Cloud, continue to manage user assignments within the Citrix Cloud library.

Removed the Azure Germany option. In line with the closure of Microsoft Cloud Deutschland on October 29, 2021, we've removed the **Azure Germany** option from the host connection creation page.

Proactive service alerts in Full Configuration. Alerts come at two levels — site-wide alerts shown in Home (flag icon) and zone-related alerts shown on the Troubleshoot tab of each zone. Currently, this feature gives you proactive warnings and alerts to make sure that your Local Host Cache and zones are configured correctly so that when an outage occurs, Local Host Cache works and your users are not impacted. For more information, see Service health alerts and Zones.

August 2023

New and enhanced features

Full Configuration: Support for provisioning AWS and GCP VMs using machine profiles. When provisioning AWS or GCP VMs using Machine Creation Services (MCS), you can now select an existing VM as the machine profile, letting VMs within the catalog inherit settings from the selected VM.

- For GCP VMs, the inherited settings include Disk Encryption Set ID, Machine size, Storage type, and Zone.
- For AWS VMs, the inherited settings vary based on the stage:
  - During catalog creation: Machine size, Tenancy type, Security group, and the number of NICs.
  - During catalog editing: Machine size and Security group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information, see Create a machine catalog.

Introducing search functionality in Machine Catalogs and Delivery Groups nodes. You can now directly search and locate machine catalogs and delivery groups within the **Machine Catalogs** and **Delivery Groups** nodes. The search functionality in these nodes provides the same interface as the **Search** node, providing seamless search experience across DaaS. For more information, see Use Search in the Full Configuration management interface.

View endpoint device status in Session Launch Diagnostics using Device Posture. The Session Launch Diagnostics feature in Monitor helps narrow down to the exact component and stage where a session failure occurred. This helps identify the exact reason for a session launch failure and take the recommended action.

As the next step in making this check comprehensive across all the components involved in the session launch sequence, you can now view the endpoint device scan results. Clicking **Endpoint Device** in the list of components shows the Device Posture scan status. Device Posture Service scans the endpoint device for compliance based on policies defined by the administrator.

Ensure that the Device Posture service is configured with DaaS as described in the Device Posture article. Errors logged by Device Posture are described in Device Posture Error Logs.

For more information, see Steps to diagnose session launch failure

New options in Full Configuration to route API requests to Azure and GCP through Citrix Cloud Connectors. Previously, API requests to Azure and GCP could be routed only through public endpoints. With a new option in **Full Configuration > Add Connection and Resources**, you can now opt for a more secure approach by routing them through Citrix Cloud Connectors. For more information, see Create a service principal and connection using Full Configuration.

Search and filter enhancements. We've made the following enhancements to improve your search experience:

- **Simplified search**: Performing a search without filters now removes search recommendations, providing a clean and straightforward search experience.
- **AND/OR operator update**: "Match all(AND operator)" and "Match any(OR operator)" options are now available in the filters panel, accessible with a single click the filters icon.
- **Streamlined filter configuration**: You can now specify and apply multiple filters seamlessly with the filters panel.
- **Cleaner interface**: The "filter pinning" ability has been removed, reducing UI clutter and making your search experience more intuitive.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Quick filter addition**: After applying filters, you can now use the plus sign to quickly add one more filter.
- **Delete saved filter sets**: You can now easily delete saved filter sets right within the search menu, without navigating to **Manage filter sets**.

For more information, see Use Search in the Full Configuration management interface.

VDA upgrade support for Azure Quick Deploy-created machine catalogs. With Full Configuration, you can now enable **VDA Upgrade** for machine catalogs created through Azure Quick Deploy and then perform **Upgrade VDA** on them for immediate or scheduled upgrades. For more information, see Upgrade VDAs using the Full Configuration interface.

Ability to reset the OS disk of a persistent VM in an MCS created machine catalog in SCVMM. You can now use the PowerShell command `Reset-ProvVMDisk` to reset the OS disk of a persistent VM in an MCS created machine catalog. The feature automates the process of resetting the OS disk. For example, it helps in resetting the VM to its initial status of a persistent development desktop catalog created using MCS. Currently, this feature is applicable to Azure, Citrix Hypervisor, SCVMM, and VMware virtualization environments. For more information on using the PowerShell command to reset the OS disk, see Reset OS disk.

Update properties of individual VMs. You can now update properties of individual VMs in a persistent MCS machine catalog using a PowerShell command. This implementation helps you to manage individual VMs efficiently without updating the entire machine catalog. Currently, this feature is applicable only to the Azure environment. For more information, see Update properties of individual VMs.

Restrict upload and download of managed disks. As per Azure policy, you cannot upload or download more than five disks or snapshots at the same time with the same disk access object. With this feature, the limit of five concurrent uploads or downloads is not enforced if you:

- Configure `ProxyHypervisorTrafficThroughConnector` in `CustomProperties`, and
- Do not configure Azure policy to create Disk Accesses automatically for each new disk to use private endpoints.

Support for assigning a specific drive letter to MCS I/O write-back cache disk. Previously, the Windows operating system automatically assigned a drive letter to MCS I/O write-back cache disk. With this feature, you can now assign a specific drive letter to an MCS I/O write-back cache disk. This implementation helps you to avoid conflicts between the drive letter of any applications that you use and the drive letter of MCS I/O write-back cache disk. This feature is applicable to only

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Windows operating system. For more information, see Assign a specific drive letter to MCS I/O write-back cache disk.

Support for machine profile in Citrix Hypervisor. In Citrix Hypervisor, you can now create an MCS machine catalog using a machine profile. The source of the machine profile input is a VM. The machine profile captures the hardware properties from a VM template and applies them to the newly provisioned VMs in the catalog. For more information, see Create a machine catalog using a machine profile.

Retry creating catalog after failure. When catalog creation fails, you can now retry creating the catalog. To ensure successful creation, check the troubleshooting information and resolve the issues. The information describes the issues found and provides recommendations for resolving them. Failed catalogs are marked with an error icon. To see the details, go to the **Troubleshoot** tab of each catalog. For more information, see Manage machine catalogs.

Permission for managing configuration sets. To enable more precise control over WEM configuration set management, we've introduced a new permission called **Manage configuration sets** to the **Machine catalogs** permission set. This permission grants exclusive access to users who can perform tasks such as binding or unbinding a configuration set and switching to a different configuration set for catalogs. For more information, see Manage configuration set for a catalog.

New option in Full Configuration to enable cleanup of stale Azure AD joined devices. We've introduced an option in Full Configuration to simplify the cleanup of stale Azure AD joined devices in Citrix DaaS. Previously, you had to run a custom PowerShell script to perform the task. Enabling this option grants host connections permission to automatically clean stale Azure AD joined devices. For more information, see Azure host connections.

Monitor image update status for catalogs using Full Configuration. You can now monitor image update statuses for non-persistent machine catalogs using a new column, **Image Update**. This column indicates whether images of a catalog are **Fully updated**, **Partially updated**, or **Pending update**.

To show the column in the **Machine Catalogs** table, follow these steps:

1. In the **Machine Catalogs** node, select the **Columns to Display** icon in the action bar.
2. Select **Machine Catalog > Image Status**.
3. Click **Save**.

Displaying the **Image update** column might degrade the console performance. We recommend displaying it only when necessary.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Secure environment for GCP-managed traffic. With this feature, you can now allow only private Google access to your Google Cloud projects. This implementation enhances security to handle sensitive data. To do this, add `ProxyHypervisorTrafficThroughConnector` in `CustomProperties` in case of Citrix Cloud deployment. If you are using a private worker pool, add `UsePrivateWorkerPool` in `CustomProperties`. For more information, see Create a secure environment for GCP managed traffic.

July 2023

New and enhanced features

Support for getting a list of orphaned resources on Azure. In Azure environments, you can now get a list of orphaned resources that are created by MCS but are no longer used by MCS. This feature helps to avoid extra costs. For more information, see Retrieve a list of orphaned resources.

Support for creating persistent multi-session machines using Full Configuration. When creating a catalog of multi-session machines, you can now specify whether to make them persistent. For persistent multi-session machines, keep in mind that changes users make to the desktops are saved and accessible to all authorized users. For more information, see Create machine catalogs.

New capability in Full Configuration to filter the AWS AMI inventory. When selecting machine templates during AWS catalog creation, you can now filter the AWS AMI inventory for a target template using these search criteria:

- Image name
- Image ID
- Image tags

The machine template list loads dynamically as you scroll down the list - 25 items are initially loaded and more loaded as you scroll.

Support for deleting Azure AD devices. With this feature, stale Azure AD devices can be consistently deleted by assigning the Cloud Device Administrator role to the service principal and modifying the custom property of the hosting connection. If you do not delete the Azure stale AD devices, then the corresponding non-persistent VM stays in the initializing state until you manually remove it from the Azure AD portal. For more information, see Identity pool of Azure Active Directory joined machine identity.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for machine profile in AWS environment. When you create a catalog to provision machines using Machine Creation Services (MCS) in AWS, you can now use a machine profile to capture the hardware properties from an EC2 instance (VM) or launch template version and apply them to the provisioned machines. Properties that are captured can include, for example, EBS volume properties, instance type, EBS optimization, and other supported AWS configurations. When editing the catalog, the machine profile of the provisioned machines can be changed by providing a different VM or launch template. For more information, see Create a catalog using a machine profile.

Export limit on search results extended to 30,000 from 10,000. We've extended the export limit on search results. Previously restricted to 10,000 items, you can now export up to 30,000 items to a CSV file. For more information, see Export search results to a CSV file.

Image refresh option. When selecting master images for machine catalogs, you can now quickly get the most up-to-date master image list using the **Refresh** option at the top right. Note that the **Refresh** option is not available for AWS catalogs. Additionally, a **Refresh** option is available for machine profiles and host groups in Azure catalogs.

June 2023

New and enhanced features

Support for getting custom properties from the machine profile input in GCP. Previously, in GCP environments, while creating an MCS machine catalog using a machine profile input, you had to explicitly specify the custom properties. The action forced an extra effort. With this feature, you can now derive the following custom properties without explicitly defining them:

- `ServiceOffering`
- `CryptoKeyId`
- `CatalogZones`
- `Storage`

When you run `New-ProvScheme` and `Set-ProvScheme` commands and do not explicitly specify the custom properties, then the values of the properties are derived from the machine profile input.

For example, `New-ProvScheme -MachineProfile` writes the machine profile's machine type to the provisioning scheme's `ServiceOffering` property unless you specify `ServiceOffering` in the `New-ProvScheme` command. If you run `Set-ProvVMScheme` twice, then the most recent command takes effect.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Remove tags in AWS environments. Previously, `Remove-ProvVM` and `Remove-ProvScheme` PowerShell commands with `ForgetVM` parameter removed the VMs and machine catalogs from the Citrix database. However, the commands didn't remove the tags. You had to individually manage the VMs and machine catalogs that weren't removed entirely from all the resources. With this feature, you can use:

- `Remove-ProvVM` with `ForgetVM` parameter to remove VMs and tags from a single VM or a list of VMs from a machine catalog.
- `Remove-ProvScheme` with `ForgetVM` parameter to remove a machine catalog from the Citrix database and resources from a machine catalog.

This implementation helps in:

- Identifying leaked resources
- Removing the additional cost of maintaining the resources that are not required

This feature is only applicable to persistent VMs. For more information, see Remove tags.

Ability to get historical errors and warnings associated with an MCS machine catalog. Previously, you only got the latest warnings and errors associated with a machine catalog. With this feature, you can now get a list of the historical warnings and errors of an MCS machine catalog. This list helps you to understand any issues with your MCS machine catalog and fix those issues.

For more information, see Retrieve warnings and errors associated with a catalog.

Increased capacity with improved performance for Citrix in Google Cloud. Citrix can now support catalogs containing up to 3,000 VDAs in a single Google Cloud project. This update brings performance improvements to both provisioning and power management operations.

Ability to reset the OS disk of a persistent VM in an MCS created machine catalog in Google Cloud and AWS environment. You can now use the PowerShell command `Reset-ProvVMDisk` to reset the OS disk of a persistent VM in an MCS created machine catalog. The feature automates the process of resetting the OS disk. For example, it helps in resetting the VM to its initial status of a persistent development desktop catalog created using MCS. Currently, this feature is applicable to AWS, Azure, Citrix Hypervisor, Google Cloud, and VMware virtualization environments. For more information on using the PowerShell command to reset the OS disk, see Reset OS disk.

Support for changing disk related custom properties of an existing catalog and existing VMs in GCP. Previously, in GCP environments, you could add the custom properties only when

© 1997–2026 Citrix Systems, Inc. All rights reserved.

you created the MCS machine catalog. With this feature, you can now change the following disk-related custom properties of an existing catalog and existing VMs of the catalog.

- `PersistOSDisk`
- `PersistWBC`
- `StorageType`
- `IdentityDiskStorageType`
- `WbcDiskStorageType`

This implementation helps you to select different storage types for different disks even after you create a catalog and thus, balance pricing associated with different storage types. For more information, see Change disk related custom properties of an existing catalog.

Dynamic session timeout support extended to VDA version 2203 LTSR CU3 or later. For single-session OS delivery groups, this feature now applies to VDAs of version 2206 CR or later, or 2203 LTSR CU3 or later. For more information, see Dynamic session timeouts.

Improved host connection creation experience in Full Configuration. After you select a resource location, the **Connection type** drop-down list now displays all Citrix-supported hypervisors and cloud services, and their availabilities depend on:

- For a resource location without accessible Cloud Connectors, only hypervisors and cloud services that support connectorless deployments are available.
- For a resource location with accessible Cloud Connectors, only hypervisors and cloud services that have their plug-ins properly installed on those connectors are available.

For more information, see Create and manage connections.

Additional component selection in VDA upgrade. You can now select which additional components to upgrade or install while upgrading a VDA. For more information, see upgrade VDAs.

IMPORTANT:

To use the additional components feature, make sure that your VDA Upgrade Agent is version 7.34 or later, which is included in the VDA installer version 2206 or later.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Full Configuration now preconfigures certain settings for Azure machines based on machine profiles. When you provision Azure VMs, Full Configuration now preconfigures the following settings based on the selected machine profile:

- Host group
- Disk Encryption Set
- Availability Zone
- License Type

Support for AWS instance hibernation. You can now launch AWS instances, set them as desired, and hibernate them. The hibernation process stores the in-memory state of the instance, along with its private and elastic IP addresses, allowing it to pick up exactly where it left off. For more information on creating VMs that support hibernation, see Instance Hibernation.

Support for optimizing AWS throttling. You can now power on and off a large number of machines in an AWS catalog without encountering throttling issues. Throttling issues occur when the number of requests sent to AWS exceeds the number of requests that the server can handle. This feature increases efficiency by reducing the number of AWS calls to power machines on and off in bulk. It also significantly reduces the time taken to power on and off machines in persistent catalogs.

Secure environment for Azure managed traffic. Previously, you relied on the public internet to let your Azure endpoints interact with resources in your environment. As a result, security concerns were raised because the public internet was accessed. With this feature, MCS enables network traffic to be routed through Citrix Cloud Connectors in your environment. This makes the environment safe because now all Azure managed traffic originates from your own environment. To do this, add `ProxyHypervisorTrafficThroughConnector` in `CustomProperties`. For more information, see Create a secure environment for Azure managed traffic.

After you set the custom properties, you can configure Azure policies to have private disk access to Azure managed disks.

Support for provisioning catalog VMs with Azure Monitor Agent. Azure Monitor Agent (AMA) collects monitoring data and delivers it to Azure Monitor. With this feature, you can provision MCS machine catalog VMs (persistent and non-persistent) with AMA installed as an extension. This implementation enables monitoring by uniquely identifying the VMs in monitoring data. For more information on AMA, see Azure Monitor Agent overview.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Currently, MCS supports only the machine profile workflow for this feature. For more information on provisioning machine catalog VMs with AMA enabled, see Provision catalog VMs with Azure Monitor Agent installed.

Enable restart schedule for an MCS catalog. Previously, you could schedule image updates by waiting for the next restart or by triggering an immediate restart of all VMs. With this feature, you can now create a one-time restart schedule for a catalog to be triggered on a desired date and time to facilitate MCS image updates. To create a restart schedule, use the `BrokerCatalogRebootSchedule` command. For more information, see Change the master image.

Manage expired client secrets in Azure Quick Deploy. In Azure Quick Deploy, you can now stay informed with alerts when client secrets expire, and easily update them to ensure continuous access to Azure resources. For more information, see Update expired client secrets.

May 2023

New and enhanced features

Search enhancements. This feature enhances visuals and interactions for filters, bringing you a better search experience. For more information, see Use Search in the Full Configuration management interface.

New user exclusions policy where you can define directory paths that are not redirected to the user layer. User exclusions apply to the user personalization layer (UPL), but not to the session host. Logoff.txt now contains all active user exclusions. For more information, see User personalization layer.

Support for updating hardware version of new VMs added in an MCS machine catalog. In VMware environments, you can now update the hardware version of the newly added VMs in an existing MCS machine catalog using a machine profile source. You do not have to create a new machine catalog to update the hardware version of the VMs added to a catalog. You must use the machine profile workflow to use this feature.

Support for filtering AWS VM instances. Previously, when you used an AWS VM instance as a machine profile input to create an MCS machine catalog, the catalog sometimes did not create or function correctly because of invalid machine profile input. With this feature, you can now list the AWS VM instances that can be used as valid machine profile VMs. To do this, use the `Get-HypInventoryItem` command. For more information, see Filtering VM instances.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

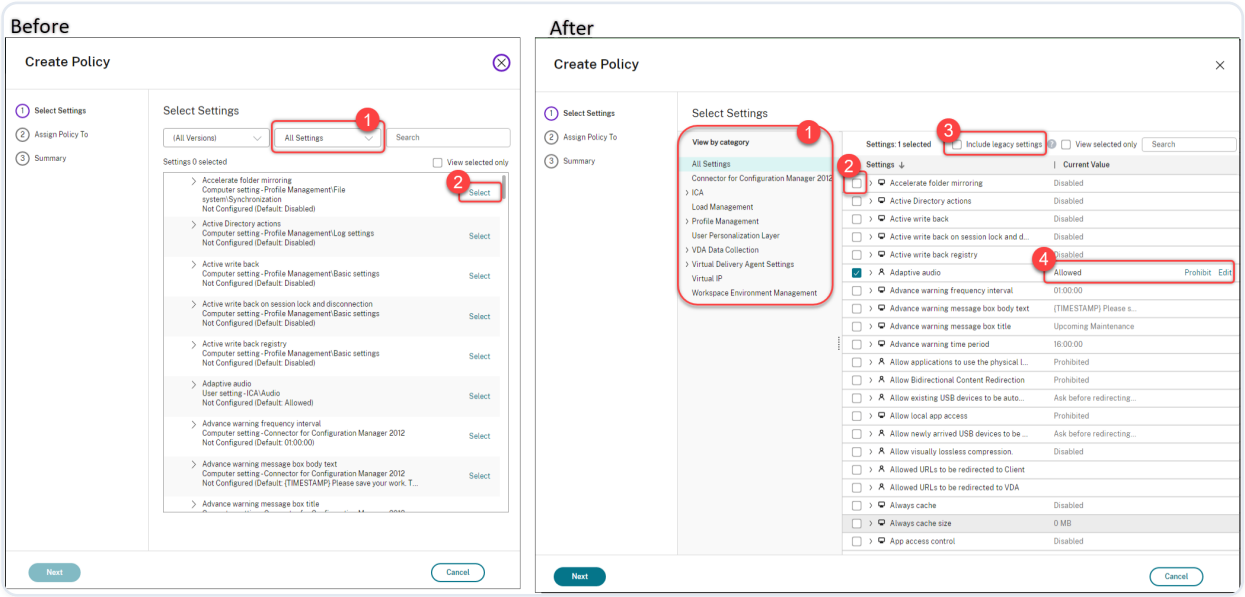
Support for converting a non-machine profile-based machine catalog to machine profile-based machine catalog in Azure environment. In the Azure environment, you can now use a VM or template spec as a machine profile input to convert a non-machine profile-based machine catalog to machine profile-based machine catalog. Existing VMs and new VMs added to the catalog take property values from the machine profile unless overwritten by explicit custom properties. For more information, see Convert a non-machine profile-based machine catalog to machine profile-based machine catalog.

Support for double encryption on managed disk in Azure environment. In Azure environment, you can now create an MCS machine catalog with double encryption. Double encryption is platform-side encryption (default) and customer-managed encryption (CMEK). Therefore, if you are a high security sensitive customer who is concerned about the risk associated with any encryption algorithm, implementation, or a compromised key, you can opt for this double encryption. Persistent OS and data disks, snapshots, and images are all encrypted at rest with double encryption. For more information, see Double encryption on managed disk.

Support for machine profile in VMware. In VMware environments, you can now create an MCS machine catalog using a machine profile. The source of the machine profile input is a VMware template. The machine profile captures the hardware properties from a VMware template and applies them to the newly provisioned VMs in the catalog. For more information, see Create a machine catalog using a machine profile.

Ability to reset the OS disk of a persistent VM in an MCS created machine catalog in Azure and Citrix Hypervisor. You can now use the PowerShell command `Reset-ProvVMDisk` to reset the OS disk of a persistent VM in an MCS created machine catalog. The feature automates the process of resetting the OS disk. For example, it helps in resetting the VM to its initial status of a persistent development desktop catalog created using MCS. Currently, this feature is applicable to Azure, Citrix Hypervisor, and VMware virtualization environments. For more information on using the PowerShell command to reset the OS disk, see Reset OS disk.

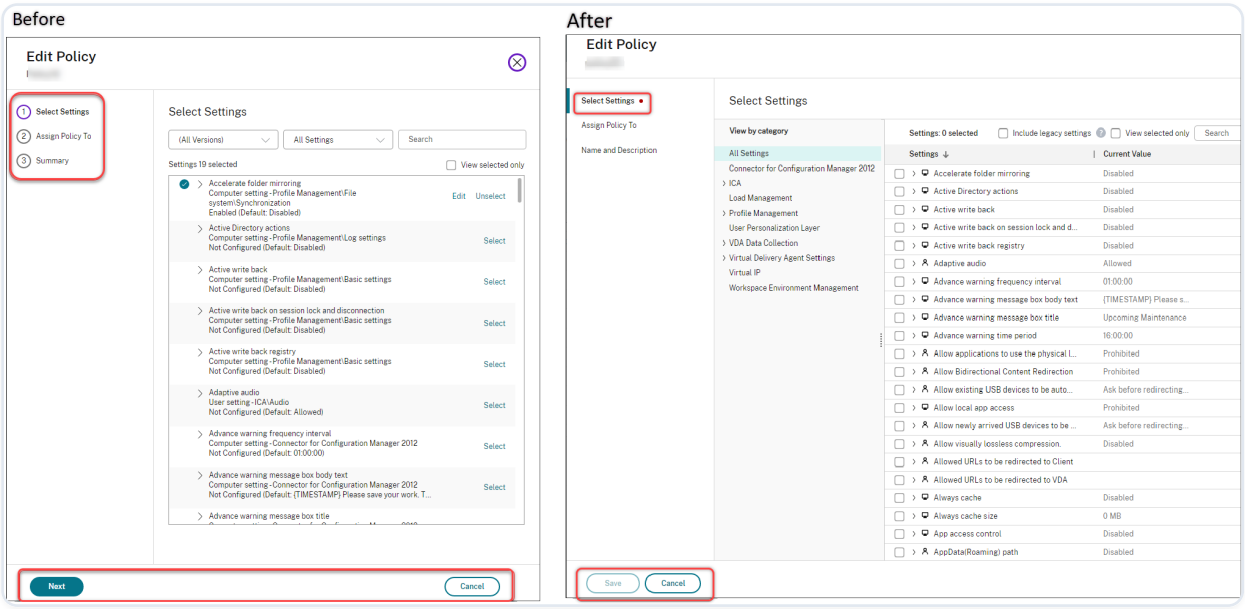
Improved host connection creation experience. You can now get the following information while you create a host connection:



- List of all Citrix supported hypervisor plug-ins, including third party plugins
- Availability of hypervisor plug-in. If the availability status is false, possible reason might be that Cloud Connector is not installed

This feature helps you to correctly set-up a resource location and thus, create a host connection. For more information, see Step 1. Connection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



User experience improvements for the Policies node. To improve the user experience and make policy management more efficient, we've implemented the following improvements to the **Full Configuration > Policies** node:

- New UI design for the **Create Policy** and **Create Template** actions:
  - Expandable folder view for policy settings. On the **Select Settings** page, all settings are displayed by category in an expandable tree view, making it easier to find a setting.
  - To select a setting, you simply click a check box instead of using the **Select** button.
  - Legacy settings have been hidden by default so that only the most relevant settings are shown. If legacy settings are needed, select **Include legacy settings**.
  - An action button has been added next to a Boolean setting, enabling you to change its value directly in the settings list.

- New UI design for the **Edit Policy** action:
  - The navigation menu has been updated to an unordered list. Each item in the list now includes a **Save** button on its page. With this new design, you can save changes made to an item without having to navigate through all items in the navigation menu. These improvements make policy management more efficient and streamlined.
  - Red dots appear next to the navigation items to indicate setting errors.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Drag to reprioritize policies. In the priority list, you can now change the priority of a policy by dragging it to a desired position.

New option to turn off forced user logoff for AutoScale. A new option, **Neither notify nor force user logoff**, is now available on the **Manage Autoscale > User Logoff Notification** page. With the option selected, Autoscale will neither force users to log off from machines in drain state nor notify users to log off and log on to a different machine. For more information, see User logoff notifications.

Ability to restart Windows 365 Cloud PCs. You can now use Citrix DaaS to restart Windows 365 Cloud PCs.

More session details. When you view a session in **Full Configuration > Search > Sessions**, the session view (in the lower pane) now includes more session details to help you troubleshoot and identify client issues:

- **Reconnect time.** The time when a session reconnected after being disconnected.
- **Client platform.** The platform used to launch the session.
- **Client version.** The version of the client platform used to launch the session.
- **Remote host IP.** The IP address of the remote host where Citrix Workspace is being hosted.

Support for renaming Azure AD security groups for VMs. For VMs added to an Azure AD security group through Citrix DaaS, you can now rename the security group using **Full Configuration > Edit Machine Catalog**. Renaming occurs after you save the change.

Default domain selection for machine accounts. When you create a catalog, the domain where the resource (connection) resides is selected by default for machine accounts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Ability to display the Azure AD assigned security groups for VMs to join. In Full Configuration, when you create Azure Active Directory joined VMs, an option, **Join an assigned security group as a member**, is now available, letting you add the Azure AD security group where the VMs reside to an assigned security group. For more information, see Create a machine catalog using an Azure Resource Manager image.

Support for changing networks for connections. In Full Configuration, you can now change networks for a connection. You can't unassociate networks from a connection if they are in use. For more information, see Edit network.

Ability to remove tags in Azure environments. Previously, `Remove-ProvVM` and `Remove-ProvScheme` PowerShell commands with `ForgetVM` parameter removed the VMs and machine catalogs from the Citrix database. However, the commands didn't remove the tags from the resources. You had to individually manage the VMs and machine catalogs that weren't deleted entirely from all the resources. With this feature, you can use:

- `Remove-ProvVM` with `ForgetVM` parameter to remove VMs and tags created on the resources from a single VM or a list of VMs from a machine catalog.
- `Remove-ProvScheme` with `ForgetVM` parameter to remove a machine catalog from the Citrix database and tags created on the resources from an entire machine catalog.

This implementation helps in identifying orphaned resources that are created by MCS but no longer used by MCS.

This feature is only applicable to persistent VMs. For more information, see Remove tags.

Failed Machines alert.The Proactive Notification and Alerting feature of the Monitor is enhanced to include a new alert, Failed Machines (in %) based on the percentage of failed machines in a delivery group. The new alert condition, allows you to configure alert thresholds as a percentage of failed machines in a delivery group. For more information, see Failed Machines section in the Alerts article.

April 2023

New and enhanced features

Publishing with specific cloud platforms using Citrix Provisioning in Image Portability Service. Specific workflows for using Image Portability Service to publish in AWS, Azure, and Google Cloud are now available. In addition, the required permissions for Azure and networking have been updated. For more details, see Migrate workloads to public cloud.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for identifying why a machine is in maintenance mode. Previously, PowerShell was your only choice to identify why a machine was in maintenance mode. You can now achieve that in Full Configuration:

1. Use Search to locate the machine.
2. Check **Maintenance Reason** on the **Details** tab in the lower pane. Or hover over the **Maintenance Mode** column. The following information can appear:

- By Administrator: Put into maintenance mode by administrator.
- Maximum Failed Registrations: Put into maintenance mode as machine exceeded maximum allowed registration attempts.

Also, a filter, **Maintenance Reason**, is now available. You can use it to identify the target machines.

The feature is useful for administrators to troubleshoot issues with machines in maintenance mode.

Use variables to notify users of remaining time before they are logged off. When forcing user logoff, you can now use `%s%` or `%m%` as variables to indicate the specified time in the notification message. To express the time in seconds, use `%s%`. To express the time in minutes, use `%m%`. For more information, see User logoff notifications.

Support for customizing power on behavior at storage type change failure. At power-on, the storage type of a managed disk might fail to change to the desired type due to a failure on Azure. Previously, in these scenarios, the VM would remain off with a failure message sent to you. With this feature, you can either choose to power on the VM even when storage cannot be restored to its configured type or choose to keep the VM powered off. For more information, see Customize power on behavior at storage type change failure.

Support for MAK activation. You can now provision persistent and non-persistent machine catalogs with VMs activated through the Multiple Activation Key (MAK). With this feature, now MCS can also communicate with provisioned VMs. This implementation helps in activating the Windows system without losing activation counts. For more information, see Volume licensing activation.

Support for Azure disk encryption at host. With this feature, you can now create an MCS machine catalog with encryption at host capability. Currently, MCS supports only the machine profile workflow for this feature. You can use a VM or a template spec as an input for a machine profile. For more information, see Azure disk encryption at host.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In this type of encryption, the server hosting the VM encrypts the data and then the encrypted data flows through the Azure storage server. Therefore, this method of encryption encrypts data end to end. For more information, see Encryption at host - End-to-end encryption for your VM data.

Support for GCP instance template as an input for machine profile. With this feature, you can now select a GCP instance template as an input for the machine profile. Instance templates are lightweight resources in GCP, therefore are very cost effective. To do this, use PowerShell commands. For more information on using PowerShell commands to create and update machine catalogs by selecting a GCP instance template, see Create a machine catalog with machine profile as an instance template.

Support for modifying Azure AD dynamic security group name. You can modify or delete an Azure AD dynamic security group name from Azure portal. This action can make the Azure AD dynamic security group name out-of-sync with the dynamic security group associated with a machine catalog. With this feature, you can now modify the Azure AD dynamic security group name associated with a machine catalog.

This modification helps you to make the Azure AD dynamic security group information stored in Azure AD identity pool object to be consistent with the information stored in Azure portal. For more information, see Modify Azure AD dynamic security group name.

Added permissions required in GCP. The permissions required to do the following are now added:

- Create host connection
- Do power management of VMs
- Provision catalogs

For more information, see About GCP permissions.

Credential handling. For enhanced security, by default, credentials are not forwarded to the cloud for users who are not in the same domain as their VDAs. Login attempts fail when all of the following conditions are met:

- The user is in a domain different from the VDA
- No trust exists between the domains
- StoreFront is installed in the same domain as the VDA

Previously under these conditions, the user couldn't be authenticated to StoreFront. So, the Cloud Connector forwarded user credentials to the cloud to route the authentication request to the correct

© 1997–2026 Citrix Systems, Inc. All rights reserved.

destination for that user. This behavior can still be configured if needed. For more information, see the `CredentialForwardingToCloudAllowed` parameter of Set-Brokersite in the DaaS PowerShell SDK.

March 2023

New and enhanced features

Support for configuring role and scope for administrators. Citrix Cloud now supports a higher degree of flexibility and customization when configuring access for an administrator. Previously, you could only select predefined pairs of roles and scopes. With this enhancement, you can select a role and then pair it with the scope of your choice.

For more information, see Configure custom access for an administrator.

Support for creating dynamic security group under existing assigned security group. Previously, you could create Azure AD dynamic security groups for a machine catalog. With this feature, you can also add an Azure AD dynamic security group under an existing Azure AD assigned security group. You can do the following:

- Get security group information.
- Get all Azure AD assigned security groups that are synced from on-premises AD server or the assigned security groups to which Azure AD roles can be assigned.
- Get all Azure AD dynamic security groups.
- Add Azure AD dynamic security group as a member of Azure AD assigned group.
- Remove the membership between Azure AD dynamic security group and Azure AD assigned security group when Azure AD dynamic security group is deleted along with the machine catalog.

For more information, see Create an Azure AD dynamic security group under an existing Azure AD assigned security group.

Support for Azure AD dynamic security group for Azure AD joined VM. Citrix now supports dynamic security group for a catalog while creating an MCS machine catalog. Dynamic security group rules place the VMs in the catalog to a dynamic security group based on the naming scheme of the machine catalog. This is useful when you want to manage the VMs by Azure Active Directory (Azure AD). This is also useful when you want to apply Conditional Access policies or distribute apps from Intune by filtering the VMs with Azure AD dynamic security group. When you delete a

© 1997–2026 Citrix Systems, Inc. All rights reserved.

catalog, the dynamic security group is also deleted. For more information, see Azure Active Directory dynamic security group.

For more information on license requirement for using dynamic security groups, see the Microsoft document Create or update a dynamic group in Azure Active Directory.

Support for adding VMs to Azure AD security groups through Full Configuration. An option, **Azure AD security group**, is now available when you create Azure AD joined VMs. The option lets you add the VMs to an Azure AD security group based on their naming scheme. For more information, see Create a Microsoft Azure catalog.

Support for changing the storage type of existing VMs to a lower tier on shutdown in Azure environments. In Azure environments, you can now save storage costs by changing the storage type of existing VMs to a lower tier when the VMs are shut down. To do this, use the StorageTypeAtShutdown custom property. For more information, see Change the storage type of existing VMs to a lower tier on shutdown.

Support for allowing security identifiers while creating virtual machines. Previously, while creating new virtual machines with the configuration specified by a provisioning scheme, you could not add a security identifier (`ADAccountSid`) to the `NewProvVM` command. With this feature, you can now add the parameter `ADAccountSid` to uniquely identify the machines while creating new virtual machines. For more information, see Add SIDs while creating virtual machines.

Ability to get warnings associated with MCS catalogs. Previously, you did not get any information indicating that there are issues with your machine catalog. With this feature, you can now get warnings to understand issues with your MCS catalogs and fix those issues.

Warnings, unlike errors, do not cause an initiated provisioning task to fail.

To get warnings, use PowerShell commands. For more information, see Retrieve warnings associated with a catalog.

Shared tenants for connections. You can now add tenants and subscriptions that share the Azure Compute Gallery with the subscription of the connection. As a result, when creating or updating catalogs, you can select shared images from those tenants and subscriptions. For more information, see Edit connection settings.

Removed support for changing the OS type for Azure catalogs. When changing catalog images, only images with the same OS type as the image in use are shown. With this enhancement, Citrix DaaS no longer supports changing the OS type for Azure catalogs after catalog creation such as, changing from Windows OS type to Linux and vice versa.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

February 2023

New and enhanced features

Support for sharing images across different Azure tenants. Previously, in Azure environments, you could share images only with shared subscriptions using Azure Compute Gallery. With this feature, you can now select an image in Azure Compute Gallery that belongs to a different shared subscription in a different tenant to create and update an MCS catalog. For more information, see Image sharing across Azure tenants.

Policy modeling. The policy modeling feature is now generally available. You can simulate policies for planning and testing purposes. For more information, see Use the Policy Modeling wizard.

Ability to turn preview features on or off. In Full Configuration > Home, as a Citrix Cloud administrator with full access, you can now turn preview features on or off without contacting Citrix. For more information, see Home page for the Full Configuration interface.

Search Session Diagnostics with user name. This feature enables the use of Session Launch Diagnostics starting with the user name if you don't have the transaction id. This feature is specifically useful for help desk administrators to triage a failed session if the end user hasn't captured the transaction id. You can search for a user name, and select a session to triage from a list of failed sessions that the user attempted to launch over the last 48 hours. The Session Launch Diagnostics page shows the details of the failed session. It lists the exact component and stage where the failure occurred. For more information, see the Session Launch Diagnostics article.

Deploy secure web and SaaS apps with Secure Private Access. On the **Full Configuration > Applications > Applications** tab, a new option, **Add Web/SaaS Applications**, is now available in the action bar. The option lets you deploy secure web and SaaS apps with Secure Private Access. Citrix Secure Private Access provides an easy, flexible way for remote users to access web, SaaS, and client-server based apps using a Zero-Trust approach. It enables single sign-on to web and SaaS apps, along with granular security controls such as watermarking and copy/paste controls, among other security features. With Citrix Secure Private Access, you can combine all your virtualized and non-virtualized apps in one place and enhance the user experience for your users. See Citrix Secure Private Access.

Filter log content for a specific time duration. A new option, **Custom**, is now available in the time duration list in **Full Configuration > Logging > Events**. Use it to specify a period of the events for which you want to filter your search. For more information, see Configuration logging.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Updates for Autoscale. We've updated the **Control when Autoscale starts powering on tagged machines** option to make it easy to understand. The option controls when Autoscale starts powering on tagged machines based on the percentage of the remaining capacity of untagged machines. When the percentage falls below the threshold (default, 10%), Autoscale starts powering on tagged machines. When the percentage exceeds the threshold, Autoscale goes into power-off mode. For more information, see Autoscaling tagged machines (cloud burst).

App protection policies. You can now enable app protection when creating or editing a delivery group. The feature provides anti-keylogging and anti-screen-capturing capabilities for client sessions. For more information, see Create delivery groups and Manage delivery groups.

Real-time GPU Utilization available for AMD GPUs. You can now see GPU Utilization of AMD Radeon Instinct MI25 GPUs and AMD EPYC 7V12(Rome) CPUs on Monitor. Monitor already supports the NVIDIA Tesla M60 GPUs. GPU Utilization displays graphs with real-time percentage utilization of the GPU, the GPU memory, and of the Encoder and the Decoder to troubleshoot GPU-related issues on multi-session and single-session OS VDAs. The AMD GPU Utilization graphs are available only for VDAs running 64-bit Windows and Citrix Virtual Apps and Desktops 7 2212 or later. For more information, see GPU Utilization.

Support for scheduling configuration updates in Azure. In Azure environments, you can now schedule a time slot for the configuration updates of the existing MCS provisioned machines using the PowerShell command `Schedule-ProvVMUpdate`. Any power on or restart during the scheduled time slot applies a scheduled provisioning scheme update to a machine. You can also cancel the configuration update before the scheduled time using `Cancel-ProvVMUpdate`.

You can schedule and cancel the configuration update of:

- A single or multiple VMs
- An entire catalog

For more information, see Schedule configuration updates.

Support for using Citrix ready images directly from Google Cloud Marketplace. You can now browse and select images offered by Citrix on the Google Cloud Marketplace to create MCS catalogs. Currently, MCS supports only the machine profile workflow for this feature. For more information, see Google Cloud Marketplace.

Limit host groups scope in SCVMM Host Connection. Previously, host connection to SCVMM required the admin to have a single top level host group configured. This implies that the admin had visibility to all host groups, clusters, or hosts beneath the single top level host group. With this feature, in large deployments where a single SCVMM manages multiple clusters in different data

© 1997–2026 Citrix Systems, Inc. All rights reserved.

centers, you can now limit the host groups scope of the admins. To do this, you can use the Delegated Admin role in the Microsoft System Center Virtual Machine Manager (VMM) console to select the host groups to which an admin must have access. For more information, see Install and configure a hypervisor.

Support for zone-redundant storage in Azure. Previously, MCS offered only locally-redundant storage. With this feature, zone-redundant storage is now an option in Azure, allowing you to select a storage type depending on what type of redundancy you want to use. Zone-redundant storage replicates your Azure managed disk across multiple availability zones, which allows you to recover from a failure in one zone by utilizing the redundancy in others. For more information see, Enable zone-redundant storage.

January 2023

New and enhanced features

Option to downgrade storage disk to Standard HDD when VMs shut down. A new option, **Enable storage cost saving**, is now available on the **Disk Settings** page when you create or update Azure catalogs. The option saves storage costs by downgrading to Standard HDD for the storage disk and the write-back cache disk when the VM shuts down. The VM switches to its original settings on restart. For more information, see Create a Microsoft Azure catalog.

Support for configuring session roaming in Full Configuration. Previously, PowerShell was your only choice to configure session roaming for applications and desktops. You can now do that in **Full Configuration**. For more information, see Manage delivery groups.

Renamed some actions to better align with their actual meanings. We've renamed the following actions in **Full Configuration > Machine Catalogs** and **Full Configuration > Delivery Groups**. The workflows for performing those actions remain unchanged.

- **Update Machines** renamed to **Change Master Image**
- **Rollback Machine** Update renamed to **Roll Back Master Image**
- **Upgrade Catalog** renamed to **Change Functional Level**
- **Upgrade Delivery Group** renamed to **Change Functional Level**
- **Undo Upgrade Catalog** renamed to **Undo Functional Level Change**
- **Undo Upgrade Delivery Group** renamed to **Undo Functional Level Change**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for organizing application groups using folders. You can now create nested folders to organize application groups for easy access. For more information, see Organize application groups using folders.

Restriction enhancements for delivery groups. Previously, when restricting the use of apps or desktops for a delivery group, you could specify only users and user groups that were allowed to use them in a delivery group. You can now also add users and user groups that you want to block. This enhancement is useful when you add a group of users to an allow list and at the same time want to block a subset of users in the allow list. For more information, see Create delivery groups.

Access Citrix Analytics for Performance™ - Session Details from Monitor. The Session Details page from Citrix Analytics for Performance is now integrated in Monitor. Click **View Session Timeline** in the Sessions page in Monitor to view the Sessions Details page from Citrix Analytics for Performance within Monitor. This requires you to have a valid Citrix Analytics for Performance entitlement. The Session Details are available for sessions that are categorized as Excellent, Fair, or Poor in Citrix Analytics for Performance.

You can view a trend of the session experience for the session for up to the last three days along with the factors contributing to the experience. This information complements the live data available in Monitor, used by the helpdesk admin while troubleshooting issues related to session experience.

For more information, see the Site Analytics article.

Non-persistent VMs are deleted from hypervisors or cloud services when you delete them or their machine catalogs in Full Configuration. The option to retain VMs in hypervisors or cloud services is now available only to persistent VMs. For more information, see Manage machine catalogs.

December 2022

New and enhanced features

Support for creating Azure AD joined, Hybrid Azure AD joined, and Microsoft Intune enabled catalogs with Azure AD joined master VMs. You can now create Azure AD joined, Hybrid Azure AD joined, and Microsoft Intune enabled catalogs with Azure AD joined, Hybrid Azure AD joined, and non-domain-joined master VMs. If you want to manage a master VM by Microsoft Intune, use VDA version 2212 or later, and do not skip image preparation while creating or updating machine catalogs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information on machine identities, see Azure Active Directory joined, Microsoft Intune, and Hybrid Azure Active Directory joined.

Support in MCS for deleting VM objects without accessing the hypervisor. You can now delete VM objects in MCS without having access to the hypervisor. When deleting a VM or provisioning scheme, MCS needs to remove tags so that the resources are no longer tracked or identified. Previously, if the hypervisor could not be accessed, the tag removal failures were ignored. With this feature, if the hypervisor is not accessible while using the `Remove-ProvVM` command the tag removal will fail, but by using the `PurgeDBOnly` option, you can still delete the VM resource object from the database. For more information, see Delete machines without hypervisor access.

November 2022

New and enhanced features

Support for delivering MSIX and MSIX app attach apps. In **Full Configuration > App Packages**, you can now upload MSIX and MSIX app attach packaged apps to Citrix Cloud, and deliver them to your users. For more information, see App packages.

Prompt for unsupported VDA versions and functional levels. The Full Configuration interface now alerts you about unsupported VDA versions and functional levels. To avoid potential issues:

- If a machine runs an unsupported VDA version, you are prompted to upgrade to a supported version.
- If the functional level of a catalog or delivery group is not supported, you are prompted to set it to a higher level.

TIP:

VDAs are covered by the CR and LTSR lifecycles of Citrix Virtual Apps and Desktops.

Ability to annotate master images extended to catalog creation. When creating an MCS catalog in **Full Configuration**, you can now annotate its master image. For more information, see Master image.

Support for exporting desktop assignment data through Full Configuration. When viewing desktop assignments for a single-session OS delivery group, you can now export the assignment data into a CSV file for auditing purposes. To do so, select such a delivery group in **Full**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration > Delivery Groups, go to the **Desktops** tab, and then click **Export** in the upper-left corner on the tab.

All Applications and Application Folders tabs consolidated into one. In **Full Configuration > Applications**, the **All Applications** and **Application Folders** tabs have been consolidated into one tab, **Applications**. This change unifies the user experience of folder view management across Full Configuration nodes.

Support for changing the storage type to a lower tier when a VM is shut down in Azure environments. In Azure environments, you can now save storage costs by switching the storage type of a managed disk to a lower tier when you shut down a VM. To do this, use the `StorageTypeAtShutdown` custom property. The storage type of the disk changes to a lower tier (as specified in the `StorageTypeAtShutdown` custom property) when you shut down the VM. After you power on the VM, the storage type changes back to the original storage type (as specified in `StorageType` or `WBCDiskStorageType` custom property). For more information, see Change the storage type to a lower tier when a VM is shut down.

Updates in Filters View. The Filters page in Monitor is updated to include separate Saved and Default filters lists for better visualization and accessibility to the filters. You can select a view from among Machines, sessions, Connections, or Application Instances. Then, you can select a filter from the list of Saved filters or Default filters to view the filtered list of data. You can use the drop-down lists to refine the filter criteria or edit existing criteria. You can save your filter in the Saved Filter list. For more information, see the Filters article.

Ability to reset the OS disk of a persistent VM in an MCS created machine catalog. In VMware virtualization environments, you can now use the PowerShell command `Reset-ProvVMDisk` to reset the OS disk of a persistent VM in an MCS created machine catalog. The feature automates the process of resetting the OS disk. For example, it helps in resetting the VM to its initial status of a persistent development desktop catalog created using MCS.

For more information on using PowerShell command to reset the OS disk, see Reset OS disk.

Support for updating machine profile and additional custom properties of MCS provisioned machines in Azure environments. Previously, in Azure environments, you could use `Request-ProvVMUpdate` to update `ServiceOffering` custom property of an MCS provisioned machine. Now, you can also update the machine profile and the following custom properties:

- `StorageType`
- `WBCDiskStorageType`
- `IdentityDiskStorageType`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `LicenseType`
- `DedicatedHostGroupId`
- `PersistWBC`
- `PersistOsDisk`
- `PersistVm`

For more information, see Update provisioned machines to current provisioning scheme state.

Support for machine profile in GCP. When you create a catalog to provision machines using Machine Creation Services (MCS) in Google Cloud Platform (GCP) environments, you can now use a machine profile to capture the hardware properties from a virtual machine and apply them to the newly provisioned VMs in the catalog. When `MachineProfile` parameter is not used, the hardware properties are captured from the master image VM or snapshot.

Machine profiles work with both Linux and Windows operating systems.

For information on how to create a machine catalog with a machine profile, see Create a machine catalog using a machine profile.

Support for updating MCS provisioned machines in GCP environments. In GCP environments, `Set-ProvScheme` changes the template (provisioning scheme) and does not affect existing machines. Using the PowerShell command `Request-ProvVMUpdate`, you can now apply the current provisioning scheme to an existing machine (or set of machines). Currently, in GCP, the property update supported by this feature is machine profile. For more information, see Update provisioned machines using PowerShell.

October 2022

New and enhanced features

Support for using machine profiles and host groups at the same time. When creating a catalog using an Azure Resource Manager master image, you can now use a machine profile and a host group at the same time. This is useful in scenarios where you want to use trusted launch for improved security and at the same time run the machines on dedicated hosts. For more information, see Microsoft Azure Resource Manager virtualization environments.

Support for organizing delivery groups using folders. You can now create a folder tree to organize delivery groups for easy access. For more information, see Organize delivery groups using folders.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for scheduling a one-time restart for machines through Full Configuration. A new option, **Once**, is now available when you create restart schedules for delivery groups. With this option, you can schedule machines in a delivery group to restart once, at a specified date and time. For more information, see Create a restart schedule.

Advanced Probe Scheduling. Improved scheduling of Application and Desktop Probes can now be done from Monitor. Using this feature, Citrix Probe Agent can be configured to run the probe tasks on specific days of the week and repeated at specified intervals during the day. This allows you to schedule a single probe task to repeat at specific times of the day and the week. You can now proactively check your site health with probes set to run regularly at suitable times. This feature simplifies probe setup and management in Monitor. For more information, see Application and Desktop Probing.

September 2022

New and enhanced features

Older versions of the Remote PowerShell SDK are now deprecated. If you are using a deprecated version, the SDK stops working and you see an error message prompting you to download the current version. If this happens, download the latest Remote PowerShell SDK from the Citrix website.

Machine catalogs with Trusted launch in Azure. In Azure environments, you can create machine catalogs enabled with Trusted launch, and use the `SupportsTrustedLaunch` property of the VM inventory to determine the VM sizes that support Trusted launch.

Trusted launch is a seamless way to improve the security of Generation 2 VMs. Trusted launch protects against advanced and persistent attack techniques. For more information, see Machine catalogs with Trusted launch.

Support for identifying Microsoft System Center Virtual Machine Manager resources created by MCS. You can now identify Microsoft System Center Virtual Machine Manager (SCVMM) resources created by MCS using tags. For more information on the tags that MCS adds to the resources, see Identify resources created by MCS.

Support for identifying VMware resources created by MCS. You can now identify VMware resources created by MCS using tags. For more information on the tags that MCS adds to the resources, see Identify resources created by MCS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for optimizing AWS Workspace throttling. You can now power on and off a large number of machines in an AWS Workspace without encountering throttling issues. Throttling issues occur when the number of requests sent to AWS Workspace exceeds the number of requests that the server can handle. Therefore, Citrix now groups multiple requests into one single request before sending it to the AWS Workspace SDK.

Ability to check machine details when viewing machine counts in Home. When viewing machine counts by availability state in **Home**, you can now click a state to view details of machines in that state. For more information, see Home page for the Full Configuration interface.

Support for machine catalog creation using an image from a different subscription in the same Azure tenant. Previously, in Azure environments, you could only select an image within your subscription to create a machine catalog. With this feature, you can now select an image in Azure Compute Gallery (formerly Shared Imaged Gallery) that belongs to a different shared subscription to create and update MCS catalogs.

For more information on creating a catalog, see Create a machine catalog using an Azure Resource Manager image.

For information on sharing image with another service principal in the same tenant, see Image sharing with another service principal in the same tenant.

For information on PowerShell commands to select an image from a different subscription, see Using PowerShell to select an image from a different subscription.

For more information on Azure Compute Gallery, see Azure Shared Image Gallery.

August 2022

New and enhanced features

Support for identifying Citrix hypervisor resources created by MCS. You can now identify Citrix hypervisor resources created by MCS using tags. For more information on the tags that MCS adds to the resources, see Identify resources created by MCS.

Support for using host groups and Azure availability zones at the same time. In Azure environments, there is now a pre-flight check to assess whether the creation of a machine catalog will be successful based on the Azure availability zone specified in the custom property and the host group's zone. Catalog creation fails if the availability zone custom property does not match the host group's zone.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

A host group is a resource that represents a collection of dedicated hosts. A dedicated host is a service that provides physical servers that host one or more virtual machines. Azure availability zones are physically separate locations within each Azure region that are tolerant to local failures.

For more information on the various combinations of availability zone and host group zone that result in successful or failed the machine catalog creation, see Using host groups and Azure availability zones at the same time.

Support for updating the folder ID of a machine catalog in VMware. In VMware virtualization environments, you can now update the folder ID of an MCS machine catalog using the custom property `FolderID` in `Set-ProvScheme`. The VMs created after updating the folder ID are created under this new folder ID. If this property is not specified in `CustomProperties`, then VMs are created under the folder where the master image is located. For more information on updating the folder ID, see Update the folder ID of a machine catalog.

Time zone setup. You can now configure the date and time format of the interface to suit your preferences using the **Date and time** setting. For more information, see Time zone setup.

Image Portability Service (IPS) now supports Amazon Web Services (AWS). By configuring the required permissions and components for AWS, IPS workflows can be used with an AWS account. See Migrate workloads to public cloud for more details.

Page file setting during image preparation in Azure environments. In Azure environments, you can now avoid potential confusion with the page file location. To that end, MCS now determines the page file location when you create the provisioning scheme during image preparation. This calculation is based on certain rules. Features like ephemeral OS disk (EOS) and MCS I/O have their own, expected page file location, and are exclusive to each other. Also, if you decouple image preparation from provisioning scheme creation, MCS correctly determines the page file location. For more information on page file location, see Page file location.

Support for updating page file setting in Azure environments. While creating a catalog in an Azure environment, you can now specify the page file setting, including its location and the size, using PowerShell commands. This overrides the page file setting determined by MCS. You can do this by running the `New-ProvScheme` command with the following custom properties:

- `PageFileDiskDriveLetterOverride`: Page file location disk drive letter
- `InitialPageFileSizeInMB`: Initial page file size in MB
- `MaxPageFileSizeInMB`: Maximum page file size in MB

For more information on updating the page file setting, see Update page file setting.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Updates to the Home page. The Get Started widget now has a new look and feel. Other updates to the Home page include:

- The newly added Refresh and Help icons in the upper right corner.
- Clickable resource counts, providing quick access to relevant resource pages.
- Enhancement to the Dislike icon. If you dislike a recommendation, the recommendation disappears. If you dislike the recommendation widget, the widget disappears.

For more information, see Home page.

Support for enabling Azure VM extensions. When using an ARM template spec as a machine profile to create a machine catalog, you can now add Azure VM extensions to the VMs in the catalog, view the list of supported extensions, and remove extensions you added. Azure VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure VMs. For example, if a VM requires software installation, antivirus protection, or the ability to run a script inside it, you can use a VM extension. For more information on how to enable Azure VM extensions, see Use PowerShell to enable Azure VM extensions.

Trusted launch support for ephemeral OS disk. You can now create provisioning schemes using ephemeral OS disk on Windows with trusted launch. Trusted launch is a seamless way to improve the security of generation 2 VMs. It protects against advanced and persistent attack techniques by combining technologies that can be independently enabled like secure boot and virtualized version of trusted platform module (vTPM). For more information on creating a machine catalog, see Create a machine catalog using an Azure Resource Manager image.

July 2022

New and enhanced features

Dynamic session timeouts for single-session OS machines. Dynamic session timeouts now support single-session OS machines. A delivery group with at least one VDA of version 2206 or later is required. Ensure that those VDAs have registered with Citrix Cloud at least once. For more information, go to Dynamic session timeouts.

Send logoff reminders without forcing user logoff in Autoscale. A new feature is now available in **User Logoff Notifications** (formerly **Force User Logoff**) in Autoscale. The feature lets you send logoff reminders to users without forcing them to log off. Doing that avoids potential data loss caused by forcing users to log off from their sessions. See User logoff notifications for details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Ability to set the Linux OS license type when creating Linux VM catalogs in Azure. Using the Full Configuration interface, you can now choose the Linux OS license type when creating Linux VM catalogs in Azure. You have two choices for bring-your-own Linux licenses: Red Hat Enterprise Linux and SUSE Linux Enterprise Server. For more information, see Create a machine catalog using an Azure Resource Manager image.

Enhanced search experience in Full Configuration. The Search node provides the following new features and enhancements:

- **Ability to export search results**. You can now export search results. To do that, click the export icon in the upper right corner.
- **New filter available**. A filter, Pending Power Action, is now available for use. Use the filter to refine your search.
- **"Does not contain" search support for certain items**. Items such as machine names and tags now support "Does not contain" search criteria.
- **Support for searching for objects when adding filters**. When adding filters for the following objects, you can now search for them: connections, machine catalogs, delivery groups, application groups, and tags.

For more information, see Use Search in the Full Configuration management interface.

Support for VMware Storage Profiles. When you create a machine catalog using a master image on a vSAN Datastore, you can now copy the storage policy such as the RAID-1 or RAID-5 information from the master image to the created target devices. For existing catalogs, the storage policy remains unchanged even if you update the catalog.

Support for RestrictedKrbHost SPN registration. All the Citrix MCS created computer accounts are now registered with `RestrictedKrbHost` Service Principal Names (SPN). This avoids the requirement to run the `setspn` command to register the SPN for the computer accounts after MCS creates them.

App Packages in Full Configuration for delivering Microsoft packaged applications. The App-V node is renamed to App Packages and redesigned to accommodate more types of Microsoft packaged apps. Previously, you had to use the discovery module to add App-V packaged apps to your environment for delivery. You can now add and deliver the apps in one place by using the App Packages node. For more information, see App packages.

Support for using ARM template specs as machine profiles. Previously, you could use only VMs as machine profiles. You can now use ARM template specs as machine profiles as well when creating Azure machine catalogs. This feature lets you take advantage of Azure ARM template

© 1997–2026 Citrix Systems, Inc. All rights reserved.

features such as versioning. To ensure that the selected spec is configured correctly and contains required configurations, we perform validation on it. If the validation fails, you are prompted to select a different machine profile. For more information, see Create a machine catalog using an Azure Resource Manager image.

Support for validating ARM template spec. You can now validate the ARM template spec to make sure that it can be used as a machine profile to create a machine catalog. There are two ways to validate the ARM template spec:

- Using the Full Configuration management interface.
- Using the PowerShell command.

For more information on validating the ARM template spec, see Create a machine catalog using an Azure Resource Manager image.

June 2022

New and enhanced features

Restart schedule support for single-session OS machines. Previously, the restart schedule feature was available only for multi-session OS machines. It's now also available for single-session OS machines. You can now create restart schedules for delivery groups containing single-session OS machines. For more information, see Create and manage restart schedules for machines in a delivery group.

Option to perform user name pre-checks. An option, **Check name**, is now available when you enter domain credentials. With the option, you can check whether the user name is valid or unique. The option is useful, for example, when:

- The same user name exists in multiple domains. You are prompted to select the desired user.
- You can't remember the domain name. You can enter the user name without specifying the domain name. If the check passes, the domain name populates automatically.

For more information, see Domain credentials.

Ability to change the network setting for an existing provisioning scheme. You can now change the network setting for an existing provisioning scheme so that the new VMs are created on the new subnetwork. Use the parameter `-NetworkMapping` in the `Set-ProvScheme` command to change the network setting. Only the newly provisioned VMs from the scheme will have the new subnetwork settings. You must also make sure that the subnetworks are under the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

same hosting unit. For more information, see Change the network setting for an existing provisioning scheme.

Retrieve region name information for Azure VMs, managed disks, snapshots, Azure VHD, and ARM template. You can now display the region name information for an Azure VM, managed disks, snapshots, Azure VHD, and ARM template. This information is displayed for the resources on the master image when a machine catalog is assigned. For more information, see Retrieve region name information for Azure VMs, managed disks, snapshots, Azure VHD, and ARM template.

Ability to use machine profile property values in Azure environment. While creating an Azure catalog with a machine profile, you can now set the property values from the ARM template spec or VM, whichever is used as a machine profile, if the values are not explicitly defined in the custom properties. The properties affected by this feature are:

- Availability zone
- Dedicated Host Group Id
- Disk Encryption Set Id
- OS type
- License type
- Service Offering
- Storage type

If some of the properties are missing from the machine profile and not defined in the custom properties, then the default value of the properties takes place wherever applicable. For more information, see Use machine profile property values.

Extended support for VDA upgrade. Using the Full Configuration interface, you can now upgrade MCS-provisioned persistent machines. You can upgrade them on a per-catalog or a per-machine basis. For more information, see Upgrade VDAs using the Full Configuration interface.

Citrix Probe Agent in Citrix Cloud Japan and Citrix Cloud Government Control Planes. Citrix Probe Agent now supports sites hosted on Citrix Cloud Japan and Citrix Cloud Government Control Planes. To use the probing agent in these planes, set the registry value in the path, "\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Citrix\ProbeAgent\AGENT\region" to 2 for Japan and 3 for the Government region. Citrix Probe Agent automates the process of checking the health of virtual apps and desktops that are published in a site. For more information, see Application and Desktop Probing.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Customize the port used for communication between VDAs and Cloud Connectors. You can now customize the port that the VDA uses to communicate with Cloud Connectors based on your specific security requirements. This feature is useful if your security team doesn't allow the default port (port 80) to be open or if the default port is already in use. For more information, see Customize the port for communicating with Cloud Connectors.

Support for organizing machine catalogs using folders. You can now create nested folders to organize machine catalogs for easy access. For more information, see Organize catalogs using folders.

Support for SCVMM 2022. Citrix DaaS now supports Microsoft's System Center Virtual Machine Manager (SCVMM) 2022. SCVMM provides a range of services to include maintaining the resources you need to deploy VMs. For more information about the new features supported in SCVMM 2022, see What's new in System Center Virtual Machine Manager.

Support for configuring maximum concurrent provisioning operations parameter on AWS. Citrix DaaS now supports `MaximumConcurrentProvisioningOperations` as a configurable custom property for MCS on AWS. `MaximumConcurrentProvisioningOperations` is the property that determines the number of VMs you can create or delete simultaneously. While MCS supports 100 maximum concurrent provisioning operations by default, you can now enter PowerShell commands to customize this value. You can enter a range from 1-1000. Setting this property to your preferred value allows you to control the number of parallel tasks you can perform when creating or deleting VMs. For details about configuring the maximum concurrent provisioning operations, see Host Connection Default Values.

May 2022

New and enhanced features

Enhanced Session launch diagnostics. Citrix DaaS now supports detailed session launch failure diagnostics. You can now view the components involved in the session launch sequence. The components which failed with last generated error codes are highlighted. This helps identify the exact reason for a session launch failure and take the recommended action.

The Transaction page is extended with the Transaction Details panel that contains a list of components indicating the error occurrence. Clicking on the component name displays the Component Details and the Last Known Failure Details. The Failure Reason and Error Code are displayed. Clicking the Learn more link leads to the specific code on Error codes containing a detailed description and recommended action. For more information, see Session Diagnostics.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for using Set-ProvServiceConfigurationData in Remote PowerShell SDK. You can now run `Set-ProvServiceConfigurationData` using Remote PowerShell SDK to do the settings on all applicable parameters. You can also skip enabling DHCP during image preparation using this command. Following is the list of settings that is supported with `Set-ProvServiceConfigurationData`:

- Change Image Preparation Timeout: `Set-ProvServiceConfigurationData -Name "ImageManagementPrep_PreparationTimeout" -value 60`
- Skip Enable DHCP: `Set-ProvServiceConfigurationData -Name ImageManagementPrep_Excluded_Steps -Value EnableDHCP`
- Skip Microsoft Windows KMS Rearm: `Set-ProvServiceConfigurationData -Name ImageManagementPrep_Excluded_Steps -Value OsRearm`
- Skip Microsoft Office KMS Rearm: `Set-ProvServiceConfigurationData -Name ImageManagementPrep_Excluded_Steps -Value OfficeRearm`
- Disable preparation VM auto shutdown: `Set-ProvServiceConfigurationData –Name ImageManagementPrep_NoAutoShutdown –Value true`
- Disable domain injection: `Set-ProvServiceConfigurationData –Name DisableDomainInjection –Value true`

Ability to set the Linux license type when creating Linux machine catalogs using PowerShell commands. Using PowerShell commands, you can set the Linux license type when creating Linux machine catalogs. You have two choices for bring-your-own Linux licenses: RHEL_BYOS and SLES_BYOS. The setting defaults to Azure Linux licensing. For more information, see Create a machine catalog using an Azure Resource Manager image.

Support for identifying all Azure resources created by MCS. You can now identify all Azure resources created by MCS such as Image, ID disk, OS disk, NIC, VM, and so on that are associated with a ProvScheme using a tag called `provschemeID`. For more information on the tags that MCS adds to the resources, see Identify resources created by MCS.

Support for adding non-Active Directory users manually. Using the Full Configuration management interface, you can now enter a semicolon-separated list of user names when adding non-Active Directory users for a catalog. Consider the format when adding users that reside in different directories. For example, if the users are in Active Directory, enter the names directly. If not, enter the names in this format: `<identity provider>:<user name>`. Example: `AzureAD:username`. For more information, see Create machine catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

April 2022

New and enhanced features

Home page for the Full Configuration interface. Full Configuration now has a home page, which provides an overview of your Citrix DaaS deployment and workloads along with information that helps you get the most from your subscription. The page comprises the following parts:

- **Service overview**. Provides an overview of your Citrix DaaS deployment and workloads.
- **Recommendations**. Recommends features that are available with your subscription and collects your feedback.
- **What's new**. Shows the latest features.
- **Preview features**. Shows features that are currently in preview.
- **Get started**. Shows steps to guide you through the initial setup.

For more information, see Home page.

Show the progress of catalog creation and updates. Full Configuration now lets you stay up to date on catalog creation and updates. You can gain an overview of the creation and update process, view the history of steps performed, and monitor the progress and running time of the current step. For more information, see Start creating the catalog.

Display available hypervisors and cloud services based on the selected zone. In Full Configuration, when creating hosting connections, you're required to select a zone before selecting a connection type. The Connection type drop-down list displays hypervisors and cloud services available with the zone. Previously, to ensure the Connection type list shows a required hypervisor or cloud service, you had to install its plug-in in every zone. With this new configuration sequence, you can now install the plug-in only in the required zone.

You can also use PowerShell command to get the list of hypervisor plug-in available with the selected zone. For more information, see Create a connection and resources.

Support for non-on-premises-AD-joined users in Full Configuration. A new field, **Select identity type**, is available in the interfaces where you assign users to provisioned desktops or apps, delivery groups, or application groups. With the field, you can now select user accounts from any of the following identity providers to which your Citrix Cloud is connected:

- Active Directory
- Azure Active Directory
- Okta

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Ability to reject invalid custom properties in Google Cloud Platform (GCP) and Azure environments. You can now avoid potential confusion if custom properties set at `New-ProvScheme` and `Set-ProvScheme` do not take effect. If you specify non-existing custom property or properties, you get an error message. For more information, see Important consideration about setting custom properties.

Support for creating Azure Active Directory joined machines. In **Full Configuration**, when you create a catalog, an **Azure Active Directory joined** identity type, is now available in **Machine Identities**. With that identity type, you can use MCS to create machines that are joined to Azure Active Directory. You also have an extra option, **Enroll the machines in Microsoft Intune**, to enroll the machines in Microsoft Intune for management.

For information about creating Azure Active Directory joined catalogs, see Create machine catalogs. For information about requirements and considerations related to Azure Active Directory join, see Azure Active Directory joined.

Support for creating hybrid Azure Active Directory joined machines. In **Full Configuration**, when you create a catalog, a **Hybrid Azure Active Directory joined** identity type, is now available in **Machine Identities**. With that identity type, you can use MCS to create hybrid Azure Active Directory joined machines. Those machines are owned by an organization and signed into with an Active Directory Domain Services account that belongs to that organization.

For information about creating hybrid Azure Active Directory joined catalogs, see Create machine catalogs. For information about requirements and considerations related to hybrid Azure Active Directory join, see Hybrid Azure Active Directory joined.

Azure trusted launch support for snapshots. In addition to images, Azure trusted launch is now available for snapshots as well. If you select a snapshot with trusted launch enabled, using a machine profile is mandatory. Also, you must select a machine profile with trusted launch enabled. For more information, see Microsoft Azure Resource Manager cloud environments.

Export machines. You can now export machines listed on the **Machines** page of the **Machine Catalog Setup** wizard to a CSV file, to be used as a template when adding machines to a catalog in bulk. For more information, see Export machines from a catalog.

Option to access Workspace Environment Management web console. An option, Environment Management (Web), is now available in the menu of the **Manage** tab. The option takes you to the new, web-based Workspace Environment Management console. To access the legacy console, use **Environment Management**. We are in the process of migrating the full set of functionalities

© 1997–2026 Citrix Systems, Inc. All rights reserved.

from the legacy console to the web console. The web console generally responds faster than the legacy console. For more information, see Workspace Environment Management service.

Ability to manage ProvScheme parameters. When you use MCS to create a catalog, you will now get an error if you set the `New-ProvScheme` parameters in unsupported hypervisors during machine catalog creation or update `Set-ProvScheme` parameters after machine catalog is created. For more information, see Create machine catalogs.

Increased resource location limits. Resource location limits for single-session VDAs and multi-session VDAs are now increased to 10000 and 1000 respectively. For more information, see Limits.

Support for restarting non-power managed machines after draining all sessions. Citrix DaaS now allows you to create restart schedules for machines that are not power managed after all sessions are drained from the machines. In the Full Configuration interface, select **Restart all machines after draining all sessions** as the **Restart duration**. For more information, see Create a restart schedule.

Support for upgrading VDA machines (preview). Using the Full Configuration interface, you can now upgrade VDA machines for your Citrix DaaS deployment. You can upgrade them on a per-catalog or a per-machine basis. The feature applies to machines that are not created using MCS (for example, physical machines). For more information, see Upgrade VDAs using the Full Configuration interface.

Machines are not shut down during outages. Citrix DaaS now prevent virtual machines from being shut down by the broker when the zone that the machines are in experiences an outage. The machines automatically become available for connections when the outage ends. You don't have to take any action to make the machines available after the outage.

Session launch diagnostics. Citrix DaaS now supports enhanced session launch failure diagnostics. Use the Citrix Workspace app-generated 32-digit (8-4-4-4-12) Transaction ID from inside Citrix Monitor (that is, Citrix Director service) to narrow down to the exact component and stage where the problem occurred and apply the recommended actions to resolve the issue. For more information, see Session launch diagnostics.

Option to access the Session Recording service. An option, Session Recording, is now available in the menu of the **Manage** tab. The introduction of the Session Recording service provides centralized management of policies, playback, and server configurations. It eases the burden on IT administrators by providing a unified entry point to manage and observe the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

distributed objects across your organization. For more information, see Session Recording service (preview).

Rebranded Citrix Virtual Apps and Desktops service. **Citrix Virtual Apps and Desktops service** has been renamed to **Citrix DaaS**. Learn more about the name change at our announcement on our blog.

The following offerings of Citrix Virtual Apps and Desktops service have been renamed.

- **Citrix Virtual Apps service Advanced** renamed to **Citrix DaaS Advanced**.
- **Citrix Virtual Apps service Premium** renamed to **Citrix DaaS Premium**.
- **Citrix Virtual Desktops™ service** renamed to **Citrix DaaS Advanced Plus**.
- **Citrix Virtual Apps and Desktops service Advanced** renamed to **Citrix DaaS Advanced Plus**.
- **Citrix Virtual Apps and Desktops service Premium** now available as **Citrix DaaS Premium and Citrix DaaS Premium Plus**.
- **Citrix Virtual Apps and Desktops Standard for Azure** renamed to **Citrix DaaS Standard for Azure**.
- **Citrix Virtual Apps and Desktops Standard for Google Cloud** renamed to **Citrix DaaS Standard for Google Cloud**.
- **Citrix Virtual Apps and Desktops Premium for Google Cloud** renamed to **Citrix DaaS Premium for Google Cloud**.

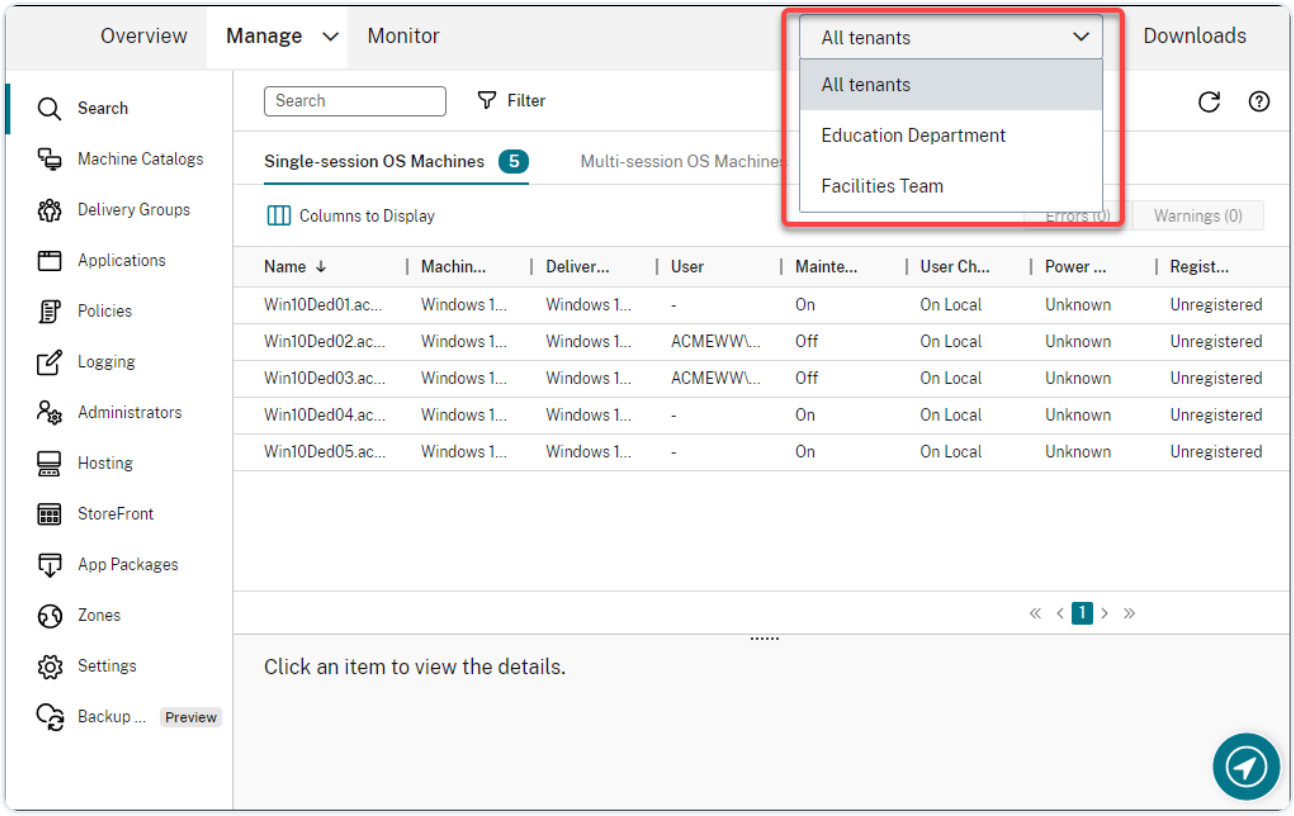
Implementing this transition in our products and their documentation is an ongoing process. Your patience during this transition is appreciated.

- The product UI, in-product content, and the images and instructions in product documentation will be updated in the coming weeks.
- It is possible that some items (such as commands and MSIs) might continue to retain their former names to prevent breaking existing customer scripts.
- Related product documentation and other resources (such as videos and blog posts) that are linked from this product documentation might still contain former names.

NOTE:

The on-premises **Citrix Virtual Apps and Desktops** product name remains the same.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Tenant support in Full Configuration. You can now create configuration partitions within a single Citrix DaaS instance. You achieve that by creating tenant scopes in **Administrators > Scopes** and associating related configuration objects, such as machine catalogs and delivery groups, with those tenants. As a result, administrators with access to a tenant can manage only objects that are associated with the tenant. This feature is useful, for example, if your organization:

- Has different business silos (independent divisions or separate IT management teams) or
- Has multiple on-premises sites and wants to maintain the same setup in a single Citrix DaaS instance.

Also, the Full Configuration interface lets you filter tenant customers by name. By default, the interface displays information about all tenants.

The feature is available for both Citrix Service Providers (CSPs) and non-CSPs. The interface in a CSP environment is essentially the same as that in a non-CSP environment except for the method used to create tenants.

- CSPs onboard tenant customers to Citrix DaaS and then configure administrator access to Citrix DaaS. For more information, see Citrix DaaS for Citrix Service Providers.
- Non-CSPs create tenant customers by first creating scopes and then configuring custom access for respective administrators. For more information, see Create and manage scopes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Updates for Autoscale. We have updated Autoscale with a blade style to bring you a better user experience. The workflows for configuring your settings remain the same. Other updates to Autoscale include:

- Renamed **Restrict Autoscale** to **Autoscaling Tagged Machines** to make it easy to understand.
- Added a new option, **Control when Autoscale starts powering on tagged machines**. The option lets you control when Autoscale starts powering on tagged machines based on the usage of untagged machines.

For more information on autoscaling tagged machines, see Autoscale tagged machines.

License validity checks. The Full Configuration interface now automatically checks the validity of licenses in use by host connections. A host connection is placed into maintenance mode if its license is invalid. As a result, you cannot perform certain operations, such as editing the connection and turning off maintenance mode. A license becomes invalid, for example, when:

- The license has expired. In this case, contact your Citrix sales representative to renew it or to purchase new licenses.
- The license has been deleted from the License Server.

Blade style applied to the Machine Catalogs and Policies nodes. Blade styles are now applied to all nodes of Full Configuration.

Support for updating MCS provisioned machines in Azure environments. `Set-ProvScheme` changes the template (provisioning scheme) and does not affect existing machines. Using Request-ProvVMUpdate command, you can now apply the current provisioning scheme to an existing machine (or set of machines). Currently, the property update supported by this feature is `ServiceOffering`. For more information, see Update provisioned machines to current provisioning scheme state.

March 2022

New and enhanced features

Citrix Virtual Apps and Desktops for Google Cloud available on Google Cloud Marketplace. Citrix Virtual Apps and Desktops Premium for Google Cloud is now available for purchase on Google Cloud Marketplace. Citrix Virtual Apps and Desktops Premium for Google Cloud runs the Citrix Virtual Apps and Desktops service control plane on Google Cloud.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure trusted launch support. Azure trusted launch is now available for the Full Configuration management interface. If you choose to select an image with trusted launch enabled, using a machine profile is mandatory. Also, you must select a machine profile with trusted launch enabled. For more information, see Microsoft Azure Resource Manager cloud environments.

Blade style applied to wizards in three more nodes in Full Configuration. The nodes are **Search**, **Delivery Groups**, and **Applications**.

Image Portability Service (IPS) has been released for general availability. IPS simplifies the management of images across platforms. This feature is useful for managing images between an on-premises Resource Location and the public cloud. The Citrix Virtual Apps and Desktops REST APIs can be used to automate the administration of resources within a Citrix Virtual Apps and Desktops site. For more information, see Migrate workloads to public cloud.

February 2022

New and enhanced features

Azure permissions. There are two sets of permissions required for security requirements and to minimize risk.

- Minimum permissions: This set of permissions gives better security control. However, new features that require additional permissions will fail because of using minimum permissions.
- General permissions: This set of permissions does not block you from getting new enhancement benefit.

For more information, see About Azure permissions.

Support for using VM's temporary disk to host the write-back cache disk in Azure environments. We added an option, **Use non-persistent write-back cache disk**, to the **Machine Catalog Setup > Disk Settings** page of the **Manage > Full Configuration** interface. Select that option if you do not want the write-back cache disk to persist for the provisioned VMs. With the option selected, we use the VM's temporary disk to host the write-back cache disk if the temporary disk has sufficient space. Doing that reduces your costs. For more information, see Microsoft Azure Resource Manager cloud environments.

Updates to AWS host connection default settings. The AWS host connection default setting values are updated to higher values and most likely same for all AWS cloud platform setup. This helps to create host connections in AWS cloud environments, without evaluating and configuring

© 1997–2026 Citrix Systems, Inc. All rights reserved.

the default setting values according to individual setup. For more information, see Host connection default values.

Added support for different storage tiers in GCP environments. You can now provide the following custom properties in the GCP environments to set the storage type of the disks attached to the newly created VM:

- StorageType
- IdentityDiskStorageType
- WBCDiskStorageType

For more information, see Citrix Virtual Apps and Desktops Service SDK.

Change certain VM settings after creating Azure VM catalogs. Using the Full Configuration management interface, you can now change the following settings after creating a catalog:

- Machine size
- Availability zones
- Machine profile
- Windows licenses

To do that, on the **Machine Catalogs** node, select the catalog and then select **Edit Machine Catalog** in the action bar. For more information, see Edit a catalog.

Support for storing Azure ephemeral OS disk either on the cache disk or temporary disk. Citrix Virtual Apps and Desktops service now allows you to store the Azure ephemeral OS disk either on cache disk or temporary disk for an Azure-enabled virtual machine. This functionality is useful for Azure environments that require a higher performant SSD disk over a standard HDD disk. For more information, see Microsoft Azure Resource Manager cloud environments.

Support for Nutanix clusters on AWS. Citrix Virtual Apps and Desktops service supports Nutanix Clusters on AWS. Nutanix Clusters simplifies how applications are run on private or multiple public clouds. For more information, see Nutanix clusters on AWS.

Support for VMware cloud on Amazon Web Services (AWS). VMware cloud on Amazon Web Services (AWS) enables you to migrate VMware based on-premises Citrix workloads to AWS cloud and your core Citrix Virtual Apps and Desktops environment to Citrix Virtual Apps and Desktops service. For more information, see VMware cloud on Amazon Web Services (AWS).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for configuring write-back cache disk for machines running on Google Cloud Platform (GCP). In the Full Configuration management interface, when provisioning machines on GCP, you can now configure the following write-back cache disk settings:

- Disk size
- Memory allocated to cache
- Disk storage type
- Disk persistence

For more information, see Create a machine catalog in the Google Cloud Platform virtualization environments article.

January 2022

New and enhanced features

Support for Nutanix clusters on AWS. Citrix Virtual Apps and Desktops service now supports Nutanix clusters on AWS. This support provides the same functionality as a Nutanix on-premises cluster. Only a single cluster is supported, *Prism Element*. For more information, see Nutanix virtualization environments.

New features available in Cloud Health Check. Cloud Health Check has been updated to a new version with features including:

- **Automatic fix.** Cloud Health Check now supports automatically detecting and fixing certain issues identified on machines where it is running. There is now a results report to show you what specific actions were taken. For more information, see Automatic fix.
- **Command line support.** Cloud Health Check can now be run from the command line. For more information, see Running Cloud Health Check on the command line.
- **Citrix Universal™ Injection Driver status.** Cloud Health Check now shows the Citrix UVI driver status and has a related event log check for Citrix UVI drivers.
- **Session launch registry check.** Cloud Health check now checks for session launch registry settings.
- **Updates to check report.** For checked items that have several check points, the final check report now lists all the checks that have been verified to show what actions were performed during the health check.

For more information, see Cloud Health Check.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Troubleshoot VDA registration and session launch issues using Full Configuration. Using the Full Configuration management interface, you can now run checks that gauge the health of VDAs. VDA health checks identify possible causes for common VDA registration and session launch issues. You can run health checks individually and in batches. For more information, see VDA health checks.

Ability to specify the Azure secret expiration date for existing connections. Using the Full Configuration management interface, you can now specify the date after which the application secret expires. For guidance on how to view the expiration date of the secret, see Microsoft Azure Resource Manager cloud environments. When using this feature, consider the following differences:

- For service principals created manually in Azure, you can directly edit the expiration date on the **Edit Connection > Connection Properties** page.
- For first-time edits of the expiration date for service principals created through Full Configuration on your behalf, go to **Edit Connection > Edit settings > Use existing**. You can make subsequent edits on the **Edit Connection > Connection Properties** page.

A button to add administrators. We added a button, **Add Administrator**, to the **Full Configuration > Administrators > Administrators** tab. The button offers a quick way to go to **Identity and Access Management > Administrators**, where you can add (invite) administrators. For more information, see Add an administrator.

New look and feel of wizards in Full Configuration. We have updated the wizards in the following nodes with a new style, including colors, fonts, and other formatting changes, to bring you a better user experience: **Administrators**, **Hosting**, **StoreFront**, **App Packages**, **Zones**, and **Settings**. The new wizards appear in blade views with wider viewports, enabling more content to display. The workflows for configuring your settings remain the same.

Support for retaining system disk when MCS I/O is enabled for machines running on Google Cloud Platform (GCP). In the Full Configuration management interface, when provisioning machines on GCP, you can now retain system disk during power cycles when MCS storage optimization (MCS I/O) is enabled. For more information, see Enabling MCS storage optimization updates.

Support for direct upload or download from EBS on Amazon Web Services (AWS). AWS now provides API to allow direct creation of EBS volume with desired content. You can now use the API to eliminate volume worker requirement for catalog creation and VM addition. For information on AWS permissions required for this functionality, see Amazon Web Services cloud environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Ability to identify Amazon Web Services (AWS) resources created by MCS. We added a new tag named `CitrixProvisioningSchemeID` to identify AWS resources created by MCS. For more information, see Identify resources created by MCS.

Ability to configure access to Manage and Monitor. The Full Configuration management interface now provides you with additional options to control whether to grant custom roles access to **Manage** and **Monitor**. For more information, see Create and manage roles.

December 2021

New and enhanced features

Support for Google Cloud VMware Engine. The platform now enables you to migrate VMware based on-premises Citrix workloads to Google Cloud and your core Citrix Virtual Apps and Desktops environment to Citrix Virtual Apps and Desktops service. For more information, see Google Cloud Platform (GCP) VMware Engine support.

Ability to specify what account names start with when specifying a naming scheme. This release introduces an option to the **Machine Catalog Setup > Machine Identities** page of the Full Configuration management interface. The option lets you specify numbers or letters the account names start with, giving you more control over how machine accounts are named during catalog creation. For more information, see Machine identities.

Support for creating Nutanix AHV XI and Nutanix AHV Prism Central (PC) connections. In the Full Configuration management interface, you can now create Nutanix AHV XI and Nutanix AHV PC connections. For more information, see Nutanix virtualization environments.

Support for selecting the storage type for OS disks when provisioning VMs on GCP. In the Full Configuration management interface, when provisioning VMs on GCP, you can now select the storage type for the OS disk. Available storage options on the **Machine Catalog Setup > Storage** page include **Standard persistent disk**, **Balanced persistent disk**, and **SSD persistent disk**. For more information, see Create a machine catalog.

Full Configuration management interface now supports Azure ephemeral disk. Previously, PowerShell was your only choice to create machines that used ephemeral OS disks. We now add an option, **Azure ephemeral OS disk**, to the **Machine Catalog Setup > Storage and License Types** page. Select the option if you want to use the VM's local disk to host the operating system disk. For more information, see Create a machine catalog using an Azure Resource Manager image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Protect Machine Creation Services (MCS) managed resources from accidental deletion. You can now protect MCS managed resources on the Google Cloud Platform (GCP) by applying GCP's `deletionProtection` flag enabled for the VMs. Using the `compute.instances.setDeletionProtection` permission or the IAM Compute Admin role, you can reset the flag to allow the resource to be deleted. This functionality is applicable for both persistent and non-persistent catalogs. For more information, see Protect accidental machine deletion.

November 2021

New and enhanced features

Annotate an image when updating machines. In the Full Configuration management interface, you can now annotate an image by adding a note for it when updating an MCS-created catalog. Each time you update the catalog, a note-related entry is created whether you add a note. If you update the catalog without adding a note, the entry appears as null (-). To view note history for the image, select the catalog, click **Template Properties** in the lower pane, and then click **View note history**. For more information, see Update a catalog.

Multi-type licensing support. The Full Configuration management interface now supports multi-type licensing, letting you specify which license entitlement you want your site (your deployment of a Citrix Virtual Apps and Desktops service product) or a delivery group to use.

- At the site level, you determine which license to use site wide when users launch an app or a desktop on their devices. The selected license applies to all delivery groups, except those configured with a different license.
- At a delivery group level, you determine which license you want the delivery group to use, enjoying the multi-type licensing flexibility and benefits.

For more information, see Licenses.

Support for displaying Azure Marketplace purchase plan information. In the Full Configuration management interface, when creating a machine catalog, you can now view purchase plan information for master images originated from Azure Marketplace images.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

October 2021

New and enhanced features

Ability to update persistent MCS catalogs. We introduced the **Update Machines** option for persistent MCS catalogs in the Full Configuration management interface. The option lets you manage the image or template the catalog uses. When updating a persistent catalog, consider the following: Only machines you add to the catalog later are created using the new image or template. We do not roll out the update to existing machines in the catalog. For more information, see Update a catalog.

Option to provision VMs on an Azure dedicated host. We added an option, **Use a host group**, to the **Machine Catalog Setup > Master Image** page of the Full Configuration management interface. The option lets you specify which host group you want to use when provisioning VMs in Azure environments. For more information, see Create a machine catalog using an Azure Resource Manager image.

Improve performance by preserving a provisioned VM when power cycling. We added a setting, **Retain VMs across power cycles**, to the **Machine Catalog Setup > Disk Settings** page of the Full Configuration management interface. The setting lets you preserve a provisioned VM when power cycling in Azure environments. For more information, see MCS storage optimization. Alternatively, you can configure the feature by using PowerShell. For more information, see Preserving a provisioned virtual machine when power cycling.

Bind a machine catalog to a Workspace Environment Management configuration set. When creating a machine catalog, you can now bind it to a Workspace Environment Management configuration set. Doing so lets you use Workspace Environment Management service to deliver the best possible workspace experience to your users. You can also choose to bind the catalog after you create the catalog. For more information, see Create machine catalogs and Manage machine catalogs.

September 2021

New and enhanced features

Add informative description for image updates. You can now add informative descriptions about changes related to image updates for machine catalogs. This functionality is useful for administrators who want to add descriptive labels when updating an image used by a catalog, for example, *Office 365 installed*. Using PowerShell commands, you can create and view these messages. For details, see Adding descriptions to an image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure VMware Solution (AVS) integration. Citrix Virtual Apps and Desktops service supports AVS, the Azure VMware Solution. AVS provides cloud infrastructure containing vSphere clusters created by Azure. Leverage the Citrix Virtual Apps and Desktops service to use AVS for provisioning your VDA workload in the same way that you would using vSphere in on-premises environments. For more information, see Azure VMware Solution Integration.

Same resource group for multiple catalogs. You can now use the same resource group for updating and creating catalogs in Citrix Virtual Apps and Desktops service. This process:

- applies to any resource group that contains one or more machine catalogs.
- supports resource groups that are not created by Machine Creation Services.
- creates the VM and associated resources.
- deletes resources in the resource group when the VM or the catalog is removed.

For more information, see Azure Resource groups.

Retrieve information for Azure VMs, snapshots, OS disk, and gallery image definition. You can display information for an Azure VM, OS disk, snapshot, and gallery image definition. This information is displayed for resources on the master image when a machine catalog is assigned. Use this functionality to view and select either a Linux or Windows image. For more information, see Retrieve information for Azure VMs, snapshots, OS disk, and gallery image definition.

New update for Automated Configuration. Automated Configuration has been updated to a new version with features including:

- Machines Creation Services (MCS) support - Automated Configuration now supports MCS catalogs. For more information, see Understanding migrating Machine Creation Services provisioned catalogs.

Other updates to Automated Configuration include:

- Enhanced Zone support by pre-populating the ZoneMapping.yml file with the names of on-premises zones during export and cloud Resource Locations when backing up.
- StoreFront has been made a top level manageable component. Prior to this, StoreFront was managed as part of Delivery Groups. This separation better facilitates site merging.
- Changed `AddMachinesOnly` to `MergeMachines` to match the pattern for current and new merge options.
- Added the use of the SecurityClient.csv file to import the ClientId and Secret when creating and updating the CustomerInfo.yml when using the support cmdlets.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Added User Zone Preferences migration.
- Fixed support for the Japanese Control Plane.
- Other fixes and improvements.

Download Automated Configuration at Citrix Downloads. For more information on Automated Configuration, see Migrate configuration to Citrix Cloud.

More scheduling options available with restart schedules. The Full Configuration management interface now provides you with additional options to control when scheduled restarts occur. In addition to the daily recurring restart schedules, you can now set weekly and monthly recurrence patterns. For more information, see Create a restart schedule.

Preserve custom columns that degrade performance. Previously, on the **Search** node of the Full Configuration management interface, custom columns that degraded performance disappeared after you refreshed the browser window or signed out of the console and then signed in. You can now control whether to preserve those custom columns. For more information, see Use Search in the Full Configuration management interface.

Use the Automated Configuration tool to back up and restore. We added a node, **Backup and Restore**, to the Full Configuration management interface. That node aggregates all resources related to the Automated Configuration tool, including information about:

- Scheduling automated backups of your Citrix Virtual Apps and Desktops configuration using a single command
- Restoring from a previous backup if necessary
- Performing backups and restores granularly
- Other use cases supported

For more information, see the Automated Configuration documentation.

Support for non-domain-joined catalogs. We added an identity type, **Non-domain-joined**, to the **Machine Catalog Setup > Machine Identities** page of the Full Configuration management interface. With that identity type, you can use MCS to create machines that are not joined to any domain. For more information, see Create machine catalogs.

Support for using a machine profile. We added an option, **Use a machine profile**, to the **Machine Catalog Setup > Master Image** page of the Full Configuration management interface. The option lets you specify which machine profile you want the VMs to inherit configurations from

© 1997–2026 Citrix Systems, Inc. All rights reserved.

when creating VMs in Azure environments. The VMs in the catalog can then inherit configurations from the selected machine profile. Examples of configurations include:

- Accelerated networking
- Boot diagnostics
- Host disk caching (relating to OS and MCSIO disks)
- Machine size (unless otherwise specified)
- Tags placed on the VM

For more information, see Create a machine catalog using an Azure Resource Manager image.

Support for Windows Server 2022. Requires minimum VDA 2106.

August 2021

New and enhanced features

Extend the number of sortable items from 500 to 5,000. On the **Search** node of the Full Configuration management interface, you can now sort up to 5,000 items by any column header. When the number of items exceeds 5,000, use filters to reduce the number of items to 5,000 or fewer to enable sorting. For more information, see Use Search in the Full Configuration management interface.

Support for additional Azure storage types. You can now select different storage types for virtual machines in Azure environments using MCS. For details, see Storage types.

Support for selecting the storage type for write-back cache disks. In the Full Configuration management interface, when creating an MCS catalog, you can now select the storage type for the write-back cache disk. Available storage types include: Premium SSD, Standard SSD, and Standard HDD. For more information, see Create machine catalogs.

Shut down suspended machines. In the **Manage > Full Configuration** interface, we added an option, **When no reconnection in (minutes)**, to the **Load-based Settings** page of the Manage Autoscale user interface for single-session OS delivery groups. The option becomes available after you select **Suspend**, letting you specify when to shut down the suspended machines. Suspended machines remain available to disconnected users when they reconnect but are not available for new users. Shutting the machines down makes them available again to handle all workloads. For more information, see Autoscale.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Extended support for using CSV files to bulk add machines to a catalog. In the **Manage > Full Configuration** interface, you can now use a CSV file to bulk add machines already in your data center to a catalog where those machines are power managed. For more information, see Create machine catalogs and Manage machine catalogs.

July 2021

New and enhanced features

Configuration logging. The **Logging** user interface has changed in **Manage > Full Configuration**. The following three tabs comprise the interface:

- **Events** (formerly, configuration logging). This tab lets you track configuration changes and administrative activities.
- **Tasks**. This tab lets you view tasks related to machine catalog operations.
- **APIs**. This tab lets you view REST API requests made during a certain time period.

For more information, see Configuration logging.

Autoscale now provides you with dynamic session timeout options. You can configure disconnected and idle session timeouts for your peak and off-peak usage times to achieve faster machine draining and cost savings. For more information, see Dynamic session timeouts.

Support for Google Cloud Platform (GCP) Customer Managed Encryption Keys (CMEK). You can now use Google's CMEK with MCS catalogs. CMEK provides greater control over keys used to encrypt data within a Google Cloud project. For more information, see Customer-managed encryption keys (CMEK). To configure this feature, see Using Customer Managed Encryption Keys (CMEK). The feature is available on the **Machine Catalog Setup > Disk Settings** page of the **Manage > Full Configuration** interface.

NOTE:

This feature is available as a preview.

Updates to the Manage tab. We have updated options in the menu of the **Manage** tab:

- **Full Configuration**: Previously, this option took you to the legacy console. It now takes you to the new, web-based console (Web Studio). The web-based console has full parity with the legacy console and includes several enhancements. We recommend that you start using it now.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Legacy Configuration**: This option takes you to the legacy console, which is scheduled for removal in September 2021. After that, **Full Configuration** will be the only interface that offers access to the full range of configuration and management actions.

Web Studio now supports choosing a power management connection for a Remote PC Access catalog. Previously, you were able to use Studio to create a Wake on LAN host connection to your resource location (selecting **Remote PC Wake on LAN** as the connection type). However, PowerShell was your only choice to associate that connection with a Remote PC Access catalog. You can now use Studio to achieve that. For more information, see Configure Wake on LAN in the Full Configuration interface.

June 2021

New and enhanced features

Access Azure Shared Image Gallery images. When creating a machine catalog, you can now access images from the Azure Shared Image Gallery on the Master Image screen. For details, see Access images from Azure Shared Image Gallery.

Support shielded virtual machines on Google Cloud Platform (GCP). You can provision shielded virtual machines on GCP. A shielded virtual machine is hardened by a set of security controls that provide verifiable integrity of your Compute Engine instances, using advanced platform security capabilities like secure boot, a virtual trusted platform module, UEFI firmware and integrity monitoring. For more information, see Shield VMs.

Enforce either HTTPS or HTTP. Use registry settings to enforce HTTPS or HTTP traffic through the XML service.

Always use standard SSD for an identity disk to reduce cost in Azure environments. Machine catalogs use the standard SSD storage type for identity disks. Azure standard SSDs are a cost-effective storage option optimized for workloads that need consistent performance at lower IOPS levels. For more information about storage types, see Azure Resource Manager master image.

NOTE:

For more information about Azure managed disk pricing, see Managed Disks pricing.

New feature available in Web Studio. The following features are now available in the web-based console:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Studio now supports authenticating to Azure to create a service principal**. You can now establish a host connection to Azure by authenticating to Azure to create a service principal. This support eliminates the need to manually create a service principal in your Azure subscription before creating a connection in Studio. For more information, see Microsoft Azure Resource Manager virtualization environments.
- **Studio now supports cloning of existing machine catalogs**. This feature enables you to clone an existing machine catalog to use as a template for a new one, eliminating the need to create a similar catalog from scratch. When cloning a catalog, you cannot change settings associated with operating system and machine management. The cloned catalog inherits those settings from the original. For more information, see Clone a catalog.
- **A new node called Settings now available in the Studio navigation pane**. The **Settings** node lets you configure settings that apply to the entire site (your deployment of a Citrix Virtual Apps and Desktops service product). The following settings are available:
  - **Load balance multi-session catalogs**. Select the load balancing option that meets your needs. This setting applies to all your catalogs. Previously, you accessed this feature by clicking the gear icon in the upper right corner of the console. For more information, see Load balance machines.
- **Enhanced search experience in Studio**. This release enhances your Studio search experience. When you use filters to perform an advanced search, the Add filters window appears in the foreground, leaving the background view unchanged. For more information, see Use Search in the Full Configuration management interface.
- **Ability to suspend and resume Google Cloud VMs in MCS**. You can now suspend and resume Google Cloud VMs in MCS as you would any VM. For details, see Manage delivery groups. To enable this ability, set the `compute.instances.suspend` and `compute.instances.resume` permissions in the Google Cloud service account. The Compute Admin role comes with these permissions.

  In Citrix Virtual Apps and Desktops, you can also use the `New-BrokerHostingPowerAction` PowerShell command to suspend and resume the VMs. For details, see New-Brokerhostingpoweraction.

  Google Cloud enforces some limitations on the type and configuration of instances that can be suspended. For additional information, refer to Suspending and resuming an instance on the Google Cloud site.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

May 2021

New and enhanced features

Session reconnection after disconnect from machine in maintenance mode. Previously, when pooled (random) single-session desktop (VDI) users were disconnected from a machine in maintenance mode, session reconnection was not allowed to any machine in the pool. Multi-session and static single-session machines always allowed session reconnection in that circumstance.

Now, using PowerShell, you can control at the delivery group level whether session reconnection is allowed after a disconnect occurs on a machine in maintenance mode. This applies to all VDAs in the group (single-session and multi-session).

For details, see Control session reconnection when disconnected from machine in maintenance mode.

Application probing and Desktop probing support in all Citrix Virtual Apps and Desktops Service editions. In addition to the existing **Premium** edition support, Application probing and Desktop probing are now available in **Citrix Virtual Apps Advanced Service** and **Citrix Virtual Apps and Desktops Advanced Service** editions.

New feature available in Web Studio. The following feature is now available in the web-based console:

- **Studio now supports selecting Azure Availability Zones**. Previously, PowerShell was your only choice to provision machines into a specific Availability Zone in Azure environments. When using Studio to create a machine catalog, you can now select one or more Availability Zones into which you want to provision machines. If no zones are specified, Machine Creation Services (MCS) lets Azure place the machines within the region. If more than one zone is specified, MCS randomly distributes the machines across them. For more information, see Provision machines into specified availability zones.

Azure emphemeral disk. Citrix Virtual Apps and Desktops service supports Azure ephemeral disk. An ephemeral disk allows you to repurpose the cache disk to store the OS disk for an Azure-enabled virtual machine. This functionality is useful for Azure environments that require a higher performant SSD disk over a standard HDD disk.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Persistent catalogs do not support ephemeral OS disks. Also, when using this feature, consider that the extra performant disk incurs an extra cost. It's beneficial to reuse the cache disk to store the OS disk instead of paying for an extra managed disk.

Ephemeral OS disks require that your provisioning scheme use managed disks and a Shared Image Gallery. For more information, see Azure ephemeral disks.

Improved performance for MCS managed VDAs on Azure. The Citrix Virtual Apps and Desktops service improves performance for VDAs managed with Machine Creation Services (MCS) on Azure. This enhancement changes the default values for *Absolute Simultaneous actions* for the hosting connection to 500, and *Maximum new actions per minute* for the hosting connection to 2,000. No manual configuration tasks are required to take advantage of this enhancement. For details, see Azure throttling.

New features available in Cloud Health Check. Cloud Health Check has been updated to a new version with features including:

- **Automatically discovering VDA machines**. Cloud Health Check can now automatically discover and retrieve VDAs from your Citrix Virtual Apps and Desktops service deployments. For more information, see Retrieve VDA machines.
- **Scheduling health checks**. Cloud Health Check now lets you set up schedules for performing periodic health checks. For more information, see Cloud Health Check scheduler.
- **Cloud Health Check version information**. You can now check which version of Cloud Health Check you are using. To view version information, click the gear icon in the upper right corner of the Cloud Health Check main window.
- **Automatic fix**. Cloud Health Check now supports automatically detecting and fixing certain issues identified on machines where it is running. For more information, see Automatic fix.

  NOTE:

  Automatic fix is available as a preview.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

April 2021

New and enhanced features

Retreive dynamic instances using AWS API. The Citrix Virtual Apps and Desktops service now queries AWS to retrieve instance types dynamically. This functionality removes the need to create a custom `InstanceTypes.xml` file for those customers wishing to use machine sizes beyond those defined in Citrix Virtual Apps and Desktops service. This information was previously supplied by the `InstanceTypes.xml` file. To facilitate this dynamic access to the available AWS instance types, users must update the permissions on their service principals to include `ec2:DescribeInstanceTypes` permissions. To support backward compatibility for customers who choose not to update their service principal permissions, the AWS instance types listed in the `InstanceTypes.xml` are used. This process generates a warning message to the MCS CDF log.

NOTE:

Citrix Studio does not display the warning message contained in the CDF log.

For more information about permissions, see Defining IAM permissions and About AWS permissions.

New feature available in Web Studio. The following feature is now available in the web-based console:

- **Studio now displays date and time of your time zone**. Previously, Studio displayed only date and time based on the system clock and time zone. Studio now supports displaying date and time local to your time zone when you hover the mouse pointer over an event item. The time is expressed in UTC.

MCS I/O support for Azure VMs without temporary storage. MCS I/O now supports machine catalog creation for VMs that do not have temporary disks or attached storage. With this support:

- The snapshot (managed disk) is retrieved from the source VM *without* temporary storage. The VMs in the machine catalog have no temporary storage.
- The snapshot (managed disk) is retrieved from the source VM *with* temporary storage. The VMs in the machine catalog have temporary storage.

For more information, see Machine Creation Services (MCS) storage optimization

New feature available in Web Studio. The following feature is now available in the web-based console:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Force log off**. Autoscale now lets you log off sessions existing on machines by force when the established grace period is reached, making the machine eligible for shutdown. Doing that enables Autoscale to power off machines much faster, thus reducing costs. You can send notifications to users before they are logged off. For more information, see Autoscale.

New update for Automated Configuration. Automated Configuration has been updated to a new version with features including:

- **Merging multiple sites** – you can merge multiple sites into a single site while avoiding name collisions using prefixes and suffixes. For more information, see Merging multiple sites into a single site.
- **Site activation** – you can select whether your on-premises or cloud deployment controls resources such as reboot schedules and power schemes. For more information, see Activating sites.

Other updates to Automated Configuration include:

- The ability to migrate administrator roles and scopes.
- A `Quiet` parameter for select cmdlets to suppress console logging.
- A `SecurityFileFolder` parameter to allow placing of the CvadAcSecurity.yml file in a secure network file share that requires authentication.
- The ability to filter by machine name in machine catalogs and delivery groups.
- Improvements to component selection parameters to use the switch parameter method, eliminating the need to add a `$true` after the component name.
- A new cmdlet (`New-CvadAcZipInfoForSupport`) to zip all your log files to send to Citrix for support.

Download Automated Configuration at Citrix Downloads. For more information on Automated Configuration, see Migrating to cloud.

Preserve GCP instances across power cycles. Non-persistent Google Cloud Platform (GCP) instances are no longer deleted when powering off. Instead, the instances are preserved across power cycles. When a non-persistent instance is powered off, the OS disk is detached and deleted. When the instance is powered on, the OS disk is recreated from the base disk, and attached to the existing instance.

Support for Azure Gen2 images. You can now provision a Gen2 VM catalog by using either a Gen2 snapshot or a Gen 2 managed disk to improve boot time performance. For more information,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

see Create machine catalogs. The following operating systems are supported for Azure Gen2 images:

- Windows Server 2019, 2016, 2012 and 2012 R2
- Windows 10

NOTE:

Creating a Gen2 machine catalog using a Gen1 snapshot, or managed disk, is not supported. Similarly, creating a Gen1 machine catalog using a Gen2 snapshot, or managed disk, is also not supported. For more information, see Support for generation 2 VMs on Azure.

Disabling table storage accounts. Machine Creation Services (MCS) no longer creates table storage accounts for catalogs that use managed disks when provisioning VDAs on Azure. For more information, see Azure table storage.

Eliminating locks in storage accounts. When creating a catalog in Azure using a managed disk, a storage account is no longer created. Storage accounts created for existing catalogs remain unchanged. This change is applicable for managed disks only. For unmanaged disks, there is no change in the existing behavior. Machine Creation Services (MCS) continues creating storage accounts and locks.

New features available in Web Studio. The following features are now available in the web-based console:

- **Use a customer-managed encryption key to encrypt data on machines**. Studio now adds a setting called **Customer-managed encryption key** to the **Machine Catalog Setup > Disk Settings** page. The setting lets you choose whether to encrypt data on the machines to be provisioned in the catalog. For more information, see Customer-managed encryption key.
- **Studio now supports restricting Autoscale to tagged machines**. Previously, you had to use PowerShell to restrict Autoscale to certain machines in a delivery group. You can now also use Studio. For more information, see Restrict Autoscale to certain machines in a delivery group.

March 2021

New and enhanced features

Azure dedicated hosts. Azure dedicated hosts allow you to provision virtual machines on hardware dedicated to a single customer. While using a dedicated host, Azure ensures that your virtual machines would be the only machines running on that host. This provides more control and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

visibility to customers thereby ensuring they meet their regulatory or internal security requirements. A pre-configured Azure host group, in the region of the hosting unit, is required when using the `HostGroupId` parameter. Also, Azure auto-placement is required. For more information, see Azure dedicated hosts.

TIP:

When using Azure dedicated hosts, selecting the **Azure Availability Zone** has no effect. The virtual machine is placed by the Azure auto-placement process.

Support for Azure server side encryption. Citrix Virtual Apps and Desktops service supports customer-managed encryption keys for Azure managed disks. With this support you can manage your organizational and compliance requirements by encrypting the managed disks of your machine catalog using your own encryption key. For more information, see Azure server side encryption.

Provision machines into specified availability zones on Azure. You can now provision machines into a specific availability zone in Azure environments. With this functionality:

- You can specify one or multiple Availability Zones on Azure. Machines are nominally equally distributed across all provided zones if more than one zone is provided.
- The virtual machine and the corresponding disk are placed in the specified zone (or zones).
- You can browse Availability Zones for a given service offering or region. Valid Availability Zones are displayed using PowerShell commands. View service offering inventory items using `Get-Item`.

For more information, see Provision machines into specified availability zones on Azure.

New features available in Web Studio. The following features are now available in the web-based console:

- **Studio now supports associating apps with custom icons**. Previously, you had to use PowerShell to add custom icons for use with published applications. You can now also use Studio to do that. For more information, see Manage application groups.
- **Studio now supports applying tags to machine catalogs**. Previously, you might use Studio to create or delete tags for use with a catalog. However, you had to use PowerShell to apply tags to the catalog. You can now also use Studio to apply or remove a tag to or from a catalog as you do with delivery groups. For more information, see Apply tags to machine catalogs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Studio now supports switching between "horizontal load balancing" and "vertical load balancing" modes**. Previously, PowerShell was your only choice to switch between horizontal and vertical load balancing modes. Studio now gives you more flexibility to control how to load balance multi-session OS machines. For more information, see Load balance machines.
- **Studio now supports including machines in maintenance mode in restart schedules**. Previously, PowerShell was your only choice to configure scheduled restarts for machines in maintenance mode. You can now also use Studio to control whether to include those machines in a restart schedule. For more information, see Create a restart schedule.
- **Studio now supports configuring Wake on LAN for Remote PC Access**. Previously, you had to use PowerShell to configure Wake on LAN for Remote PC Access. You can now also use Studio to configure the feature. For more information, see Configure Wake on LAN.
- **Studio now supports applying AWS instance properties and tagging operational resources**. When creating a catalog to provision machines in AWS by using MCS, you can specify whether to apply the IAM role and tag properties to those machines. You can also specify whether to apply machine tags to operational resources. You have the following two options:

  - **Apply machine template properties to virtual machines**
  - **Apply machine tags to operational resources**

  For more information, see Applying AWS instance properties and tagging operational resources.

Azure Shared Image Gallery. Citrix Virtual Apps and Desktops service supports Azure Shared Image Gallery as a published image repository for MCS provisioned machines in Azure. Administrators have the option of storing an image in the gallery to accelerate the creation and hydration of OS disks. This process improves the boot and application launch times for non-persistent VMs. For details about this feature, see Azure shared image gallery.

NOTE:

Shared Image Gallery functionality is compatible with managed disks. It is not available for legacy machine catalogs.

Storage buckets created in same Google Cloud Platform region as the machine catalog. In previous releases, MCS created temporary storage buckets during provisioning as part of the disk upload process. These buckets spanned multiple regions, which Google defines as a large geographic area containing two or more geographic places. These temporary buckets resided in

© 1997–2026 Citrix Systems, Inc. All rights reserved.

the United States geographic location, no matter where the catalog was provisioned. MCS now creates storage buckets in the same region where you provision your catalogs. Storage buckets are no longer temporary; they remain in your Google Cloud Platform project after you complete the provisioning process. Future provisioning operations use the existing storage bucket, if one exists in that region. A new storage bucket is created if one does not exist in the specified region.

February 2021

New and enhanced features

Support for Azure Gen2 images. You can now provision managed disks using Gen2 VMs in Azure environments to improve boot time performance. The following operating systems are supported:

- Windows Server 2019, 2016, 2012 and 2012 R2
- Windows 10

NOTE:

With this support, only a subset of VMs is supported. For example, some VMs can be both Gen1 and Gen2 types, while other VMs can only be Gen1. For more information, see Support for generation 2 VMs on Azure.

Machine restart schedules. Citrix Studio now adds an option called **Restart all machines after draining sessions** to the **Restart duration** menu. The option lets you choose whether to restart all machines after draining all sessions. When the restart time is reached, machines are put into the drain state and restarted when all sessions are logged off. For more information, see Create a restart schedule.

New features available in Web Studio. The following features are now available in the web-based console:

- **Studio now supports using CSV files to bulk add machines to a catalog**. This feature enables you to use a CSV file to:
  - Bulk add machines to a multi-session or single-session OS catalog where machines are not power managed through Studio.
  - Bulk add machines to a Remote PC Access catalog. Previously, you had to choose OUs to bulk add machines to a Remote PC Access catalog. Doing that, however, is not easy in scenarios with OU structure restrictions. The feature gives you more flexibility to bulk add

© 1997–2026 Citrix Systems, Inc. All rights reserved.

machines. You can add only machines (for use with user auto-assignments) or add machines along with user assignments.

For more information, see Create machine catalogs and Manage machine catalogs.

- **Extended support for Citrix Managed Azure.** Citrix Managed Azure is now available in the following Citrix Virtual Apps and Desktops service editions: Standard for Azure, Advanced, Premium, and Workspace Premium Plus.
- **Support for placing master images in Azure Shared Image Gallery**. Studio now provides you an option to place master images in Azure Shared Image Gallery (SIG). SIG is a repository for managing and sharing images. It lets you make your images available throughout your organization. We recommend that you store a master image in SIG when creating large non-persistent machine catalogs because doing that enables faster reset of VDA OS disks. For more information, see Microsoft Azure Resource Manager virtualization environments.
- **Retain system disk for MCS machine catalogs in Azure**. Studio now lets you control whether to retain system disks for VDAs during power cycles. Ordinarily, the system disk is deleted on shutdown and recreated on startup. This ensures that the disk is always in a clean state but results in longer VM restart times. If system writes are redirected to the cache and written back to the cache disk, the system disk remains unchanged. To avoid unnecessary disk recreation, use the **Retain system disk during power cycles** option, available on the **Machine Catalog Setup > Disk Settings** page. Enabling the option reduces VM restart times but increases your storage costs. The option can be useful in scenarios where an environment contains workloads with sensitive restart times. For more information, see MCS storage optimization.
- **Studio now supports creating MCS machine catalogs with persistent write-back cache disk**. Previously, PowerShell was your only choice to create a catalog with persistent write-back cache disk. You can now use Studio to control whether the write-back cache disk persists for the provisioned VMs in Azure when you are creating a catalog. If disabled, the write-back cache disk is deleted during each power cycle to save storage costs, causing any data redirected to the disk to be lost. To retain the data, enable the **Use persistent write-back cache disk** option, available on the **Machine Catalog Setup > Disk Settings** page. For more information, see MCS storage optimization.

Support for App protection for Citrix Virtual Apps and Desktops Service with StoreFront. For more information, see the App protection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

January 2021

New features available in Web Studio. The following features are now available in the web-based console:

- **Studio now supports associating apps with custom icons**. Previously, you had to use PowerShell to add custom icons for use with published applications. You can now also use Studio to do that. For more information, see Manage application groups.
- **Studio now supports applying tags to machine catalogs**. Previously, you might use Studio to create or delete tags for use with a catalog. However, you had to use PowerShell to apply tags to the catalog. You can now also use Studio to apply or remove a tag to or from a catalog as you do with delivery groups. For more information, see Apply tags to machine catalogs.
- **Studio now supports switching between "horizontal load balancing" and "vertical load balancing" modes**. Previously, PowerShell was your only choice to switch between horizontal and vertical load balancing modes. Studio now gives you more flexibility to control how to load balance multi-session OS machines. For more information, see Load balance machines.
- **Studio now supports including machines in maintenance mode in restart schedules**. Previously, PowerShell was your only choice to configure scheduled restarts for machines in maintenance mode. You can now also use Studio to control whether to include those machines in a restart schedule. For more information, see Create a restart schedule.
- **Studio now supports configuring Wake on LAN for Remote PC Access**. Previously, you had to use PowerShell to configure Wake on LAN for Remote PC Access. You can now also use Studio to configure the feature. For more information, see Configure Wake on LAN.
- **Studio now supports applying AWS instance properties and tagging operational resources**. When creating a catalog to provision machines in AWS by using MCS, you can specify whether to apply the IAM role and tag properties to those machines. You can also specify whether to apply machine tags to operational resources. You have the following two options:

  - **Apply machine template properties to virtual machines**
  - **Apply machine tags to operational resources**

  For more information, see Applying AWS instance properties and tagging operational resources.
- **AWS dedicated host**. Citrix Studio now adds an option called **Use dedicated host** to the **Machine Catalog Setup > Security** page. This setting is suitable for deployments with licensing restrictions or security requirements that need your use of a dedicated host. With a dedicated host, you own an entire physical host and are billed on an hourly basis. Owning that

© 1997–2026 Citrix Systems, Inc. All rights reserved.

host lets you spin up as many EC2 instances as that host permits, without more charges. For more information, see AWS tenancy.

- **Studio now supports running a restart schedule immediately**. Studio now lets you run a restart schedule immediately to restart all applicable machines in the schedule. For more information, see Immediately run a restart schedule.
- **Autoscale**. Autoscale provides the following new features and enhancements:
  - **Studio now supports displaying machines in drain state**. Previously, PowerShell was your only choice to identify machines in drain state. You can now use Studio to identify machines that are in drain state. For more information, see Display machines in drain state.
  - **Studio now supports defining peak times at a granular level of 30 minutes for VDI delivery groups**. Previously, you had to use PowerShell to define the peak times for the days included in a schedule at a granular level of 30 minutes for VDI delivery groups. You can now also use Studio to do that. This support enables you to set the minimum number of machines running in a VDI Delivery Group separately for each half hour of the day.

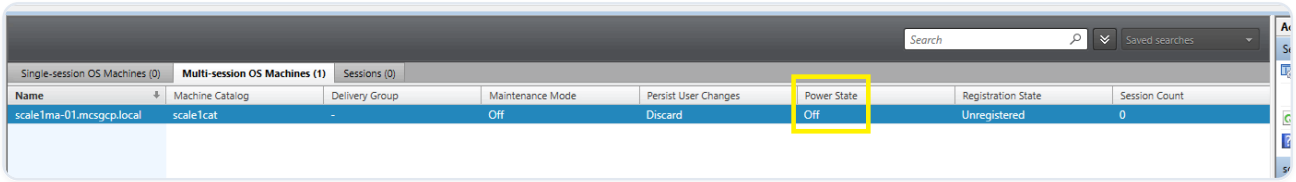
Azure Shared Image Gallery. Citrix Virtual Apps and Desktops service supports Azure Shared Image Gallery as a published image repository for MCS provisioned machines in Azure. Administrators have the option of storing an image in the gallery to accelerate the creation and hydration of OS disks from the master image. This process improves the boot and application launch times for non-persistent VMs.

The gallery contains the following three elements:

- Gallery. Images are stored here. MCS creates one gallery for each machine catalog.
- Gallery Image Definition. This definition includes information (operating system type and state, Azure region) about the master image. MCS creates one image definition for each master image created for the catalog.
- Gallery Image Version. Each image in a Shared Image Gallery can have multiple versions, and each version can have multiple replicas in different regions. Each replica is a full copy of the master image. Citrix Virtual Apps and Desktops service always creates one Standard_LRS image version (version 1.0.0) for each image with the appropriate number of replicas in the catalog's region. This configuration is based on the number of machines in the catalog, the configured replica ratio, and the configured replica maximum.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:



Shared Image Gallery functionality only works with managed disks. It is not available for legacy machine catalogs.

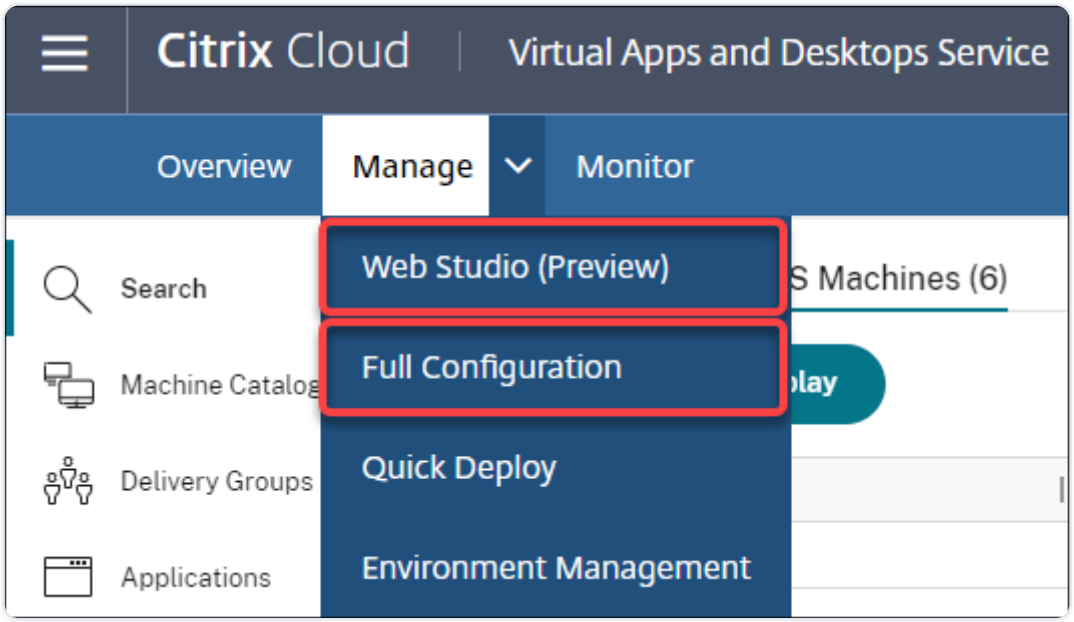
For details about this feature, see Configure shared image gallery.

Storage buckets created in same Google Cloud Platform region as the machine catalog. In previous releases, MCS created temporary storage buckets during provisioning as part of the disk upload process. These buckets spanned multiple regions, which Google defines as a large geographic area containing two or more geographic places. These temporary buckets resided in the United States geographic location, no matter where the catalog was provisioned. MCS now creates storage buckets in the same region where you provision your catalogs. Storage buckets are no longer temporary; they remain in your Google Cloud Platform project after you complete the provisioning process. Future provisioning operations use the existing storage bucket. If one exists in that region, or a new storage bucket is created if one does not exist in the specified region.

PowerShell option that sets default to re-use pooled VDAs during an outage. A new PowerShell command option (`-DefaultReuseMachinesWithoutShutdownInOutage`) extends the ability to reuse pooled desktop VDAs that haven't been shut down during an outage, by default. See Application and desktop support.

Google Cloud Platform on-demand provisioning. Citrix Virtual Apps and Desktops service updates how the Google Cloud Platform (GCP) provisions machine catalogs. When creating a machine catalog, the corresponding machine instance is not created in GCP and the power state is set to **OFF**. Machines are not provisioned at catalog creation time but rather the first time the machines are powered on. For example, after you create a catalog, the VM power state is set to **Off**:

December 2020



New and enhanced features

Web Studio is available as a preview. A new, web-based console is now available. We are in the process of migrating the full set of Studio functionalities from the legacy console to the new, web-

© 1997–2026 Citrix Systems, Inc. All rights reserved.

based console. The web-based console generally responds faster than the legacy console. By default, you automatically log on to the web-based console. You can easily switch between the web-based console and the legacy console from within the **Manage** tab to perform your configuration or site management tasks. Click the down arrow next to **Manage** and select an option:

- **Web Studio (Preview)**. Takes you to the new, web-based console.
- **Full Configuration**. Takes you to the legacy console.

The following features are available only in the web-based console:

- **Standard SSD disk type support for Azure**. Studio now adds support for standard SSD disk type. Azure standard SSDs are a cost-effective storage option optimized for workloads that need consistent performance at lower IOPS levels. For more information, see Create a machine catalog using an Azure Resource Manager master image.
- **Studio now supports configuring the power-off delay for static VDI delivery groups**. Previously, you might configure the power-off delay for static VDI delivery groups only through the PowerShell SDK. Studio now lets you configure the power-off delay in the Autoscale user interface for static VDI delivery groups. For more information, see Autoscale.

October 2020

New and enhanced features

Dismiss multiple hypervisor alerts. Citrix Monitor now supports automatic dismissal of hypervisor alerts older than a day. For more information, see Hypervisor Alerts Monitoring.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Remove external IP address. An external IP address on a temporary virtual machine that is used to prepare a provisioned image in the Google Cloud Platform (GCP) is no longer required. This external IP address enables the temporary virtual machine to access the Google public API to complete the provisioning process.

Enable Private Google Access to permit the VM to access the Google public API directly from the subnet. For more information, see Enable Google Private access.

New model addresses how machine identities are managed. Machine identities used in machine catalogs have been managed and maintained using Active Directory. All machines created by MCS will now be joining Active Directory. The new Citrix Virtual Apps and Desktops service model addresses how machine identities are managed. This model allows the creation of machine catalogs using *workgroup*, or, non-domain joined machines.

TIP:

This functionality supports a new identity service, *FMA trust*, added to Citrix Cloud for non-domain joined machines.

MCS communicates with the new FMA trust service for identity management. Identity information is stored in the identity disk as a pair of GUID and private key pairs, instead of the domain SID and machine account password paradigm used by Active Directory. VDAs using non-domain joined machines use this GUID and private key combination for broker registration. For more information, see Configure support for non-domain joined catalogs.

Use direct upload for Azure managed disks. This release allows you to use direct upload when creating managed disks in an Azure environment. This functionality reduces costs associated with extra storage accounts. You no longer have to stage the VHD into a storage account before converting it to a managed disk. Also, direct upload eliminates the need to attach an empty managed disk to a virtual machine. Directly uploading to an Azure managed disk simplifies the workflow by enabling you to copy an on-premises VHD directly for use as a managed disk. Supported managed disks include Standard HDD, Standard SSD, and Premium SSD.

For more information on this feature, see the Microsoft Azure blog.

For more information about Azure managed disks, see the documentation page.

Single Resource Group in Azure. You can now create and use a single Azure resource group for updating and creating catalogs in Citrix Virtual Apps and Desktops. This enhancement applies to both the full scope and narrow scope service principals. The previous limit of 240 VMs per 800

© 1997–2026 Citrix Systems, Inc. All rights reserved.

managed disks per Azure Resource Group has been removed. There is no longer a limit on the number of virtual machines, managed disks, snapshots, and images per Azure Resource Group.

For more information, see Microsoft Azure Resource Manager virtualization environments.

September 2020

New and enhanced features

Quick Deploy. The new Quick Deploy feature replaces the earlier Azure Quick Deploy. The new feature offers a quick way to get started with the Citrix Virtual Apps and Desktops service using Microsoft Azure. You can use Quick Deploy to deliver desktops and apps, and configure Remote PC Access.

Session Administrator (built-in role). Citrix Studio now adds a new built-in role called **Session Administrator**. The role lets an administrator view delivery groups and manage their associated sessions and machines on the **Filters** page of the **Monitor** tab. With this feature, you can configure access permissions of existing administrators or administrators you invite in a way that aligns with their role in your organization. For more information about the built-in role, see Built-in roles and scopes. For information about how to assign the built-in role to an administrator, see Delegated administration and monitoring.

For a more granular level of control over access to the **Filters** page related to sessions and machines, create a custom role and select one of the following for the Director object: **View Filters page - Machines only**, **View Filters page - Sessions only**. For information about creating a custom role, see Create and manage roles.

Support for a new machine type. This release adds support for the NV v4 and the DA v4 series of AMD machines, when configuring Premium Disks for a machine catalog. For more information, see Create delivery groups.

August 2020

New and enhanced features

Limited access to the Remote PowerShell SDK during an outage. Previously, you might not use PowerShell commands during an outage. Now, Local Host Cache allows limited access to the Remote PowerShell SDK during an outage. See What is unavailable during an outage.

Support for two new Citrix Virtual Apps and Desktops service editions. Citrix Monitor now supports two new Citrix Virtual Apps and Desktops service editions, namely, **Citrix Virtual Apps**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Advanced service and **Citrix Virtual Apps and Desktops Advanced service**. For more information, see the Citrix Monitor Feature compatibility matrix.

Support for shared Virtual Private Cloud (VPC) in Google Cloud Platform. The Citrix Virtual Apps and Desktops service supports Shared VPC on Google Cloud Platform as a host resource. You can use Machine Creation Services (MCS) to provision machines in a Shared VPC and manage them using Citrix Studio. For information about Shared VPC, see Shared Virtual Private Cloud.

Zone selection support for Google Cloud Platform. The Citrix Virtual Apps and Desktops service supports zone selection on Google Cloud Platform. This feature allows administrators to specify one or multiple zones within a region for catalog creation.

For sole-tenant type VMs, zone selection provides administrators with the ability to place sole tenant nodes across zones of their choice. For non-sole tenant VMs, zone selection provides the ability to place VMs deterministically across zones of their choice thereby providing flexibility in designing the deployment. For configuration information, see Enable zone selection.

Also:

- Sole tenancy provides exclusive access to a sole tenant node, which is a physical compute engine server dedicated to hosting only your project's VMs. These nodes allow you to group your VMs together on the same hardware or separate your VMs from other project's VMs.
- Sole tenant nodes help you meet dedicated hardware requirements for Bring Your Own License (BYOL) scenarios. They also enable you to comply with network access control policy, security, and privacy requirements such as HIPAA.

NOTE:

Sole tenancy is the only route to using Windows 10 VDI deployments on Google Cloud. Server VDI also supports this method. A detailed description for sole tenancy can be found on the Google documentation site.

Improved boot performance for Azure system disks. This release supports improved boot performance for Citrix Cloud implementations using Azure when MCSIO is enabled. With this support, you can retain the system disk. This provides the following advantages:

- VMs and applications now boot and launch with performance similar to how the golden image is served.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Reduction in API quota consumption, deleting and creating the system disk, and state transition delay caused when you delete a VM.

For example, use the PowerShell `PersistOSDisk` custom property in the `New-ProvScheme` command to configure this feature.

```
-CustomProperties '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />

<Property xsi:type="StringProperty" Name="PersistOsDisk" Value="true" />

</CustomProperties>'
```

For more configuration information, see Improve boot performance.

July 2020

New and enhanced features

Support for granular, role-based access to the Filters page. Citrix Studio now provides more granular control over access to the **Monitor > Filters** page when you create a custom role. Specifically, you can assign permissions to view any combination of **Machines**, **Sessions**, **Connections**, and **Application Instances** to a custom role. The following are four more options for the **Director** object in the **Create Role** window:

- View Filters page - Application Instances only
- View Filters page - Connections only
- View Filters page - Machines only
- View Filters page - Sessions only

For information about creating roles, see Create and manage roles.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Power-off delay support for assigned VDI machines (PowerShell only). In earlier releases, the power-off delay applied only to unassigned machines. Starting with this release, the power-off delay applies to both assigned and unassigned machines. For more information, see How Autoscale power manages machines.

Support for Windows Client licenses. The Citrix Virtual Apps and Desktops service now supports using Windows Client licenses to provision VMs in Azure. To run Windows 10 VMs in Azure, verify that your volume licensing agreement with Microsoft qualifies for this usage. For more information, see Create a machine catalog using an Azure Resource Manager master image.

May 2020

New and enhanced features

Machine restart schedules. You can now indicate whether a restart schedule affects machines that are in maintenance mode. This feature is available only in PowerShell. For details, see Scheduled restarts for machines in maintenance mode.

Resource availability. You can now ensure resource availability during an outage without having to publish resources in every zone (resource location). For details, see Resource availability.

April 2020

New and enhanced features

Enhanced scheduling granularity for VDI Delivery Groups (PowerShell only). Autoscale now supports defining the peak times for the days included in a schedule at a granular level of 30 minutes. You can set the minimum number of machines running in a VDI Delivery Group separately for each half hour of the day. Also, Autoscale can now scale up or down the number of powered-on machines in VDI Delivery Groups on a half-hourly basis instead of on an hourly basis. For more information, see Broker PowerShell SDK commands.

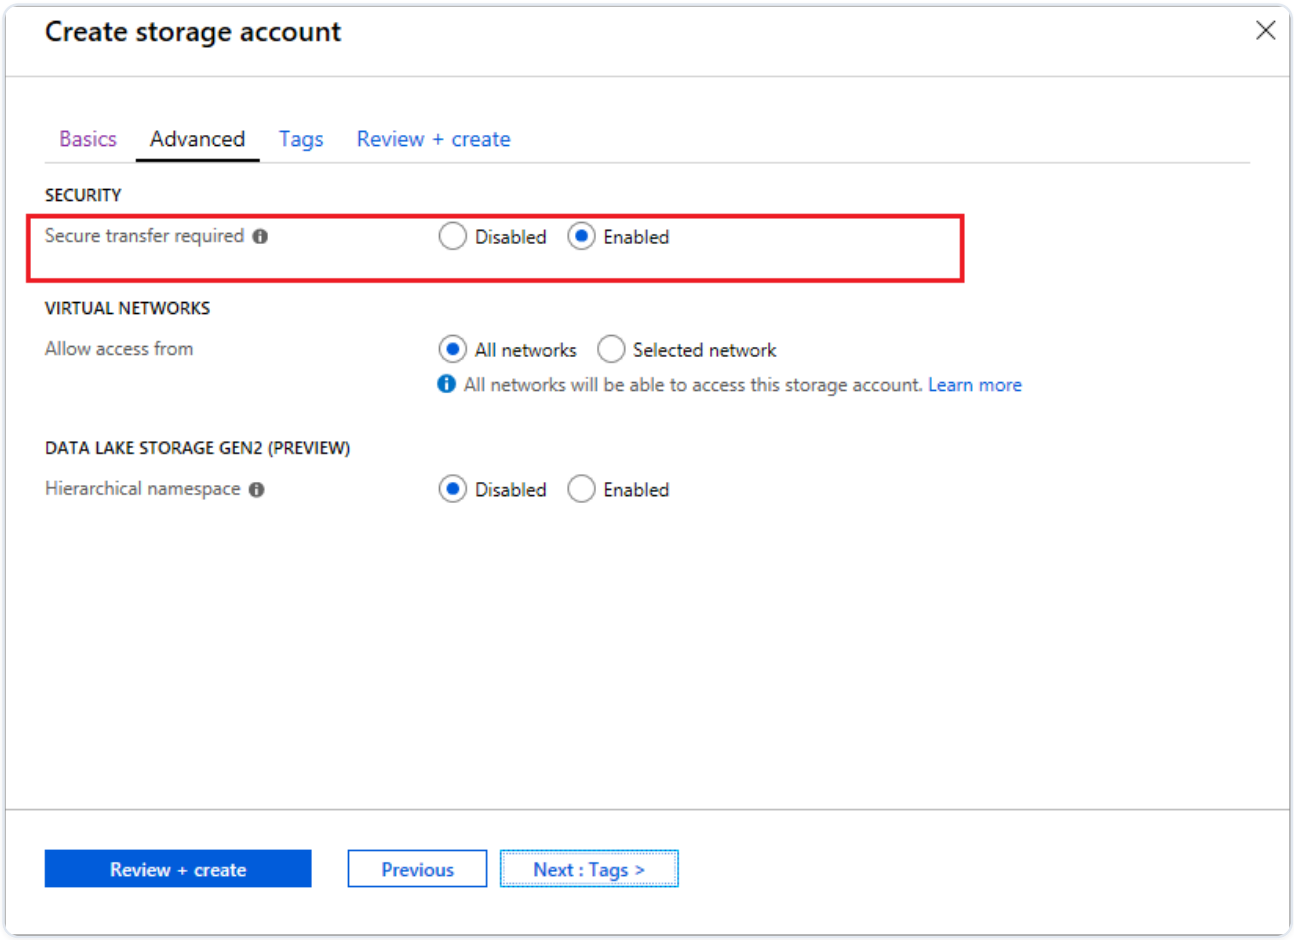
MTU Discovery. The Citrix protocol Enlightened Data Transport (EDT) now has MTU Discovery capabilities. MTU Discovery allows EDT to automatically determine and set the payload size for the session. This feature enables the ICA session to adjust to networks with non-standard Maximum Transmission Unit (MTU) or Maximum Segment Size (MSS) requirements. The ability to adjust avoids packet fragmentation that might result in degraded performance or failure to establish an ICA session. This update requires a minimum of Citrix Workspace app 1911 for Windows. If using Citrix Gateway, the minimum Citrix ADC firmware version required is 13.0.52.24 or 12.1.56.22. For more information, see EDT MTU Discovery.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

March 2020

New and enhanced features

PVS target device metrics. Citrix Monitor now provides a PVS target device metrics panel on the Machine Details page. Use the panel to view the status of Provisioning target devices for single-session and multi-session OS machines. Several metrics for Network, Boot, and Cache are available on this panel. These metrics help you monitor and troubleshoot PVS target devices to ensure that they are up and running. For more information, see PVS target device metrics.



AWS instance property capturing. MCS now reads properties from the instance from which the AMI was taken and applies the IAM role and tags of the machine to the machines provisioned for a given catalog. When using this optional feature, the catalog creation process finds the selected AMI source instance, reading a limited set of properties. These properties are then stored in an AWS Launch Template, which is used to provision machines for that catalog. Any machine in the catalog inherits the captured instance properties. For more information, see AWS instance property capturing.

AWS operational resource tagging. This release introduces an option to tag resources created by Citrix components during provisioning. Each tag represents a label consisting of a customer-defined key and an optional value that improve your ability to manage, search for, and filter resources. For more information, see AWS operational resource tagging.

Secure transfer in Azure storage. Machine Creation Services (MCS) provides an enhancement for storage accounts created by MCS-provisioned catalogs in Azure Resource Manager environments. This enhancement automatically enables the secure transfer required property. This option enhances storage account security by only allowing requests to the account from secure connections. For more information, see Require secure transfer to ensure secure connections on the Microsoft site.

Enable the **Secure transfer required** property when creating a storage account in Azure:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for Azure SSD managed disks. Machine Creation Services (MCS) supports standard SSD managed disks for Azure virtual machines. This disk type provides consistent performance, and delivers better availability compared to HDD disks. For more information, see Standard SSD Disks for Azure Virtual machine workloads.

Use the PowerShell `StorageAccountType` custom property in the `New-ProvScheme` command or `Set-ProvScheme` command to configure this feature:

```
<Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" /><Property xsi:type=`"StringProperty`"
Name=`"StorageAccountType`" Value=`"StandardSSD_LRS`" /><Property
xsi:type=`"StringProperty`" Value=`"Windows_Server`" />
```

NOTE:

This feature is only available when using managed disks, that is, the custom property `UseManagedDisks` is set to **true**. For unmanaged disks only Standard HDD and Premium SSD are supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

January 2020

New and enhanced features

Language bar in Citrix Studio. Starting with this release, Citrix Studio provides a language bar to facilitate correct keyboard mapping.

- If the language of Citrix Cloud or the display language of your browser is set to **English** or **Japanese**, the language bar does not appear.
- If the language of Citrix Cloud or the display language of your browser is set to **German**, **Spanish**, or **French**, the language bar appears after you log on to Citrix Studio. There are two language options on the language bar list. Select an option that matches the topmost language of your browser.

  TIP:

  - Settings that you configure for the language bar might not take effect. In this case, log out and log back on.
  - You might fail to input certain symbols and localized characters by using the language bar. To resolve the issue, you need to configure the language of Citrix Cloud, the display language of your browser, and the local keyboard layout. For more information, see Knowledge Center article CTX310743.

Restart schedule maximum delay timer (PowerShell only). If a scheduled restart of machines in a Delivery Group doesn't begin because of a site database outage, you can specify how long to wait beyond the scheduled start time. If the database connection is restored during that interval, the restarts begin. If the connection isn't restored during that interval, the restarts don't begin. For details, see Scheduled restarts delayed due to database outage.

Vertical load balancing (PowerShell only). Previously, the service used horizontal load balancing for all RDS launches, which assigns incoming load to the least-loaded RDS machine. That remains the default. Now, you can use PowerShell to enable vertical load balancing as a site-wide setting.

When vertical load balancing is enabled, the broker assigns incoming load to the most-loaded machine that has not reached a high watermark. This saturates existing machines before moving on to new machines. As users disconnect and free up existing machines, new load is assigned to those machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

By default, horizontal load balancing is enabled. To view, enable, or disable vertical load balancing, the `Get-BrokerSite`, and `Set-BrokerSite` cmdlets now support the `UseVerticalScalingForRdsLaunches` setting. For more information, see Load manage machines in Delivery Groups.

December 2019

New and enhanced features

Service for Citrix Service Providers (CSP). CSPs can now onboard tenant customers to the Virtual Apps and Desktops service, configure customer administrator access to the service, and provide shared or dedicated workspaces to customers' users using federated domains. For more information, see Citrix Virtual Apps and Desktops service for Citrix Service Providers.

Support for determining why a machine is in maintenance mode (PowerShell only). Using PowerShell, you can now determine why a machine is in maintenance mode. To do so, use the parameter `-MaintenanceModeReason`. The feature is useful for administrators to troubleshoot issues with machines in maintenance mode. For details, see `<https://developer-docs.citrix.com/projects/citrix-virtual-apps-desktops-sdk/en/latest/Broker/Get-BrokerMachine/>`.

Autoscale. Autoscale now provides the capability to create machines and delete them dynamically. You can use the capability by using a PowerShell script. The script helps you dynamically scale up or down the number of machines in the Delivery Group based on the current load conditions. For more information, see Dynamically provision machines with Autoscale.

November 2019

New and enhanced features

GroomStartHour. Monitor now supports **GroomStartHour** - a new configuration that helps administrators to determine the time of the day that grooming should start running. For more information, see the Citrix Virtual Apps and Desktops SDK documentation.

OData Pagination. Monitor now supports **OData pagination**. All OData v4 endpoints return a maximum of 100 records per page with a link to the next 100 records in the response. For more information, see Accessing Monitor Service data using the OData v4 endpoint in Citrix Cloud.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

October 2019

New and enhanced features

App-V. App-V functionality is now available in Citrix Cloud. You can add App-V packages to the Delivery Controller in your Citrix Cloud configuration, in either single- or dual admin mode. The *Virtual Apps and Desktops Service App-V package discovery module*, available in Citrix Downloads, allows you to import App-V packages and register Microsoft App-V servers. The apps they contain are then available to your users. This PowerShell module allows you to register Microsoft App-V Management and Publishing Servers using DNS URLs, avoiding the need for servers behind load balancing mechanisms to be registered using their actual machine URL. For more information, see Citrix Virtual Apps and Desktops service discovery module for App-V packages and servers.

Google Cloud Platform. Citrix Virtual Apps and Desktops service now adds support for using Machine Creation Services (MCS) to provision machines on the Google Cloud Platform (GCP). For more information, see Google Cloud Platform virtualization environments.

September 2019

New and enhanced features

VDA support for Azure Virtual Desktop. For supported operating systems and VDA versions see VDAs in an Azure Virtual Desktop environment.

Enhanced power policy. In earlier releases, a VDI machine transitioning to a time period where an action (disconnect action="**Suspend**" or "**Shutdown**") was required remained powered on. This scenario occurred if the machine disconnected during a time period (peak or off-peak times) where no action (disconnect action="**Nothing**") was required.

Starting with this release, Autoscale suspends or powers off the machine when the specified disconnection time elapses, depending on the disconnect action configured for the destination time period. For more information, see Power manage VDI machines transitioning to a different time period with disconnected sessions.

Machine catalogs: Tags. You can now use PowerShell to apply tags to machine catalogs. For more information, see Apply tags to machine catalogs.

Session startup duration. Monitor now displays the session startup duration divided into Workspace App Session Startup and VDA Session Startup time periods. This data helps you to understand and troubleshoot high session startup duration. Further, the time duration for each

© 1997–2026 Citrix Systems, Inc. All rights reserved.

phase involved in the session startup helps in troubleshooting issues associated with individual phases. For example, if the Drive Mapping time is high, you can check if all the valid drives are mapped properly in the GPO or script. This feature is available on VDAs 1903 or later. For more information, see Diagnose session startup issues.

August 2019

New and enhanced features

Session Auto Reconnect. The Sessions page on the Trends tab now includes information about the number of auto reconnects. Auto reconnects are attempted when the Session Reliability or Auto Client Reconnect policies are in effect. The auto reconnect information helps you view and troubleshoot network connections having interruptions, and also analyze networks having a seamless experience.

The drilldown provides additional information like Session Reliability or Auto Client Reconnect, time stamps, Endpoint IP, and Endpoint Name of the machine where the Workspace app is installed. This feature is available for Citrix Workspace app for Windows, Citrix Workspace app for Mac, Citrix Receiver™ for Windows, and Citrix Receiver for Mac. This feature requires VDAs 1906 or later. For more information, see:

- Sessions
- Auto client reconnect policy settings
- Session reliability policy settings
- Session Auto Reconnect

July 2019

New and enhanced features

Configuration Logging. You can now use the Remote PowerShell SDK to periodically delete Configuration Logging database content. For details, see Schedule periodic data deletion.

Autoscale. Autoscale now provides the flexibility to power manage only a subset of machines in a Delivery Group. This feature can be useful in cloud bursting use cases, where you want to use on-premises resources to handle workloads before cloud-based resources address other demands (that is, burst workloads). For more information, see Restrict Autoscale to certain machines in a Delivery Group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Local App Access and URL redirection. Citrix Studio now lets you add the Add Local App Access Application option to the Studio user interface for your Site by using the PowerShell SDK. For more information, see Provide access only to published applications.

Operating system name changes. Operating system names on the **Create Machine Catalog > Machine Catalog Setup > Operating System** and the **Monitor** pages have changed:

- Multi-session OS (formerly Server OS): The multi-session OS machine catalog provides hosted shared desktops for a large-scale deployment of standardized Windows multi-session or Linux OS machines.
- Single-session OS (formerly Desktop OS): The single-session OS machine catalog provides VDI desktops ideal for various users.

Citrix Profile Management duration in Profile Load. Monitor now includes profile processing duration in the Profile Load bar of the Logon duration chart. This is the duration Citrix Profile Management takes to process user profiles. This information helps administrators to troubleshoot high profile load durations with greater accuracy. This enhancement is available on VDAs 1903 and later. For more information, see Profile Load.

Desktop probing. Desktop probing is a feature of the Citrix Virtual Apps and Desktops service. It automates health checks of virtual desktops published on a site, which improves user experience. To initiate desktop probing, install and configure the Citrix Probe Agent on one or more endpoints. Desktop probing is available for Premium licensed Sites. This feature requires Citrix Probe Agent 1903 or later. For more information, see Application and Desktop Probing.

NOTE:

Citrix Probe Agent now supports TLS 1.2.

June 2019

New and enhanced features

Restrict by tags. Tags are strings that identify items such as machines, applications, desktops, Application Groups, and policies. After creating a tag and adding it to an item, you can tailor certain operations to apply to only items that have a specified tag. For more information, see Application Groups and Tags.

Email Notifications. Citrix Virtual Apps and Desktops service sends email notifications related to alerting and probing directly. This eliminates the need to configure the SMTP email server. The

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Notification Preferences box is enabled by default and Citrix Cloud sends alert notifications to the email addresses provided in the **Notification Preferences** section. Ensure that the email address `donotreplynotifications@citrix.com` is white-listed in your email setup.

May 2019

New and enhanced features

Autoscale. Autoscale is a feature of Citrix Virtual Apps and Desktops service that provides a consistent, high-performance solution to proactively power manage your machines. It aims to balance costs and user experience. Autoscale incorporates the deprecated Smart Scale technology into the Studio power management solution. For more information, see Autoscale. You can monitor the metrics of Autoscale-managed machines from the Trends pages on the **Monitor** console. For more information, see Monitor Autoscale-managed machines.

February 2019

New and enhanced features

Hypervisor alerts monitoring. Alerts from Citrix Hypervisor and VMware vSphere are now displayed on the **Monitor** > **Alerts** tab to help monitor the following states/parameters of hypervisor health:

- CPU usage
- Memory usage
- Network usage
- Hypervisor connection unavailable
- Disk usage (vSphere only)
- Host connection or power state (vSphere only)

For more information, see the Hypervisor alerts monitoring section in Alerts and Notifications.

Communications over earlier TLS versions. To improve the security of the service, Citrix will block any communication over Transport Layer Security (TLS) 1.0 and 1.1 as of March 15, 2019, allowing only TLS 1.2 communications. For more information, see TLS versions. For comprehensive guidance, see CTX247067.

Application Groups. Application Groups let you manage collections of applications. You can create Application Groups for applications shared across different Delivery Groups or used by a subset of users within Delivery Groups. For more information, see Create Application Groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Logon Performance - Profile Drilldown. The **Logon Duration** panel on the **User Details** page within **Monitor** now includes information on the **Profile load phase** drilldown of the logon process. Profile drilldown provides useful information about user profiles for the current session that can help administrators troubleshoot high profile load issues. A tool tip with the following user profiles information is displayed:

- Number of files
- Profile size
- Number of large files

A detailed drill-down provides information about the individual folders, their size, and the number of files. This feature is available on VDAs 1811 and later. For more information, see Diagnose user logon issues.

Microsoft RDS license health. Monitor the Microsoft RDS (Remote Desktop Services) license status on the **Machine Details** panel on the Machine Details and the User Details page for Server OS machines. An appropriate message is displayed for the license status. You can hover over the info icon to see further details. For more information, see the Microsoft RDS license health section in Troubleshooting Machines.

Application Probing. This feature automates the assessment of the health of Virtual Apps published in a Site.

To initiate application probing:

- On one or more endpoint machines, install the Citrix Application Probe Agent
- Configure the Citrix Application Probe Agent with the credentials of Citrix Workspace and Citrix Virtual Apps and Desktops service.
- Configure the applications to be probed, the endpoint machines to run the probe on, and the scheduled probe time in **Monitor** > **Configuration** of the Citrix Virtual Apps and Desktops service.

The agent tests the launch of selected applications via Citrix Workspace and reports back the probe results on the **Monitor** console of Citrix Virtual Apps and Desktops service in:

- the Applications page – the last 24-hours' data and the **Trends** > **Application Probe Results** page
- the historical probe data along with the stage when the probe failure occurred - Workspace Reachability, WorkspaceAuthentication, WorkspaceEnumeration, ICA download, or Application launch

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The failure report is emailed to configured email addresses. You can schedule application probes to run during off-peak hours across multiple geographical locations. In that way, you can use the results to proactively troubleshoot issues related to provisioned applications, hosting machines, or connections before the users experience them. For more information, see Application and Desktop Probing.

January 2019

New and enhanced features

Delegated Administration with custom scope. Monitoring now supports custom scope for built-in delegated administrator roles. For more information on the available built-in roles for monitoring and how to assign them, see Delegated administrator roles.

December 2018

New and enhanced features

The date after which Citrix will block communication over Transport Layer Security (TLS) 1.0 and 1.1 has changed from December 31, 2018 to January 31, 2019. For details, see Deprecation of TLS versions.

November 2018

New and enhanced features

Machine historical data available using OData API: Historical data containing machine analytics is now available through the OData API. This data is collected on an hourly basis and rolled up for the day.

- Number of powered on machines (for power managed machines)
- Number of registered machines
- Number of machines in maintenance mode
- Total number of machines

The data is aggregated for the time period during which the Monitoring Service is running. For more information on the usage of the OData API and examples, see Citrix Monitor Service 7 1808. The database schema is available at Monitor Service Schema.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Logon Performance - Interactive session drilldown: The **Logon Duration** panel on the **User and Session Details** view includes information on the **Interactive Session** phase of the logon process. The time taken for each of the three subphases (**Pre-userinit**, **Userinit**, and **Shell**) is displayed on the **Interactive Session** bar as a tooltip. This provides more granular troubleshooting and remediation of this phase of the logon. The cumulative time delay between the subphases and a link to the documentation is also provided. This feature is available on Delivery Controller version 7 1808 and later. The **Interactive Session** drilldown bar shows the time duration for the current session only. For more information, see Diagnose user logon issues.

Logon Performance - GPO drilldown: The **Logon Duration** panel on the **User and Session** details view contains the GPO (Group Policy Objects) duration. This is the total time taken to apply the GPOs on the virtual machine during the logon process. Now, you can see the drilldown of each policy applied as per CSEs (Clients-Side Extension) as a tool tip on the GPO bar. For each policy application, the drilldown displays the status and the time taken. This additional information eases troubleshooting and remediation of issues involving high GPO duration. The time durations in the drilldown represent the CSE processing time only and do not add up to the total GPO time. This feature is available on Delivery Controller version 7 1808 and later. For more information, see Diagnose user logon issues.

Fixes

Custom report queries saved during monitoring are not available after a Cloud upgrade.

October 2018

New and enhanced features

Applications: Limit per machine. You can now limit the number of application instances per machine. This limit applies to all machines in the Site. This limit is an addition to the existing application limit for all users in the Delivery Group and the limit per user. This capability is available only through PowerShell, not in Studio. For details, see Configure application limits.

Windows Server 2019. You can now install VDAs for multi-session OS (formerly VDAs for Server OS) on Windows Server 2019 machines, as noted in System requirements.

September 2018

New and enhanced features

Delegated Administration. With Delegated Administration, you can configure the access permissions that all of your administrators need, in accordance with their role in your organization.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For details, see Delegated Administration. Monitoring supports allocation of built-in roles. Built-in roles are available with full scope. For more information about built-in roles for monitoring and how to assign them, see Delegated administrator roles.

Configuration Logging. Configuration Logging allows administrators to keep track of configuration changes and administrative activities. For details, see Configuration Logging.

Several PowerShell cmdlets in the Remote PowerShell SDK that were previously disabled are now enabled, for use with Configuration Logging:

- Log:GetLowLevelOperation
- Log:GetHighLevelOperation
- Log:GetSummary
- Log:GetDataStore
- Log:ExportReport

Local Host Cache. Local Host Cache is now fully available. Local Host Cache enables connection brokering operations to continue when a Cloud Connector in a resource location cannot communicate with Citrix Cloud. For details, see Local Host Cache.

Citrix Provisioning. To provision VDAs, you can now use Citrix Provisioning or the existing Machine Creation Services. For Citrix Provisioning information specific to the cloud environment, see Citrix Provisioning managed by Citrix Cloud.

Fixes

In earlier versions, when using Azure on-demand provisioning, all VMs were deleted when powered-off. Now, only pooled VMs are deleted. Persistent (dedicated) VMs are not deleted when powered-off.

August 2018

- **New product names**

  If you've been a Citrix customer or partner for a while, you'll notice new names in our products and in this product documentation. If you're new to this Citrix product, you might see different names for a product or component.

  The new product and component names stem from the expanding Citrix portfolio and cloud strategy. Articles in this product documentation use the following names.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Citrix Virtual Apps and Desktops:** Citrix Virtual Apps and Desktops offers a virtual app and desktop solution, provided as a cloud service and as an on-premises product, giving employees the freedom to work from anywhere on any device while cutting IT costs. Deliver Windows, Linux, web, and SaaS applications or full virtual desktops from any cloud: public, on-premises, or hybrid. Virtual Apps and Desktops was formerly XenApp and XenDesktop.
- **Citrix Workspace app:** The Citrix Workspace app incorporates existing Citrix Receiver technology and other Citrix Workspace client technologies. It has been enhanced to deliver more capabilities to provide end users with a unified, contextual experience where they can interact with all the work apps, files, and devices they must do their best work. For more information, see this blog post.
- **Citrix SD-WAN™:** NetScaler SD-WAN, a crucial technology for our customers and partners transforming their branch networks and WANs with cloud technology, is now Citrix SD-WAN.
- **Citrix Secure Web Gateway™:** As the Citrix Networking portfolio expands, we're proud to offer our robust Citrix Secure Web Gateway Service, previously known as NetScaler Secure Web Gateway.
- **Citrix Gateway:** Our robust NetScaler® Unified Gateway, which allows secure, contextual access to the apps and data you must do your best work, is now Citrix Gateway.
- **Citrix Content Collaboration™ and Citrix Files for Windows:** The advanced access, collaboration, workflows, rights management, and integration features of ShareFile are now available in the Citrix Content Collaboration component set in our secure, contextual, integrated Citrix Workspace. Citrix Files for Windows allows you to access your Content Collaboration files directly through a mapped drive, providing a native Windows Explorer experience.
- **Citrix Hypervisor**: The technology from XenServer for virtualization infrastructure, based on the XenProject hypervisor, is now Citrix Hypervisor.

Here's a quick recap:

IS	WAS
Citrix Virtual Apps and Desktops	XenApp® and XenDesktop
Citrix Workspace app	Incorporates Citrix Receiver and extensive enhancements
Citrix SD-WAN	NetScaler SD-WAN

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IS	WAS
Citrix Secure Web™ Gateway	NetScaler Secure Web Gateway
Citrix Gateway	NetScaler Unified Gateway
Citrix Content Collaboration	ShareFile
Citrix Files for Windows	ShareFile Desktop App, ShareFile Sync, ShareFile Drive Mapper
Citrix Hypervisor	XenServer
Citrix Provisioning	Citrix Provisioning Services

Implementing this transition in our products and their documentation is an ongoing process.

- In-product content might still contain former names. For example, you might see instances of earlier names in console text, messages, and directory/file names.
- It is possible that some items (such as commands and MSIs) might continue to retain their former names to prevent breaking existing customer scripts.
- Related product documentation and other resources (such as videos and blog posts) that are linked from this product's documentation might still contain former names.
- For Citrix Hypervisor: The new name is used on the Citrix website and in informational product materials from September 2018. You will also see the new name on the administrator consoles of some Citrix products, such as Citrix Virtual Apps and Desktops. The XenServer product release and technical documentation materials continue to use XenServer 7.x until early 2019.

Your patience during this transition is appreciated.

For more detail about our new names, see `<https://www.citrix.com/about/citrix-product-guide/>`.

- **Product and component version number changes**

  Citrix installs and manages most of the Citrix Virtual Apps and Desktops components, so you won't be concerned with those version numbers. However, you might see version numbers when installing Cloud Connectors, and when installing or upgrading VDAs in resource locations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Citrix Virtual Apps and Desktops product and component version numbers are displayed in the format: **YYMM.*c.m.b***

- YYMM = Year and month when the product or component released. For example, a September 2018 release appears as 1809.
- c = Citrix Cloud release number for the month.
- m = Maintenance version (if applicable).
- b = Build number. This field is shown only on the About page of the component, and in the OS's feature for removing or changing programs.

For example, **Citrix Virtual Apps and Desktops 1809.1.0** indicates that the component released in September 2018. It is associated with Citrix Cloud release 1 in that month, and is not a maintenance version. Some displays show only the version's year and month: for example, **Citrix Virtual Apps and Desktops 1809**.

In earlier releases (7.18 and earlier), version numbers were displayed in the format: 7.*version*, where version incremented by one for each release. For example, the VDA release following XenApp and XenDesktop 7.17 was 7.18. Earlier releases (7.18 and earlier) will not be updated with the new numbering format.

- **Deprecation of TLS versions.** To improve the security of the Citrix Virtual Apps and Desktops service, Citrix will block any communication over Transport Layer Security (TLS) 1.0 and 1.1, effective December 31, 2018. For details, see Deprecation of TLS versions.
- **Google Cloud Platform virtualization environment.** The Citrix Virtual Apps and Desktops service supports the ability to manually power cycle Virtual Apps and Desktops VMs on the Google Cloud Platform (GCP). For more information, see Google Cloud Platform virtualization environments.

July 2018

- **Export of Filters data.** You can now export real-time monitoring data on the **Monitor** > **Filters** tab to CSV format files. The export feature is available from the Machines, Sessions, Connections, and Application Instances Filters pages. You can select a predefined custom filter or select suitable filter criteria, choose required columns on the table, and export the data. Data of up to 100,000 records can be exported. The exported CSV files give a comprehensive view of the real-time data, and helps ease analysis of large data sets.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

June 2018

- **Azure Resource Manager connections.** In the Studio connection creation wizard, the Azure environment selection on the **Connection** page includes all Azure Clouds that are valid for your Azure subscription. General availability for Azure US Government Cloud and Azure Germany Cloud replaces the preview versions of those two environments in earlier releases.

May 2018

- **Azure Quick Deploy.** When your resource location uses Azure Resource Manager machines to deliver applications and desktops, you can now choose a deployment method:
  - Full Configuration: This existing method uses the Studio management console, which guides you through creating a machine catalog and then creating a Delivery Group.
  - Azure Quick Deploy: This new option offers a simpler interface that offers faster deployment of apps and desktops.
- **Citrix Health Assistant link.** The Machine Details page of an unregistered machine on the Monitoring console now contains a **Health Assistant** button. Currently, the button links to Troubleshoot machines and to the Knowledge Center article, Citrix Health Assistant - Troubleshoot VDA Registration and Session Launch where you can download the tool. Citrix Health Assistant is a tool to troubleshoot configuration issues in unregistered VDAs. The tool automates several health checks to identify possible root causes for common VDA registration, session launch, and time zone redirection configuration issues.
- **Interactive Session drilldown.** In the monitoring console, the **User Details view > Logon Duration** panel now includes information on the **Interactive Session** stage of the logon process. To provide more granular troubleshooting and remediation of this phase of the logon, **Interactive Session** now has three subphases: **Pre-userinit**, **Userinit**, and **Shell**. In this release, hovering over **Interactive Session** displays a tooltip showing the subphases and a link to the documentation. For a description of the subphases and how to improve the performance of each phase, see Diagnose user logon issues.

March 2018

- **Application instance prediction (Preview feature).** This is the first monitoring feature based on predictive analytics. Predicting resource usage patterns is important for administrators to organize resources and the required number of licenses on each resource. The Application instance prediction feature indicates the number of hosted application instances that are likely to be launched per Site or Delivery Group over time. Machine learning algorithms based on

© 1997–2026 Citrix Systems, Inc. All rights reserved.

data models created with existing historical data are used to do the prediction. Tolerance level indicates the prediction quality.

For more information see Application instance prediction in Monitor. Submit your feedback regarding the usefulness and usability of this feature in the Citrix Cloud discussion forum.

- **Delivery Groups APIs - Preview**

  The Delivery Groups APIs Preview provides a set of REST APIs that you can use to automate the management of Delivery Groups. The complete set of available APIs can be viewed and tried out in the Citrix Cloud API documentation at `<https://developer.cloud.com/>`.

- **Web Studio authentication**

  The service management console on Citrix Cloud now uses a bearer token to authenticate customers. The bearer token is required to authenticate access to the Delivery Groups REST API.

- **Access Monitor Service data using OData Version 4 API (Preview feature)**

  You can create your customized monitoring and reporting dashboards based on the Monitor Service data by using the OData V.4 endpoint. OData V.4 is based on ASP .Net Web API and supports aggregation queries. Use your Citrix Cloud user name and bearer token to access the data with the V4 endpoint. For more information and examples, see Access Monitor Service data using the OData v4 endpoint in Citrix Cloud.

  Share your feedback on the utility of this feature in the Citrix Cloud discussion forum.

Fixes

- You can rename, move, and delete application folders.

January 2018

- **RDS license check.** Creation of machine catalogs containing Windows Server OS machines now includes an automatic RDS license check. Any RDS license issues found are displayed, so that you can take the appropriate steps to prevent a gap in service. For details, see Create machine catalogs.
- **Access to machine console from Monitor.** The Machine Details panel from Monitor now provides access to consoles of machines hosted on the XenServer hypervisor version 7.3. You can now troubleshoot issues in VDAs directly from Monitor. For more information, see Machine Console access in Troubleshoot machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

December 2017

New and enhanced features

- **Citrix Workspace.** Citrix Workspace is now available for **new** XenApp and XenDesktop Service customers. For more information, see Workspace Configuration.
- **Applications Analytics.** You can now analyze and monitor the performance of applications efficiently with the new Application Analytics page available from **Monitor** > **Applications** tab. The page provides a consolidated view of the health and usage of all applications published on your Site. It shows metrics such as the number of instances per application, and faults and errors associated with the published applications. This feature requires VDAs Version 7.15 or later.

  For more information, see Application Analytics section in Monitor.

November 2017

New and enhanced features

- **Local Host Cache.** Local Host Cache enables connection brokering operations to continue when a Cloud Connector in a resource location cannot communicate with Citrix Cloud. For details, see Local Host Cache.
- **Azure Managed Disks.** Azure Managed Disks are now used by default for MCS-provisioned VMs in Azure Resource Manager environments. Optionally, you can use conventional storage accounts. For details, see Microsoft Azure Resource Manager virtualization environments.
- **Help desk administrator.** When managing service administrators for a Citrix Cloud customer account, you now have a new choice: Help Desk Administrator. A help desk administrator can access the Monitor functions on the service. For details, see Manage.

Fixes

- You can now use the service management console wizard to create a Remote PC Access machine catalog. In earlier releases, you had to use a PowerShell cmdlet to create a catalog (as documented in CTX220737). Then, you had to return to the management console to create a Delivery Group. Now, you create the catalog and the Delivery Group sequentially on the management console.
- MCS-created catalogs can use existing Active Directory machine accounts.
- When monitoring a deployment, scrolling in a sorted **Trends > Sessions** table displays accurate results.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

More information

- Known issues.
- For information about third-party software that is included in the service, see Third party notifications.

Known issues

Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) has the following known issues:

- Updating a vTPM-enabled master image for an MCS non-persistent machine catalog through a Nutanix AHV Prism Central connection triggers a VM recreation that might invalidate DNS reservations, and necessitate re-enrollment for software utilizing MAC addresses for licensing.
- When using a machine profile that has multiple network interfaces (NICs) with Accelerated Networking enabled, ensure that the selected VM size supports Accelerated Networking on all NICs. Some Azure VM sizes (for example, Standard_D2ads_v5) restrict Accelerated Networking to a single NIC. If the machine profile enables Accelerated Networking on more NICs than the VM size allows, machines fail to power on with the error `VmSizeRestrictedToSingleNicWithAcceleratedNetworkingEnable`. To resolve this, either select a VM size that supports Accelerated Networking on multiple NICs, or update the machine profile to enable Accelerated Networking on only one NIC.
- Adding a large batch of VMs to an MCS catalog using a Nutanix AHV Prism Central host connection might fail with an `OutOfMemory` error. To avoid this, reduce the number of VMs created in a single batch. We recommend adding a maximum of 10 VMs at a time.
- Hourly costs for certain Azure Windows Instance SKUs (for example, `Standard_DS*{_}v2{_}*`) are displayed as **Unavailable** in Studio. This occurs because our cost feature depends on the public Azure Resource Pricing API, and this API, by design, no longer provides pricing information for certain meter data it has deprecated from its own reporting. This limitation affects the display of retail and effective prices for the Windows Instance SKUs within the system.
- If the user's Azure UPN contains a dot as the twentieth character, the Windows Server VDA is unable to create a local user account.
- When creating an MCS machine catalog in a Red Hat OpenShift virtualization environment, you can’t use a master image and a machine profile that have different operating system types. This is due to how Red Hat OpenShift manages each OS type. Therefore, using a Windows VM as the master image with a non-Windows (example, Linux) VM as the machine profile, or the other way around, is not supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Currently, the VMs created using `InstanceType` are not supported as a master image.
- When the metainstaller is used to install the Citrix Virtual Apps and Desktops components on a machine running Windows Server 2025, then MsiInstall events are not being written to the event logs.
- After you create a backup and navigate to the **Components** tab for that selected backup, you see empty data for a component that has a resource after you click **View component members**.
- When trying to restore AWS, Azure, GCP, and XenServer® hosting connections, the **Restore count** on the **Restore Progress** page is **1** and displays only the restore action result of XenServer.
- After you create a backup, the **Hosting Connections** component count on the **Backup progress** page is displayed as **0**.
- In a VMware environment hosted on AWS, the MCS machine catalog creation fails if the master image is vTPM enabled. This issue affects all Citrix Virtual Apps and Desktops versions and is due to a problem in the VMware environment. For assistance, contact VMware support.
- If you use Microsoft Entra Domain Services: End user logon UPNs must contain the domain name that was specified when enabling Microsoft Entra ID Domain Services. Logons cannot use UPNs for a custom domain you create, even if that custom domain is designated as primary.

For issues related to current VDAs, see Known issues.

Deprecations and removals

This article gives you advanced notice of Citrix DaaS (formerly Citrix Virtual Apps and Desktops service) features that are being phased out, so that you can make timely business decisions. Citrix monitors customer use and feedback to determine when features are withdrawn. Announcements can change in subsequent releases and might not include every deprecated feature or functionality. For details about product lifecycle support, see the Product Lifecycle Support Policy article.

NOTE:

Citrix Virtual Apps and Desktops deprecations and removals are described in their own Deprecation article.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Deprecations and removals

The following list shows the Citrix DaaS™ features that are deprecated or removed.

- *Deprecated* items are not removed immediately. Citrix® continues to support them but they will be removed in a future release.
- *Removed* items are removed, or no longer supported, in Citrix DaaS. Dates in **bold** face indicate the latest updates.

ITEM	DEPRECATION ANNOUNCED IN RELEASE	REMOVED IN RELEASE	ALTERNATIVE
Support for the third-party HPE Moonshot Machine Manager plug-in	May 2024	-	Use Citrix-managed HPE Moonshot plug-in
The **Last Boot Time (UTC)** column in Studio and the **LastBootTime** field in **Get-ProvVM** and **Get-ProvVMDetails** responses	July 2026	-	-
Studio UI option for App-V full infrastructure	April 2026		Migrate to the App-V Single Admin model
Per-delivery-group license overrides (multi-type licensing)	April 2026	Citrix DaaS uses site-level license settings only. Delivery group overrides are ignored and the **License Assignment**

Features in preview

Features in preview are available to use in non-production or limited production environments, and to give customers an opportunity to share feedback. Citrix® does not accept support cases for features in preview but welcomes feedback for improving them. Citrix might act on feedback based on its severity, criticality, and importance.

List of features in preview

The following table lists the features in the preview.

TITLE	ENABLEMENT FORM (CLICK THE ICON)	FEEDBACK FORM (CLICK THE ICON)
Citrix Integration with Azure Local for Linux workload		NA
Secure Private Access integration with Monitor	NA	NA
Enrollment of Hybrid Entra ID joined non-persistent VMs into Microsoft Intune		NA
VUS Multi Release Support	NA	NA

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Citrix Integration with Azure Local for Linux workload

Azure Local is a hyper-converged infrastructure (HCI) solution that connects the on-premises system to Azure for cloud-based services, monitoring, and management.

With this feature, MCS supports Azure Local as a new platform, and thus supports:

- Provisioning of Azure Arc-enabled Linux VMs on Azure Local.
- Power management of Linux VMs created on Azure Local.

For more information, see Citrix Integration with Azure Local for Linux workload.

Secure Private Access integration with Monitor

This preview allows admin to monitor and troubleshoot all Secure Private Access sessions in Monitor.

Available actions include viewing the details of the following:

- Secure Private Access active sessions for a user under the Select a Session popup > Active Sessions tab
- Secure Private Access failed or blocked enumerations and failed app launches under the Select a Session popup > Denied Access tab
- Session and application details view for active and failed app launches, as well as for failed and blocked enumerations

For more information, see Secure Private Access integration with Monitor (Preview) page.

Enrollment of Hybrid Entra ID joined non-persistent VMs into Microsoft Intune

With this preview, you can now enroll Hybrid Entra ID joined non-persistent VMs into Microsoft Intune (with Configuration Manager) for co-management. This feature applies to single and multi-session non-persistent VMs and on all hypervisors and cloud services, ensuring uniform device management across your infrastructure. To avail the feature, the VDA version must be 2407 or later. For more information, see Enrollment of Hybrid Entra ID joined non-persistent VMs into Microsoft Intune.

VUS Multi Release Support

Previously VUS only allowed upgrades to the most recent version of the VDA released in each of the Upgrade Track. This new tech preview feature enables you to upgrade to new as well as previously released versions of the VDA. This feature is supported for catalog level Upgrades and individual machine Level VDA upgrades. For more information, see VUS Multi Release Support.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Preview to general availability (GA)

- Tenant co-management for CSP multitenant DaaS
- Integration with Nutanix Prism Central on AHV
- Image management
- Support for creating and managing Azure confidential VMs using Full Configuration
- Support for Citrix-managed HPE Moonshot plug-in
- Azure hibernation
- Policy sets
- Cost savings
- Diagnose historical user sessions
- Infrastructure monitoring
- Infrastructure policy
- Monitor multiple Citrix DaaS instances

© 1997–2026 Citrix Systems, Inc. All rights reserved.

System requirements

Introduction

System requirements for components that are not covered here (such as Citrix Workspace™ app and Citrix Provisioning™) are described in their respective documentation.

Specific recommendations for sizing VMs that deliver desktops and applications cannot be provided because of the complex and dynamic nature of hardware offerings. Every deployment has unique needs. Generally, sizing a VM is based on the hardware and not the user workloads (except for RAM; you need more RAM for applications that consume more.) The Citrix Tech Zone contains the latest guidance on VDA sizing.

IMPORTANT:

VDA versions mentioned in this article are subject to the Citrix product lifecycle. For more information, see the Product Matrix on the Citrix web site.

For more information about using LTSR VDAs with Citrix DaaS, see CTX205549.
Remember: In a Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) deployment, you don't need to install or manage the core components (Delivery Controllers, the site database, or management and monitoring consoles). For Virtual Delivery Agent (VDA) installation guidance, see:

- Install VDAs
- Install VDAs using the command line.

Cloud Connectors

For details, see Cloud Connector Technical Details.

Hypervisor connectivity validation

To support the transition of hypervisor management (XenServer, VMware, AWS) from Cloud Connectors to the Cloud Delivery Controller, Citrix DaaS provides an automated connectivity

© 1997–2026 Citrix Systems, Inc. All rights reserved.

validation engine. This tool verifies that the service can reach your resource location endpoints without impacting production environments.

Pre-Migration validation

Before the plugin moves to the cloud, the system runs a health check in **Validation Mode** to identify configuration gaps in:

- **Networking:** Firewall rules, DNS resolution, and routing.
- **Security:** SSL/TLS certificate trust and handshakes.
- **Authentication:** Credential validity from the new execution context.

Actionable reporting

Validation results are surfaced directly in the **Studio UI** and **Migration Readiness Checks**. If a check fails, the system provides specific error details (e.g., connection timeouts or certificate mismatches) via:

- **Health Status Indicators:** Real-time visibility in the management console. See https://docs.citrix.com/en-us/citrix-daas/manage-deployment/vda-health-checks#run-health-checks-for-vdas
- **Event Logs:** Detailed records for pre-migration remediation.
- **Post-Migration Alerts:** Continuous monitoring of NGS-related setup issues.

VDAs in an Azure environment

Supported operating systems:

- Windows 11 multi-session
- Windows 11 single-session
- Windows 10 multi-session
- Windows 10 single-session
- Windows Server 2025
- Windows Server 2022 (requires minimum VDA 2106)
- Windows Server 2019
- Windows Server 2016

© 1997–2026 Citrix Systems, Inc. All rights reserved.

All VDAs that haven't reached end of life are supported for use with Citrix DaaS. For LTSR VDAs, we recommend using them with the latest Cumulative Update. For more information about the lifecycle of VDAs, see Citrix Product Matrix.

Windows Server 2012 R2 is supported only with VDA 1912 (and later CUs).

Windows Server requires Microsoft RDS licensing.

For information about Azure Virtual Desktop, see the Microsoft documentation.

VDAs in Amazon WorkSpaces Core Managed Instances

Supported operating systems:

- Windows 11 single-session
- Windows 10 single-session
- Windows Server 2025
- Windows Server 2022
- Windows Server 2019
- Windows Server 2016
- Ubuntu Server 24.04 LTS
- Debian 12

VDA for single-session OS

The following information applies to the latest VDA release.

Supported operating systems:

- Windows 11
- Windows 10
    - For edition support, see CTX224843. That article also contains links to Citrix known issues with the supported Windows versions.
    - Desktop composition redirection and legacy graphics mode are not supported on Windows 10.

Requirements:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Microsoft .NET Framework 4.8 is installed automatically, if it (or a later version) is not already installed.
- Microsoft Visual C++ 2015-2019 Redistributable.
  - If the machine contains an earlier version of that runtime (such as 2015-2017), the Citrix® installer upgrades it.
  - If the machine contains a version earlier than 2015, Citrix installs the newer version in parallel.

Remote PC Access uses this VDA, which you install on physical office PCs. This VDA supports Secure Boot for Citrix Virtual Desktops™ Remote PC Access.

Several multimedia acceleration features (such as HDX™ MediaStream Windows Media Redirection) require that Microsoft Media Foundation be installed on the machine on which you install the VDA. If the machine does not have Media Foundation installed, the multimedia acceleration features are not installed and do not work. Do not remove Media Foundation from the machine after installing the Citrix software. Otherwise, users cannot log on to the machine. On most supported Windows desktop OS editions, Media Foundation support is already installed and cannot be removed. However, N editions do not include certain media-related technologies. You can obtain that software from Microsoft or a third party.

More information:

- For Linux VDA information, see the Linux Virtual Delivery Agent product documentation.
- To use the server VDI feature, you can use the command line interface to install a single-session VDA on a supported Windows Server machine. See Server VDI for guidance.
- For information about installing a VDA on an older machine, see Earlier operating systems.
- See also VDAs in an Azure Virtual Desktop environment.

VDA for multi-session OS

The following information applies to the latest VDA release.

Supported operating systems:

- Windows Server 2025 (requires minimum VDA 2407)
- Windows Server 2022 (requires minimum VDA 2106)
- Windows Server 2019, Standard and Datacenter Editions
- Windows Server 2016, Standard and Datacenter Editions

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Windows 11
- Windows 10 (64-bit) all supported versions

The installer automatically deploys the following requirements:

- Microsoft .NET Framework 4.8 is installed automatically, if it (or a later version) is not already installed.
- Microsoft Visual C++ 2015-2019 Redistributable.
  - If the machine contains an earlier version of that runtime (such as 2015-2017), the Citrix installer upgrades it.
  - If the machine contains a version earlier than 2015, Citrix installs the newer version in parallel.

The installer automatically installs and enables Remote Desktop Services role services, if they are not already installed and enabled. This triggers a restart.

Several multimedia acceleration features (such as HDX MediaStream Windows Media Redirection) require that the Microsoft Media Foundation be installed on the machine on which you install the VDA. If the machine does not have Media Foundation installed, the multimedia acceleration features are not installed and do not work. Do not remove Media Foundation from the machine after installing the Citrix software. Otherwise, users cannot log on to the machine. On most Windows Server versions, the Media Foundation feature is installed through the Server Manager. However, N editions do not include certain media-related technologies. You can obtain that software from Microsoft or a third party.

If Media Foundation is not present on the VDA, these multimedia features do not work:

- Flash Redirection
- Windows Media Redirection
- HTML5 Video Redirection
- HDX RealTime Webcam Redirection

More information:

- For Linux VDA information, see the Linux Virtual Delivery Agent articles.
- For information about installing a VDA on a Windows operating system that is no longer supported, see Earlier operating systems.
- See also VDAs in an Azure Virtual Desktop environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Hosts / virtualization resources

The following host/virtualization resources (listed alphabetically) are supported. Where applicable, the *major.minor* versions are supported, including updates to those versions. CTX131239 contains the most current hypervisor version information, plus links to known issues.

- **Amazon Web Services (AWS)**
  - You can provision applications and desktops on supported Windows server operating systems.
  - The Amazon Relational Database Service (RDS) is not supported.

  For more information, see AWS cloud environments.
- **Amazon WorkSpaces Core Managed Instances**

  For more information, see AWS cloud environments.
- **XenServer (formerly Citrix Hypervisor™)**

  CTX131239 contains current version information, plus links to known issues.

  For more information, see XenServer virtualization environments.
- **Google Cloud Platform**

  For more information, see Google Cloud environments and Getting Started with Citrix DaaS on Google Cloud.
- **HPE Moonshot**

  For more information, see HPE Moonshot virtualization environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

You must not install the VDA software on any Citrix DDC or StoreFront server. The VDA must be a stand-alone system. Installing multiple components on a single VM is only permissible when developing a proof-of-concept or when publishing the Studio admin console to administrators only. In this case you must ensure non-admin users do not have access to DDC/StoreFront VMs.

Active Directory functional levels

The following functional levels for the Active Directory forest and domain are supported:

- Windows Server 2016
- Windows Server 2012
- Windows Server 2008 R2

For more information about Active Directory, see Active Directory joined.

HDX technologies

For specific HDX feature support and requirements, see HDX.

Universal Print Server

The Universal Print Server comprises client and server components. The UpsClient component is included in the VDA installation. You install the UpsServer component on each print server where shared printers reside that you want to provision with the Citrix Universal™ Print Driver in user sessions.

The UpsServer component is supported on:

- Windows Server 2025
- Windows Server 2019
- Windows Server 2016

Requirements:

- Microsoft .NET Framework 4.8 (minimum)
- Microsoft Visual C++ 2015-2022 Redistributable.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If the machine contains an earlier version of that runtime (such as 2015-2017), the Citrix installer upgrades it.
- If the machine contains a version earlier than 2015, Citrix installs the newer version in parallel.

For multi-session VDAs, user authentication during printing operations requires the Universal Print Server to be joined to the same domain as the VDA.

Standalone client and server component packages are also available for download.

For more information, see Provision printers.

Service connectivity

See System and Connectivity Requirements for Internet connection information. That information includes requirements that are common to most Citrix Cloud services, plus requirements specific to Citrix DaaS.

Other

- The Microsoft Group Policy Management Console (GPMC) is required if you store Citrix policy information in Active Directory rather than the site configuration database. The machine on which you install `CitrixGroupPolicyManagement_x64.msi` must have Visual Studio 2015 runtime installed. For more information, see the Microsoft documentation.
- This product supports PowerShell versions 3 through 5.
- For product components and features that you can install on Windows Servers, Server Core and Nano Server installations are not supported, unless noted.
- For details about resource limits in a deployment, see Limits.
- For supported StoreFront versions, see the StoreFront system requirements.
- For information about ports that Citrix DaaS uses, see Communications Ports Used by Citrix Technologies.
- For information about requirements when using the Quick Deploy management interface, see Requirements.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limits

The values in this article indicate the limits of a single Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) instance. Citrix has extensively tested these limits and recommends for the best end user and admin experience. These limits are soft limits and not technically enforced (except for the number of Active Directory domains and the total number of VDAs per resource location). When the number of concurrent users exceeds 125,000, Citrix can scale and combine multiple Citrix DaaS instances, to deliver a unified experience at any scale.

The information in this article is dynamic. Check back frequently for updates. If you have current requirements that the published limits do not address, contact your Citrix® representative for assistance as early as possible.

Configuration limits

If policies exceed the limit, Citrix recommends using the Workspace Environment Management service or Active Directory Group Policy Objects (GPOs).

RESOURCE	LIMIT
Active Directory domains	250
Application folders	1,000
Application Groups	750
Applications	5,000
Catalogs	2,000
Delivery Groups	2,000
Host connections	200
Resource locations	250
Policies (Studio)	200

© 1997–2026 Citrix Systems, Inc. All rights reserved.

RESOURCE	LIMIT
Tags	20,000
VDAs	130,000

Resource location limits

The following table lists the limits for each resource location.

If your requirements exceed these limits, Citrix recommends using additional resource locations.

RESOURCE	LIMIT
Total VDAs (hard limit)	10,000
Total sessions	25,000
Active Directory domains	1
Host connections	40

Citrix Cloud Connectors are assigned to resource locations and link workloads to Citrix DaaS. For information about Cloud Connector limits, see Size and scale considerations for Cloud Connectors.

Provisioning limits

The provisioning limits in the following table are the Citrix recommended maximums for a single public provider subscription.

You are likely to reach quota limits from your public cloud vendor at lower levels. In such cases, contact the vendor to raise your subscription quota. For larger-scale deployments, Citrix recommends a hub-and-spoke model, where VDAs are distributed across multiple subscriptions and host connections.

For more information, see the following reference architectures:

- Citrix DaaS on AWS
- Citrix virtualization on Google Cloud
- Citrix DaaS on Azure

© 1997–2026 Citrix Systems, Inc. All rights reserved.

RESOURCE	LIMIT
VDAs per AWS region	3,000
VDAs per Google Cloud Platform project	3,000
VDA per Microsoft Azure subscription per region	5,000

NOTE:

The limits are Citrix recommended.

Usage limits

For information about administrator roles and the differences between them, see:

- Manage Studio administrators
- Monitor (Director) administrators

RESOURCE	LIMIT
Concurrent Monitor (Director) full administrators	40
Concurrent Monitor (Director) help desk administrators	200
Concurrent Monitor (Director) session administrators	50
Concurrent Manage (Studio) cloud administrators	100
Concurrent Manage (Studio) help desk administrators	60
Concurrent end users	125,000
Resources published to a single user	250

© 1997–2026 Citrix Systems, Inc. All rights reserved.

RESOURCE	LIMIT
Session launches per minute	3,000

- Monitor (Director) supports the aggregation of up to four Citrix DaaS™ tenants (spokes) under a single tenant (hub).
- A help desk administrator on the hub instance can monitor and troubleshoot users, machines, endpoints, and transactions from all aggregated instances (hub and spokes) as per the Delegated Administration configuration on the specific instance.
- The number of concurrent administrators per Citrix DaaS instance is as per the Usage Limits table.

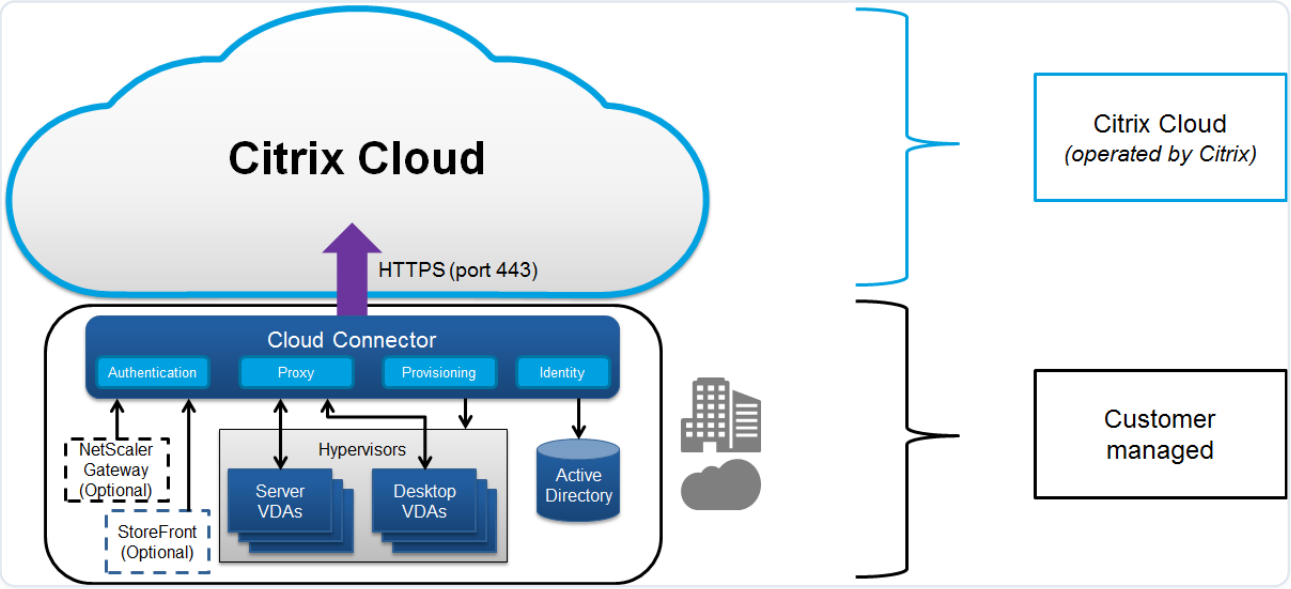
Limits change log

The following table tracks the configuration limit modification:

DATE	RESOURCE	DESCRIPTION
18 Feb 2025	Configuration limit of Resource locations	The limit increased from 200 to 250.
18 Feb 2025	Configuration limit of Active Directory domains	The limit increased from 100 to 250.
18 Aug 2025	Configuration limit of Tags	The limit increased from 10,000 to 20,000.
24 Feb 2025	Number of Application Groups	The limit increased from 250 to 750.
24 Feb 2025	Number of VDAs	The limit increased from 100,000 to 130,000.
12 Dec 2024	Resource locations	The limit increased from 100 to 200.
23 May 2024	VDAs per AWS account per region	The limit increased from 1500 to 3000.
22 Nov 2023	Active Directory domains	Limit increased from 85 to 100.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

DATE	RESOURCE	DESCRIPTION
	Catalogs	The limit increased from 1000 to 2000.
	Delivery Groups	The limit increased from 1000 to 2000.
	Resource locations	The limit increased from 85 to 100.
	Resource location -> Total sessions	Limit increased from 20,000 to 25,000.
04 Oct 2023	Tags	The limit increased from 500 to 10,000.
07 Dec 2023	Provisioning limits -> VDA per Microsoft Azure subscription per region	The limit increased from 2,500 to 5,000.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Technical security overview

Security overview

This document applies to Citrix DaaS (formerly Citrix Virtual Apps and Desktops service) hosted in Citrix Cloud. This information includes Citrix Virtual Apps Essentials and Citrix Virtual Desktops Essentials.

Citrix Cloud manages the operation of the control plane for Citrix DaaS environments. The control plane includes the Delivery Controllers, management consoles, SQL database, license server, and optionally StoreFront™ and Citrix Gateway. The Virtual Delivery Agents (VDAs) hosting the apps and desktops remain under the customer's control in the data center of their choice, either cloud or on-premises. These components are connected to the cloud service using an agent called the Citrix Cloud Connector. If customers elect to use Citrix® StoreFront Cloud, they can also choose to use the Citrix Gateway Service instead of running Citrix Gateway within their data center. The following diagram illustrates Citrix DaaS and its security boundaries.

Citrix cloud-based compliance

Visit the Citrix Trust Center for more information regarding Citrix Cloud Certifications, and check back frequently for updates.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The use of Citrix Managed Azure Capacity with various Citrix DaaS™ editions and Universal Hybrid Multi-Cloud has not been evaluated for Citrix SOC 2 (Type 1 or 2), ISO 27001, HIPAA, or other cloud compliance requirements.

Data flow

Citrix DaaS does not host the VDAs, so the customer's application data and images required for provisioning are always hosted in the customer setup. The control plane has access to metadata, such as user names, machine names, and application shortcuts, restricting access to the customer's Intellectual Property from the control plane.

Data flowing between the cloud and customer premises uses secure TLS connections over port 443.

Data isolation

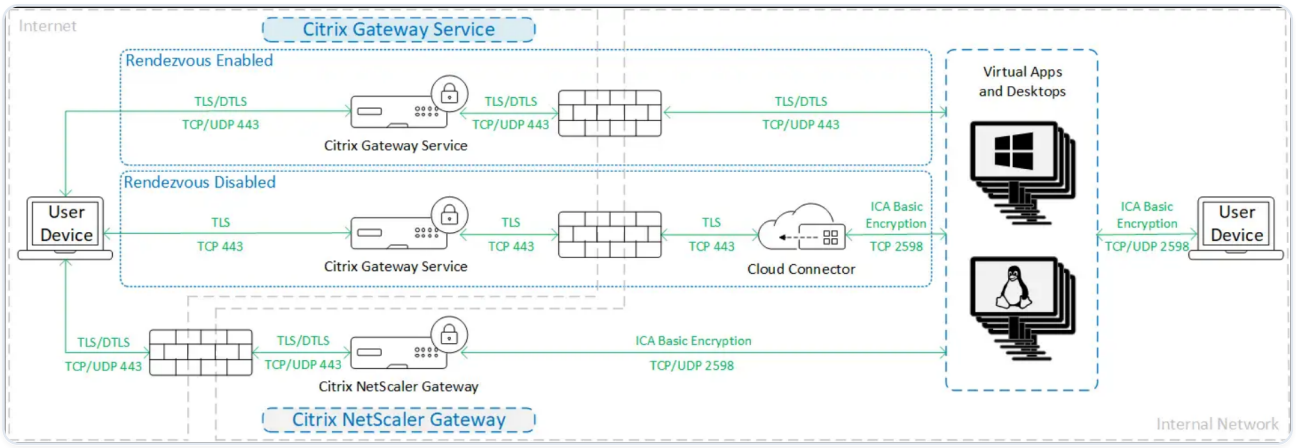
Citrix DaaS stores only the metadata needed for the brokering and monitoring of the customer's applications and desktops. Sensitive information, including images, user profiles, and other application data remains on the customer premises or in their public cloud vendor's subscription.

Service editions

The capabilities of Citrix DaaS vary by edition. For example, Citrix Virtual Apps Essentials™ supports only Citrix Gateway service and Citrix® StoreFront Cloud. Consult that product documentation to learn more about supported features.

ICA® Security

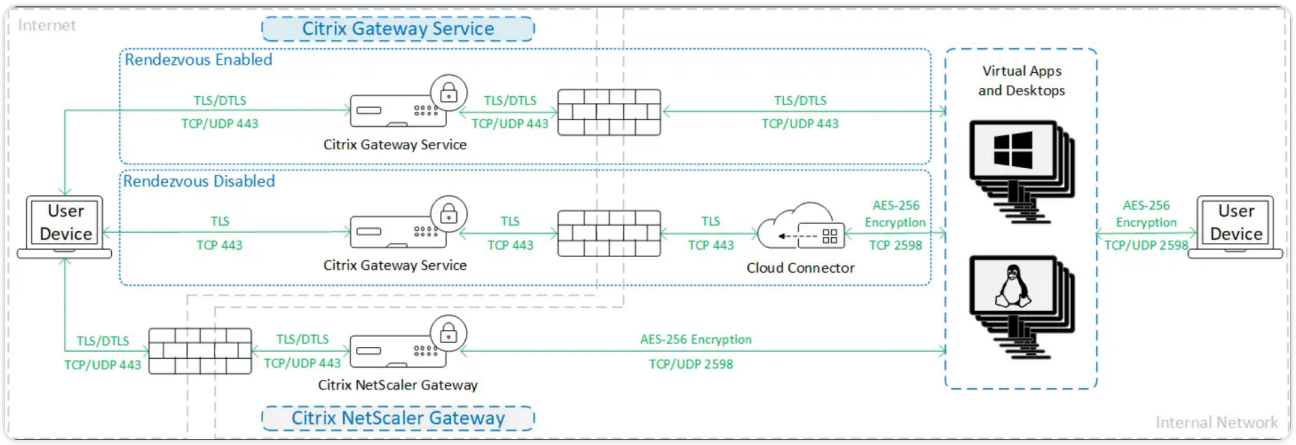
Citrix DaaS provides several options for securing ICA traffic in transit. The following are the options available:



- **Basic encryption:** The default setting.
- **Secure HDX™:** Allows true end-to-end encryption of session data using AES-256.
- **SecureICA:** Allows encrypting session data using RC5 (128-bit) encryption.
- **HDX Direct:** Allows using network-level encryption using TLS/DTLS.
- **VDA TLS/DTLS:** Allows using network-level encryption using TLS/DTLS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

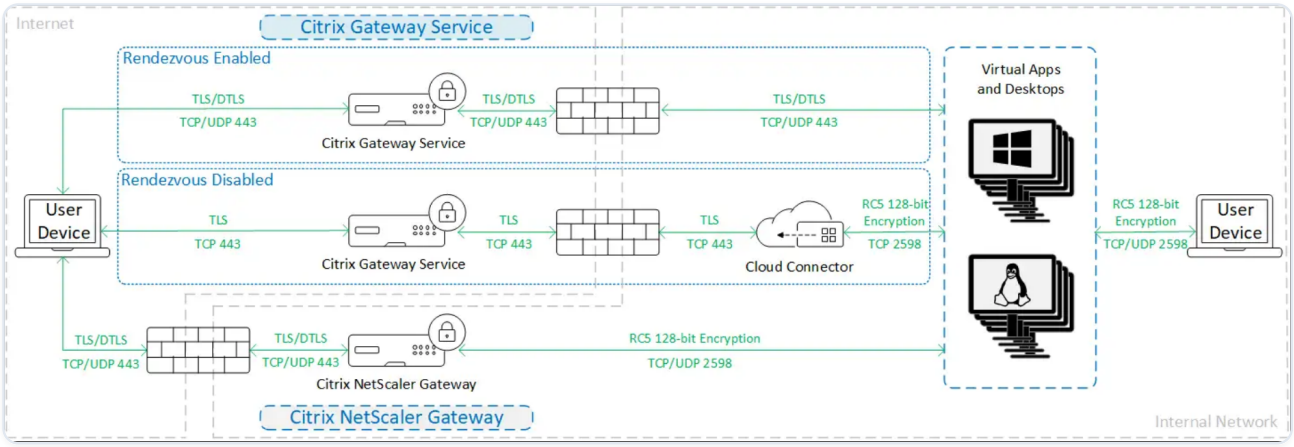
- **Rendezvous protocol:** Available only when using the Citrix Gateway Service. When using the Rendezvous protocol, all segments of the ICA sessions' connections are encrypted using TLS/DTLS.



Basic encryption

When using basic encryption, traffic is encrypted as shown in the following diagram.

Secure HDX



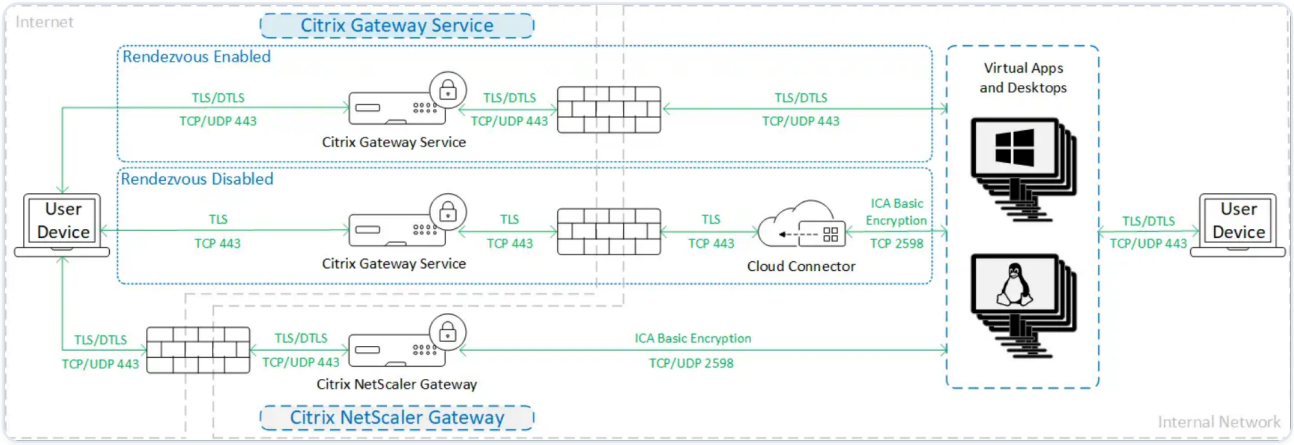
When using Secure HDX, traffic is encrypted as shown in the following diagram.

SecureICA

When using SecureICA, traffic is encrypted as shown in the following diagram.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

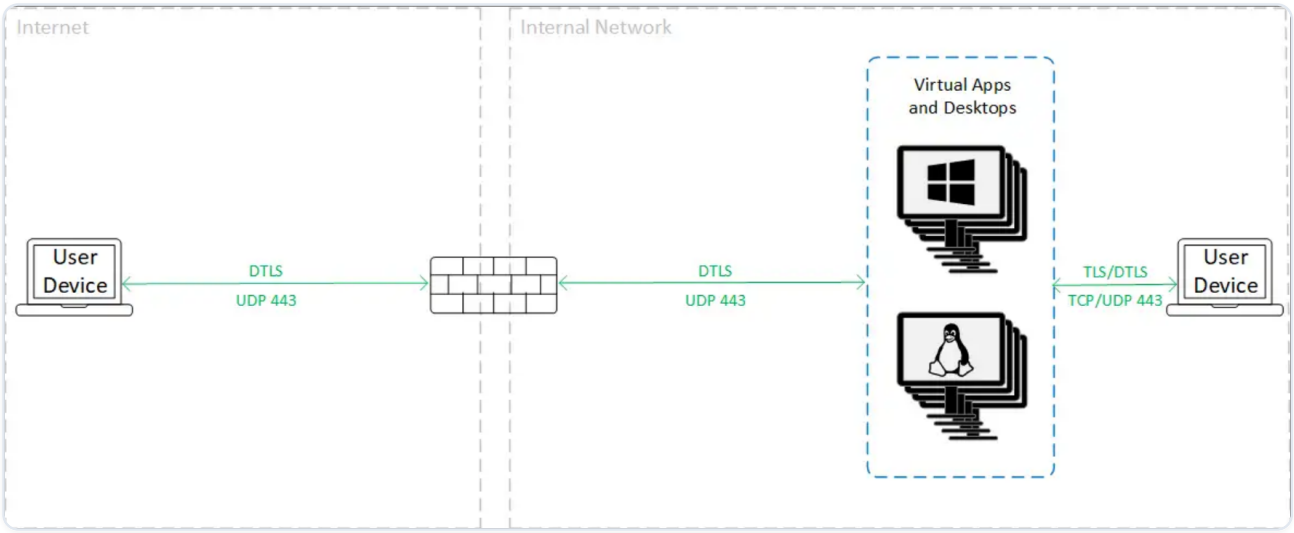


It is recommended to use Secure HDX instead. Secure ICA was deprecated with the release of Citrix Virtual Apps and Desktops 2402.

SecureICA is not supported when using Workspace app for HTML5.

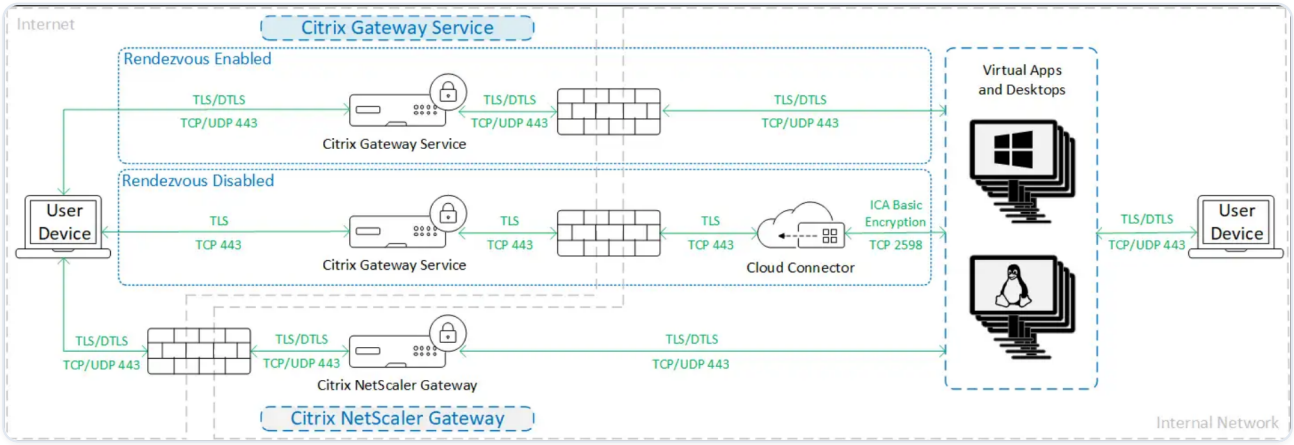
HDX Direct

Internal



When using HDX Direct in Internal only mode, traffic is encrypted as shown in the following diagram.

External



When using HDX Direct in Internal and External mode, traffic is encrypted as shown in the following diagram.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

VDA TLS/DTLS

When using VDA TLS/DTLS encryption, traffic is encrypted as shown in the following diagram.

NOTE:

When using the Gateway Service without Rendezvous, the traffic between the VDA and the Cloud Connector is not TLS encrypted, because the Cloud Connector does not support connecting to the VDA with network-level encryption.

More resources

For more information about the ICA security options and how to configure them, see:

- Secure HDX: Secure HDX
- HDX Direct: HDX Direct
- SecureICA: Security policy settings
- VDA TLS/DTLS: Transport Layer Security

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Rendezvous protocol: Rendezvous protocol

Credential handling

Citrix DaaS handles four types of credentials:

- User Credentials: When end users authenticate using their Active Directory username and password, these are stored to provide single sign on to the VDAs. When using customer-managed StoreFront, these are normally encrypted by the connector before sending to DaaS, for more information see Client access via StoreFront.
- Administrator Credentials: Administrators authenticate against Citrix Cloud. Authentication generates a one-time signed JSON Web Token (JWT) which gives the administrator access to Citrix DaaS.
- Hypervisor Passwords: On-premises hypervisors that require a password for authentication have an administrator-generated password that is directly stored encrypted in the SQL database in the cloud. Citrix manages peer keys to ensure that hypervisor credentials are only available to authenticated processes.
- Active Directory (AD) Credentials: Machine Creation Services™ uses the Cloud Connector for creating machine accounts in a customer's AD. Because the machine account of the Cloud Connector has only read access to AD, the administrator is prompted for credentials for each machine creation or deletion operation. These credentials are stored only in memory, and are held only for a single provisioning event.

Deployment considerations

Citrix recommends that users consult the published best practices documentation for deploying Citrix Gateway applications and VDAs within their environments.

Cloud Connectors

Communication with Citrix Cloud

All connections from Citrix Cloud Connectors to DaaS and other Citrix Cloud services use HTTPS with TLS 1.2.

HTTPS for XML service and STA

If you use on-premise StoreFront or NetScaler Gateways, it is recommended that you enable HTTPS and disable HTTP on the connector. For more information, see HTTPS Configuration.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Network access requirements

In addition to the ports described at Inbound and outbound ports configuration, Cloud Connectors have the following network access requirements:

- The Citrix Cloud Connectors require only port 443 outbound traffic to the internet, and can be hosted behind an HTTP proxy.
- Within the internal network, the Cloud Connector needs access to the following for Citrix DaaS:
  - VDAs: Port 80, both inbound and outbound. plus 1494 and 2598 inbound if using Citrix Gateway service
  - StoreFront servers: Port 443 inbound if using HTTPS (recommended) or port 80 if using HTTP (not recommended).
  - Citrix Gateways, if configured as a STA: Port 443 inbound if using HTTPS (recommended) or port 80 if using HTTP (not recommended).
  - Active Directory domain controllers
  - Hypervisors: Outbound only. See Communications Ports Used by Citrix Technologies for specific ports.

Traffic between the VDAs and Cloud Connectors is encrypted using Kerberos message-level security.

Security Keys

You can use Security Keys to ensure that only authorized StoreFront servers and Citrix Gateway appliances are able to connect to DaaS via the cloud connectors. This is especially important if you have enabled XML trust.

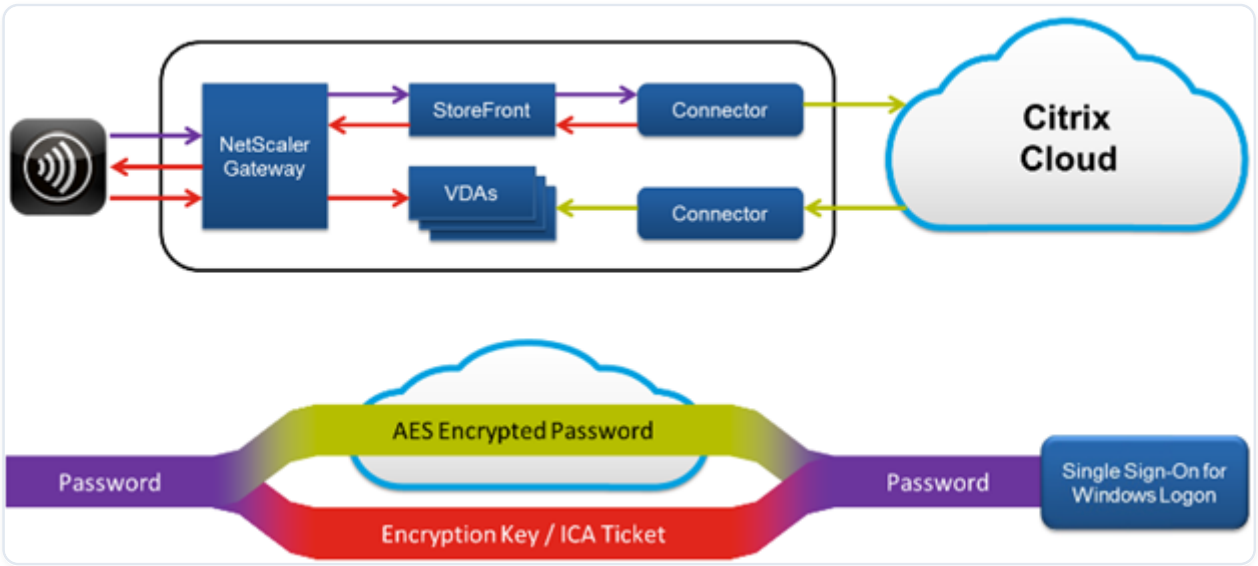
Client access

You can provide client access via either Citrix hosted Citrix® StoreFront Cloud or by hosting your own StoreFront deployment.

Users can connect to their store using either Citrix Workspace app or a web browser. For security recommendations for Citrix Workspace app, see the documentation for each platform.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Client access via Citrix® StoreFront Cloud



Citrix® StoreFront Cloud is a Citrix managed service that enables client apps to access DaaS resources without needing any on-premises infrastructure. For supported versions of Citrix Workspace app and other requirements, see Citrix® StoreFront Cloud System Requirements. For information on security, see Citrix® StoreFront Cloud security overview.

Client access via Citrix StoreFront

As an alternative to Citrix® StoreFront Cloud, you can provide client access by deploying Citrix® StoreFront in your local environment. This offers greater security configuration options and flexibility for deployment architecture, including the ability to maintain user credentials on-premises. The StoreFront server can be hosted behind a Citrix Gateway to provide secure remote access, enforce multifactor authentication, and add other security features. For more information see Secure your StoreFront deployment.

User credentials

If the user authenticated to StoreFront with their active directory credentials, when a user launches an application, StoreFront passes the credentials to the Cloud Connector. By default the Cloud Connector encrypts user credentials using AES encryption and a random one-time key generated for each launch. The key is never passed into the cloud, and returned only to Citrix Workspace app. The Citrix Workspace app then passes this key to the VDA to decrypt the user password during session launch for a single sign-on experience. The flow is shown in the following figure.

It is important that you configure HTTPS between the client, gateway, storefront and connector to ensure that the password is always encrypted within your network.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

With the default behavior, as Citrix Cloud does not have access to the credentials, it is unable to forward the credentials to other Cloud Connectors or Connector Appliances for validation. This is required if you use multiple domains without trust relationships. You can disable this behavior and allow credentials to be uploaded to Citrix cloud so that it can forward them to other cloud connectors and Connector Appliances for validation. To configure this use the DaaS PowerShell SDK cmdlet Set-Brokersite with parameter `CredentialForwardingToCloudAllowed`.

Connecting to Cloud Connectors using HTTPS

It is recommended that you configure StoreFront to connect to the Cloud Connectors using HTTPS to ensure all communication is encrypted. This requires that you have enabled HTTPS for XML service and STA. To Configure StoreFront to connect using HTTPS, see Add resource feeds for Citrix Desktops as a Service and Add Citrix Gateway appliance.

XML trust

By default, when StoreFront connects to DaaS for actions such as enumeration and launch, StoreFront must pass through the user's Active Directory credentials so that DaaS can authenticate the user and check the user's group membership. However when using other authentication methods such as domain pass-through, smart cards or SAML, StoreFront does not have the active directory password. In this case you must enable "XML Trust". With XML trust enabled, DaaS allows StoreFront to perform actions on behalf of a user such as enumerating and launching applications without validating the user's password. Before enabling XML trust, use Security Keys or another mechanism such as firewalls or IPsec to ensure that only trusted StoreFront servers are able to connect to the Cloud Connectors.

To enable XML trust in Studio, go to **Settings > Site settings** and turn on **Enable XML trust**.

To use the Citrix DaaS SDK to check the XML trust current value, run Get-BrokerSite and inspect the value of `TrustRequestsSentToTheXMLServicePort`.

To use the Citrix DaaS SDK to enable or disable XML trust, run Set-BrokerSite with parameter `TrustRequestsSentToTheXMLServicePort`.

Citrix Gateway service

Using the Citrix Gateway service avoids the need to deploy Citrix Gateway within customer data centers.

For details, see Citrix Gateway service.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

All TLS connections between the Cloud Connector and Citrix Cloud are initiated from the Cloud Connector to the Citrix Cloud. No in-bound firewall port mapping is required.

On-premise NetScaler® gateway

You can use an on-premise NetScaler gateway to provide access to resources. The Gateway must be able to reach cloud connectors to redeem STA tickets. It is recommended you configure the gateway to connect to the Cloud Connectors using HTTPS, see HTTPS for XML service and STA. If you have enabled Security keys then you must configure the gateway to include the keys.

More information

The following resources contain security information:

- Technical security overview for Citrix Managed Azure.
- Citrix Trust Center: The trust center has documentation about standards and certifications that are important in maintaining a secure and compliant IT environment.
- Secure Deployment Guide for the Citrix Cloud Platform: This guide provides an overview of security best practices when using Citrix Cloud and describes the information Citrix Cloud collects and manages. This guide also contains links to comprehensive information about the Citrix Cloud Connector.
- System and Connectivity Requirements.
- Securing Citrix Virtual apps and Desktops on-prem.

NOTE:

This document is intended to provide the reader with an introduction to and overview of the security functionality of Citrix Cloud; and to define the division of responsibility between Citrix and customers with regard to securing the Citrix Cloud deployment. It is not intended to serve as a configuration and administration guidance manual for Citrix Cloud or any of its components or services.

Technical security overview for Citrix Managed Azure

See Technical security overview for more information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Virtual channel allow list

The virtual channel allow list is a feature that allows you to control which non-Citrix virtual channels are allowed in your environment. By default, the virtual channel allow list feature is enabled. As a result, only Citrix virtual channels are allowed to open in Citrix Virtual Apps and Desktops™ sessions. If there is a need to use custom virtual channels, whether homegrown or from a third party, these need to be explicitly added to the allow list.

Configuration

The virtual channel allow list is enabled by default. You can configure this feature using the following settings in the Citrix policy:

- **Virtual channel allow list**: to enable or disable the feature and to add virtual channels to the list.
- **Virtual channel allow list log throttling**: sets the throttling period for the virtual channel allow list event logging.
- **Virtual channel allow list logging**: sets the logging level for the virtual channel allow list.

Adding virtual channels to the allow list

To add a virtual channel to the allow list, you need the following information:

1. The virtual channel name as defined in the code, which can be up to seven characters long. For example, `CTXCVC1`.
2. The paths to the processes that open the virtual channel on the VDA machine. For example, `C:\Program Files\Application\run.exe`.

Once you have the required information, you must add the virtual channel to the allow list using the Virtual channel allow list policy setting. To add a virtual channel to the list, enter the virtual channel name followed by a comma, and then the path to the process that accesses the virtual channel. If there are multiple processes, you can add these processes by separating each process with commas.

For single processes

Using the previous examples, add the following entry to the list:

```
CTXCVC1,C:\Program Files\Application\run.exe
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For multiple processes

If there are multiple processes, add the following entry to the list:

`CTXCVC1,C:\Program Files\Application\run.exe,C:\Program Files\Application\run2.exe`

Using wildcards

The use of wildcards (*) is supported. You can use wildcards when the names of directories or executables change based on the version of the application, or if the third-party component is installed in the users' profiles.

You can use wildcards in the following scenarios:

- To replace the full directory name. For example: `C:\Program Files\Application*\run1.exe`
- To replace part of the directory name. For example: `C:\Program Files\Application\v*\run1.exe`
- To replace the executable's name. For example: `C:\Program Files\Application\v1.2*.exe`
- To replace part of the executable's name. For example: `C:\Program Files\Application\v1.2\run*.exe`

The following restrictions apply:

- The wildcard can only be used to replace a single directory. For example, if the executable is located in `C:\Program Files\Application\v1.2\run1.exe`
  - Allowed: `C:\Program Files\Application*\run1.exe`
  - Not allowed: `C:\Program Files*\run1.exe`
- Entries must contain the file name extension.
  - Allowed: `C:\Program Files\Application\v1.2*.exe`
  - Not allowed: `C:\Program Files\Application\v1.2*`
- All paths must be local.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Network paths are not allowed.
- Wildcard support is available from Citrix Virtual Apps and Desktops 2206.
- Wildcard support is available in Citrix Virtual Apps and Desktops 2203 LTSR from CU2.

Using system environment variables

You can use system environment variables to simplify the definition of the trusted processes in your allow list. You can use any of the out-of-box variables, such as `%programfiles%`, `%programfiles(x86)%`, `%systemdrive%`, and `%systemroot%`.

You can also use custom environment variables as long as they are defined at the system level.

The following examples depict out-of-box environment variables:

- `%programfiles%\Application\v1.2\run.exe`
- `%programfiles%\Application*\run.exe`
- `%programfiles(x86)%\Application\v1.*\run.exe`

The following example depicts a custom system environment variable:

- Custom variable name: `app`
- Custom variable value: `%programfiles%\Application\`
- Allow list entry: `CTXCVC1,%app%\run.exe`

NOTE:

User environment variables are not supported.

Environment variable support is available from Citrix Virtual Apps and Desktops version 2209.

Obtain virtual channel names and processes

The easiest way to obtain the name of the virtual channel and the process that opens it on the VDA machine is to get the information from the developer or a third-party vendor that provided the virtual channel.

Alternatively, you can obtain information by applying the feature's logs and following these steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Once the client and server components of the custom virtual channel are in place, launch a virtual application or virtual desktop.
2. In the VDA machine's System event log, look for the custom virtual channel's name and the process that tried to open it. For more information on available events, see Event logs.
3. Log out from the session.
4. Add an entry in the virtual channel allow list policy settings for the identified virtual channel and process.
5. Restart the machine.
6. Once the VDA is registered, run the virtual application or virtual desktop to validate that the custom virtual channels open successfully.

Considerations for Citrix virtual channels

All built-in Citrix virtual channels are trusted and allowed to open without further configuration. However, the following two features require explicit entries in the allow list because of external dependencies:

- Multimedia Redirection
- HDX RealTime Optimization Pack for Skype for Business

Multimedia Redirection

If you use a media player other than Windows Media Player as your system media player, you need to add it to the allow list as a trusted process. The following information is required for the allow list entry:

- Virtual channel name: `CTXMM`
- Process: Path to the media player used in your VDA machine. For example, `C:\Program Files (x86)\Windows Media Player\wmplayer.exe`.
- Allow list entry: `CTXMM,C:\Program Files (x86)\Windows Media Player\wmplayer.exe`

HDX RealTime Optimization Pack for Skype for Business

The following information is required for the allow list entry:

- Virtual channel name: `CTXRMEP`
- Process: Path to the Skype for Business executable in your VDA machine, which can vary based on the version of Skype for Business or if you used a custom installation path. For example, `C:\Program Files\Microsoft Office\root\Office16\lync.exe.`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Allow list entry: `CTXRMEP,C:\Program Files\Microsoft Office\root\Office16\lync.exe`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Delivery methods

A single delivery method likely cannot meet all of your requirements.

You can consider several application delivery methods. Choosing the appropriate method helps improve scalability, management, and user experience.

- **Installed app:** The application is part of the base desktop image. The install process involves dll, exe, and other files copied to the image drive in addition to registry modifications. For details, see Create machine catalogs.
- **Streamed app (Microsoft App-V):** The application is profiled and delivered to the desktops across the network on-demand. Application files and registry settings are placed in a container on the virtual desktop, isolated from the base operating system and each other. This action helps address compatibility issues. For details, see App-V.
- **Layered app (Citrix App Layering):** Each layer contains a single application, agent, or operating system. By integrating one OS layer, one platform layer (for example, VDA) and many application layers, an administrator can easily create new, deployable images. Layering simplifies ongoing maintenance, as an OS, agent and application exists in a single layer. When you update the layer, all deployed images containing that layer are updated. See Citrix App Layering.
- **Hosted Windows app:** An application installed on a multi-user Citrix Virtual Apps host and deployed as an application and not a desktop. A user accesses the hosted Windows app seamlessly from the VDI desktop or endpoint device, hiding the fact that the app is running remotely. For details, see Create delivery groups.
- **Local app:** An application deployed on the endpoint device. The application interface appears within the user's hosted VDI session even though it runs on the endpoint. For details, see Local App Access and URL redirection.

For desktops, you can consider Citrix Virtual Apps™ published desktops or VDI desktops.

Citrix Virtual Apps published apps and desktops

Use multi-session OS machines to deliver Citrix Virtual Apps published apps and published desktops.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use case:

- You want inexpensive server-based delivery to minimize the cost of delivering applications to many users, while providing a secure, high-definition user experience.
- Your users perform well-defined tasks and do not require personalization or offline access to applications. Users can include task workers such as call center operators and retail workers, or users that share workstations.
- Application types: any application.

Benefits and considerations:

- Manageable and scalable solution within your data center.
- Most cost effective application delivery solution.
- Hosted applications are managed centrally and users cannot modify the application, providing a user experience that is consistent, safe, and reliable.
- Users must be online to access their applications.

User experience:

- User requests one or more applications from StoreFront™, their Start menu, or a URL you provide to them.
- Applications are delivered virtually and display seamlessly in high definition on user devices.
- Depending on profile settings, user changes are saved when the user's application session ends. Otherwise, the changes are deleted.

Process, host, and deliver applications:

- Application processing takes place on hosting machines, rather than on the user devices. The hosting machine can be a physical or a virtual machine.
- Applications and desktops reside on a multi-session OS machine.
- Machines become available through machine catalogs.
- Machines from machine catalogs are organized into delivery groups that deliver the same set of applications to groups of users.
- Multi-session OS machines support delivery groups that host either desktops or applications, or both.

Session management and assignment:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Multi-session OS machines run multiple sessions from a single machine to deliver multiple applications and desktops to multiple, simultaneously connected users. Each user requires a single session from which they can run all their hosted applications.

  For example, a user logs on and requests an application. One session on that machine becomes unavailable to other users. A second user logs on and requests an application which that machine hosts. A second session on the same machine is now unavailable. If both users request more applications, no additional sessions are required because a user can run multiple applications using the same session. If two more users log on and request desktops, and two sessions are available on that machine, that one machine now uses four sessions to host four different users.
- Within the delivery group to which a user is assigned, a machine on the least loaded server is selected. A machine with session availability is randomly assigned to deliver applications to a user when that user logs on.

VM hosted apps

Use single-session OS machines to deliver VM hosted applications

Use case:

- You want a client-based application delivery solution that is secure, provides centralized management, and supports many users per host server. You want to provide those users with applications that display seamlessly in high-definition.
- Your users are internal, external contractors, third-party collaborators, and other provisional team members. Your users do not require offline access to hosted applications.
- Application types: Applications that might not work well with other applications or might interact with the operation system, such as Microsoft .NET framework. These types of applications are ideal for hosting on virtual machines.

Benefits and considerations:

- Applications and desktops on the image are securely managed, hosted, and run on machines within your data center, providing a more cost effective application delivery solution.
- Upon logon, users can be randomly assigned to a machine within a delivery group that is configured to host the same application. You can also statically assign a single machine to deliver an application to a single user each time that user logs on. Statically assigned machines allow users to install and manage their own applications on the virtual machine.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Running multiple sessions is not supported on single-session OS machines. Therefore, each user consumes a single machine within a delivery group when they log on, and users must be online to access their applications.
- This method can increase the amount of server resources for processing applications and increase the amount of storage for users' personal vDisks.

User experience:

- The same seamless application experience as hosting shared applications on multi-session OS machines.

Process, host, and deliver applications:

- The same as multi-session OS machines except they are virtual single-session OS machines.

Session management and assignment:

- Single-session OS machines run a single desktop session from a single machine. When accessing applications only, one user can use multiple applications (and is not limited to a single application). The operating system sees each application as a new session.
- Within a delivery group, logged-on users can access either a statically assigned machine (each time the user logs on to the same machine), or a randomly assigned machine that is selected based on session availability.

VDI desktops

Use single-session OS machines to deliver Citrix Virtual Desktops™ VDI desktops.

VDI desktops are hosted on virtual machines and provide each user with a desktop operating system.

VDI desktops require more resources than Citrix Virtual Apps published desktops, but do not require that applications installed on them support server-based operating systems. Also, depending on the type of VDI desktop you choose, these desktops can be assigned to individual users. This allows users a high level of personalization.

When you create a machine catalog for VDI desktops, you create one of these types of desktops:

- **Random non-persistent desktop, also known as pooled VDI desktop:** Each time a user logs on to one of these desktops, that user connects to a desktop selected from a pool of desktops. That pool is based on a single image. All changes to the desktop are lost when the machine restarts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Static non-persistent desktop:** During the first logon, a user is assigned a desktop from a pool of desktops. (Each machine in the pool is based on a single image.) After the first use, each time a user logs on to use one of these desktops, that user connects to the same desktop that was assigned on first use. All changes to the desktop are lost when the machine restarts.
- **Static persistent desktop:** Unlike other types of VDI desktops, users can fully personalize these desktops. During the first logon, a user is assigned a desktop from a pool of desktops. Subsequent logons from that user connect to the same desktop that was assigned on first use. Changes to the desktop are retained when the machine restarts.

Remote PC Access

Remote PC Access is a feature of Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) that enables organizations to easily allow their employees to access corporate resources remotely in a secure manner. The Citrix platform makes this secure access possible by giving users access to their physical office PCs. If users can access their office PCs, they can access all the applications, data, and resources they need to do their work. Remote PC Access eliminates the need to introduce and provide other tools to accommodate teleworking. For example, virtual desktops or applications and their associated infrastructure.

Remote PC Access uses the same Citrix DaaS™ components that deliver virtual desktops and applications. As a result, the requirements and process of deploying and configuring Remote PC Access are the same as those required for deploying Citrix DaaS for the delivery of virtual resources. This uniformity provides a consistent and unified administrative experience. Users receive the best user experience by using Citrix HDX to deliver their office PC session.

For more information, Remote PC Access.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Plan and build a deployment

If you're not familiar with the components, terminology, and objects used with Citrix DaaS (formerly Citrix Virtual Apps and Desktops service), see Citrix DaaS.

If you're migrating from a Citrix Virtual Apps and Desktops deployment, see Migrate to cloud.

IMPORTANT:

To ensure that you get important information about Citrix Cloud™ and the Citrix services you subscribe to, make sure you can receive all email notifications.

In the upper right corner of the Citrix Cloud console, expand the menu to the right of the customer name and OrgID fields. Select **Account Settings**. On the **My Profile** tab, select all entries in the **Email Notifications** section.

How to use this article

To set up your Citrix DaaS™ deployment, complete the tasks summarized below. Links are provided to each task's details.

Review the entire process before starting the deployment, so you know what to expect. This article also links to other helpful information sources.

NOTE:

If you plan to use the Quick Deploy workflow to provision Microsoft Azure machines, follow the setup guidance in Get started with Quick Deploy.

Plan and prepare

In the Citrix Tech Zone documentation, see a step-by-step proof of concept guide for this service.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Sign up

Sign up for a Citrix account and request a Citrix DaaS demo.

Set up a resource location

A resource location contains resources required to deliver applications and desktops to users. Creating resource locations enables DaaS to use those resources. To learn more about resource locations, see Connect to Citrix Cloud.

Before creating machines, you must connect a resource location to DaaS:

- Domain-joined machines require that you have Cloud Connectors installed in the resource location. In this case, you can create:
  - Identity pool of on-premises Active Directory joined machine identity
  - Identity pool of Microsoft Entra joined machine identity
  - Identity pool of Microsoft Entra hybrid joined machine identity

  For high availability, we recommend that you install two Cloud Connectors in each resource location. See Cloud Connector installation.

  More information:

  - What are resource locations and Cloud Connectors?
  - Video about installing Cloud Connectors:

    
- Non-domain-joined machines don’t require Cloud Connectors but require that you have Rendezvous V2 enabled. The Rendezvous protocol allows VDAs to bypass the Cloud Connectors to connect directly and securely with DaaS. See Rendezvous V2. In this case, you can:
  - Identity pool of non-domain-joined machine identity

If you're using the Quick Deploy interface to provision Azure VMs, Citrix creates the resource location and Cloud Connectors for you.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a connection to the resource location

After you add a resource location and Cloud Connectors, create a connection to the resource location using Studio.

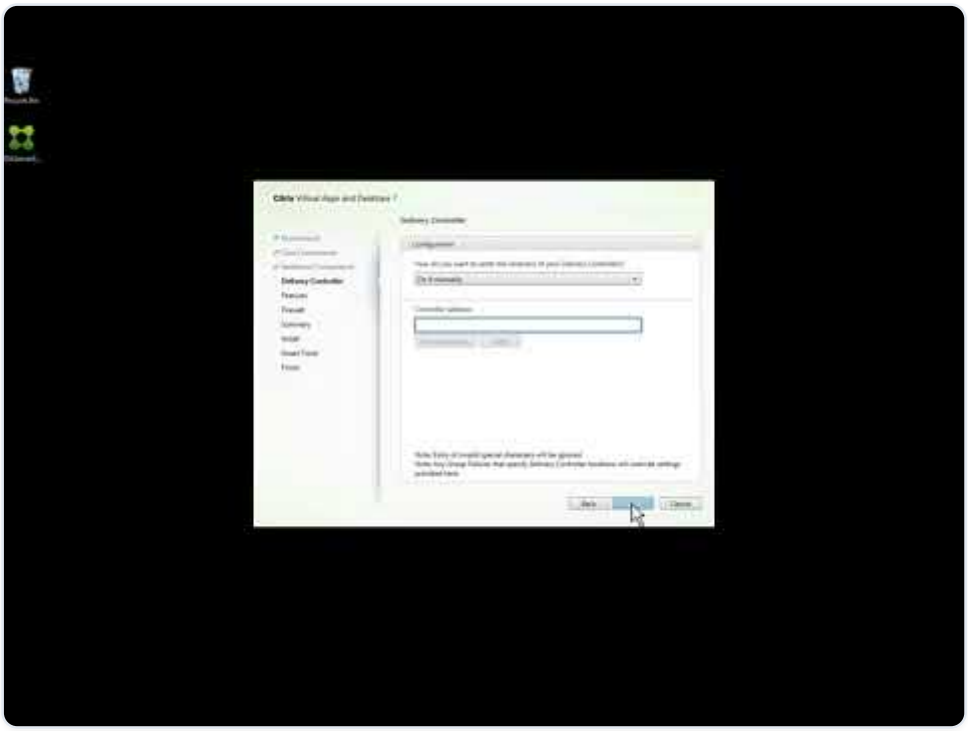
This step isn't necessary in either of the following cases:

- You're building a simple proof of concept deployment
- You're using the Quick Deploy interface to provision Azure VMs.

More information:

- What are hosts?
- What are host connections?

Install VDAs



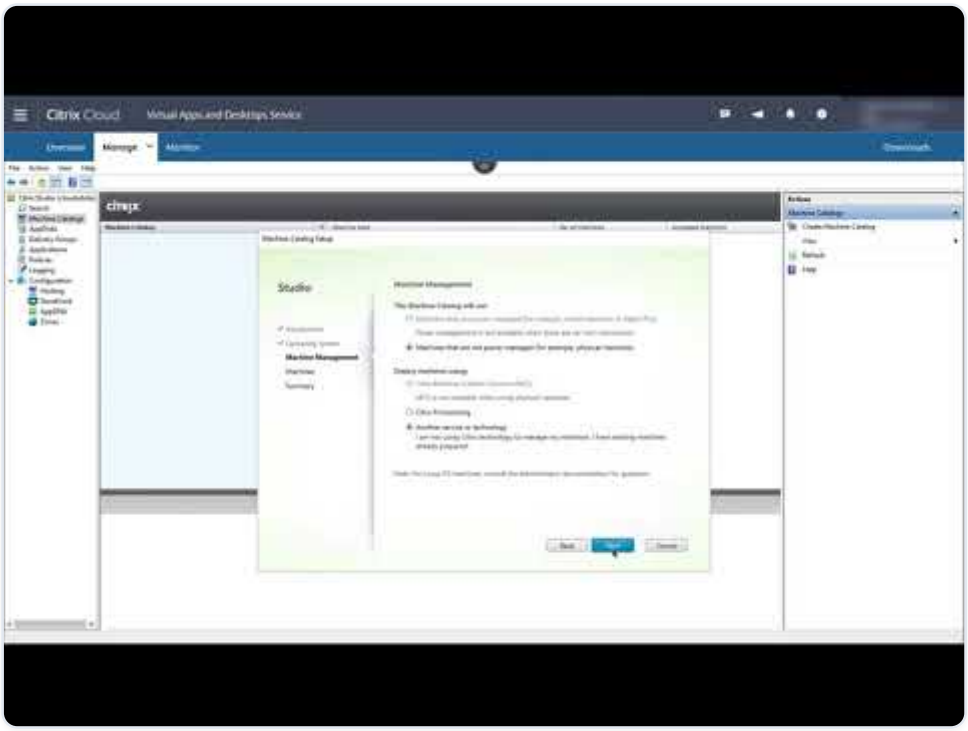
Each machine that delivers applications and desktops to users must have a Citrix Virtual Delivery Agent (VDA) installed on it.

- For a simple proof of concept deployment, download and install a VDA on one machine.
- If you're using an image to provision VMs, install a VDA on the image.
- For a Remote PC Access deployment, install the core version of the VDA for single-session OS on each physical office PC.

How-to and more information:

- What are VDAs?
- Installation preparation and instruction
- Command-line VDA installation
- Video about downloading and installing a VDA:

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Create a catalog

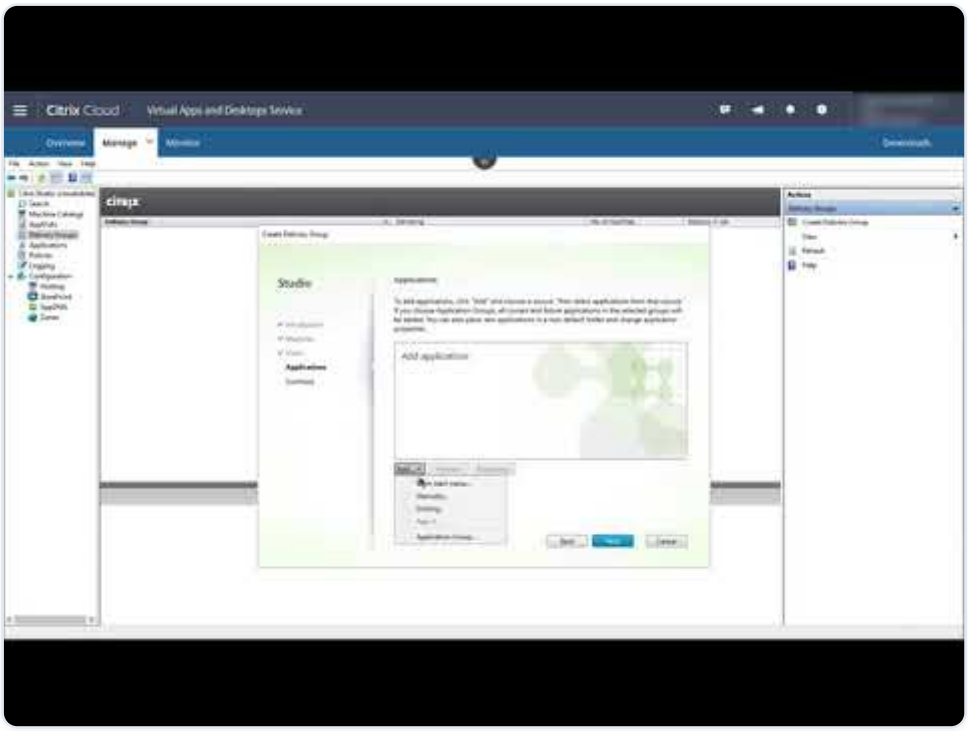
After you create a connection to your resource location (if needed), you create a catalog. If you're using Studio, the workflow guides you automatically to this step.

How-to and more information:

- What are catalogs?
- Create a catalog
- Use the Quick Deploy interface to deploy a catalog containing Azure VMs.
- Video about creating a catalog using Studio:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a delivery group



After you create your first catalog, the **Manage** workflow guides you to create a delivery group.

This step isn't necessary if you're using the Quick Deploy interface to provision Azure VMs.

How-to and more information:

- What are delivery groups?
- Create a delivery group
- Video about how to create a delivery group:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Deploy other components and technologies

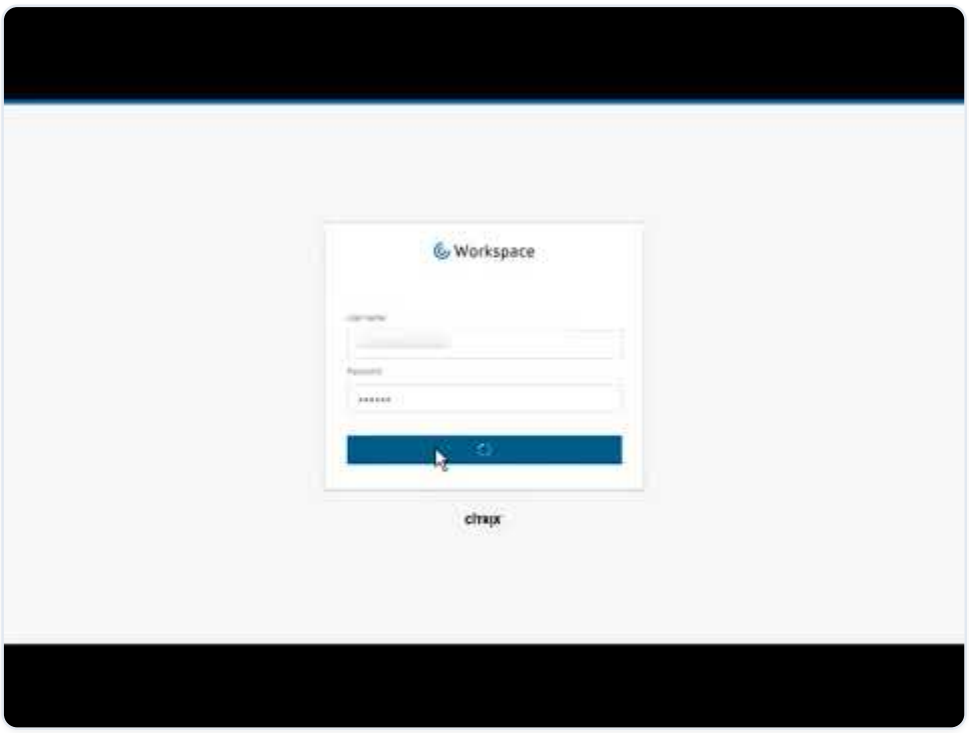
After you complete the tasks above that set up the Citrix DaaS deployment, you'll find information about provisioning and configuring other components and technologies in the Citrix solution, such as:

- Citrix policies
- StoreFront
- App Layering
- Workspace Environment Management (WEM) Service
- Citrix Gateway service
- Zones
- Federated Authentication Service (FAS)

Complete other tasks that apply to your configuration. For example, if you plan to deliver Windows Server workloads, configure a Microsoft RDS License Server.

Launch applications and desktops

After you configure your deployment, publishing occurs automatically. Applications and desktops that you configured are available to users in their stores. A user simply navigates to their store URL and selects an application or desktop, which launches immediately.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Send the store URL to your users. You can find the store URL in two locations:

- From the Citrix Cloud console, select **StoreFront Cloud** from the menu in the upper left corner. The **Access** tab contains the store URL.
- From the Citrix DaaS **Overview** page, the store URL appears near the bottom of the page.

More information:

- Video about users launching applications and desktops from their stores:

More information

The Citrix Cloud Learning series provides education courses that are organized by your path:

- If you're new to Citrix DaaS, see New to Citrix DaaS Learning Path.
- If you're migrating from a Citrix Virtual Apps and Desktops deployment, see Migrating Citrix Virtual Apps and Desktops to Citrix Cloud Learning Path.

Sign up for Citrix DaaS™

Introduction

You can subscribe to Citrix DaaS through Citrix or through the Azure Marketplace.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you plan to use Citrix Managed Azure, you can also order the Citrix Azure Consumption Fund through Citrix or through the Azure Marketplace.

- When you order through Citrix, you can order Citrix DaaS and the Citrix Azure Consumption Fund at the same time.
- When you order through Azure Marketplace, you first order Citrix DaaS. Then, you can place another order for the Citrix Azure Consumption Fund.

If you order only Citrix DaaS now, you can order the Citrix Azure Consumption Fund later, either through Azure Marketplace or your Citrix account representative.

Demos and trials

You can evaluate Citrix DaaS by request through Citrix. From a trial, you can convert to a paid service subscription.

During a trial, you can optionally use a Citrix Managed Azure subscription for catalogs, images, and network connections. If you have Citrix-managed resources at the time you convert to a paid subscription, you must either purchase consumption or delete those Citrix-managed resources. If you do not purchase consumption, those resources are deleted automatically, which might affect users.

If you currently subscribe to a Citrix DaaS service

Generally, a Citrix Cloud™ account allows you to subscribe to only one of Citrix DaaS's services (or one edition) at a time per Citrix OrgID. For example, you can subscribe to Citrix DaaS Premium edition OR Citrix DaaS for Azure, but not both.

If you currently subscribe to a Citrix DaaS, and want to subscribe to this service, you have two choices:

- Subscribe to this service using a different Citrix Cloud account (OrgID).
- Decommission Citrix DaaS you already have, and then order this service. For decommission instruction, see CTX239027.

Order through Citrix

You can order this service (and the Citrix Azure Consumption Fund) through Citrix Cloud or through your Citrix account representative.

Through Citrix Cloud:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Follow the guidance in Sign up for Citrix Cloud to get a Citrix Cloud account and Organization ID.
- You can request a Citrix DaaS demo. In the Citrix DaaS tile, click **Request Demo**. Provide the requested information.

  A Citrix representative will contact you to discuss your requirements, environment, and plans. Depending on our representative's assessment, you will be authorized to participate in an administrator demo or a proof of concept trial. For more information, see Citrix Cloud Service Trials.

When you are authorized for a trial, the text on Citrix DaaS tile in the Citrix Cloud console changes to **Manage**.

Order through Azure Marketplace

You can order the following Citrix offerings through Azure Marketplace:

- Citrix DaaS for Azure
- Citrix DaaS Advanced edition
- Citrix DaaS Premium edition
- Workspace Premium Plus

If you plan to host your Citrix Virtual Apps and Desktops workloads on Microsoft Azure, and want to use a Citrix Managed Azure subscription, order the Citrix Azure Consumption Fund after ordering Citrix DaaS or Workspace Premium Plus.

With the Citrix Azure Consumption Fund, you're charged each month for your consumption, which can vary depending on the hosting resources you choose and the hours of use. You can review your consumption use through Citrix Cloud.

From the Azure Marketplace:

- You cannot combine Citrix DaaS and consumption fund in one order.
- The order process for the Citrix Azure Consumption Fund is essentially the same as ordering Citrix DaaS, but you must have previously ordered Citrix DaaS.

Requirements for ordering through Azure Marketplace

- The OrgID of your Citrix Cloud account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - If you have a Citrix Cloud account, but don't know the OrgID, look in the upper right corner of the Citrix Cloud console. Or, look at the email you received when you created the account.
  - If you don't have a Citrix Cloud account, follow the guidance in Sign up for Citrix Cloud.

- An Azure account and at least one Azure subscription in that account.

Procedure for ordering through Azure Marketplace

Follow this procedure to order a Citrix DaaS or Workspace Premium Plus through Azure Marketplace. (If you want to use Citrix Managed Azure, place another order for the Citrix Azure Consumption Fund, after you order Citrix DaaS.)

1. Sign in to the Azure Marketplace using your Azure account credentials.
2. Search for and then navigate to the Citrix offering you want to order.
3. Select **Get it now**.
4. On the **One more thing** message, fill in the required information, enable the consent check box, and then select **Continue**.
5. Review the tabs containing information about the product, plans, pricing, and usage. When you're ready, select a plan (if more than one is available), and then select **Set up + subscribe**.
6. On the **Basics** tab:
   - **Subscription:** Indicates the plan that you selected.
   - **Resource group:** Select or create a resource group.
   - **Name:** Enter a name for your subscription order so you can easily identify it later.
   - The **Plan** information shows the price for the selected plan, based on the billing term. To change the plan term, select **Change plan**. Select the term you want and select **Change plan**.
7. On the **Review + subscribe** tab, review the contact information, and update it, if needed. Review the basic subscription information. Select **Subscribe**.
8. On the **Subscription in progress** page, select **Configure account now**. (If the button is disabled, wait a moment.) You're taken to a Citrix activation page.
9. On the activation page:
   - Use the **Sign in** link to sign in to Citrix Cloud. A successful sign-in automatically populates the **Organization ID** field.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Quantity:** Enter the number of users. (An initial order must be at least 25.) An estimated price is displayed.
- Agree to the terms and conditions, and then select **Activate Order**.

After ordering through Azure Marketplace

Citrix sends you an email when your service is provisioned. Provisioning can take a while. If you don't receive the email by the following day, contact Citrix Support. When you receive the email from Citrix, you can begin using Citrix DaaS.

Fulfillment of a Citrix Azure Consumption Fund order does not take much time. When Citrix is notified of the order, a banner appears in the Citrix DaaS console, indicating that a Citrix Managed Azure subscription will be prepared for you.

Do not delete Citrix DaaS resource in Azure. Deleting that resource cancels your subscription.

Order through Google Cloud Marketplace

You can order the following Citrix offerings through Google Cloud Marketplace:

- Citrix DaaS Standard for Google Cloud
- Citrix DaaS Premium for Google Cloud

You need the following to order through Google Cloud Marketplace:

- The OrgID of your Citrix Cloud account.
  - If you have a Citrix Cloud account, but don't know the OrgID, look in the upper right corner of the Citrix Cloud console. Or, look at the email you received when you created the account.
  - If you don't have a Citrix Cloud account, follow the guidance in Sign up for Citrix Cloud.
- A Google Cloud account and at least one Google Cloud subscription in that account.

To place your order:

1. Sign in to Google Cloud Marketplace
2. Follow the instructions on the Citrix DaaS for Google Cloud page to make your purchase.

Citrix sends you an email when your service is provisioned. Provisioning can take a while. If you don't receive the email by the following day, contact Citrix Support. When you receive the email from Citrix, you can begin using Citrix DaaS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Do not delete Citrix DaaS resource in Google Cloud. Deleting that resource cancels your subscription.

What's next

After your order is fulfilled, continue with the next steps in Plan and build a deployment.

For example:

- If you haven't already set up your hypervisor or cloud service, or Active Directory, see Set up a resource location.
- If your host environment and Active Directory are already set up, see Create a connection.

Citrix DaaS™ for Microsoft Azure

With Studio, you can deploy and manage virtual apps and desktops on Microsoft Azure. Detailed steps are as follows:

1. Sign in to Citrix Cloud.
2. Click on the **DaaS** tile to open Studio.
3. Deploy virtual apps and desktops using one of these workflows:

    - **Quick Deploy > Microsoft Azure** (recommended for fast, guided deployment). For more information, see Quick Deploy for Microsoft Azure.

      NOTE:

      To perform advanced configurations or management options for your deployment, use the Studio related nodes. For more information see Studio.

    - **Studio** (recommended for advanced configuration requirements). For more information, see Get started: Plan and build a deployment.

For more information about the difference between the Quick Deploy and the Studio workflows, see the following section.

Quick Deploy for Microsoft Azure

In Studio, the **Quick Deploy > Microsoft Azure** interface offers fast deployment of apps and desktops when you're using Microsoft Azure to host your desktops and apps. This interface offers *basic* configuration, *without* advanced features.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

With Quick Deploy, you can:

- Provision virtual machines and catalogs that deliver desktops and apps hosted in Microsoft Azure.
- Create Remote PC Access catalogs for existing machines.

For more information, see Citrix DaaS Standard for Azure.

NOTE:

With Quick Deploy, you can use a Citrix-Managed Azure subscription, or your own Azure subscription.

Differences between Quick Deploy and Studio workflows

As an alternative to Quick Deploy, the Studio workflow offers advanced configuration features. See the following table for details.

FEATURE	QUICK DEPLOY	STUDIO
Deploy using Azure	Yes	Yes *
Citrix® prepared images available	Yes	No
Simplified user experience	Yes	No

* When using a Citrix Managed Azure subscription, you must use Quick Deploy when creating an image or catalog.

If you're familiar with using the Studio workflow to create and manage catalogs, Quick Deploy has the following differences:

- Different terminology.
  - In Quick Deploy, you create a catalog.
  - In Machine Catalogs, you create a machine catalog. In practice, it's often referred to as simply catalog.
- Resource location and Cloud Connectors.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Quick Deploy automatically creates a resource location including two Cloud Connectors when you create your first catalog.
    - In the Studio workflow, creating a resource location and adding Cloud Connectors are separate steps that you must complete in Citrix Cloud before creating a catalog.

- Images used to create catalogs.

    - Quick Deploy offers several Citrix prepared images of Windows and Linux machines. You can use these images to create catalogs.

      You can also use these images to create images and then customize the new images to suit your unique deployment needs. This feature is known as the image builder. You can also import images from your own Azure subscription.
    - In the Studio workflow, you customize images from the supported host you're using. Citrix prepared images are not available.

- Catalog displays:

    - Catalogs created in Quick Deploy are visible in the Quick Deploy and the Studio section displays.
    - Catalogs created in the Studio workflow are not visible in the Quick Deploy display.

- Delivery groups:

    - You do not create delivery groups in Quick Deploy. In Quick Deploy, you specify the machines, applications, desktops, and users (subscribers) in the catalog.

      Citrix automatically creates a delivery group for each Quick Deploy catalog, using the same name as the catalog. That action occurs behind the scenes. You don’t need to do anything to create the delivery group. The delivery group appears only in the Delivery Groups node, not in Quick Deploy.
    - In the Studio workflow, you create a delivery group and indicate which machines it contains. Optionally, you also specify applications, desktops, and users. You can also create application groups.

- Layout and user interface.

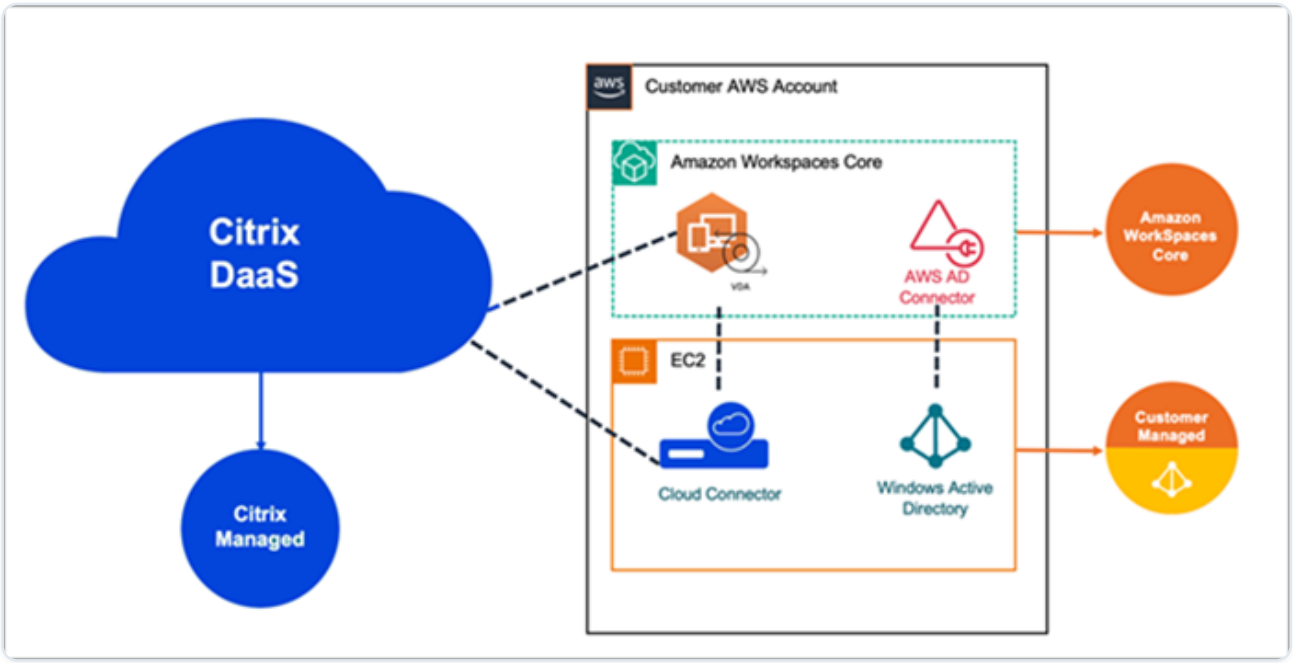
    - The Quick Deploy interface has a different layout and style from the Studio workflow. Quick Deploy contains more on-screen guidance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The interfaces aren't mutually exclusive. You can use Quick Deploy to create some catalogs, and then use the Machine Catalogs node to create other catalogs.

Citrix HDX™ Plus for Windows 365

Citrix HDX Plus for Windows 365 allows you to integrate Citrix Cloud™ with Windows 365 to use Citrix HDX technologies for an enhanced and more secure Windows 365 Cloud PC experience in addition to other Citrix Cloud services for enhanced manageability.



For more information, see Citrix HDX Plus for Windows 365

Citrix DaaS™ Quick Deploy for Amazon WorkSpaces Core Bundles

Introduction

This article describes how to prepare and create a deployment with Citrix® for Amazon WorkSpaces Core. Amazon WorkSpaces Core resides in Amazon Web Services (AWS).

The following is the representation of the AWS implementation and its management with Citrix DaaS:

Prepare and create a deployment

The deployment checklist in the **Quick Deploy** interface contains links to procedures 1-6.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Before you start, complete the prerequisites in Citrix Cloud and AWS.
2. Create a resource location in Citrix Cloud. (This procedure is also included as a prerequisite.)
3. Connect your AWS account. This procedure enables permissions so that the Citrix DaaS can connect to AWS.
4. Create a directory connection. This procedure configures a connection that allows access to your organization's Active Directory.
5. Import an image. This procedure enables you to create a desktop experience for your users.
6. Create a deployment. This procedure specifies the machines to be deployed and the users who can access them through their store.

Before you start

Make sure you've completed the following tasks before you begin preparing and creating your deployment.

There is one exception: Creating a resource location in Citrix Cloud is listed as a prerequisite. It is also the first procedure in the deployment checklist. So, if you create the resource location as part of the prerequisites, skip that procedure in the checklist sequence. Similarly, complete that procedure in the checklist if you didn't do it earlier.

Prerequisites to complete in Citrix Cloud

- Create a Citrix Cloud account and subscribe to the Citrix DaaS.
- Create a Citrix Cloud resource location. (This procedure is also linked in the Quick Deploy interface.)

Prerequisites to complete in AWS

- Create an AWS user account. The account must have:
  - Role permissions for the Citrix API client.
  - Permissions for programmatic access. For more information, see AWS account programmatic access permissions.
  - Create the workspaces_DefaultRole role. For more information, see Create the workspaces_DefaultRole Role.
- In your Active Directory:
  - Use the AD Connector option to store and manage information. For more details, see AD Connector.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Create an OU where VMs are created. That OU must have a Citrix policy for communication with the Cloud Connectors and Citrix Cloud. See the Reference section for details.
    - Set up a group policy for the Citrix Cloud Connector™ configuration:

        a. Download the latest Group Policy Management Console provided by Citrix (CitrixGroupPolicyManagement_64.msi) from the Citrix download site.

        b. Install the MSI (that machine must have the Visual Studio 2015 runtime installed). Then create a Citrix policy that contains the Controllers policy setting. That setting specifies the Cloud Connector addresses.

- Create or use an existing NAT gateway. For more information, see NAT gateway.
- Create or use one or more existing security groups that allow the Citrix Cloud Connectors to communicate with the deployed VMs. For more information, see Control traffic to your AWS resources using security groups
- To use Windows 10 or Windows 11 desktop images with dedicated tenancy, set up BYOL for your account. You can complete this step after connecting your account. For more information, see Set up BYOL for your account.

  NOTE:

  Windows 10 N and Windows 11 N versions are not supported for BYOL.

- If you plan to use BYOL, ensure you have sufficient Windows 10 or Windows 11 licenses. For more information, see Bring Your Own Windows desktop licenses.
- Using Citrix DaaS for Amazon WorkSpaces Core automatically enables the Bring Your Own Protocol (BYOP) feature in Amazon WorkSpaces Core.

General preparation

Review each procedure before you start. Benefit: This will help the processes to be completed easily.

Create a resource location

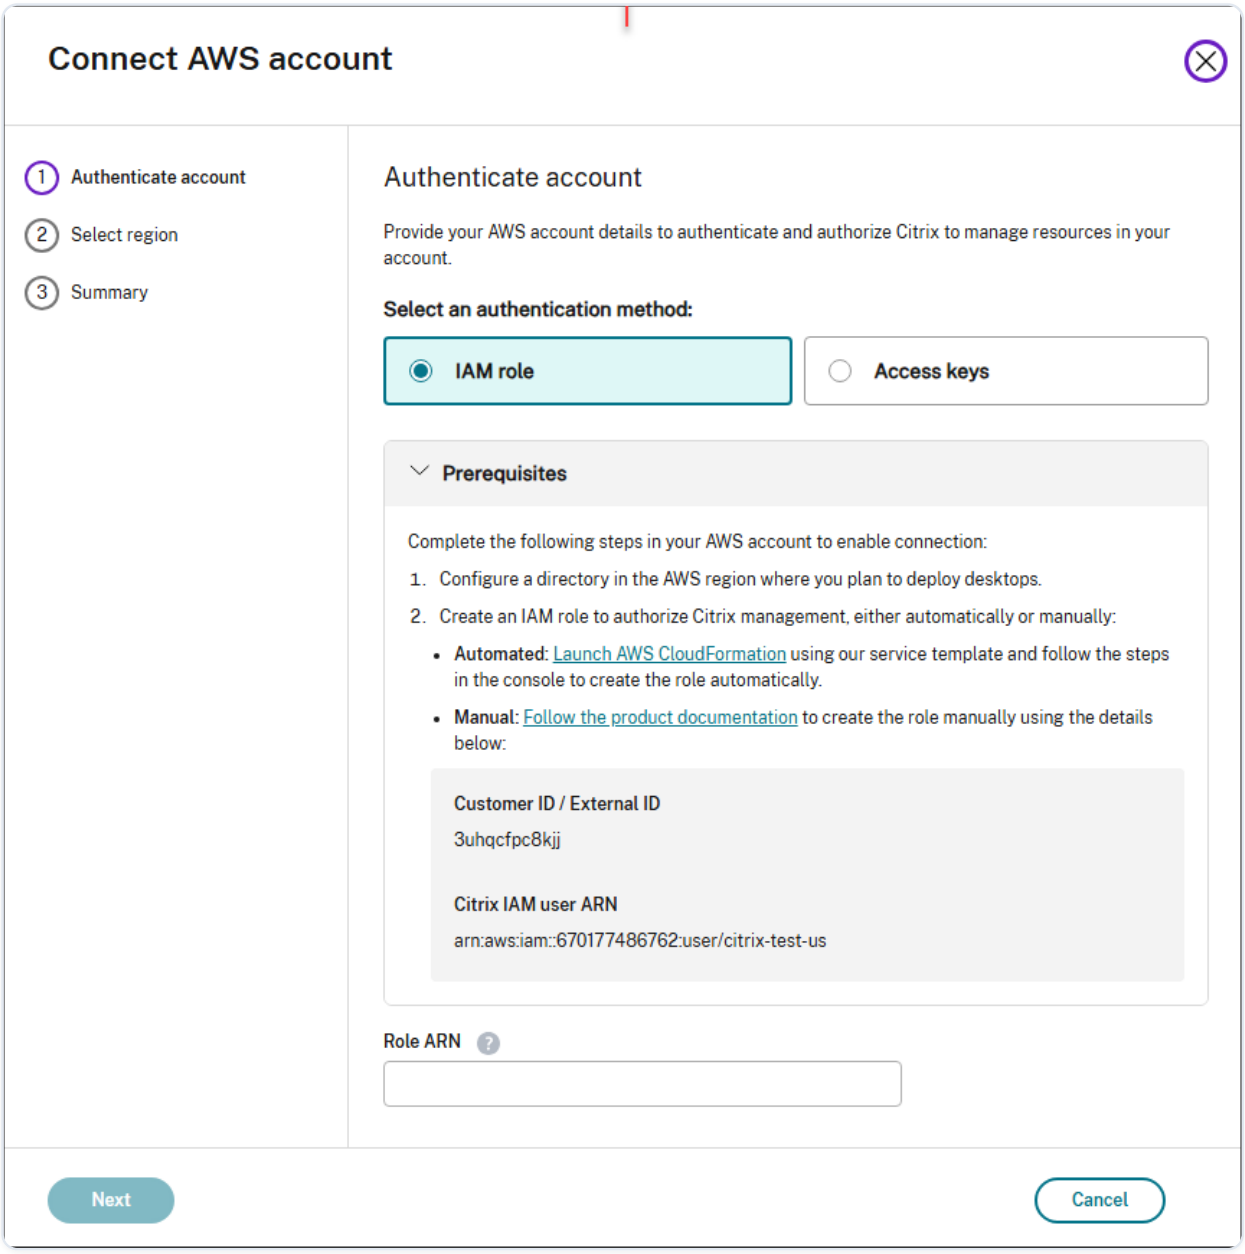
You create a resource location in Citrix Cloud.

- A resource location contains two or more Cloud Connectors that communicate with Citrix Cloud. The servers on which you install the Cloud Connectors must be in an EC2 VPC,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

domain-joined, and have Internet connectivity. The Cloud Connectors must be in the same VPC as the directory you plan to use.

- For more information on Cloud Connectors, see Citrix Cloud Connector and how to provision them.
- The resource location can also contain your Active Directory servers. For more information, see Connect Active Directory to Citrix Cloud.



Connect your AWS account

This procedure enables permissions for the Citrix DaaS to connect to AWS.

To connect your AWS account, follow these steps:

1. In the DaaS tile, click **Manage** to open **Studio**.
2. In the left pane, select **Quick Deploy > Amazon WorkSpaces Core > Accounts**, then click **Connect account**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. In the **Authenticate account** page, complete these steps:

   a. Expand the **Prerequisites** panel to review the setup requirements.

   b. In the **Prerequisites** panel, download the AWS CloudFormation template from the **Connect account** wizard and save it locally. You will upload this template later when you create the AssumeRole stack in AWS.

   c. In the **Role ID** field, enter the Amazon Resource Name (ARN) of the role that authorizes Citrix to manage your resources.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TIP:

- The Role ID can be found in the AWS management console by navigating to **IAM > Roles**.
- If you are using the `CloudFormation` script, then navigate to CloudFormation and click the corresponding stack that was used to create the role. Navigate to the **Resources** tab and click the resource with LogicalID `CitrixAssumeRole`.

d. Enter a friendly name for the account in the **Name** field.

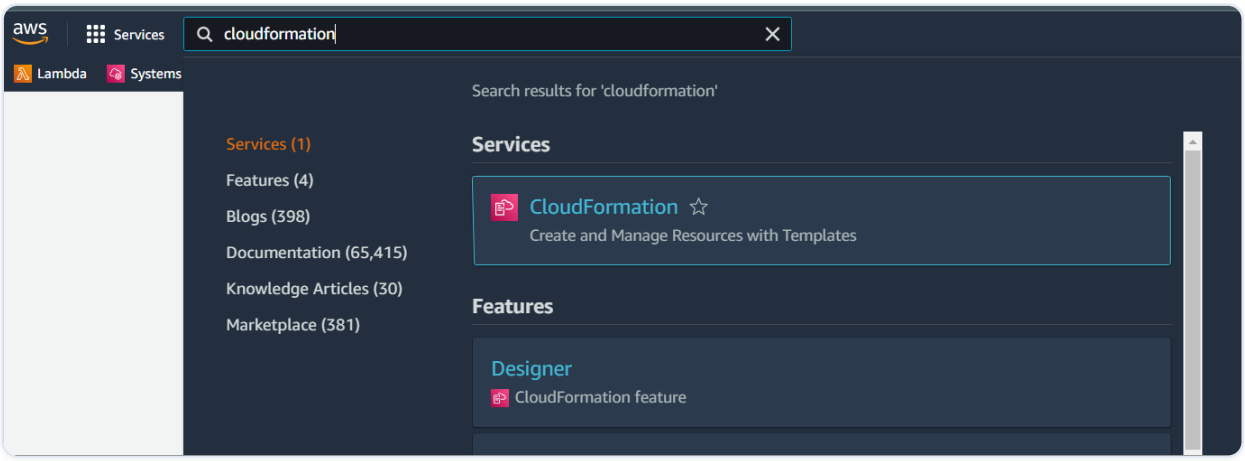
e. Click **Next**. The **Pick region** page opens.

NOTE:

- You cannot connect two accounts in the same region for the same AWS account.
- To create an AssumeRole, see Create AssumeRole for Amazon WorkSpaces Core integration.

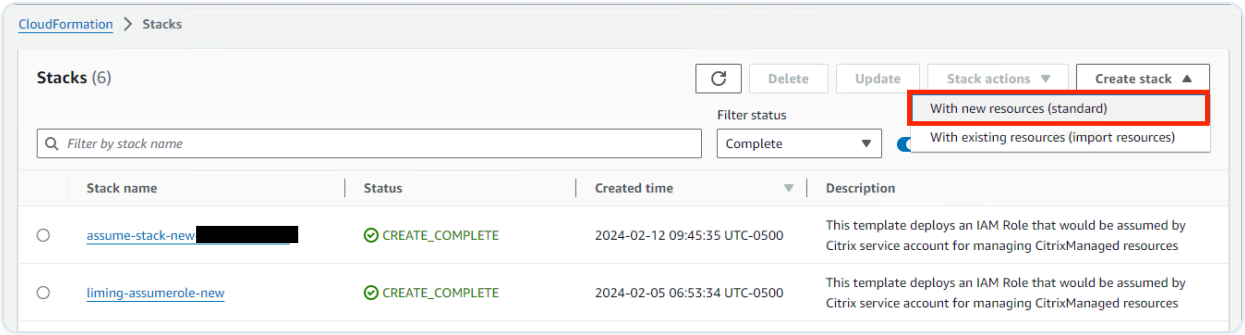
4. On the **Pick region** page, select the region where you want to deploy your desktops and click **Next**. The **Summary** page opens.
5. On the **Summary** page, review the information you provided. Click **Connect**. The connection process might take several hours to complete.

NOTE:



After you connect your account, you can configure BYOL at any time. For more information, see Set up BYOL for your account.

Create AssumeRole for Amazon WorkSpaces Core integration

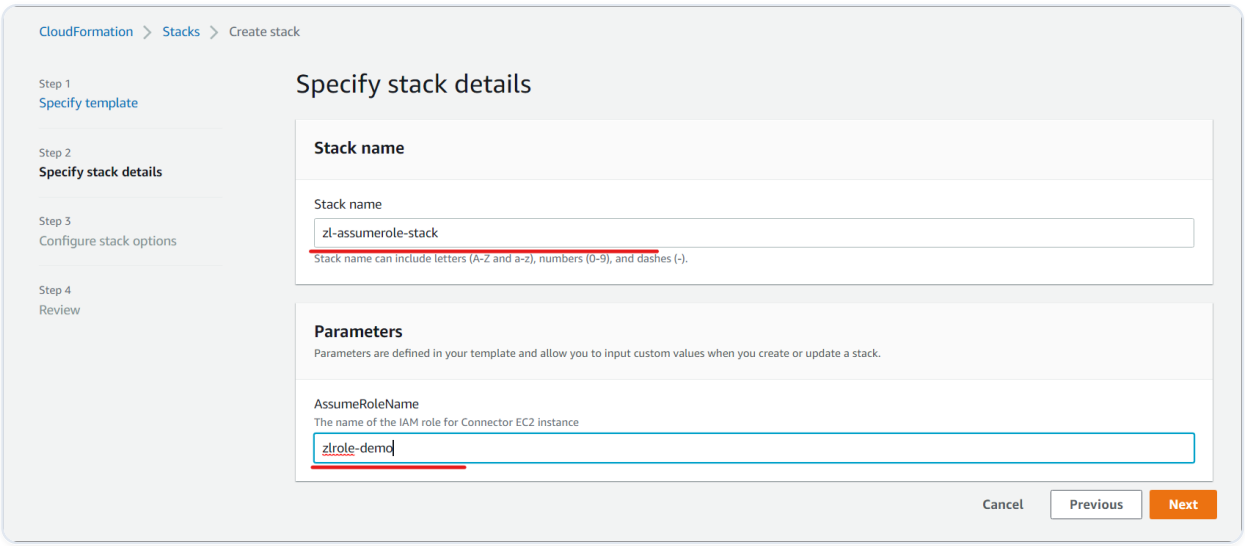


To create AssumeRole for Amazon WorkSpaces Core, follow these steps:

1. In your browser window, open the **Amazon Web Services** website and sign in.
2. In the **Search** field, type **cloudformation** and press **Enter**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Under **Services** select **CloudFormation**. The **Stacks** window opens.

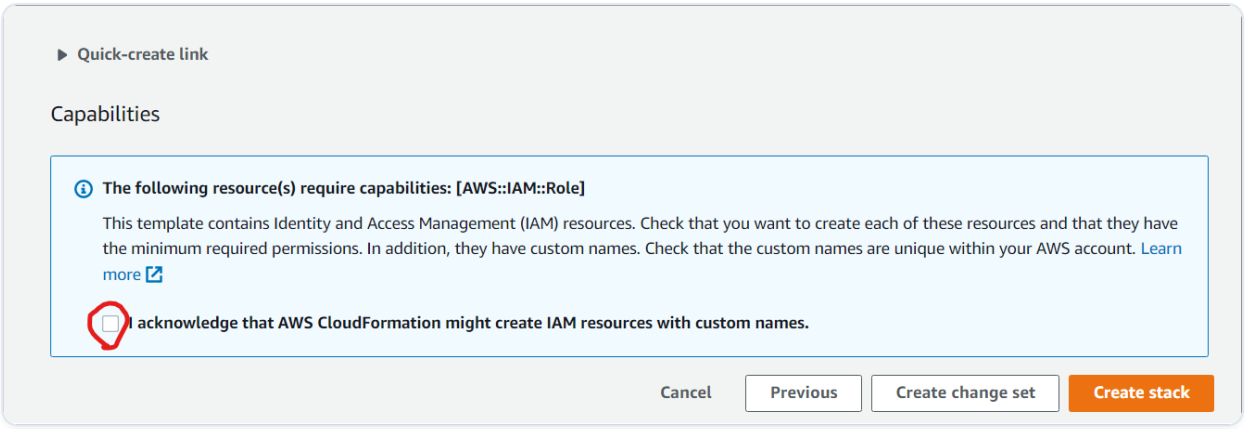


4. Click **Create stack > With new resources (standard)** at the top right corner. The **Create stack** window opens.

   a. Under **Prerequisite – Prepare template**, select **Template is ready**.

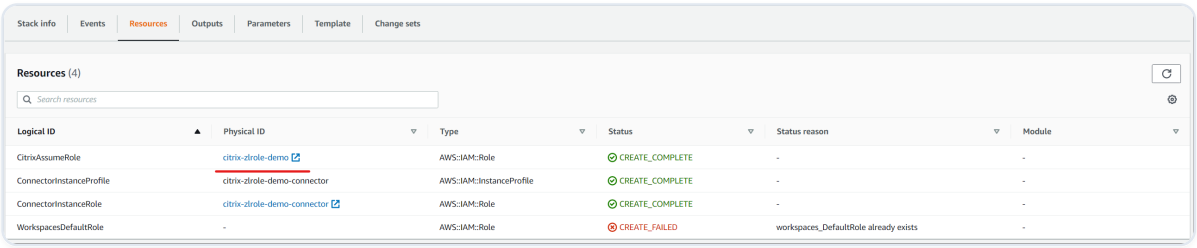
   b. Under **Specify template**, click **Upload a template file > Choose file** and click **Next**. The **Specify stack details** pane opens.

5. In the **Specify stack details** pane, provide a **Stack name** and **AssumeRoleName** and click **Next**. The **Configure stack options** pane opens.

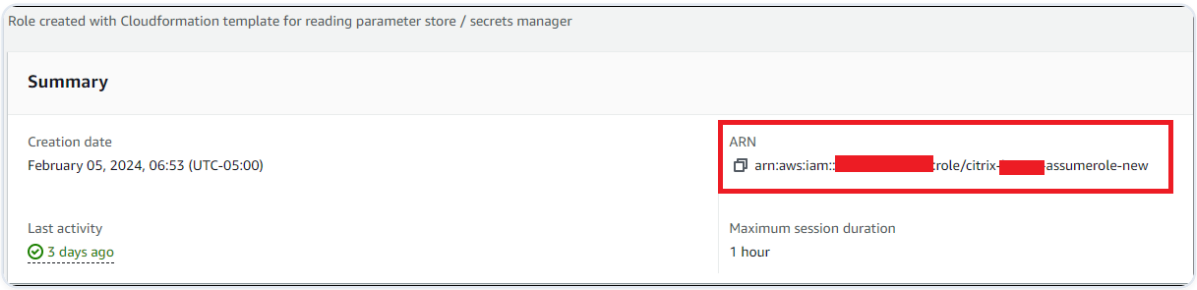


© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. In the **Configure stack options** pane, select the **Preserve successfully provisioned resources** option. This option preserves the state of successfully provisioned resources. Resources without a last known stable state are deleted upon the next stack operation.



7. In the **Capabilities** pop-up window, select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** checkbox and click **Create stack**.



- The **Events** tab shows the status of the Stack created.
- In the **Resources** tab, select the Physical ID corresponding to the **AssumeRole** created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The Summary pane shows the **Amazon Resource Name** (ARN) generated.

NOTE:

Stack creation might fail because **workspaces_DefaultRole** has already been created. This does not affect the **AssumeRole** creation.

8. Resume the procedure from step 3 in Connect your AWS account.

(Optional) Set up BYOL for your account

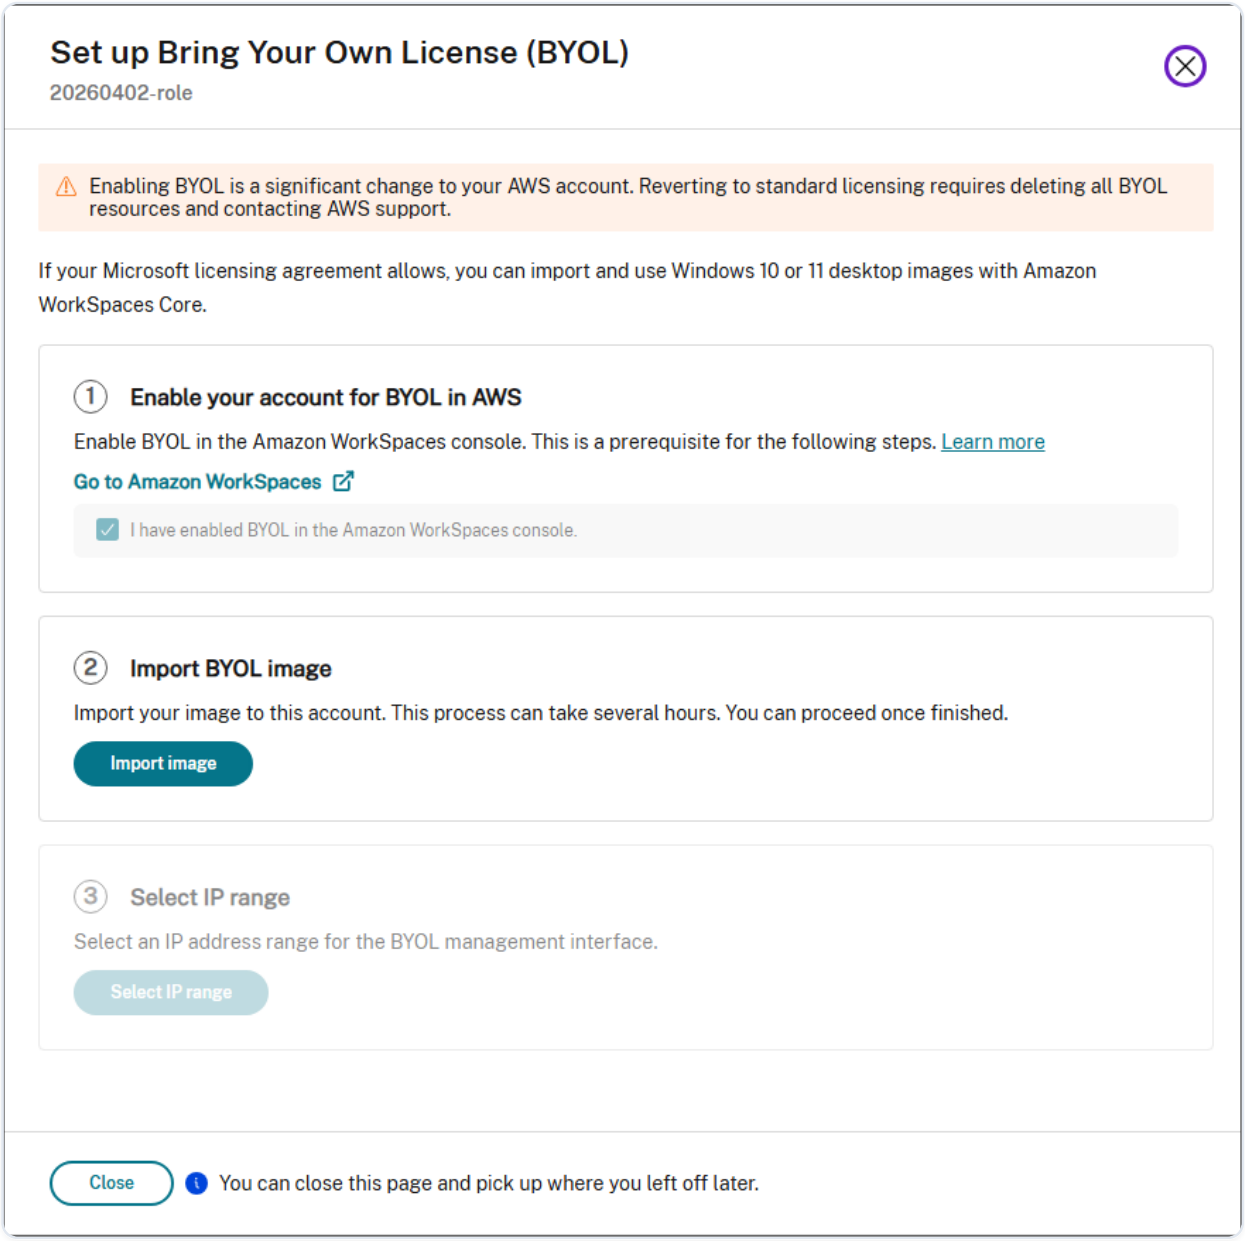
Bring Your Own License (BYOL) lets you import and use Windows 10 or Windows 11 desktop images for your Citrix DaaS for Amazon WorkSpaces Core deployment. BYOL enables dedicated tenancy for directory connections and access to EC2-based machine images.

IMPORTANT:

Enabling BYOL is a permanent change for your AWS account and can only be reversed by removing all resources and contacting AWS support.

You can set up BYOL for an authenticated AWS account from the **Accounts** list or from the account detail panel.

Prerequisites:



- The AWS account is in the **Authenticated** state.
- BYOL has not yet been configured for the account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- BYOL is enabled in the AWS WorkSpaces Console for your account. To enable it, contact your AWS account manager, sales representative, or the AWS Support Center. For more information, see Enable BYOL for your account using the Amazon WorkSpaces console.

To set up BYOL for your account, follow these steps:

1. In **Web Studio**, go to **Quick Deploy > Amazon WorkSpaces Core > Accounts**.
2. Select the AWS account for which you want to set up BYOL.
3. Click **Set up BYOL**. The **Set up BYOL** wizard opens.

4. On the **Enable your account for BYOL in AWS** step:
   a. Click **Go to Amazon WorkSpaces** to open the AWS WorkSpaces Console and enable BYOL for your account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. After enabling BYOL in AWS, select the **Confirm I've enabled BYOL** checkbox.

c. Click **Next**.

5. On the **Import BYOL image** step, click **Import image** to import a Windows 10 or Windows 11 desktop image into your account.

   NOTE:

   Importing an image might take several hours. You can close this page and return later to check the import status.

After BYOL setup is complete, the account detail panel shows the BYOL status, IP range, and available images.

Create a directory connection

NOTE:

Deregister your AWS Directory at the beginning of this step. After you create a Directory Connection with Citrix DaaS, the selected directory gets registered to create Amazon WorkSpaces with Citrix DaaS.

This procedure creates a connection that allows access to your organization's Active Directory.

Prerequisites:

- A resource location containing two Cloud Connectors.
- A security group.
- An OU in your Active Directory.

For prerequisite details, see Before you start.

You can start this procedure from one of two places:

- A link on the Get Started checklist.
- From Studio, select **Studio > Quick Deploy > Amazon WorkSpaces Core > Directory connections**. Then click **Create Directory Connection**.

Follow the **Create directory connection** sequence:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. **Connect directory:** Select the account from the drop-down menu. Select either **Dedicated** or **Shared** for the tenancy.
2. **Resource location:** Select the account and directory. (The selected account must have at least one directory.)
    - Select two subnets in which the desktop machines will be deployed. The subnets must be in appropriate availability zones.
    - Specify a friendly name for this connection.
    - When you're done, click **Next**.
3. **Virtual machine settings:** The settings you select apply to all VMs that use this directory connection.
    - The OU selected must match the OU targeted by the Citrix Group Policy.
    - Select a security group.
    - Indicate whether you want to give administrator privileges to each user assigned to VMs.

Import an image

This procedure enables you to create a desktop experience for your users. You can now import two types of images:

- EC2 Image - To import this image, the prerequisite is to install Citrix Virtual Delivery Agent and all its drivers. The image must also be prepared for BYOL. A BYOL script is available at: BYOLChecker.zip.
- Workspace Image - To import this image, the prerequisite is to install Citrix Virtual Delivery Agent and all its drivers.

To import the image, follow the steps:

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core**, click **Images**.
2. In **My Images**, click **Import Image**.
    a. **Prerequisites:** Provides the prerequisites details for EC2 image and Workspace image. Click **Next: Choose image**.
    b. **Choose image**
        - Provide a friendly name for the image.
        - Select an account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- From the **Image** drop-down list, you can select EC2 or WSI type of images.
  - If you select **EC2**, then choose the application to install from the **Application** drop-down menu and click **Next: Summary**. EC2 type images support only single-sessions.
  - If you select **WSI**, then ensure that the session support and ingestion process align with the image setup. Although a mismatch does not overwrite the image's settings, but might cause deployment failure due to incompatibility. Select session support as single or multi-session.
- Provide a description and click **Next: Summary**.
- Click **Next**. The **Summary** page opens.

3. In the **Summary** page review the information you provided and click **Import Image**.

> **NOTE:**
>
> Importing an image might take several hours.

4. Select any image and click **View Detail**. The details page shows the options selected while creating the images, such as Account, Session support, Tenancy, Applications, and others.

> **NOTE:**
>
> When you create a deployment, in the **Image and performance** page:

- If the **Directory connection** selected has a dedicated tenancy, then the images listed are only single-sessions. In the **Desktops** page you can choose to create desktops with or without assigning users.
- If the Directory connection selected has a shared tenancy, then the images listed are both single and multi-sessions. If you select an image with multi session, then in the **Desktops** page, only **Create desktops without assigning users** option is enabled.

Requirements for Dedicated Tenancy Images

- The images must be either Windows 10 Pro or Windows 11 Pro.
- Run the BYOLChecker script during the image preparation.
- The image can only be set in single-session support.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- When creating an AMI image in EC2, the snapshot must be unencrypted.
- The default ingestion protocol during image import is regular. However, customers can opt for the graphical G4DN ingestion protocol, which installs additional drivers and requires higher-tier machines.
- During image import, customers can add an office application to be installed. This will limit workspace creation to preassigned users deployment.
- The images require the directory connection to be set as dedicated.
- You can create preassigned single-session deployments or decoupled (pooled) single-session deployments.

Requirements for Default or Shared Tenancy Images

- Select the Windows Server BYOP bundle to create a workspace.
- The workspace must be unencrypted, and only the **Always On** mode is supported.
- Connect to the workspace from the connector using the private IP address via RDP and log in with the same user credentials the workspace is assigned to. The image cannot be saved if there are multiple user profiles on the machine.
- Install VDA and run the image checker application.
- VDA can be configured as either single-session or multi-session.
- Restart the workspace and save it as an image.
- After the image is saved, it can be imported into the Citrix environment.
- The default ingestion protocol during image import is regular. However, if the base bundle was G4DN-based, you can opt for the graphical G4DN ingestion protocol.
- The images require the directory connection to be set as shared.
- If you set up and saved the image as a single-session, you can create preassigned single-session deployments or decoupled (pooled) single-session deployments.
- If you set up and saved the image as a multi-session, you can only create decoupled (pooled) multi-session deployments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

OS, Directory Type, and Session Support Compatibility

IMAGE	SESSION SUPPORT	AWS DIRECTORY TENANCY	DEPLOYMENT TYPE	PERSISTENCE
Windows Desktop 11 Pro	Single-Session	Dedicated	Dedicated or Pooled	Persistent
Windows Desktop 10 Pro	Single-Session	Dedicated	Dedicated or Pooled	Persistent
Windows Server 2022	Multi-Session	Shared	Pooled	Persistent
Windows Server 2022	Single-Session	Shared	Dedicated or Pooled	Persistent
Windows Server 2019	Multi-Session	Shared	Pooled	Persistent
Windows Server 2019	Single-Session	Shared	Dedicated or Pooled	Persistent

NOTE:

All instances are persistent and using the pools feature, the instances are assigned on the first use basis. The instances remain provisioned without an assigned user. When a user logs in for the first time, that instance is assigned to the user for all future logins.

Integrate Microsoft Office 2019 Image when importing an image

To integrate Microsoft Office 2019 image while importing an image:

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core**, click **Images**.
2. In **My Images**, click **Import Image**.
3. In **Import Image > Prerequisites**, click **Next: Choose Image**.
4. In **Import Image > Choose image:**
    - Select an account from the **Account** dropdown.
    - Select an AMI from the **AMI** dropdown.

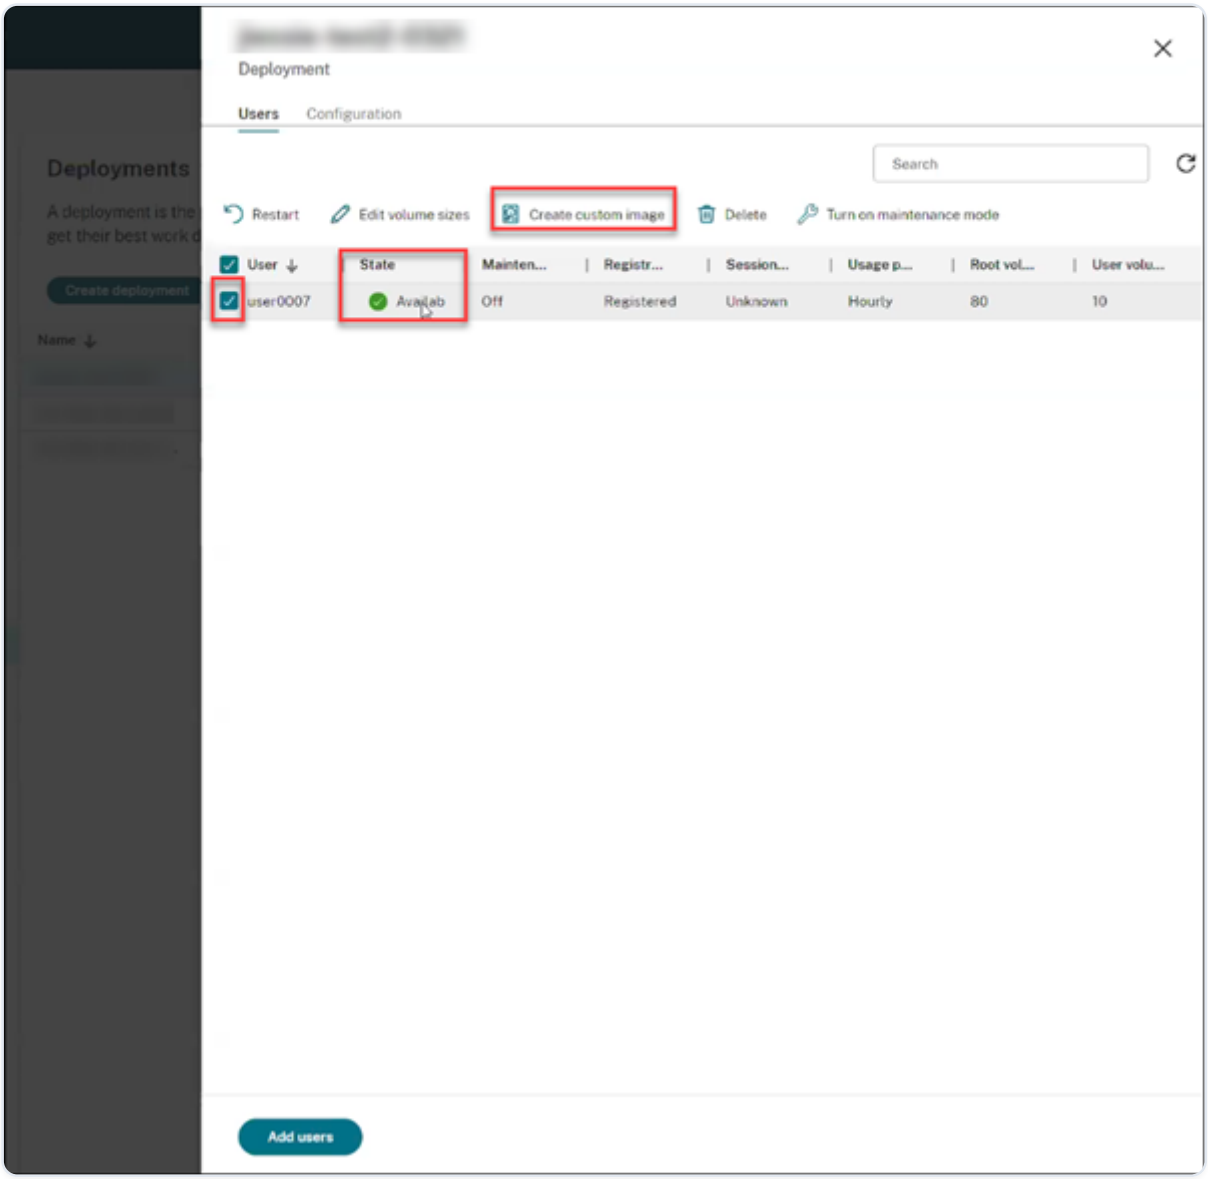
© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Enter the name of the image in the **Name** field.
- Select the **Include Microsoft Office 2019 Professional Plus** in the image.
- Enter a description in the **Description** field.

5. In **Import Image > Choose image**, click **Next: Summary**.
6. In **Choose Image > Summary**, ensure that **Selected** appears for **Microsoft Office 2019**.
7. In **My Images**, click **Import Image**. The status of the recently deployed image displays **importing** until the import operation completes.
8. In **My Images**, select the recently deployed image and click **View Detail**.
9. In the **Detail** panel, the **Microsoft Office 2019** field displays **Included**.

NOTE:

Only the following versions of the OS are compatible:



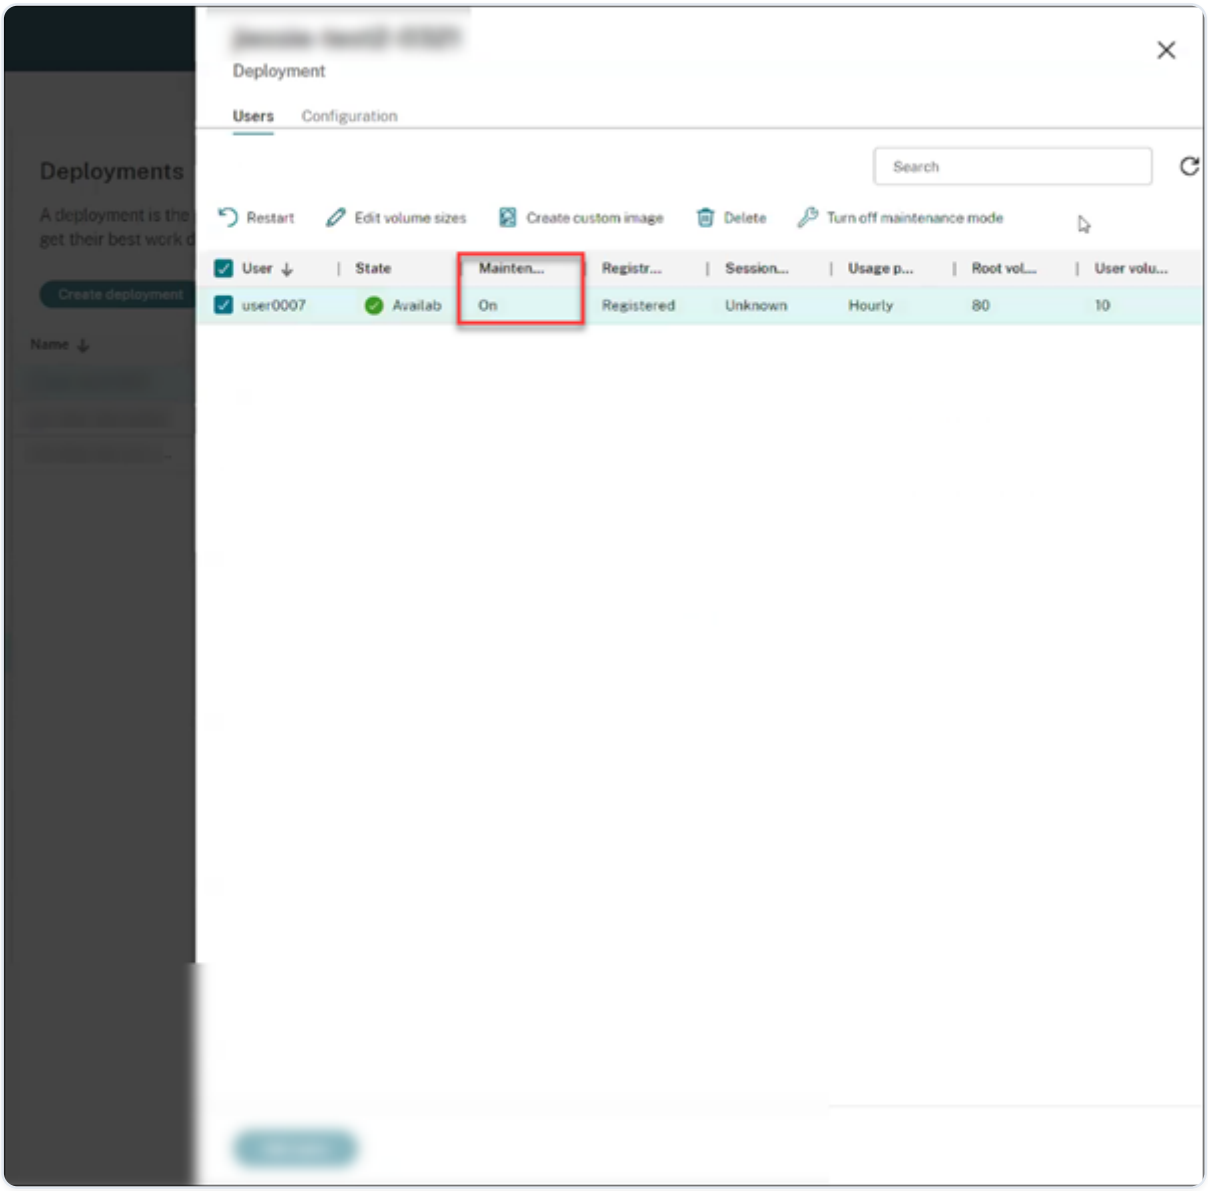
- Windows 10 Version 21H2 (December 2021 Update)
- Windows 10 Version 22H2 (November 2022 Update)
- Windows 10 Enterprise LTSC 2019 (1809) (1809)
- Windows 10 Enterprise LTSC 2021 (21H2) (21H2)
- Windows 11 Version 22H2 (October 2022 release)

Create a custom image from an existing WorkSpaces instance

To create a custom image for a user:

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core**, select **Deployments**.
2. Select the deployment containing machines you want to manage and click **View detail**.
3. In the **Deployment** pane, under the **Users** tab, select the **User** whose workspace state is available and click **Create custom image**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



NOTE:

You can create a custom image only for the deployment whose workspace state is available.

4. In the **Create custom image** pane:
   - Verify the **Image properties**, **OS** and **Account** information of the selected user.
   - Note the warning message that indicates the time the desktop deployment will be in maintenance mode during the process.
   - Fill the mandatory fields like **Image name** and **Description**. The **Image name** field suggests the allowed characters for image names.
5. Click **Create**. The **Images** node window opens.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Click the **Refresh** button. The newly created custom image is listed with the **Status** as **Pending**.
7. Select the custom image and click **View Detail**. The Image window opens with details like **Status**, **Account**, **ID**, **OS**, and **Description**.
8. Click **Deployments** in the left navigation. The **Status** of the new deployment shows as **Updating**.
9. Select the new deployment and click **View detail**.
    - In the **Deployment** pane, the **Maintenance** tab shows as **On**.

As a best practice:

- Use a separate Virtual Private Cloud (VPC) that is not connected to your production environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For Windows WorkSpaces, avoid configuring any Group Policy Objects (GPOs) before creating the image. For more information, see Best practices.
- Use a dedicated AD Connector for image creation.
- Use a dedicated OU in the Active Directory for image creation. For more information, see Best practices for successful BYOL image creation for Amazon WorkSpaces.

Create a deployment

A deployment is a group of desktops that users can access from their store. This procedure specifies the characteristics of the virtual machines to be deployed as desktops, and which AD users can use them.

NOTE:

The computer name is set by Amazon when the workspace is created and is used as an identifier to ensure accurate workspace data. You cannot modify the computer name using Citrix DaaS for Amazon Workspaces Core.

Prerequisites

Complete all the steps listed in Prepare and create a deployment.

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core > Deployments**, click **Create deployment**.
2. In the **Image and performance** page,
    a. if you select a dedicated tenancy, as the Directory connection, then the image drop down lists the images that have Dedicated tenancy. Images with Dedicated tenancy support only single-sessions.
    b. if you select a shared tenancy as the Directory connection, then the Image drop down lists the images that have Default tenancy. Images with Shared tenancy support both single and multi-sessions.
    c. Select the **Performance** and **Root volume sizes**. Click **Next: Encryption**.
3. **Encryption**: In the **Select encryption key preference** section:
    a. The **Use AWS managed KMS key** option is selected by default. This encrypts both root and user volume and is managed by AWS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. If you select the **Use customer managed key** option, ensure to first create the key in **AWS Key Management**. Once created, enter the key into the **Key Alias** field and click **Next: Desktops**.

> **NOTE:**
>
> Encryption keys can be found in the **Key Management Service (KMS)** console under **AWS managed keys** or **Customer managed keys**.

4. **Desktops**:

   a. A new option to select **Create desktops without assigning users**, is added. If you select this option, it is recommended to configure the user profile location to be stored on the D: drive or at an external location. By default, the user profile is stored on the C: drive. The user data and settings on the C: drive are lost if you rebuild the WorkSpace. Specify the number of desktops you want to add to the deployment. The **Desktop assignment type** for this option is **Random pool unassigned**. Click **Next: Summary**.

> **NOTE:**
>
> The **Create desktops without assigning users** option is not available for images with AWS provided applications. Therefore, you must assign users while creating desktops.

   a. If you select the existing **Assign users while creating desktops** option, search and select the users who will be allowed to access the desktops. If you want to customize the volume sizes for a user, select **Edit user and root volume sizes**, and then specify the sizes. The **Desktop assignment type** for this option is **Static preassigned**. Click **Next: Summary**.

5. **Summary:** Review the information you provided and provide a **Deployment name**. Click **Create deployment**. The **Deployment** page shows the new **Desktops** column with the assigned desktop details.
6. Re-sync: Click Re-sync for a deployment that is in Pending state or if the number of machines listed in a deployment does not match with the number of machines listed in AWS.
7. Select a deployment and click **View detail**. The deployment details page shows three tabs:

   a. **Desktops**: Select a desktop and the settings to modify is displayed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. **Applications**: This tab allows you to add new applications and to delete the existing applications. For more information about adding applications to an existing deployment, see Step 6. Applications.

c. **Users**: This tab is available only for unassigned deployments to assign users or groups to launch the desktop. Click **Add**. Update the required settings and click **Find now**. You can select more than one user from the table and click **Ok > Done**. You can add more users and also delete an existing user by selecting appropriate options.

d. **Configuration**: This tab shows the assignment type of the selected desktop. If it is an unassigned desktop, then the **Desktop assignment type** is **Random pool unassigned**.

Integrate Microsoft 365 Windows apps

To integrate Microsoft 365 Apps, see Microsoft 365 Apps for enterprise now available on Amazon WorkSpaces services and Microsoft 365 Bring Your Own License (BYOL).

Manage machines in a deployment

In addition to the machine management features described in Manage machine catalogs, for some actions, you can select machines to manage from a deployment.

To manage machines in a deployment:

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core**, select **Deployments**.
2. In the **Deployments** pane, select the deployment containing machines you want to manage.
3. Click **View details**.
4. In the **Deployment details** pane, select the machine you want to manage.
5. From the actions displayed, select the action you want to perform on the machine:

- Click **Edit volume size** to change the volume size of the machine.
- Click **Delete** to delete the machine from the deployment and AWS. If a machine is in a delivery group, it can be deleted only if it is maintenance mode.
- Click **Turn maintenance mode on/off** to turn maintenance mode on (if it is off) or off (if it is on) for the machine.

Add applications to a deployment

To add applications to an existing deployment:

1. In **Web Studio > Quick Deploy > Amazon WorkSpaces Core**, select Deployments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

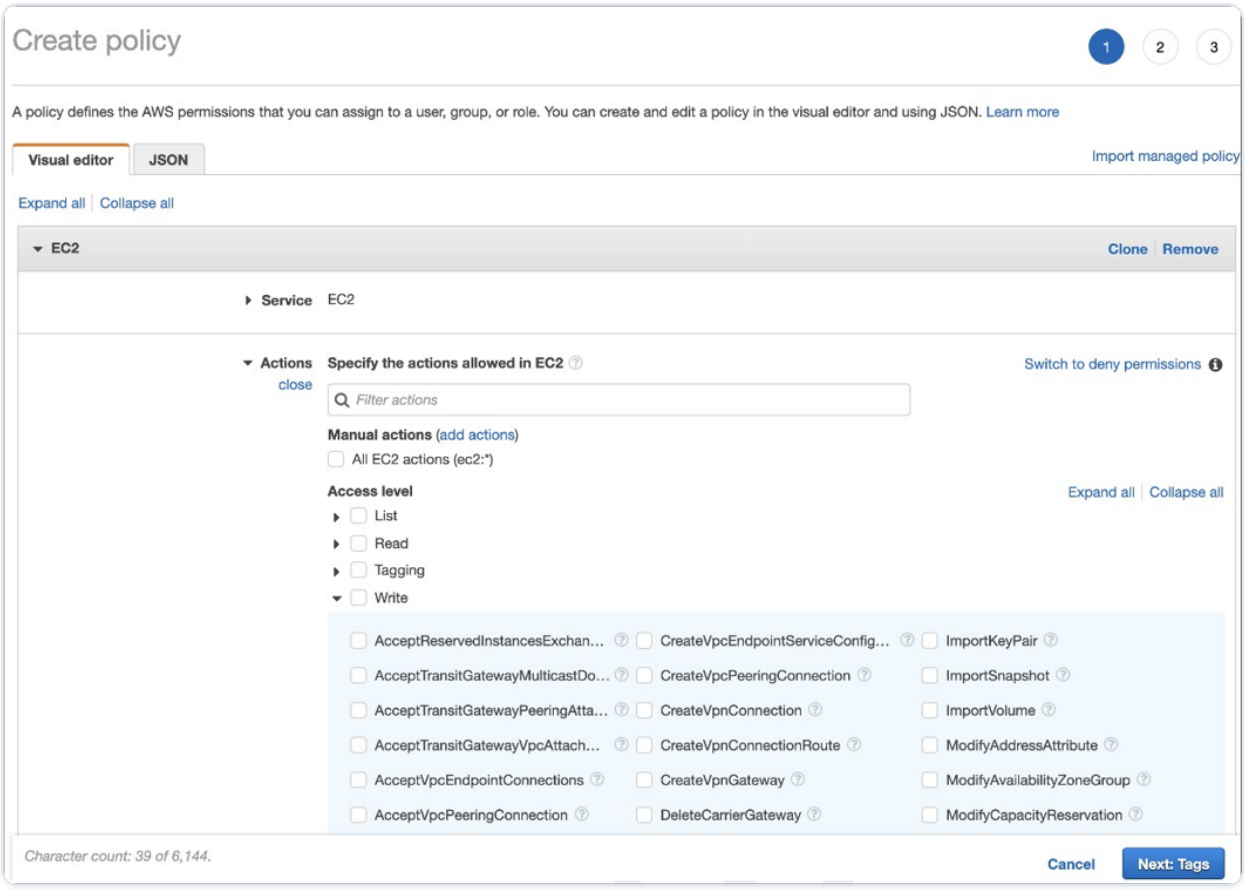
2. In the Deployments pane, select the deployment to which you want to add the applications.
3. Click Add applications. The Add Application pane opens.
4. Click the Add menu and select one of the following sources to add the applications:
    - From Start menu
    - Manually
    - Application packages
    - Existing
    - Application group

For more information about adding applications to an existing deployment, see Step 6. Applications.

Use persistent desktops with a non-persistent user profile

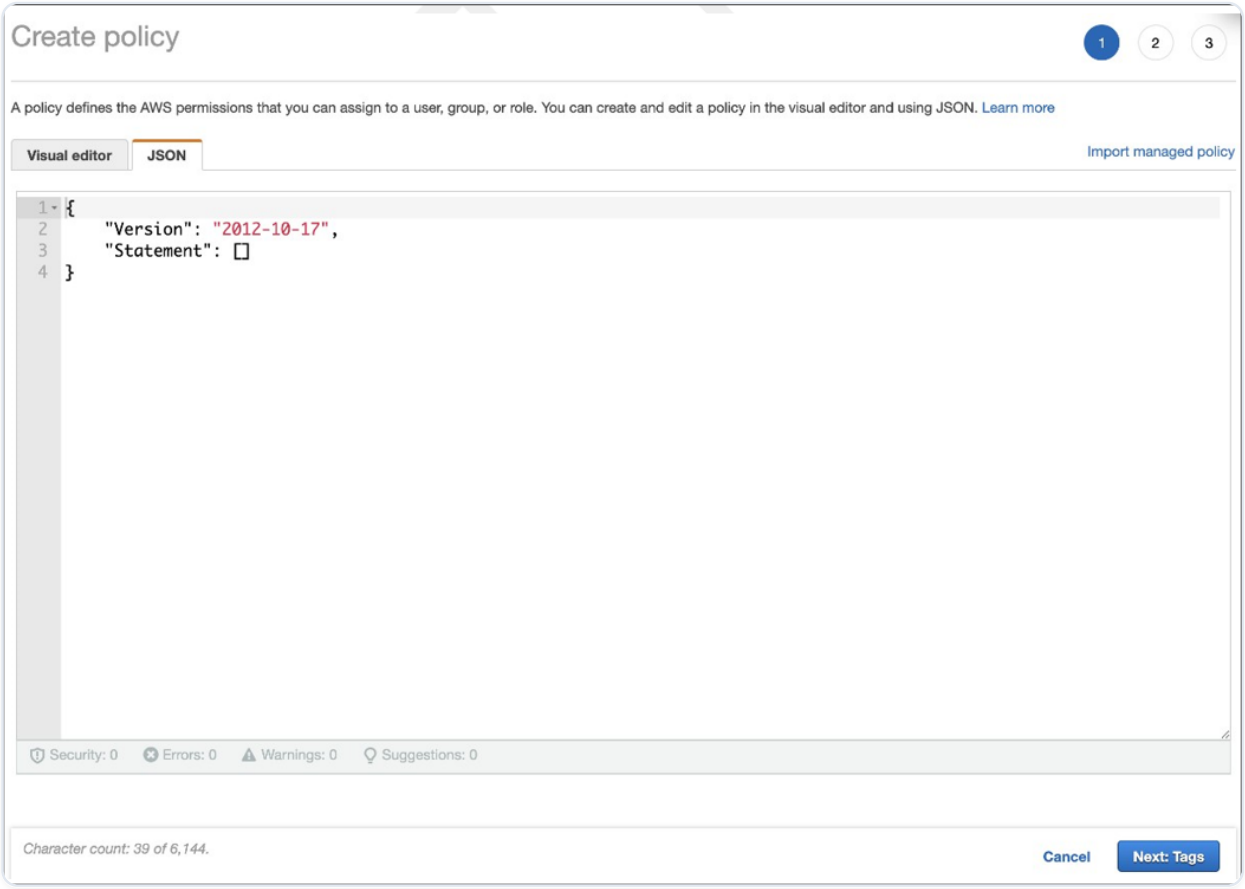
Workspace Environment Management™ can be used to configure Profile Management settings to enable persistent desktops with non-persistent user profiles. This provides you with a customizable desktop experience while maintaining easy management and centralized storage of user profiles, creating a flexible and scalable solution for virtual desktop environments. Do the following to configure the setting:

1. From the WEM console, navigate to **Configuration Set > Policies and Profiles > Citrix Profile Management Settings**.
2. Select **Enable Profile Management Configuration** and navigate to **Profile Handling** tab.
3. Select **Delete locally cached profiles on logoff**.



Reference

AWS account programmatic access permissions



The AWS user account must have certain programmatic access permissions to make API calls to the AWS resource layer. Programmatic access creates an access key ID and a secret access key. You can create a policy containing these permissions in the IAM console. As shown in the following graphics, you can use the visual editor (adding the permissions one by one) or the JSON (adding the snippet below). For more information, see Creating an IAM user in your AWS account.

- On the **Visual editor** tab, add the permissions one-by-one.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- On the **JSON** tab, add the snippet shown after the following graphic.

Citrix DaaS™ for Google Cloud

With Studio, you can deploy and manage virtual apps and desktops on Google Cloud. For information about supported features, see the Citrix Virtual Apps and Desktops feature matrix.

To deploy and manage Google Cloud apps and desktops using Studio, follow these steps:

1. Order Citrix DaaS for Google Cloud from the Google Cloud Marketplace.
2. Sign in to Citrix Cloud.
3. In the **DaaS** tile, click **Manage** to open Studio.
4. Deploy virtual apps and desktops using one of these workflows provided in the **Manage** section:

    - Quick Deploy (recommended for fast, guided deployment). For more information, see Quick Deploy for Google Cloud.

      NOTE:

      To perform advanced configurations or management options, convert your deployment to the full configuration mode. For more information, see Convert a deployment.

    - Full Configuration (recommended for advanced configuration requirements). For more information, see Get started: Plan and build a deployment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

For step-by-step instructions on deploying and configuring virtual apps and desktops on Google Cloud, see this Citrix Tech Zone article: Citrix virtualization on Google Cloud. This article covers defining the deployment architecture, preparing the Google Cloud project, configuring network services, and deploying Active Directory.

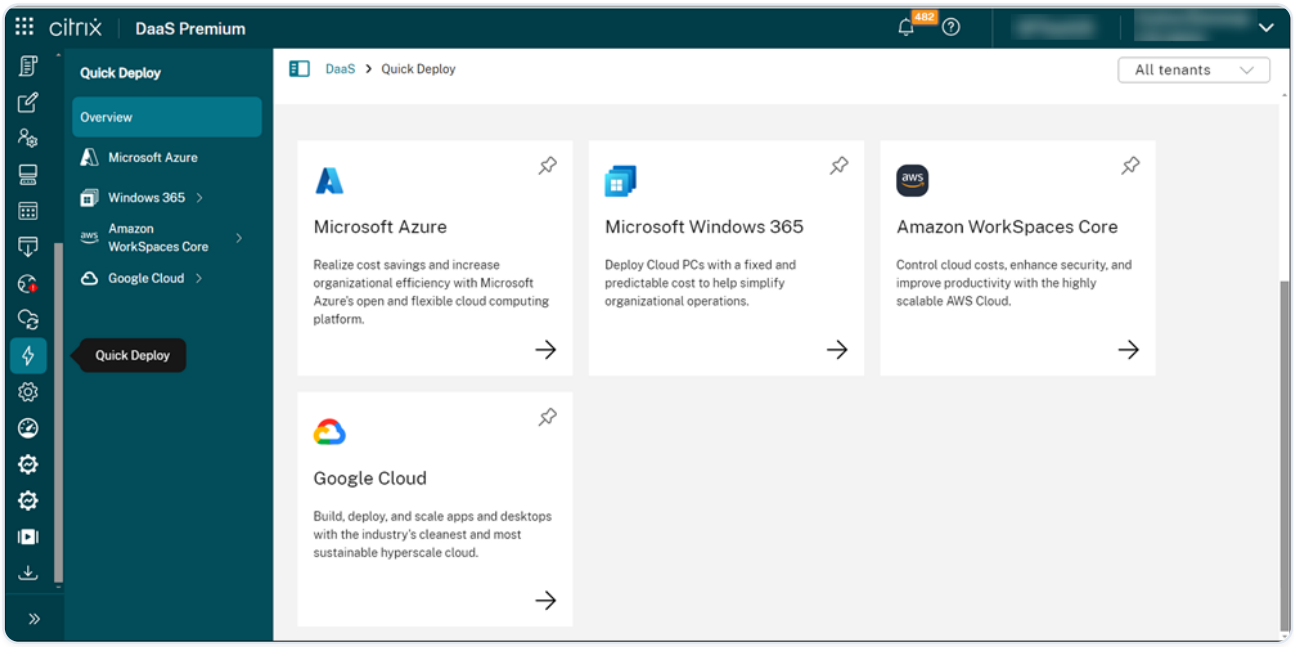
Quick Deploy for Google Cloud

Quick Deploy for Google Cloud provides a simplified user experience for connecting Citrix DaaS to Google Cloud and creating a deployment of virtual apps and desktops. Its streamlined user interface guides admins along the key steps of this journey and removes unnecessary complications.

This interface offers basic configuration, without advanced features.

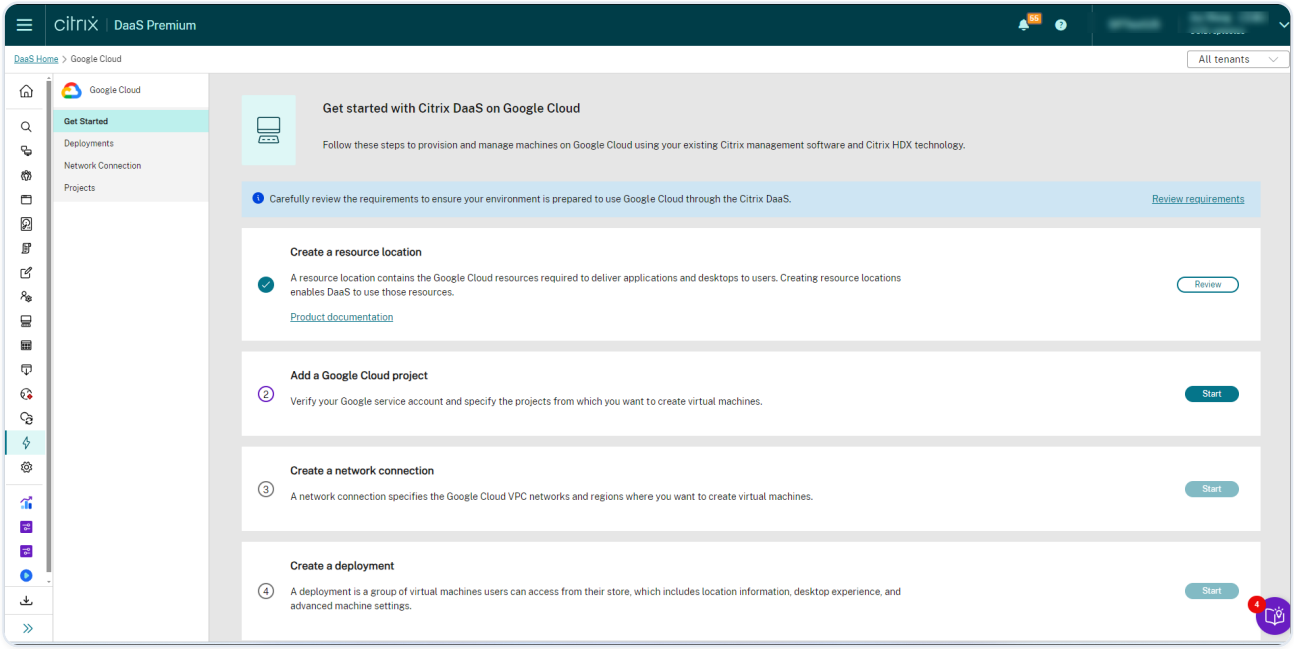
To deploy virtual apps and desktops using Quick Deploy, follow the onscreen wizard to complete these steps:

1. Launch Quick Deploy for Google Cloud
2. Create a resource location
3. Add a Google Cloud project
4. Create a network connection
5. Create a deployment



After you create a deployment, perform these tasks as necessary:

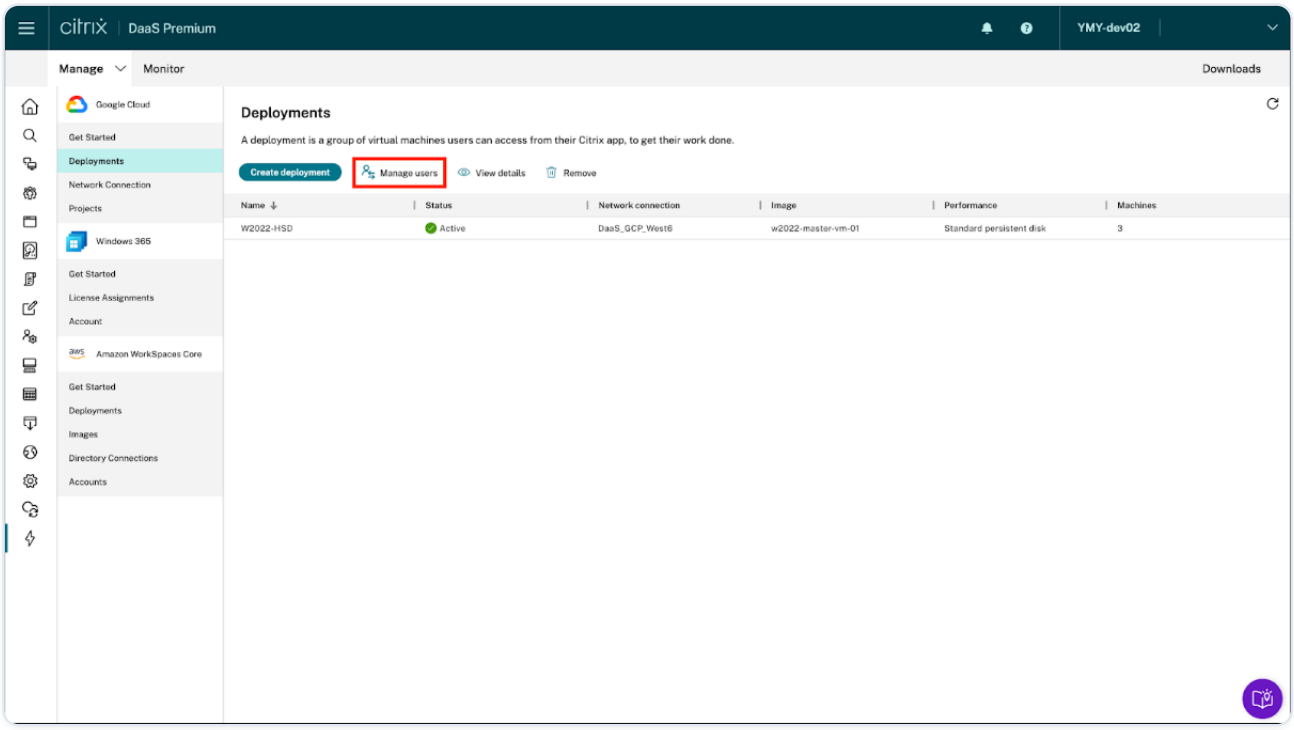
- Grant users access rights
- Convert a deployment to the full configuration mode for advanced settings and management option.



Launch Quick Deploy for Google Cloud

Quick Deploy for Google Cloud can be accessed from within Studio, by selecting the Quick Deploy node.

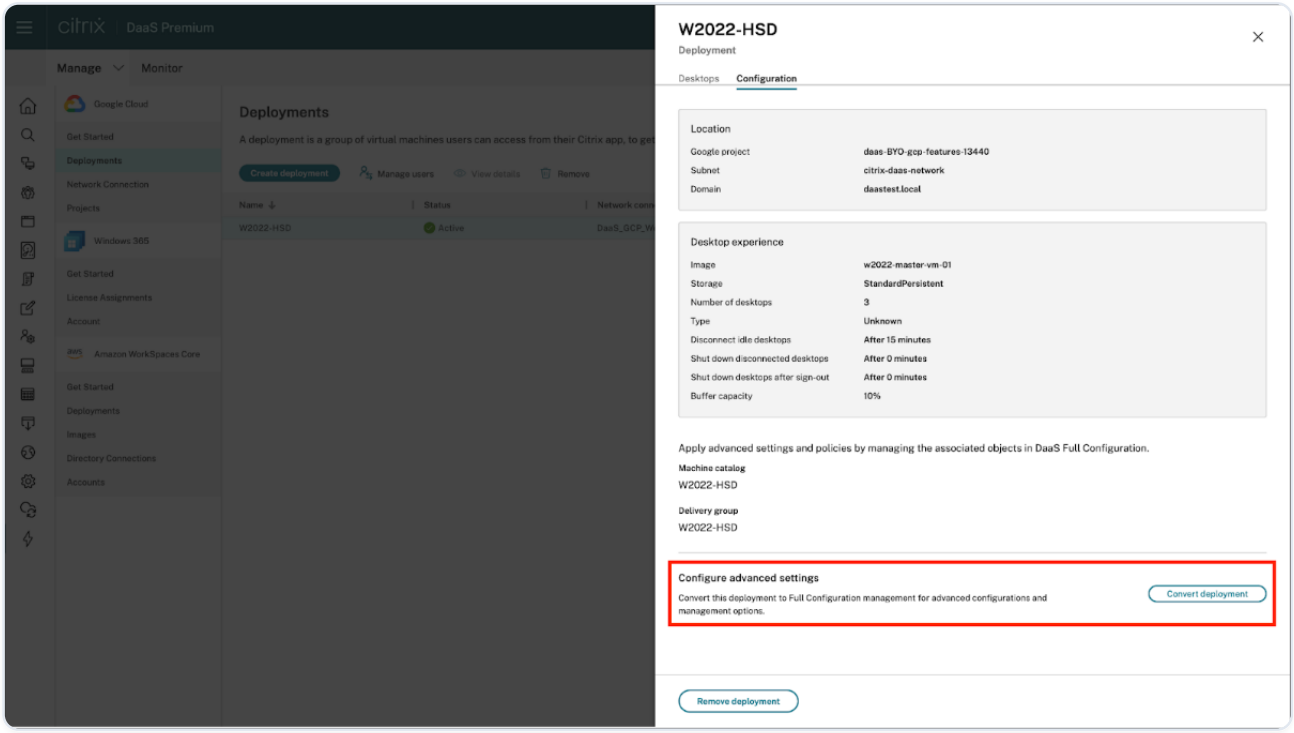
© 1997–2026 Citrix Systems, Inc. All rights reserved.



To begin the Quick Deploy process, review the steps provided on the Get Started page. Start with **Review requirements**.

Manage user access rights

After a deployment is created, grant users access permissions as necessary. To complete this task, select the respective deployment and then select **Manage users**.

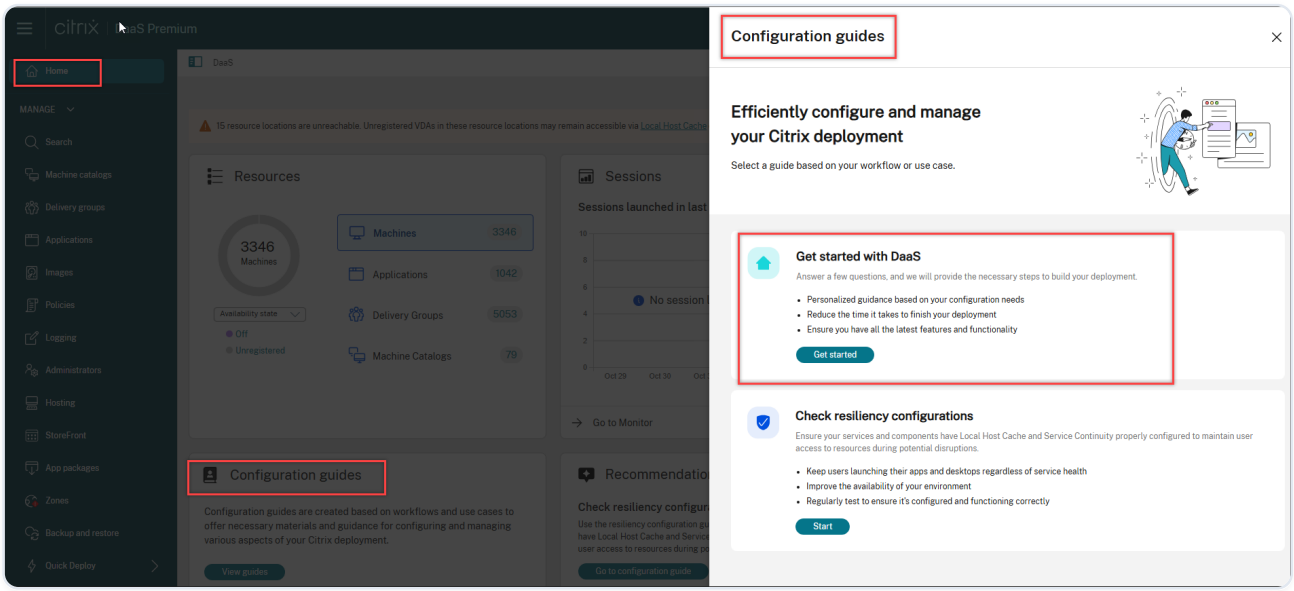


© 1997–2026 Citrix Systems, Inc. All rights reserved.

Convert a deployment

Before you perform any advanced configurations or management activities, ensure you convert the deployments. To convert a deployment:

1. Click **Deployments** in the left navigation.
2. Select a deployment and click **View details**.
3. Click the **Configuration** tab and select **Convert deployment**.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Once a deployment is converted, the action is irreversible and the converted deployments no longer appears in Quick Deploy.

Use DaaS get-started guide

DaaS get-started guide streamlines and simplifies the DaaS deployment process for both new and experienced administrators. Using the guide, you can quickly set up your DaaS deployments by answering a series of questions.

This article walks you through the processes of setting up five typical DaaS deployment scenarios.

Benefits

Benefits of using this guide include:

- **Easy to get started**. This guide connects essential deployment steps through a questionnaire-led, step-by-step workflow. If you're a new administrator, you can quickly set up your deployment while learning concepts and terminology through contextual help.
- **Simplify complex configurations**. This guide provides pre-configured settings wherever necessary and provides access to Studio for advanced configurations. If you're an experienced administrator, you can use the guide as a starting point for complex configurations.

Supported deployment scenarios

This guide provides quick deployments for these scenarios:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

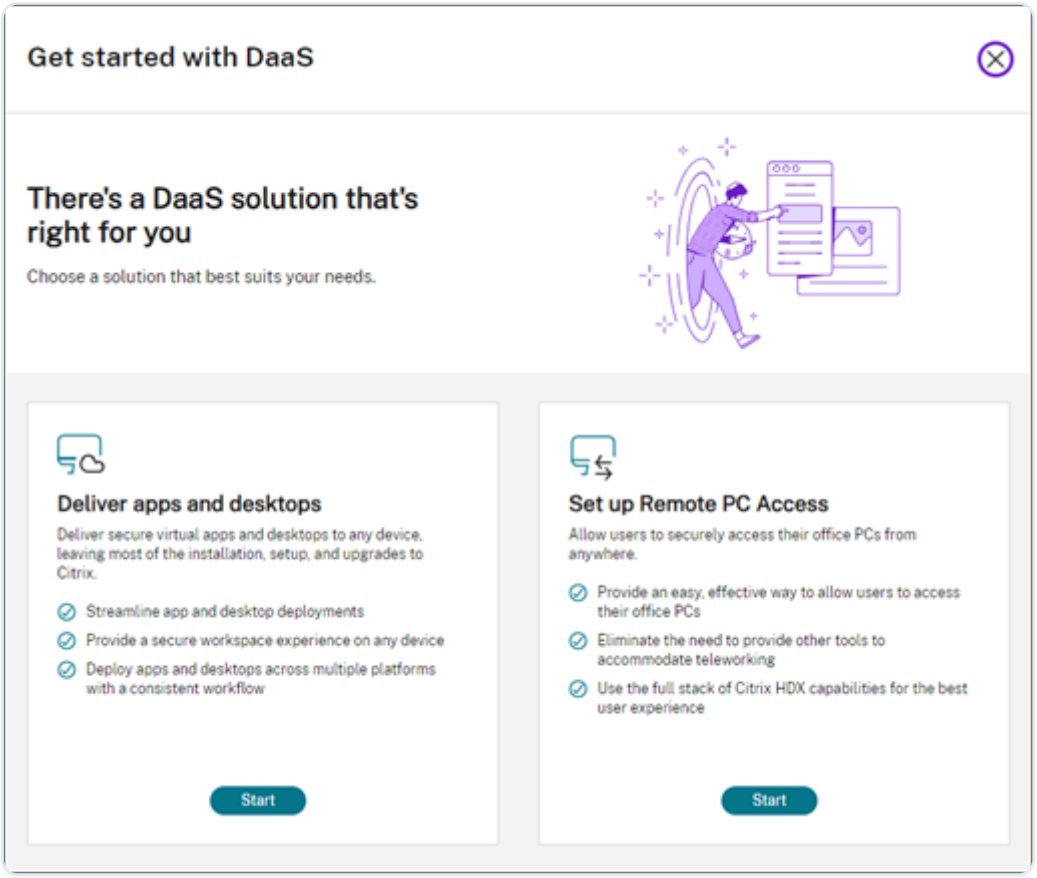
WHAT TO DELIVER?	MACHINES ALREADY EXIST?	MACHINE TYPE	REMARK
Virtual apps and desktops	No	Virtual machines (Provisioned by DaaS)	Power managed
Virtual apps and desktops	Yes	Virtual machines or blade PCs	Power managed
Virtual apps and desktops	Yes	Physical or virtual machines	Not power managed
Office PCs	Yes	Physical machines	Power managed
Office PCs	Yes	Physical machines	Not power managed

See the following sections for detailed instructions:

- Deliver apps and desktops from scratch (power managed)
- Deliver apps and desktops using existing machines (power managed)
- Deliver apps and desktops using existing machines (not power-managed)
- Deliver office PCs (power managed)
- Deliver office PCs (not power-managed)

Terminology

The following are DaaS-specific terms:



- **Resource location.** Contains the resources required to deliver apps and desktops to users.
- **Host connection.** Connects DaaS to a host (hypervisor or cloud service) in a resource location. Creating host connections is required when you want to create and manage machines on hosts or to power manage existing machines.
- **Master image.** Serves as a template for replicating virtual machines on your host. It includes the operating system, applications, Virtual Delivery Agent (VDA), and other software.
- **Machine catalog.** Collection of identical machines. They can be virtual or physical depending on your needs. You can create a machine catalog to create identically configured machines on a host or import machines into DaaS for management.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Delivery group.** Contains machines from machine catalogs. Also, it specifies which users can use those machines and which applications and desktops are available to those users.
- **Machine Profile.** Specifies the properties of virtual machines. VMs in a catalog can inherit properties from a machine profile.

Access the guide

1. Go to the **DaaS > Home** page.
2. Locate **Get started with DaaS**.
3. Click **Get Started** to initiate your deployment process.

NOTE:

You can exit the process at any time by clicking **Close** and the guide saves your settings automatically. To continue your configuration, click **Continue**. To start fresh, click **Start over**.

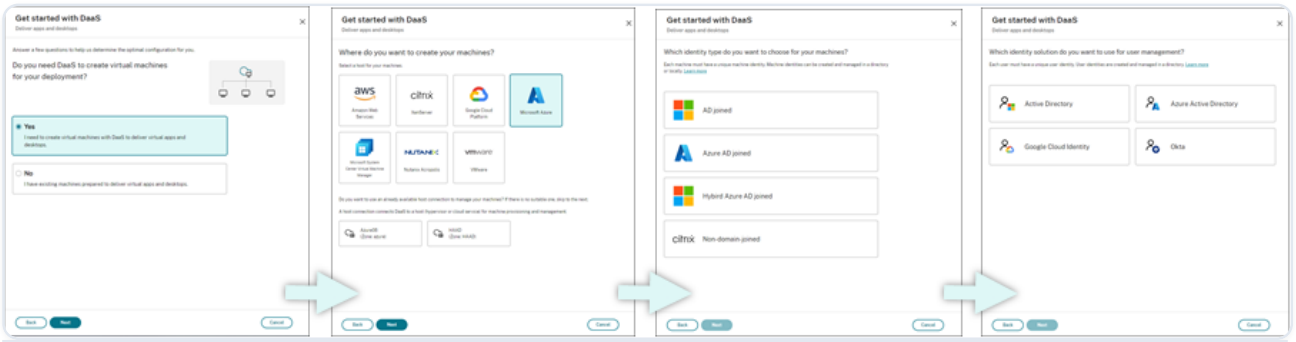
Deliver apps and desktops from scratch (power managed)

This section guides you through the deployment process of creating VMs and delivering apps and desktops using them.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prerequisites

Before you start, you need:



- Connectivity from Citrix Cloud™ to the target identity provider

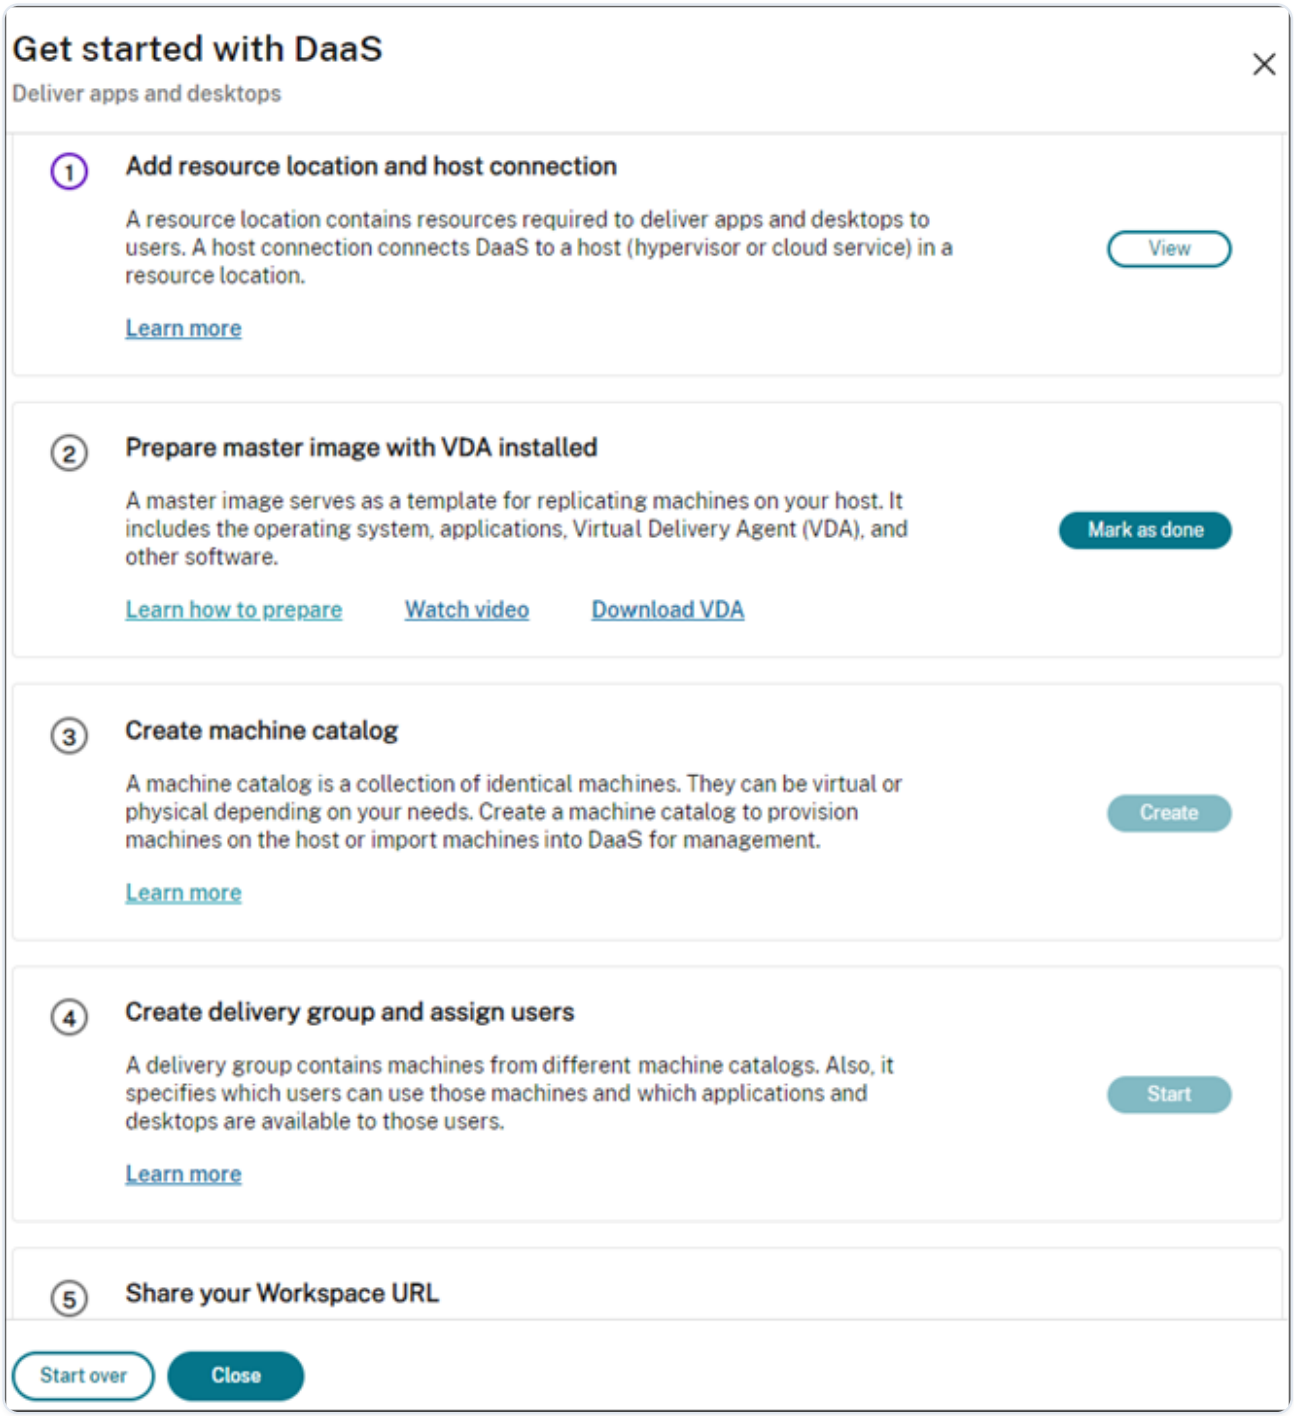
  For more information, see the corresponding section in Identity providers.
- Role: Full Administrator or Cloud Administrator
- Required permissions on the target hypervisor or cloud service.

  For more information, see the corresponding sections in the Create and manage connections.
- Administrator credentials for VM account creation

Preparation

Answer the onscreen questions to complete the following infrastructure-level settings. See the following table for details.

#	SETTING	DESCRIPTION
1	Specify whether VM creation is needed	Select **Yes**.
2	Select the host type	Select a host type for your deployment.
		Options: AWS, XenServer (formerly Citrix Hypervisor™), Google Cloud Platform, Microsoft Azure, Microsoft System Center Virtual Machine Manager, Nutanix Acropolis, and VMware



© 1997–2026 Citrix Systems, Inc. All rights reserved.

#	SETTING	DESCRIPTION
3	Select the machine identity type	Select an identity type for machine management.
		Options: AD joined, Microsoft Entra joined, Microsoft Entra hybrid joined, and Non-domain-joined
4	Select the user identity type	Select an identity type for user management.
		Options: Active Directory, Microsoft Entra ID, Google Cloud Identity, and Okta

Deployment steps

After you complete the infrastructure-level settings, steps specific to this deployment scenario appear as follows.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Follow the onscreen instructions to complete the settings.

Step 1: Add a resource location and host connections

Set up your resource location by installing Cloud Connectors and configure connections to hypervisors or cloud services in the location.

1. Name the resource location.
2. Download and install Cloud Connectors on at least two Windows Server machines.
3. Detect installed Cloud Connectors.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Add and configure host connections for the resource location. Detailed settings of a connection include:

   - Connection details, such as the connection address, user name, and password.
   - Storage resources
   - Network resources

   NOTE:

   DaaS creates and manages VMs on hosts through those connections. You must specify connections when you create machine catalogs.

Step 2: Prepare master images for your machines

Prepare master images on VMs in your resource location. For more information, see Prepare a master image on the hypervisor or cloud service.

Step 3: Create machine catalogs

Create a machine catalog to create a group of identically configured machines on a host. Detailed steps are as follows:

1. Name the catalog.
2. Select the machine type.

   Options: Multi-session, Single-session static (personal desktops), and Single-session random (pooled desktops).

3. Select a host connection.

   Options originate from all host connections that you've configured for your resource locations in Step 1.

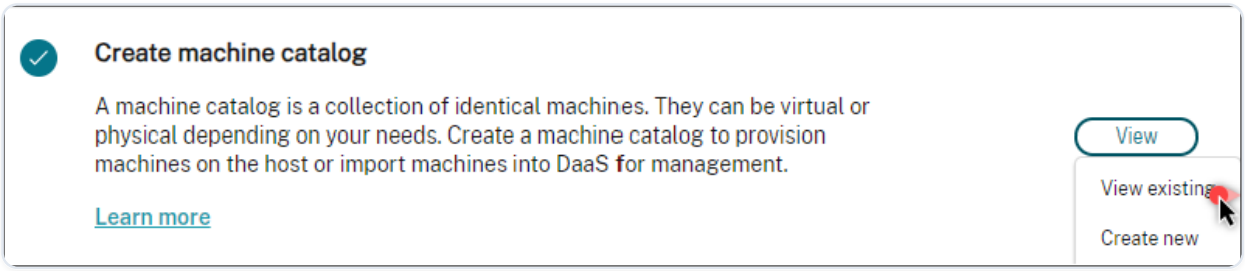
4. Select a master image.
5. Select a machine profile.

   NOTE:

   Machine profile support is currently available for Azure, GCP, and AWS cloud services, and the use of machine profile is optional for GCP.

6. Set how many machines you want to create.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



7. Set the machine identities.

   By default, the machine identity type that you selected in the preparation phase is shown. Provide the required identity settings for the VMs, such as domain, OU, and naming scheme.

8. Enter the administrator credentials required for machine creation.
9. Click **Create**.

> **TIP:**
>
> The **Create** button is available only after you provide all required settings.

To view the catalog creation progress, select **View > View existing**.

Step 4: Create delivery groups and assign users

> **TIP:**
>
> Before creating delivery groups, view the existing catalogs to ensure that at least one catalog has been created successfully. Otherwise, you're prevented from creating delivery groups.

Creating a delivery group includes the following subtasks:

- Add VMs to the group
- Assign users to the group
- Specify which apps and desktops you want to make available to assigned users

1. Name the group.
2. Add machines to the group by selecting a machine catalog and specifying how many VMs are available for the group.
3. Specify available applications and desktops for this group:

   - To add applications from a running machine in the selected catalog, click **Add new > From start menu**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To add applications deployed on network shares, click **Add new > Manually**, and then provide the required settings, such as path, working directory, and more.
- (Visible only with multi-session OS machines) For desktop delivery, keep **Enable desktop delivery** selected.

4. Add users who can access apps and desktops in this group.

Step 5: Share the store URL with your users

Go to **StoreFront Cloud \> Access**, and then share the store URL with your users.

Deliver apps and desktops using existing machines (power managed)

This section guides you through the deployment process of delivering apps and desktops using existing machines (power managed).

Prerequisites

Before you start, you need:

- Connectivity from Citrix Cloud to the target identity provider

  For more information, see the corresponding section in Identity providers.
- Role: Full Administrator or Cloud Administrator

Preparation

Answer the onscreen questions to complete the following infrastructure-level settings.

#	SETTING	DESCRIPTION
1	Specify whether VM creation is needed	Select **No**.
2	Select whether power management is required	Select **Machines that are power managed (for example, virtual machines or blade PCs)**.
3	Select the host platform	Select the host platform where your existing machines reside.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

#	SETTING	DESCRIPTION
		Options: AWS, Citrix®, Google Cloud Platform, Microsoft Azure, Microsoft System Center Virtual Machine Manager, Nutanix Acropolis, and VMware
4	Select the user identity type	Select an identity type for user management.
		Options: Active Directory, Microsoft Entra ID, Google Cloud Identity, and Okta

Deployment steps

After you complete the infrastructure-level settings, steps specific to this deployment scenario appear. Follow the onscreen instructions to complete the settings.

Step 1: Add a resource location and host connections

Set up your resource location by installing Cloud Connectors and configure connections to hypervisors or cloud services in your location.

1. Name the resource location.
2. Download and install Cloud Connectors on at least two Windows Server machines.
3. Detect installed Cloud Connectors.
4. Add and configure host connections for the resource location. Examples of connection settings include the connection address, user name, and password.

NOTE:

DaaS power manages machines in resource locations through connections. You need to specify a connection when importing your machines to a catalog.

Step 2: Create machine catalogs

Create a machine catalog and import your machines to it.

1. Name the catalog

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Select the machine type.

   Options: Multi-session, Single-session static (personal desktops), and Single-session random (pooled desktops).
3. Select a resource location.
4. Import machines to the catalog. Machines are organized by host connection. Choose a host connection to import associated machines.
5. Click **Create**.

Step 3: Create delivery groups and assign users

To create a delivery group, you must:

- Add VMs to the group
- Assign users to the group
- Specify which apps and desktops you want to make available to assigned users

1. Name the group.
2. Select a machine catalog as needed, and then specify how many machines are available for the delivery group.
3. Specify available applications and desktops for this group:
   - To add applications from a running machine in the selected catalog, click **Add new > From start menu**.
   - To add applications deployed on network shares, click **Add new > Manually**, and then provide the required settings, such as path, working directory, and more.
   - (Visible only with multi-session OS machines) For desktop delivery, keep **Enable desktop delivery** selected.
4. Add users to the group.

Step 4: Share the store URL with your users

Go to **Citrix® StoreFront Cloud \> Access**, and then share the store URL with your users.

Deliver apps and desktops using existing machines (not power-managed)

This section guides you through the deployment process of delivering apps and desktops using existing machines (not power-managed).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prerequisites

Before you start, you need:

- Connectivity from Citrix Cloud to the target identity provider

  For more information, see the corresponding section in Identity providers
- Role: Full Administrator or Cloud Administrator

Preparation

Answer the onscreen questions to complete the following infrastructure-level settings.

#	SETTING	DESCRIPTION
1	Specify whether VM creation is needed	Select **No**.
2	Select whether power management is required	Select **Machines that are not power managed (for example, physical machines)**.
3	Select the user identity type	Select an identity type for user management.
		Options: Active Directory, Microsoft Entra ID, Google Cloud Identity, and Okta

Deployment steps

After you complete the infrastructure-level settings, steps specific to this deployment scenario appear. Follow the onscreen instructions to complete the settings.

Step 1: Add a resource location

Set up your resource location by installing Cloud Connectors.

1. Name the resource location.
2. Download and install Cloud Connectors on at least two Windows Server machines.
3. Detect installed Cloud Connectors.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Creating host connections is required only when you want to power manage machines.

Step 2: Create a machine catalog

Create a machine catalog and import your machines to it.

1. Name the catalog
2. Select the machine type.

   Options: Multi-session, Single-session static (personal desktops), and Single-session random (pooled desktops).
3. Select a resource location.
4. Import machines to the catalog.

   To ease machine search, use partial computer names and directory selection.
5. Click **Create**.

Step 3: Create delivery groups and assign users

To create a delivery group, you must:

- Add VMs to the group
- Assign users to the group
- Specify which apps and desktops you want to make available to assigned users

1. Name the group.
2. Select a machine catalog as needed, and then specify how many machines are available for the delivery group.
3. Specify available applications and desktops for this group:
   - To add applications from a running machine in the selected catalog, click **Add new > From start menu**.
   - To add applications deployed on network shares, click **Add new > Manually**, and then provide the required settings, such as path, working directory, and more.
   - (Visible only with multi-session OS machines) For desktop delivery, keep **Enable desktop delivery** selected.
4. Add users to the group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Step 4: Share the store URL with your users

Go to **Citrix® StoreFront Cloud \> Access**, and then share the store URL with your users.

Deliver office PCs (power managed)

This section guides you through the deployment process of delivering office PCs (power managed).

Prerequisites

Before you begin, you need:

- Machine names of the PCs.
- Citrix Virtual Delivery Agent (VDA) is installed on each PC. (This step can be done after catalog creation.)

  For more information, see Download VDA.

Preparation

Answer the onscreen questions to complete the following infrastructure-level settings.

#	STEP	DESCRIPTION
1	Select the machine allocation type.	Select how the machines are assigned.
		Options: Static auto-assigned, Static preassigned, and Random pool unassigned
2	Determine whether to allow users to power on machines	Select **I want remote users to power on machines by themselves**.
3	Select the user identity type	Select an identity type for user management.
		Options: Active Directory, Microsoft Entra ID, Google Cloud Identity, and Okta

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Deployment steps

After you complete the infrastructure-level settings, steps specific to this deployment scenario appear. Follow the onscreen instructions to complete the settings.

Step 1: Add a resource location and host connections

Set up your resource location by installing Cloud Connectors and add a connection of the **Remote PC Wake on LAN** type.

1. Name the resource location.
2. Download and install Cloud Connectors on at least two Windows Server machines.
3. Detect installed Cloud Connectors.
4. Click **Add new** to add a connection:
    a. Select a resource location (zone).
    b. Select **Remote PC Wake on LAN** for **Connection type**.
    c. Enter a name for the connection.

NOTE:

DaaS power manages machines through the configured connections. You must configure connections of the **Remote PC Wake on LAN** type when creating Remote PC Access catalogs for power-managed machines.

Step 2: Create a Remote PC Access catalog

Create a machine catalog and import your office PCs to it.

1. Name the catalog
2. Select a resource location.
3. Select a machine allocation type. By default, the type that you selected in the preparation phase is shown.
4. Select the **Wake on LAN connection**. Options are the connections of the **Remote PC Wake on LAN** type that you configured for the selected location.
5. Import your machines.
6. Click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Step 3: Create delivery groups and assign users

Create a delivery group to group machines that you want to deliver and specify who can access them.

1. Name the group.
2. Select a machine catalog as needed. Only the **Remote PC Access** catalogs appear.
3. Assign users to the group.

Step 4: Share the store URL with your users

Go to **Citrix® StoreFront Cloud \> Access**, and then share the store URL with your users.

Deliver office PCs (not power-managed)

This section guides you through the deployment process of delivering office PCs (not power-managed).

Prerequisites

Before you begin, you need:

- Machine names of the PCs.
- Citrix Virtual Delivery Agent (VDA) is installed on each PC. (This step can be done after catalog creation.)

  For more information, see Download VDA.

Preparation

Answer the onscreen questions to complete the following infrastructure-level settings.

#	SETTING	DESCRIPTION
1	Select the machine allocation type.	Select how the machines are assigned.
		Options: Static auto-assigned, static preassigned, and random pool unassigned
2	Determine whether to allow users to power on machines	Keep **I want remote users to power on machines by themselves** cleared.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

#	SETTING	DESCRIPTION
3	Select the user identity type	Select an identity type for user management.
		Options: Active Directory, Microsoft Entra ID, Google Cloud Identity, and Okta

Deployment steps

After you complete the infrastructure-level settings, steps specific to this deployment scenario appear. Follow the onscreen instructions to complete the settings.

Step 1: Add a resource location

Set up your resource location by installing Cloud Connectors.

1. Name the resource location.
2. Download and install Cloud Connectors on at least two Windows Server machines.
3. Detect installed Cloud Connectors.

NOTE:

Creating host connections is required only when you want to power manage machines.

Step 2: Create a Remote PC Access catalog

Create a catalog and import your office PCs to it.

1. Name the catalog
2. Select a resource location.
3. Select an allocation type. By default, the type that you selected in the preparation phase is shown.
4. Import your machines.
5. Click **Create**.

Step 3: Create delivery groups and assign users

Create a delivery group for machines that you want to deliver and specify who can access them.

1. Name the group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Select a machine catalog as needed. Only the **Remote PC Access** catalogs appear.
3. Assign users for the group.

Step 4: Share the store URL with your users

Go to **Citrix® StoreFront Cloud \> Access**, and then share the store URL with your users.

Machine identities

Each machine must have a unique machine identity, also known as computer account. Machine identities can be created and managed in the machines locally or in a directory, such as on-premises Active Directory (AD) or Microsoft Entra ID. Citrix supports hosting virtual applications and desktops on machines that are Active Directory joined, Microsoft Entra joined, Microsoft Entra hybrid joined, or non-domain joined.

Machine identity types

The following machine identity types are supported.

MACHINE IDENTITY TYPE	DESCRIPTION
AD joined	Identities are created and managed in on-premises Active Directory. Provisioned machines are joined to on-premises Active Directory using the assigned machine identities.
Microsoft Entra joined	Identities are created and managed in Entra ID. Provisioned machines are joined to Entra ID using the assigned machine identities. Importing VMs to Citrix DaaS is not supported.
Microsoft Entra hybrid joined	Identities are created in on-premises Active Directory and are synced with Entra ID through Microsoft Entra Connect. Provisioned machines are joined to on-premises Active Directory and Entra ID. The machines are then Entra hybrid joined. For importing an Entra hybrid joined VM, the VM is treated as an Active Directory joined VM by Citrix DaaS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

MACHINE IDENTITY TYPE	DESCRIPTION
Non-domain-joined	Identities are created and managed in the machines locally. Importing VMs to Citrix DaaS is not supported.

Supported Configurations

The following are details of the supported configurations for each scenario.

Supported infrastructure

MACHINE IDENTITY	CITRIX DAAS™	CITRIX® STOREFRONT CLOUD	CITRIX STOREFRONT	CITRIX GATEWAY SERVICE	CITRIX GATEWAY
AD joined	Yes	Yes	Yes	Yes	Yes
Microsoft Entra joined	Yes	Yes	Preview	Yes	No
Microsoft Entra hybrid joined	Yes	Yes	Yes	Yes	Yes
Non-domain-joined	Yes	Yes	Yes	Yes	Yes

NOTE

Neither Local Host Cache nor Service Continuity are available for Non-domain joined session hosts when using Storefront.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Supported Citrix® StoreFront Cloud authentication identity providers

MACHINE IDENTITY	MICROSOFT ENTRA ID	ACTIVE DIRECTORY	ACTIVE DIRECTORY AND TOKEN	OKTA	SAML	CITRIX GATEWAY	ADAPTIVE AUTHENTICATION
AD joined	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Microsoft Entra joined	Yes	No	No	No	Yes	No	No
Microsoft Entra hybrid joined	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Non-domain-joined	Yes	Yes	Yes	Yes	Yes	Yes	Yes

NOTE

- If using an identity provider other than Active Directory or Active Directory + Token with AD joined or Entra hybrid joined deployments, you need Citrix Federated Authentication Service (FAS) to achieve single sign-on (SSO) to the virtual app or desktop session. Refer to the FAS documentation for details.

If you plan to use SAML as your identity provider and require access to Microsoft Entra joined session hosts, see the Citrix Cloud documentation for information on configuring SAML with Entra ID identities.

Active Directory joined

Identities are created and managed in on-premises Active Directory. Provisioned machines are joined to on-premises Active Directory using the assigned machine identities. For more information on supported functional levels for the forest and domain, see Active Directory functional levels.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For information on how to create identity pool of on-premises Active Directory (AD) joined machine identity using Citrix DaaS, see Identity pool of on-premises Active Directory joined machine identity.

Microsoft Entra joined

This article describes the requirements to create Microsoft Entra joined catalogs using Citrix DaaS™ in addition to the requirements outlined in the Citrix DaaS system requirements section.

Requirements

- Control plane: See Supported Configurations
- VDA type: Single-session (desktops only) or multi-session (apps and desktops)
- VDA version: 2203 or later
- Provisioning type: Machine Creation Services™ (MCS), Persistent and Non-persistent using Machine Profile workflow
- Assignment type: Dedicated and pooled
- Hosting platform: Azure only
- Rendezvous V2 must be enabled
- Single sign-on: See Microsoft Entra single sign-on for DaaS

Limitations

- Service continuity is not supported.
- Logging in with Windows Hello in the virtual desktop is only supported with PIN. Biometric authentication methods (facial recognition, fingerprint recognition, and iris recognition) are not supported at this time.
- Support only Microsoft Azure Resource Manager cloud environments.
- If single sign-on is disabled, the first time a virtual desktop session is launched, the Windows sign-in screen may show the logon prompt for the last logged on user without the option to switch to another user. The user must wait until the logon times out and the desktop's lock screen appears, and then click the lock screen to reveal the logon screen once again. At this point, the user is able to select **Other Users** and enter their credentials. This is the behavior with every new session when the machines are non-persistent.
- When multiple machine catalogs are joined to the same Azure tenant, each catalog must use a unique `NamingScheme`. If different catalogs use the same `NamingScheme`, VMs might be created with duplicate names, which causes the Entra ID join to fail due to name conflicts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Considerations

Image configuration

- Consider optimizing your Windows image using the Citrix Optimizer tool.

Microsoft Entra joined

- Consider disabling Windows Hello so users are not prompted to set it up when they log into their virtual desktop. If you are using VDA 2209 or later, this is done automatically. For earlier versions, you can do this in one of two ways:
  - Group policy or local policy
    - Navigate to **Computer Configuration > Administrative Templates > Windows Components > Windows Hello for Business**.
    - Set **Use Windows Hello for Business** to:
      - **Disabled**, or
      - **Enabled** and select **Do not start Windows Hello provisioning after sign-in**.
  - Microsoft Intune
    - Create a device profile that disables Windows Hello for Business. Refer to Microsoft documentation for details.
- Users must be granted explicit access in Azure to log into the machines using their Microsoft Entra credentials. This can be facilitated by adding the role assignment at the resource group level:
  a. Sign into the Azure portal.
  b. Select **Resource Groups**.
  c. Click the resource group where the virtual desktop workloads reside.
  d. Select **Access control (IAM)**.
  e. Click **Add role assignment**.
  f. Search for **Virtual Machine User Login**, select it on the list, and click **Next**.
  g. Select **User, group, or service principal**.
  h. Click **Select members** and select the users and groups you want to provide access to the virtual desktops.
  i. Click **Select**.

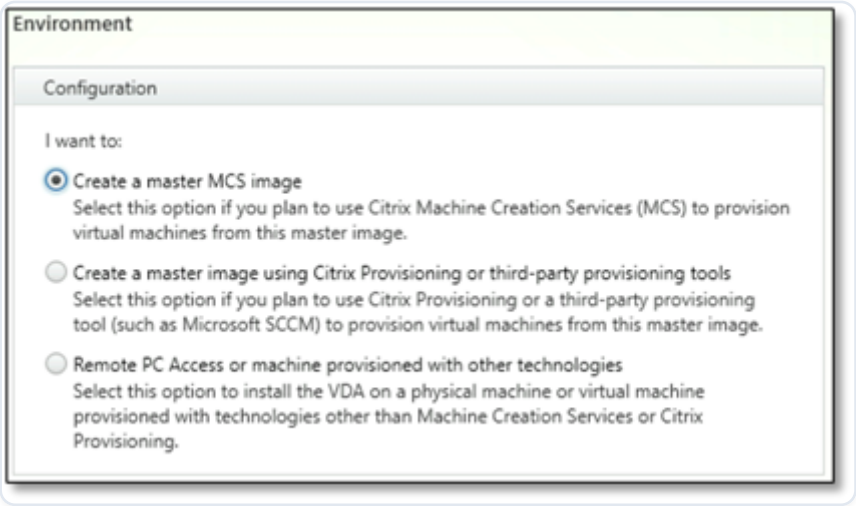
© 1997–2026 Citrix Systems, Inc. All rights reserved.

j. Click **Review + assign**.

k. Click **Review + assign** once again.

NOTE:

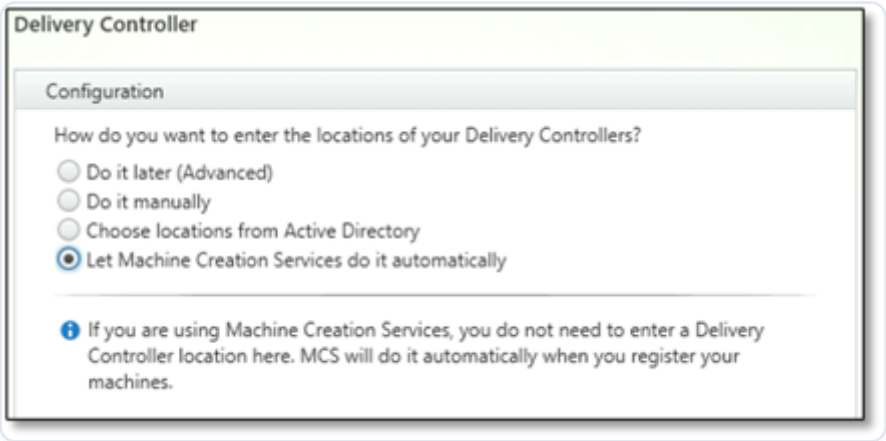
If you choose to let MCS create the resource group for the virtual desktops, you add this role assignment after the machine catalog is created.



- Master VMs can be Microsoft Entra joined or non-domain-joined. This functionality requires VDA version 2212 or later.

VDA installation and configuration

Follow the steps for installing the VDA:



1. Make sure to select the following options in the installation wizard:

   - In the Environment page, select **Create a master MCS image**.

   - In the Delivery Controller™ page, select **Let Machine Creation Services do it automatically**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. (Only for VDA versions earlier than 2311) After the VDA is installed, add the following registry value:

   - Key: HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\VirtualDesktopAgent
   - Value type: DWORD
   - Value name: GctRegistration
   - Value data: 1

3. For Windows 11 22H2 based master VM, create a scheduled task in the master VM that executes the following command at system startup using SYSTEM account. This task of scheduling a task in the master VM is only required for VDA version 2212 or earlier.

   ```
   reg ADD HKLM\Software\AzureAD\VirtualDesktop /v Provider /t REG_SZ /d Citrix /f
   ```

4. If you join the master VM to Microsoft Entra ID, and then manually remove the join by `dsregcmd` utility, make sure that the value of `AADLoginForWindowsExtensionJoined` under HKLM\Software\Microsoft\Windows Azure\CurrentVersion\AADLoginForWindowsExtension is zero.

Where to go next

Once the resource location and hosting connection are available, proceed to create the machine catalog. For more information on creating identity pool of Microsoft Entra joined machine identity, see Identity pool of Microsoft Entra joined machine identity.

Microsoft Intune

This article describes the requirements to create Microsoft Intune enabled catalogs using Citrix DaaS™ in addition to the requirements outlined in the Citrix DaaS system requirements section.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Microsoft Intune is a cloud-based service that focuses on mobile device management (MDM) and mobile application management (MAM). You control how your organization's devices are used, including mobile phones, tablets, and laptops. For more information, see Microsoft Intune. The devices must meet the minimum system requirements. For more information, see the Microsoft documentation Supported operating systems and browsers in Intune.

IMPORTANT:

Before enabling this feature, verify that your Azure environment meets the licensing requirements to use Microsoft Intune. For more information, see the Microsoft documentation: `<https://docs.microsoft.com/en-us/mem/intune/fundamentals/licenses>`. Do not enable the feature if you do not have the appropriate Intune license.

You can create:

- Microsoft Entra joined catalogs enrolled in Microsoft Intune for persistent and non-persistent, single-session and multi-session VMs. For requirements, limitations, and considerations, see Requirements for Microsoft Entra joined catalogs enrolled in Microsoft Intune.
- Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune for persistent single and multi-session VMs using device credential with co-management capability. For requirements, limitations, and considerations, see Requirements for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune. You can also create Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune for non-persistent single and multi-session VMs. However, this is currently under Preview. See Enrollment of Hybrid Entra ID joined non-persistent VMs into Microsoft Intune.

Requirements for Microsoft Entra joined catalogs enrolled in Microsoft Intune

- Control plane: Citrix DaaS
- VDA type: Single-session and multi-session OS VDA
- VDA version

TYPE OF CATALOG	VDA VERSION
Microsoft Entra joined catalogs enrolled in Microsoft Intune for persistent, single and multi-session VMs	2203 and later

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TYPE OF CATALOG	VDA VERSION
Microsoft Entra joined catalogs enrolled in Microsoft Intune for non-persistent, single-session and multi-session VMs	2407 and later

- Provisioning type: Machine Creation Services™ (MCS) persistent and non-persistent machine catalogs using the Machine Profile workflow only

Limitations for Microsoft Entra joined catalogs enrolled in Microsoft Intune

- Do not skip image preparation while creating or updating machine catalogs.

Considerations for Microsoft Entra joined catalogs enrolled in Microsoft Intune

- Create a device profile that disables Windows Hello for Business.
- Use VDA version 2212 or later if Microsoft Intune must manage a master VM.
- Configure Microsoft Intune to delete the stale devices. This ensures that your device records stay current. For information on deleting the stale devices, see Automatically delete devices with cleanup rules.

Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

Microsoft Entra hybrid joined catalogs, persistent single and multi-session VMs, enrolled in Microsoft Intune use the device credentials with co-management capability.

Co-management enables you to concurrently manage Windows 10 or later devices by using both Configuration Manager and Microsoft Intune. For more information, see Co-management.

Prerequisites for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

Before enabling this feature, verify that:

- Your Azure environment meets the licensing requirements to use Microsoft Intune. For more information, see the Microsoft documentation.
- You have a valid Configuration Manager deployment with co-management enabled. For more information, see the Microsoft documentation.

Requirements for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

- Control plane: Citrix DaaS
- VDA type: Single-session or multi-session

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- VDA version: 2407 or later
- Provisioning type: Machine Creation Service (MCS), Persistent
- Assignment type: Dedicated and pooled
- Hosting platform: Any hypervisor or cloud service

Limitations for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

- Do not skip image preparation while creating or updating machine catalogs.
- Internet-based client management (IBCM) of Configuration Manager is not supported.

Considerations for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

- Intune enrollment might be delayed if too many machines in the catalog are powered on simultaneously.

  Microsoft imposes a per-tenant Intune enrollment restriction that limits the number of devices that can be enrolled within a specific time frame. The allowable number of devices varies depending on the number of Microsoft Intune licenses associated with the tenant. Consult your Microsoft account team to find out the allowable limit for your tenant. This approach helps Microsoft Intune enrollment scale better for large environments.

  For persistent machines, there might be an initial wait time required for all devices to complete Intune enrollment.
- Configure Cloud Attach of Configuration Manager. For more information, see the Microsoft documentation.
- Manually install Configuration Manager client on the master VM without assigning the site code with `.\CCMSetup.exe /mp:SCCMServer /logon FSP=SCCMServer`. The SCCMServer is the SCCM server name in your environment. For more information, see the Microsoft documentation.
- MCS created machines use the automatic site assignment mechanism to find site boundary groups that are published to Active Directory Domain Services. Ensure that the boundaries and boundary groups of **Configuration Manager** are configured in your environment. If automatic site assignment is not available, a static Configuration Manager site code can be configured in the master VM through the following registry setting:

  Key:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\MachineIdentityServiceAgent\DeviceMa
nagement
```

Value name: `MdmSccmSiteCode`

Value type: **String**

Value data: `the site code to be assigned`

- Configure Microsoft Intune to delete the stale devices. This ensures that your device records stay current. For information on deleting the stale devices, see Automatically delete devices with cleanup rules.

Where to go next

- For information on creating an identity pool of Microsoft Intune enabled machine identity, see Identity pool of Microsoft Intune enabled machine identity.

Microsoft Entra hybrid joined

This article describes the requirements to create Microsoft Entra hybrid joined joined catalogs using Citrix DaaS in addition to the requirements outlined in the Citrix DaaS system requirements section.

This article describes the requirements to create Hybrid Azure Active Directory (HAAD) joined catalogs using Citrix DaaS™ in addition to the requirements outlined in the Citrix DaaS system requirements section.

Hybrid Azure AD joined machines use on-premises AD as the authentication provider. You can assign them to domain users or groups in on-premises AD. To enable Azure AD seamless SSO experience, you need to have the domain users synced to Azure AD.

NOTE:

Microsoft Entra hybrid joined VMs are supported in both federated and managed identity infrastructures.

Requirements

- Control plane: See Supported Configurations
- VDA type: Single-session (desktops only) or multi-session (apps and desktops)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- VDA version: 2212 or later
- Provisioning type: Machine Creation Services™ (MCS), Persistent and Non-persistent
- Assignment type: Dedicated and pooled
- Hosting platform: Any hypervisor or cloud service

Limitations

- If Citrix Federated Authentication Service (FAS) is used, single sign-on is directed to on-premises AD rather than Microsoft Entra ID. In this case, it is recommended to configure Microsoft Entra certificate-based authentication so that the primary refresh token (PRT) is generated upon user logon, which facilitates single sign-on to Microsoft Entra resources within the session. Otherwise, the PRT will not be present and SSO to Microsoft Entra resources will not work. For information on achieving Microsoft Entra single sign-on (SSO) to hybrid joined VDAs using Citrix Federated Authentication Service (FAS), see Hybrid-joined VDAs.
- Do not skip image preparation while creating or updating machine catalogs. If you want to skip image preparation, make sure the master VMs are not Microsoft Entra or Microsoft Entra hybrid joined.

Considerations

- Creating Microsoft Entra hybrid joined machines requires the `Write userCertificate` permission in the target domain. Make sure that you enter credentials of an administrator with that permission during catalog creation.
- The hybrid Microsoft Entra joining process is managed by Citrix. You need to disable `autoWorkplaceJoin` controlled by Windows in the master VMs as follows. The task of manually disabling `autoWorkplaceJoin` is only required for VDA version 2212 or earlier.

  a. Run `gpedit.msc`.

  b. Navigate to **Computer Configuration > Administrative Templates > Windows Components > Device Registration**.

  c. Set **Register domain joined computers as devices** to **Disabled**.

- Select the Organizational Unit (OU) that is configured to be synced with Microsoft Entra ID when you create the machine identities.
- For Windows 11 22H2 based master VM, create a scheduled task in the master VM that executes the following commands at system startup using SYSTEM account. This task of scheduling a task in the master VM is only required for VDA version 2212 or earlier.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$VirtualDesktopKeyPath = 'HKLM:\Software\AzureAD\VirtualDesktop'

$WorkplaceJoinKeyPath = 'HKLM:
\SOFTWARE\Policies\Microsoft\Windows\WorkplaceJoin'

$MaxCount = 60

for ($count = 1; $count -le $MaxCount; $count++)

{

  if ((Test-Path -Path $VirtualDesktopKeyPath) -eq $true)

  {

    $provider = (Get-Item -Path
$VirtualDesktopKeyPath).GetValue("Provider", $null)

    if ($provider -eq 'Citrix')

    {

        break;

    }

    if ($provider -eq 1)

    {

        Set-ItemProperty -Path $VirtualDesktopKeyPath -Name "Provider"
-Value "Citrix" -Force

        Set-ItemProperty -Path $WorkplaceJoinKeyPath -Name
"autoWorkplaceJoin" -Value 1 -Force

        Start-Sleep 5

        dsregcmd /join
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        break

    }

  }

  Start-Sleep 1

}
```

- By default, Microsoft Entra Connect synchronizes every 30 minutes. The provisioned machines can take up to 30 minutes to be Microsoft Entra hybrid joined during the first boot.

Where to go next

For more information on creating identity pool of Microsoft Entra hybrid joined machine identity, see Identity pool of Microsoft Entra hybrid joined machine identity.

Non-domain-joined

This article describes the requirements to create non-domain-joined catalogs using Citrix DaaS™ in addition to the requirements outlined in the Citrix DaaS system requirements section.

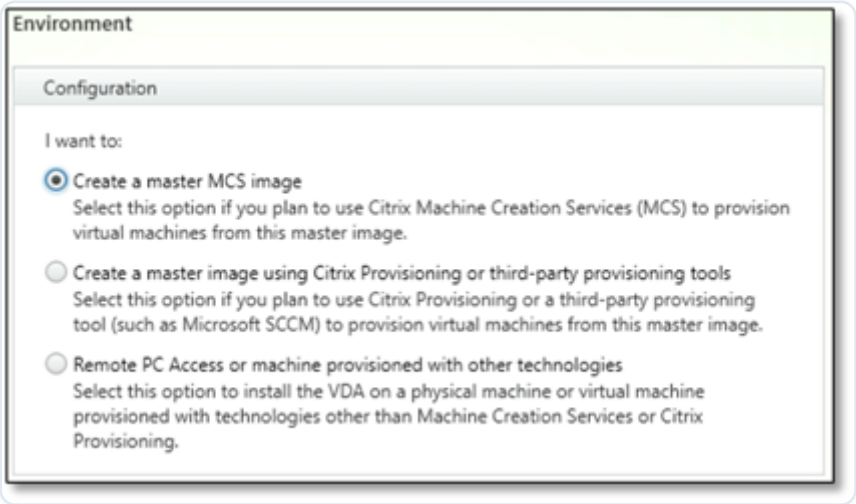
Requirements

- Control plane: See Supported Configurations
- VDA type: Single-session (desktops only) or multi-session (apps and desktops)
- VDA version: 2203 or later
- Provisioning type: Machine Creation Services™ (MCS), Persistent and Non-persistent
- Assignment type: Dedicated and pooled
- Hosting platform: All platforms supported by MCS
- Rendezvous V2 must be enabled
- Cloud Connectors: Only required if you plan to provision machines on on-premises hypervisors or if you want to use Active Directory as the identity provider in Workspace.

Limitations

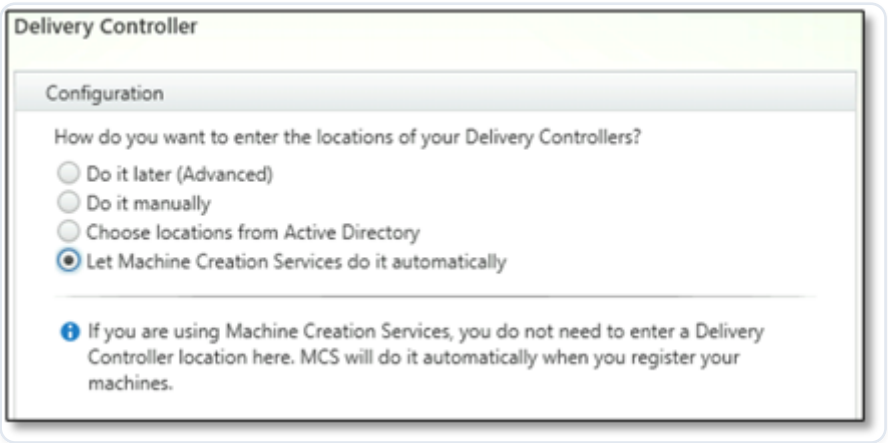
- Service continuity is not supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- Whenever we use a multi session non domain joined VDA, the local user's profile data is not retained and is deleted on logoff.

VDA installation and configuration



Follow the steps for installing the VDA:

1. Make sure to select the following options in the installation wizard:

    - In the Environment page, select **Create a master MCS image**.

    - In the Delivery Controller™ page, select **Let Machine Creation Services do it automatically**.

2. After the VDA is installed, add the following registry value:

    - Key: HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\VirtualDesktopAgent
    - Value type: DWORD
    - Value name: GctRegistration
    - Value data: 1

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

Once the resource location and hosting connection are available, proceed to create the machine catalog. For more information on creating identity pool of non-domain-joined machine identity, see Identity pool of non-domain-joined machine identity.

Session authentication

Citrix supports multiple methods for authenticating users into virtual desktop and application sessions. The available options depend on how your environment is configured; specifically, the directory service where user accounts reside (e.g. Active Directory or Microsoft Entra ID), the directory service where the session host machines are joined, and the identity provider used for initial logon into the Citrix environment. These factors determine whether authentication can be handled through traditional credentials, smart cards, federated assertions, or certificate-based mechanisms. This section outlines the available authentication methods and how they align with different deployment scenarios.

Microsoft Entra single sign-on

You can leverage single sign-on (SSO) when using Microsoft Entra ID credentials to access virtual applications and desktops on Microsoft Entra joined or Microsoft Entra hybrid joined session hosts.

Supported infrastructure

The following is an overview of the infrastructure components supported for Microsoft Entra single sign-on:

MACHINE IDENTITY	CITRIX DAAS	CITRIX DAAS LOCAL	CITRIX STOREFRONT CLOUD	CITRIX STOREFRONT	CITRIX GATEWAY SERVICE	NETSCALER GATEWAY
Microsoft Entra joined	Yes	No	Yes	No	Yes	Yes
Microsoft Entra hybrid joined	Yes	Yes	Yes	Yes	Yes	Yes

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- For details on configuring Microsoft Entra single sign-on with **Citrix DaaS Local**, refer to the Citrix DaaS Local documentation.
- For details on configuring Microsoft Entra single sign-on with **StoreFront**, refer to the StoreFront documentation.

Supported identity providers

The following is an overview of the Workspace identity providers supported for Microsoft Entra single sign-on:

MACHINE IDENTITY	ENTRA ID	ACTIVE DIRECTORY	ACTIVE DIRECTORY + TOKEN	OKTA	SAML	NETSCALER GATEWAY	ADAPTIVE AUTHENTICATION
Microsoft Entra joined	Yes	No	No	No	Yes	No	No
Microsoft Entra hybrid joined	Yes	No	No	No	Yes	No	No

NOTE

If you are planning to use SAML as your IdP, you must ensure your SAML provider is configured properly to support Entra based authentication. See SAML using Microsoft Entra ID and Microsoft Entra identities for workspace authentication.

Supported access methods

The following are the access methods available in a Citrix environment:

- **Native access:** You use the native Citrix Workspace app client to access your store and establish the session connection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Browser access:** You access your store through a browser and connect to the virtual app or desktop session using the Citrix Workspace app for HTML5 client.
- **Hybrid access:** You access your store through a browser and connect to the virtual app or desktop session using the native Workspace app client.

The following is an overview of the access methods supported for Microsoft Entra single sign-on:

ACCESS METHOD	WINDOWS	LINUX	MAC	CHROME OS	ANDROID	IOS
Native	Yes	Yes	Yes	Yes	Yes	Yes
Browser	Yes	Yes	Yes	Yes	Yes	Yes
Hybrid	Yes	Yes	Yes	No	No	No

System requirements

The following are the system requirements for using Microsoft Entra single sign-on:

- Control plane: Citrix DaaS
  - Citrix Cloud Commercial (US, EU, and APS)
  - Citrix Cloud Japan
- User portal: Citrix® StoreFront Cloud
- Virtual Delivery Agent (VDA)
  - Windows: version 2507 or newer
- Citrix Workspace app
  - Windows: version 2507 or newer
  - Linux: version 2508 or newer (version 2601 or newer required for hybrid access)
  - Mac: version 2508 or newer (version 2511 or newer required for hybrid access)
  - HTML5: version 2511 or newer
  - Chrome OS: version 2511 or newer
  - Android: version 2511 or newer
  - iOS: version 2511 or newer
- Citrix Web Extension

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - Microsoft Edge
  - Google Chrome

- Session host OS:
  - Windows 11, version 24H2 with 2025-09 Cumulative Updates for Windows 11 (KB5065789) or later installed (build 26100.6725)
  - Windows Server 2025 with 2026-01 Cumulative Updates for Windows Server 2025 (KB5073379) or later installed (build 26100.32230)

NOTE

The Citrix Web Extension is only needed if your users will be leveraging hybrid access in **Windows**, **Linux**, or **Mac** devices. If your users leverage native or browser access, the Citrix Web Extension is not needed.

Considerations

- If your users will be leveraging hybrid access, they must use either Microsoft Edge or Google Chrome, and install the Citrix Web Extension. Microsoft Entra single sign-on with hybrid access is not supported with other browsers.
- Auto Client Reconnect is not supported when Microsoft Entra single sign-on is used to log into the session. This feature is automatically disabled when this logon method is used. Session Reliability is still available for automatic reconnection in case of network disruptions.
- When a virtual desktop is locked, the default behavior is to display the Windows lock screen. Depending on your authentication requirements, you might need to change the session lock behavior. See Session lock behavior for more details.
- If using Microsoft Entra hybrid joined session hosts, single sign-on does not work by default for members of privileged groups such as Domain Admins. To enable it, add the group or user to the Read-Only Domain Controller (RODC) allowlist for Microsoft Entra Kerberos access. See Microsoft Entra Kerberos TGT and Active Directory access control for details.
- Microsoft Entra External ID is not supported at this time. If you need to provide access to guest users, refer to SAML using Entra ID for Guest and B2B identities for workspace authentication.
- Microsoft Entra single sign-on requires the Windows setting **Allow Custom SSPs and APs to be loaded into LSASS** to be enabled (default). Note that if you deploy the **Security Baseline for Windows 10 and later** template via Microsoft Intune, this setting is automatically disabled

© 1997–2026 Citrix Systems, Inc. All rights reserved.

and will block SSO, so you must update your Intune device configuration policy to keep it enabled.

How to configure Microsoft Entra single sign-on

Overview

The configuration of Microsoft Entra single sign-on consists of the following steps:

1. Azure and Microsoft Entra ID configuration
    a. Register the Citrix resource and client applications.
    b. Enable the Microsoft Entra ID Remote Desktop Services authentication protocol for the Citrix resource application.
    c. Hide the user consent prompt.
    d. Approve the client application.
    e. Create a Kerberos server object (Microsoft Entra hybrid joined environments only).
    f. Review Microsoft Entra Conditional Access policies.
2. Citrix configuration
    a. Provision session hosts with the required OS version, identity type, and VDA version.
    b. Configure Citrix® StoreFront Cloud:
        i. Configure an appropriate Identity Provider.
        ii. Enable Microsoft Entra single sign-on
    c. Configure your Delivery Groups' logon type if needed.

Details of each configuration step are provided in the sections that follow.

Azure and Microsoft Entra ID configuration

In order to leverage Microsoft Entra single sign-on, you must first allow Microsoft Entra authentication for Windows in your Microsoft Entra ID tenant, which enables issuing the required authentication tokens that allow users to sign in to the Microsoft Entra joined and Microsoft Entra hybrid joined session hosts.

The person making the Azure configuration must be assigned one of the following Microsoft Entra built-in roles or equivalent at a minimum:

- Application Administrator

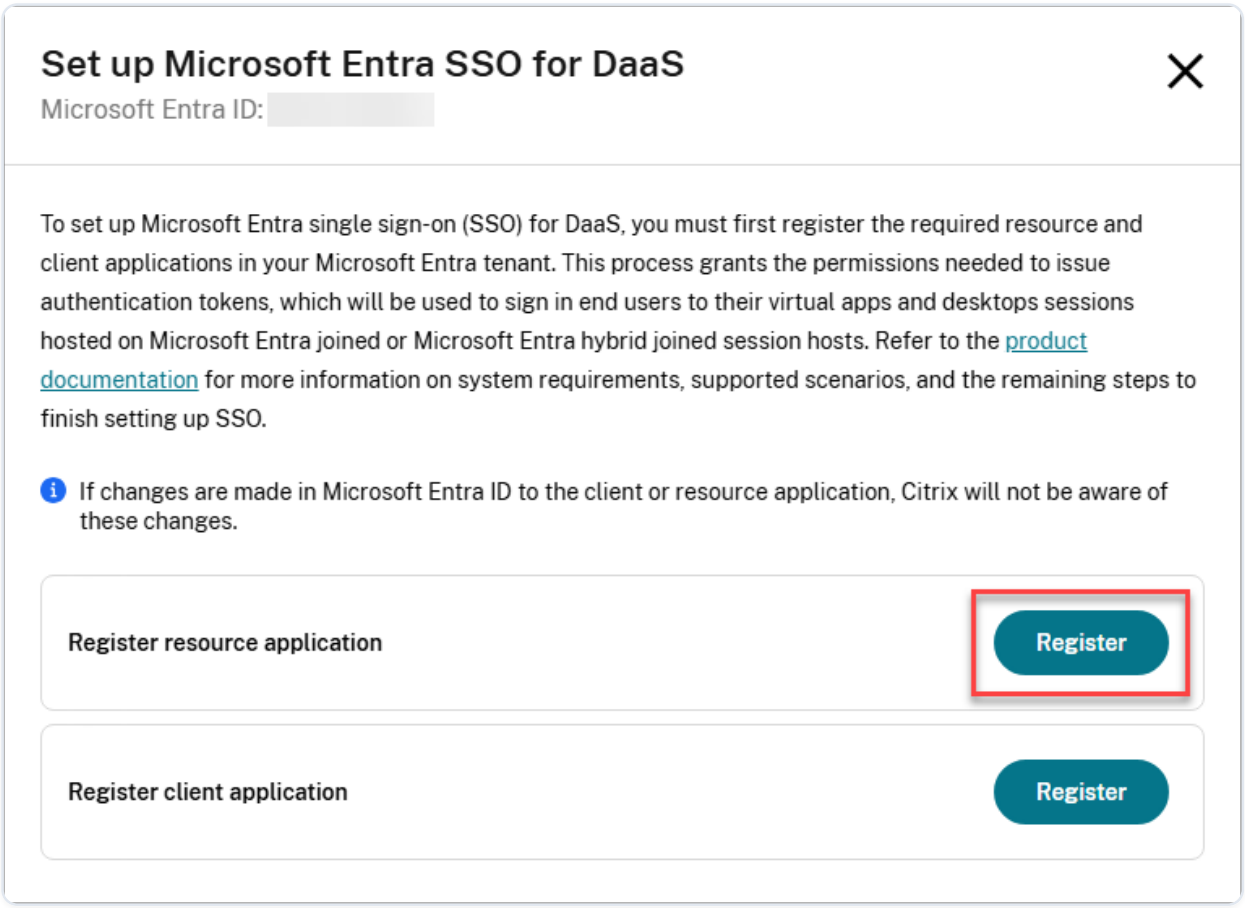
© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Cloud Application Administrator

The configuration can be completed through Azure Portal, using Microsoft Graph PowerShell SDK, or Microsoft Graph API. The following sections provide details for completing the configuration through Azure Portal. If you prefer to use Microsoft Graph PowerShell SDK or Microsoft Graph API, refer to Microsoft Entra single sign-on Azure configuration.

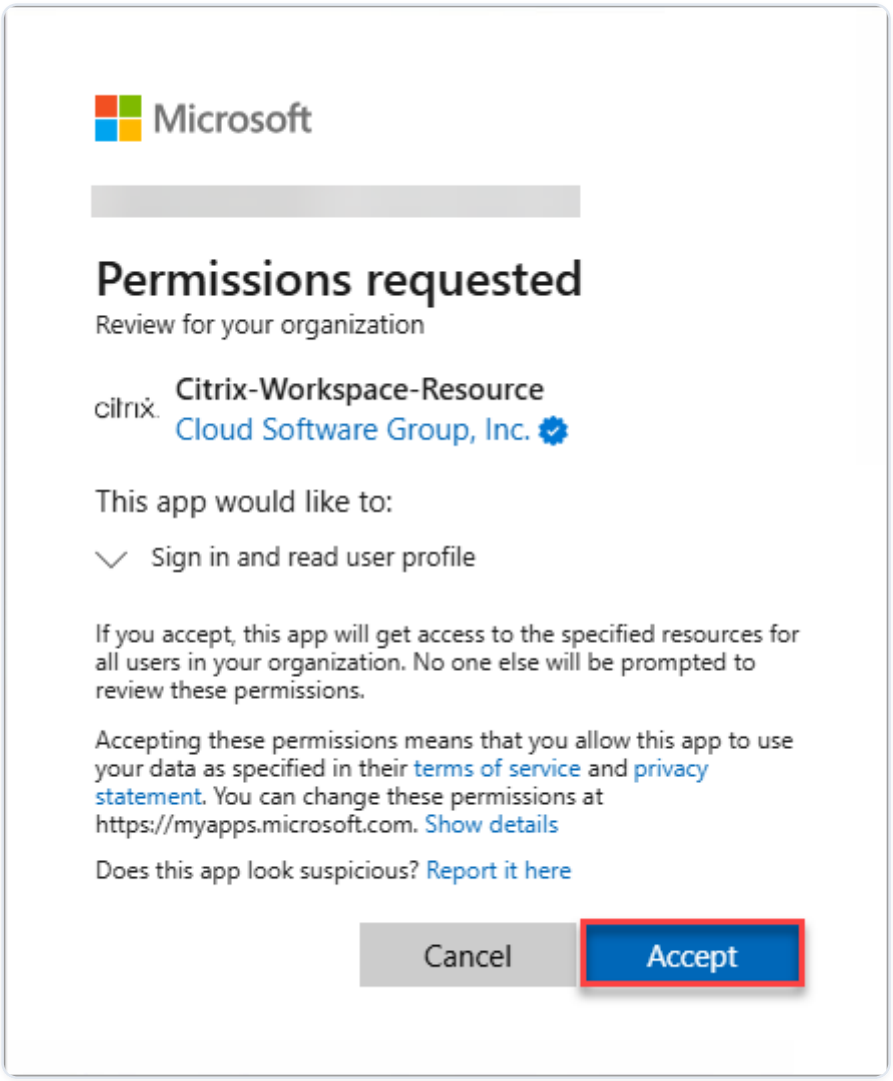
REGISTER CITRIX APPLICATIONS

Microsoft Entra single sign-on requires an Entra ID Resource Application and an Entra ID Client Application. The Resource Application represents the Windows OS when requesting the RDP Access Token. The Client Application represents the Citrix Workspace app.



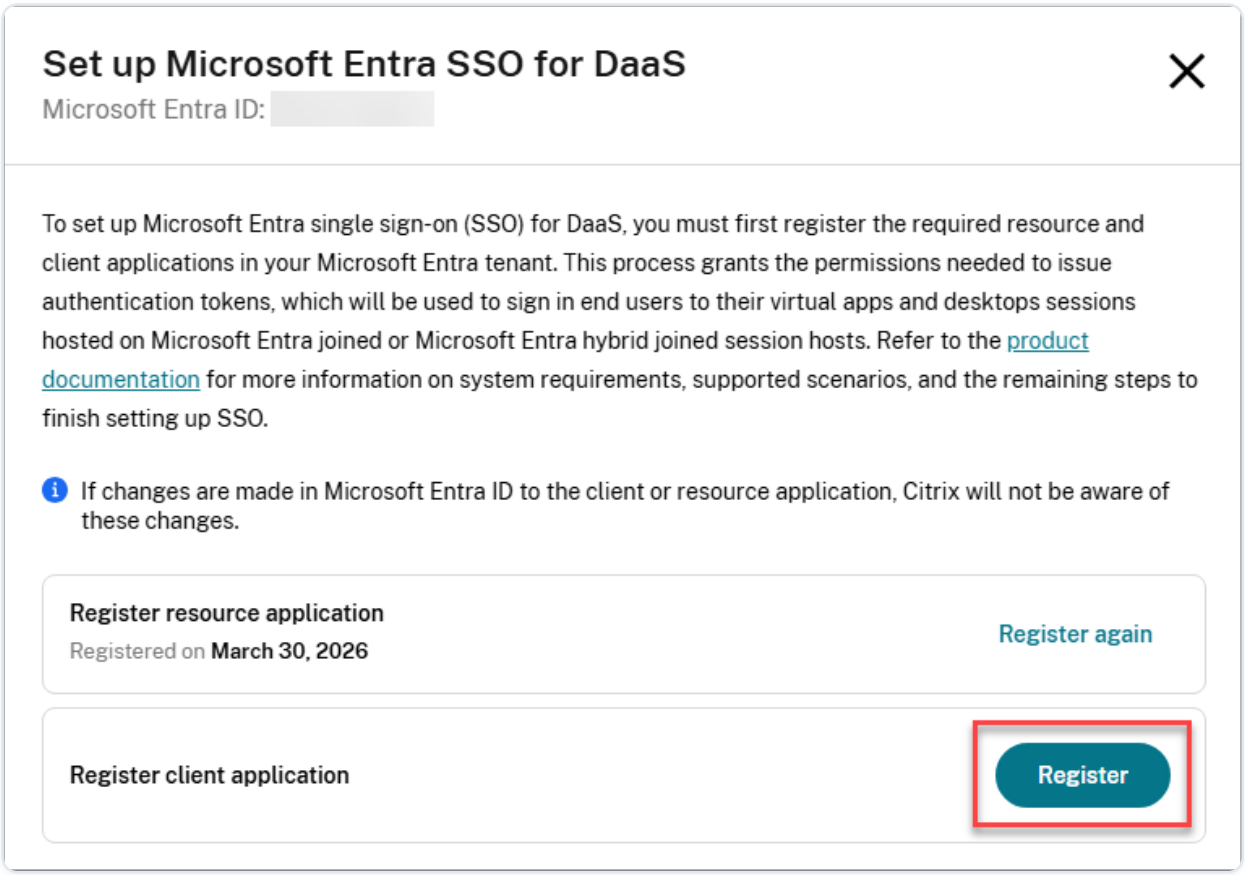
You can register the Citrix Resource and Citrix Client applications through the **Citrix Cloud portal**:

1. Open the menu on the upper left corner and select `Identity and access management`.
2. In the `Authentication` page, look for the Microsoft Entra ID identity provider for which you want to enable Microsoft Entra single sign-on.
3. Open the options menu and select `Set up Microsoft Entra SSO`.



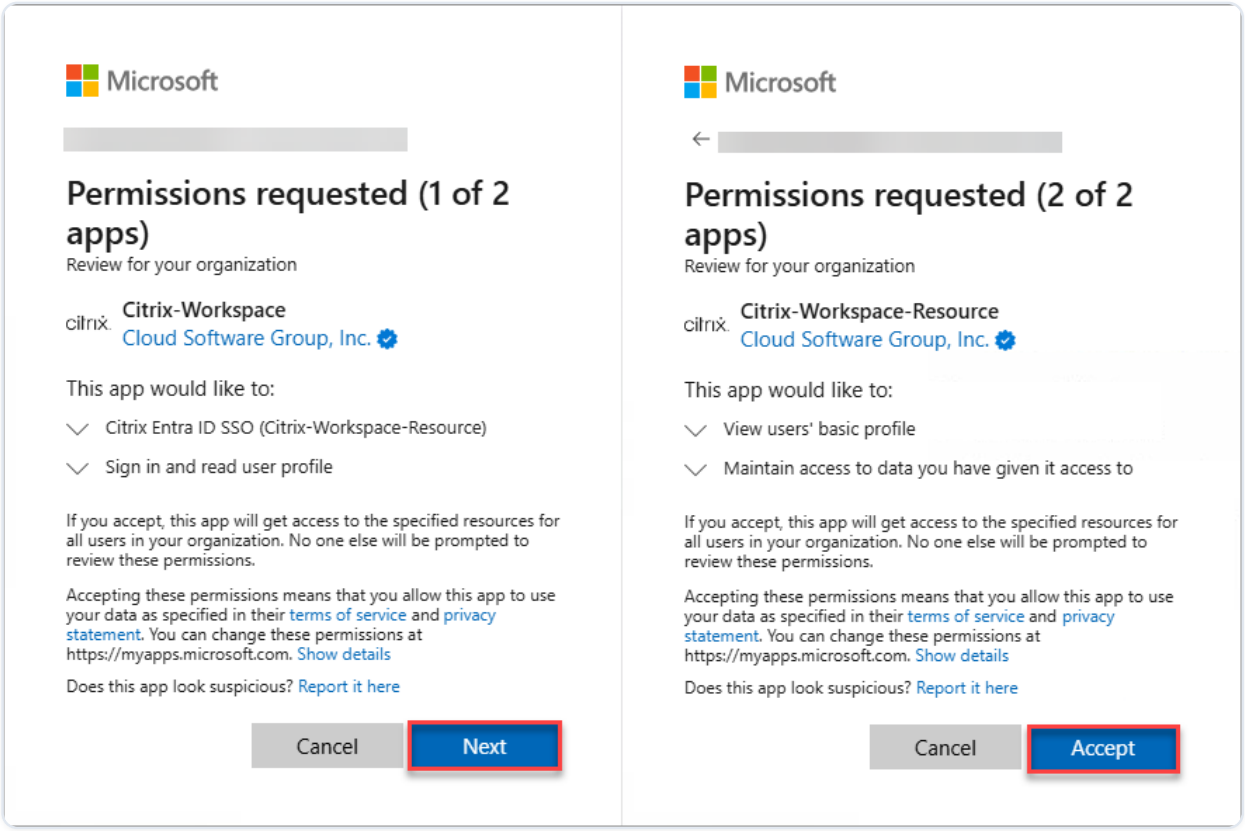
4. Click on `Register` next to **Register resource application**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Accept the permissions requested for the Citrix Resource application.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



6. Click on `Register` next to **Register client application**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. Accept the permissions requested for the Citrix Client application.

Alternatively, you can use the following consent URLs to register the applications. Please make sure to register the Resource app first, followed by the Client app.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Citrix Cloud US, EU, APS
  - Resource app: `https://login.microsoftonline.com/common/adminconsent?client_id=3a510bb1-e334-4298-831e-3eac97f8b26c`
  - Client app: `https://login.microsoftonline.com/common/adminconsent?client_id=85651ebe-9a8e-49e4-aaf2-9274d9b6499f`
- Citrix Cloud Japan
  - Resource app: `https://login.microsoftonline.com/common/adminconsent?client_id=0027603f-364b-40f2-98be-8ca4bb79bf8b`
  - Client app: `https://login.microsoftonline.com/common/adminconsent?client_id=0fa97bc0-059c-4c10-8c54-845a1fd5a916`

The following are the applications' permissions:

Citrix Resource application

A service principal is created with the following permissions:

API NAME	CLAIM VALUE	PERMISSION	TYPE
Microsoft Graph	User.Read	Sign in and read user profile	Delegated

For Citrix Cloud US, EU, and APS, the application is called Citrix-Workspace-Resource (application ID 3a510bb1-e334-4298-831e-3eac97f8b26c).

For Citrix Cloud Japan, the application is called Citrix-Workspace-Resource-JP (application ID 0027603f-364b-40f2-98be-8ca4bb79bf8b).

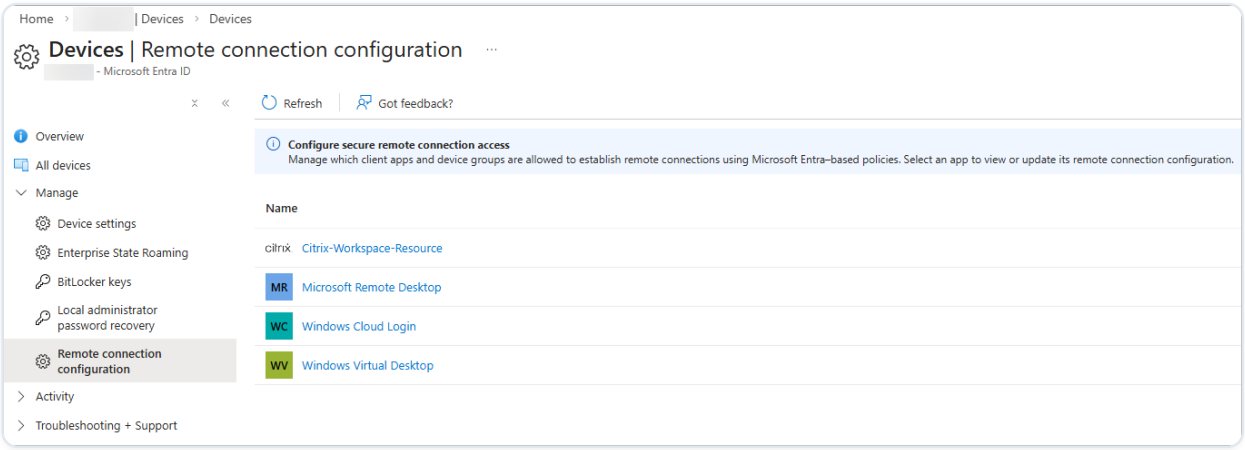
Citrix Client application

A service principal is created with the following permissions:

API NAME	CLAIM VALUE	PERMISSION	TYPE	
Citrix-Workspace-Resource Citrix-Workspace-Resource-JP	user_impersonation	Citrix Entra ID SSO	Delegated	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

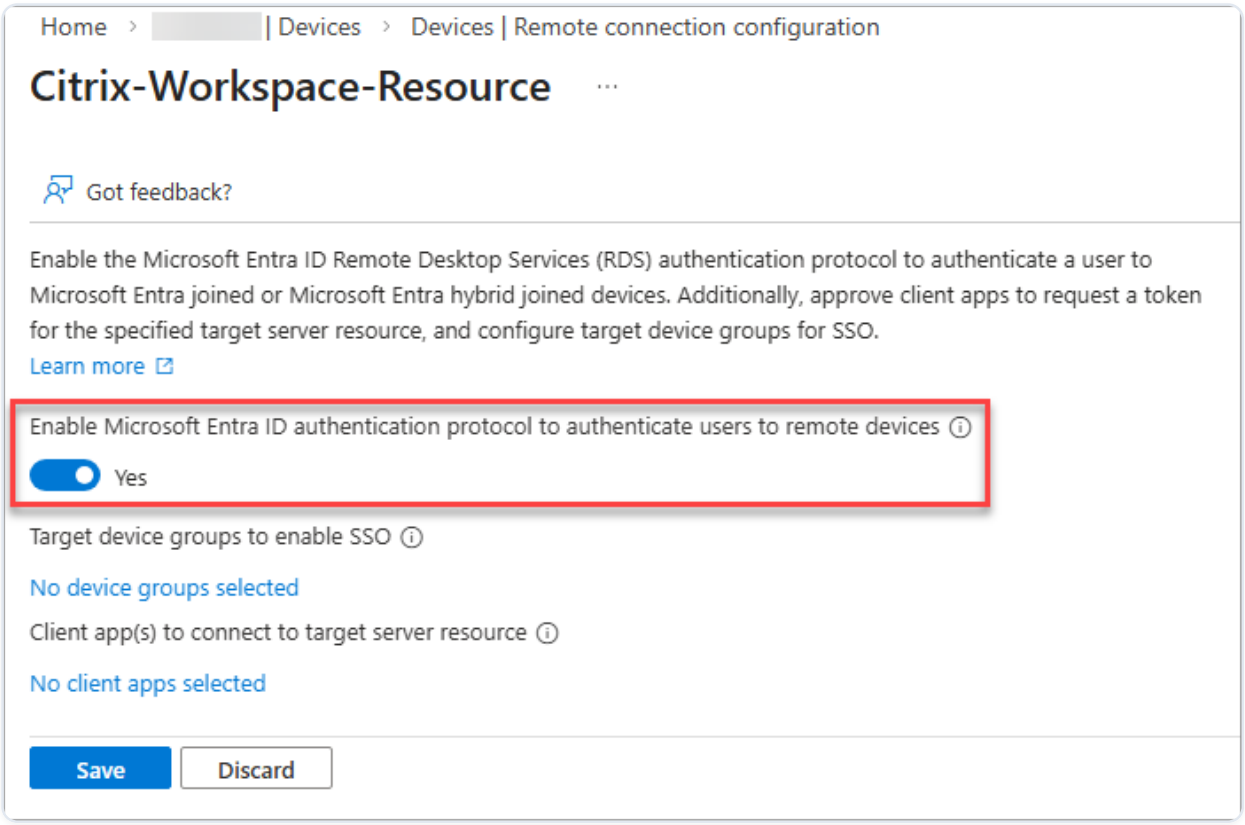
API NAME	CLAIM VALUE	PERMISSION	TYPE
Microsoft Graph	User.Read	Sign in and read user profile	Delegated



For Citrix Cloud US, EU, and APS, the application is called Citrix-Workspace (application ID 85651ebe-9a8e-49e4-aaf2-9274d9b6499f).

For Citrix Cloud Japan, the application is called Citrix-Workspace-JP (application ID 0fa97bc0-059c-4c10-8c54-845a1fd5a916).

ENABLE MICROSOFT ENTRA ID REMOTE DESKTOP SERVICES AUTHENTICATION PROTOCOL



You must enable the Microsoft Entra ID Remote Desktop Services authentication protocol in the Citrix Resource application. To do so:

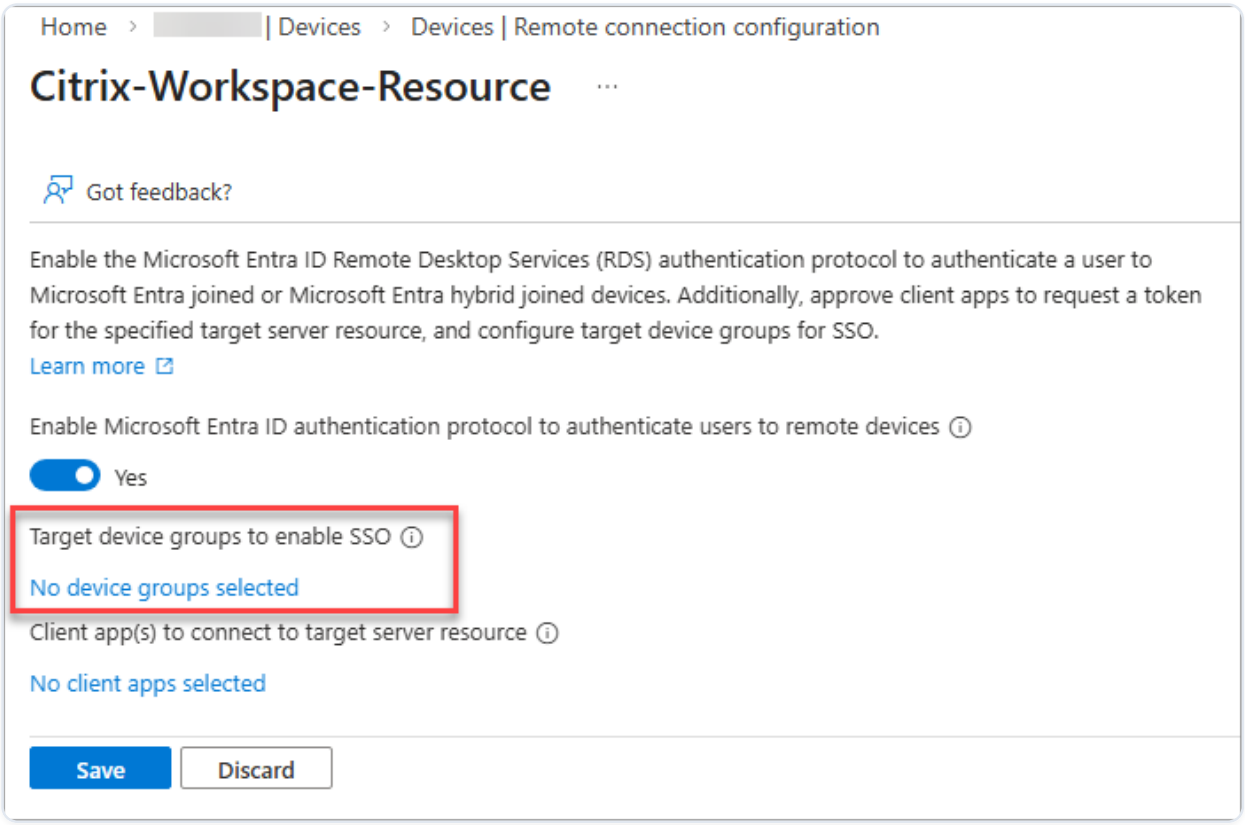
1. In Azure Portal, navigate to `Microsoft Entra ID` > `Devices` > `Manage` > `Remote connection configuration`.

2. Select **Citrix-Workspace-Resource**.
3. Enable **Microsoft Entra ID Remote Desktop Services authentication protocol**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Proceed to hide the user consent prompt.

HIDE THE USER CONSENT PROMPT DIALOG



By default, users are prompted to allow the Remote Desktop connection when connecting to a Microsoft Entra joined or Microsoft Entra hybrid joined session host with Microsoft Entra single sign-on enabled, in which they must select **Yes** to allow single sign-on. Microsoft Entra will remember up to 15 unique session hosts for 30 days before prompting again.

You can hide this dialog by configuring a list of target devices. To configure the list of devices, you must create one or more groups in Microsoft Entra ID that contain the Microsoft Entra joined and/or Microsoft Entra hybrid joined session hosts and then authorize the groups in the resource application, up to a maximum of 10 groups.

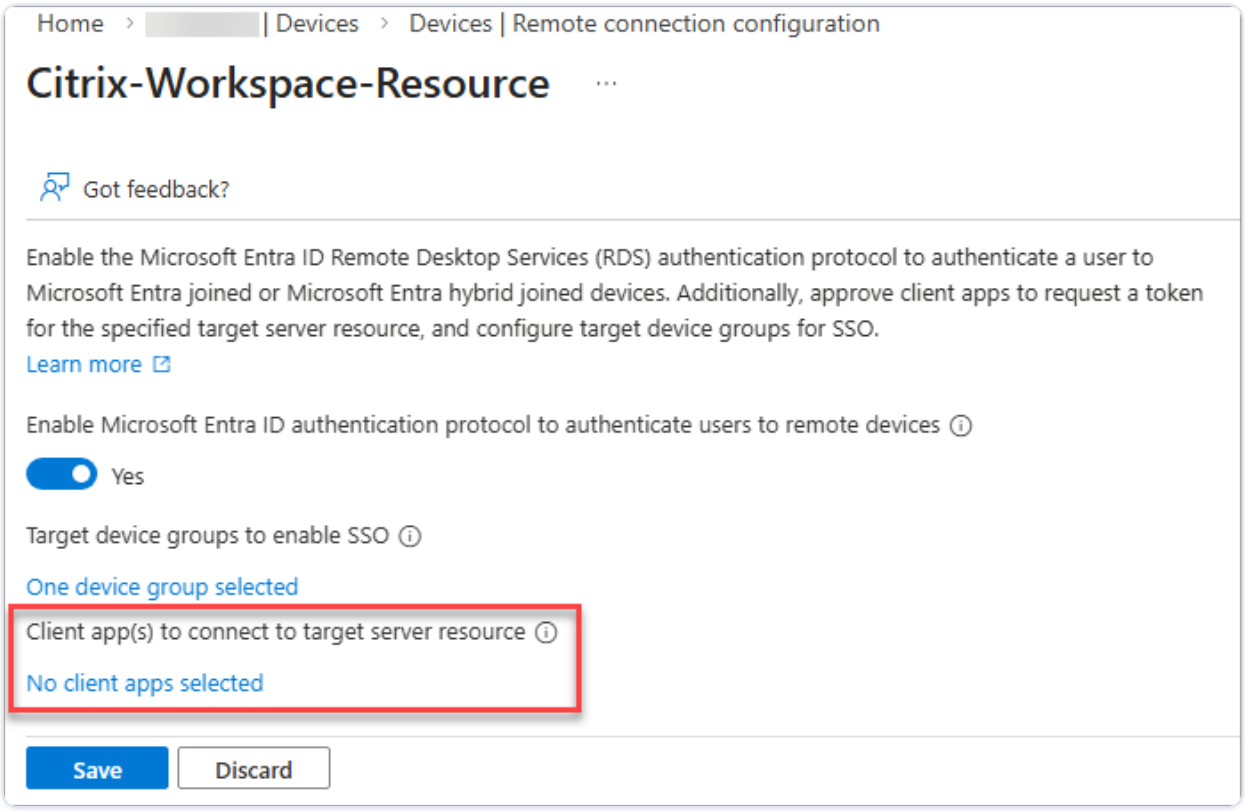
Once you have enabled the Microsoft Entra ID Remote Desktop Services authentication protocol and the groups have been created:

1. Click on the link to add the target device groups and select the appropriate groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

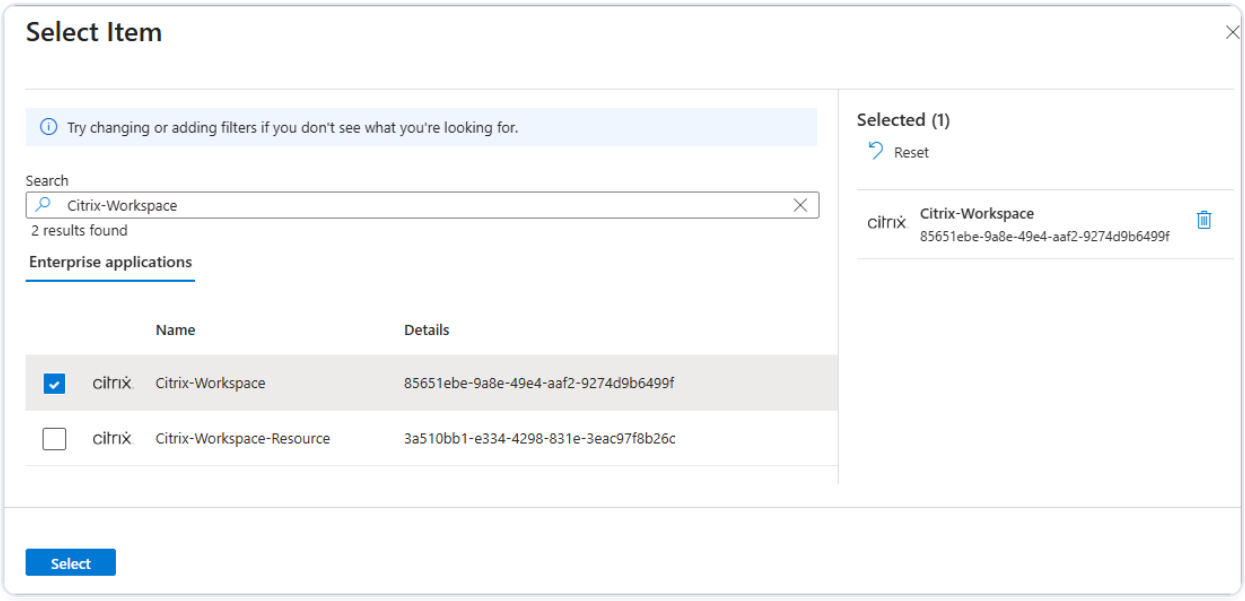
NOTE

It is highly recommended to create a dynamic group to simplify the membership management for the group. While dynamic groups normally update within 5-10 minutes, large tenants can take up to 24 hours.



Dynamic groups requires the Microsoft Entra ID P1 license or Intune for Education license. For more information, see Dynamic membership rules for groups.

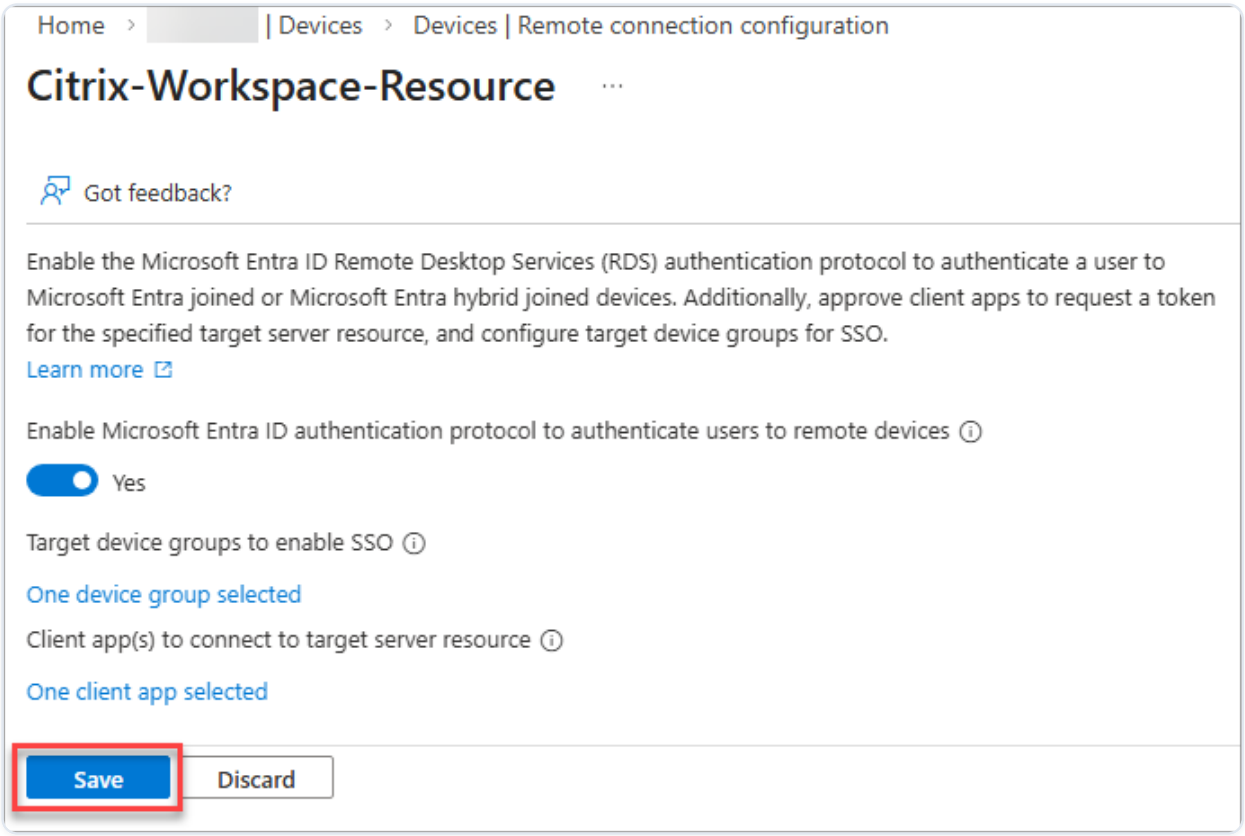
APPROVE THE CLIENT APPLICATION



You must explicitly add the Citrix Client application as an approved client in the Citrix Resource application:

1. Click on the link to add your trusted client applications.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. Select the Citrix Client application.

3. Select **Save** to apply the configuration changes to the Citrix Resource application.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE A KERBEROS SERVER OBJECT

If your session hosts are Microsoft Entra hybrid joined, you must configure a Kerberos server object in the Active Directory domain where the user and computer accounts reside. See Create a Kerberos Server object for details.

REVIEW MICROSOFT ENTRA CONDITIONAL ACCESS POLICIES

If you use or plan to use Microsoft Entra Conditional Access policies, these need to be applied to the Citrix Resource application.

For detailed guidance on configuring Conditional Access when using Microsoft Entra single sign on for DaaS, refer to the Microsoft documentation. Remember that the required Conditional Access settings must be applied to the **Citrix Resource application**, not the Citrix Client application or Microsoft applications.

Citrix configuration

CITRIX SESSION HOSTS

Ensure the system requirements for the session hosts are met:

1. Ensure the session hosts are either Microsoft Entra joined or Microsoft Entra hybrid joined.
2. Install the required operating system version and build as specified in the system requirements.
3. Install the required VDA version as specified in the system requirements.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Microsoft Entra hybrid joined session hosts

If you are deploying Microsoft Entra hybrid joined session hosts with Citrix Machines Creation Services, Citrix Provisioning, or Windows 365, you can proceed to the next section. If you are provisioning Microsoft Entra hybrid joined hosts using any other tool or method, you must add the following registry value to your session hosts:

- Key: `HKLM\SYSTEM\CurrentControlSet\Control\Citrix`
- Value type: **DWORD**
- Value name: `AzureADJoinType`
- Data: `1`

Session lock behavior

When a virtual desktop is locked, the default behavior is to display the Windows lock screen. At this point, the supported authentication methods for unlocking the desktop are **username and password** or **smart card**.

NOTE

Citrix web sign-in (preview) allows you to unlock your desktop using web-based Entra authentication. See Web sign-in for details.

If you have a passwordless deployment where users don't know their passwords, it's recommended to configure the session lock behavior to disconnect the session instead of showing the lock screen.

- **Multi-session session hosts**

  You can configure this behavior by enabling the **Disconnect remote session on lock for Microsoft identity platform authentication** setting through Intune or Group Policy. For detailed steps, see Configure the session lock behavior for Azure Virtual Desktop.

- **Single-session session hosts**

  If you are using **VDA version 2603 or newer**, you can configure this behavior by enabling the **Disconnect remote session on lock for Microsoft identity platform authentication** setting through Intune or Group Policy. For detailed steps, see Configure the session lock behavior for Azure Virtual Desktop.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you are using VDA version 2511 or older, the **Disconnect remote session on lock for Microsoft identity platform authentication** setting is not supported. However, you can achieve the same behavior by creating a Windows scheduled task.

The following example script creates a scheduled task on single-session hosts that runs `cmd.exe /c tsdiscon` when the desktop is locked:

```
# Create the TaskService COM object

$service = New-Object -ComObject "Schedule.Service"

$service.Connect()

# Get the root folder and create a new task definition

$rootFolder = $service.GetFolder("\")

$taskDef = $service.NewTask(0)

# Registration info

$taskDef.RegistrationInfo.Description = "Disconnect session when
workstation is locked"

# Principal (Users group, least privilege)

$principal = $taskDef.Principal

$principal.GroupId = "S-1-5-32-545"

$principal.RunLevel = 0  # 0 = LeastPrivilege

# Settings

$settings = $taskDef.Settings
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$settings.Enabled = $true

$settings.AllowDemandStart = $true

$settings.DisallowStartIfOnBatteries = $false

$settings.StopIfGoingOnBatteries = $false

$settings.AllowHardTerminate = $false

$settings.StartWhenAvailable = $false

$settings.RunOnlyIfNetworkAvailable = $false

$settings.IdleSettings.StopOnIdleEnd = $true

$settings.IdleSettings.RestartOnIdle = $false

$settings.Hidden = $false

$settings.RunOnlyIfIdle = $false

$settings.DisallowStartOnRemoteAppSession = $false

$settings.UseUnifiedSchedulingEngine = $true

$settings.WakeToRun = $false

$settings.ExecutionTimeLimit = "PT0S"   # Unlimited

$settings.Priority = 7

$settings.MultipleInstances = 1         # IgnoreNew

# Trigger: SessionLock

$trigger = $taskDef.Triggers.Create(11)  # 11 =
TASK_TRIGGER_SESSION_STATE_CHANGE

$trigger.StateChange = 7                 # 7 = SessionLock
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$trigger.Enabled = $true

# Action: tsdiscon

$action = $taskDef.Actions.Create(0)     # 0 = Exec

$action.Path = "cmd.exe"

$action.Arguments = "/c tsdiscon"

# Register the task

$rootFolder.RegisterTaskDefinition(

    "Disconnect on Lock",  # Task name

    $taskDef,

    6,                     # TASK_CREATE_OR_UPDATE

    $null, $null,          # No specific user/password

    3                      # TASK_LOGON_GROUP

) | Out-Null
```

If you later need to remove the scheduled task, you can run the following command:

```
Unregister-ScheduledTask -TaskName "Disconnect on Lock" -Confirm:$false
```

CITRIX ACCESS AND CONTROL PLANE

Workspace authentication

You must configure Citrix® StoreFront Cloud to use Microsoft Entra ID or SAML as the IdP. Please refer to the Citrix® StoreFront Cloud documentation for details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

If you are planning to use SAML as your IdP, you must ensure your SAML provider is configured properly to support Entra based authentication. See SAML using Microsoft Entra ID and Microsoft Entra identities for authentication.

Managing Workspace access

If your users will be accessing their store through a web browser, no additional configuration is required. If you want to enforce native access, you can configure Citrix® StoreFront Cloud to `Require end users to access their store from the Citrix client app` under the store's access configuration.

Enabling Microsoft Entra single sign-on in Workspace

After authentication is configured, you must enable the use of Microsoft Entra single sign-on:

1. Create a Service principal in Citrix Cloud:
    a. Go to **Identity and access management > API access > Service principals**.
    b. Click on **Create service principal**.
    c. Enter a **name** for the service principal and click **Next**.
    d. Set Access for the service principal:
        i. Select **Full access**, or
        ii. Select **Custom access > General > Citrix® StoreFront Cloud**, then click **Next**.
    e. Set the secret **expiration time** and click **Next**.
    f. Click **Complete**.
    g. Save both the secret and ID.
2. Download and extract the Citrix® StoreFront Cloud PowerShell module to your workstation, or any machine you can use for administrative purposes.
3. Open PowerShell in the machine in which you downloaded the Citrix® StoreFront Cloud PowerShell module.
4. Run the following commands:

```
Import-Module -Name
“<extractedPath>\Citrix.Workspace.StoreConfigs.psm1”

Set-StoreConfigurations -StoreUrl "https://
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<yourPrimaryStore>.cloud.com" -ClientId "<clientId>" -ClientSecret
"<clientSecret>" -AzureAdSsoEnabled $True
```

NOTE:

This is a global setting that will be applied to all the stores in your Citrix Cloud tenant. At this time, it is not possible to enable or disable this setting on specific stores based on the store URL provided in the command.

5. Run the following command to verify the setting was configured properly:

```
Get-StoreConfigurations -StoreUrl "https://
<yourPrimaryStore>.cloud.com" -ClientId "<clientId>" -ClientSecret
"<clientSecret>"
```

Delivery group configuration

1. If your session hosts are Microsoft Entra hybrid joined, assign the virtual apps and/or desktops to the appropriate Microsoft Entra users or groups. Any existing assignments to Active Directory users or groups may be removed, but it is not required.
2. If you are provisioning your Microsoft Entra joined session hosts with anything other than Citrix Machine Creation Services, Citrix Provisioning, or Windows 365, you will need to configure the logon type for the Delivery Groups. If you are using Microsoft Entra hybrid joined session hosts, the logon type for the delivery group must be configured regardless of provisioning method.

    a. If you do not already have the Citrix Remote PowerShell SDK installed, download it and install it on your workstation, or any machine you can use for administrative purposes.

    b. Open a PowerShell prompt in the machine in which you installed the Citrix Remote PowerShell SDK.

    c. Run the following commands:

    Microsoft Entra joined

    ```
    asnp citrix*

    Get-XDAuthentication
    ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-BrokerDesktopGroup -Name <dgName> | Set-BrokerDesktopGroup
-MachineLogOnType "AzureAd"
```

Microsoft Entra hybrid joined

```
asnp citrix*

Get-XDAuthentication

Get-BrokerDesktopGroup -Name <dgName> | Set-BrokerDesktopGroup
-MachineLogOnType "HybridAzureAd"
```

Configuring Microsoft Entra single sign-on on the VDA

By default, Microsoft Entra single sign-on is enabled on the VDA. To enable or disable this capability for a subset of session hosts, use the Microsoft Entra single sign-on policy setting.

CLIENT DEVICE

Ensure the system requirements for the client devices are met:

1. Install the required Citrix Workspace app version as specified in the system requirements.
2. If your users will be leveraging hybrid access, make sure the Citrix Web Extension is installed. If your users will be using native or browser access, the Citrix Web Extension is not needed.

Troubleshooting

Known issues

- After enabling Microsoft Entra single sign-on, users may encounter the Microsoft error **AADSTS293005** when launching their virtual desktop, indicating `RDP protocol is not enabled for the requested resource application. Please configure the RemoteDesktopSecurityConfiguration property on resource service principal to enable RDP protocol.` To resolve this issue, restart Citrix Workspace app.
- Users may encounter a 30-second delay when launching sessions if their Citrix Workspace app does not support Microsoft Entra single sign-on or if they use hybrid access without the Citrix Web Extension.
- Users may encounter a 30-second delay when launching sessions if Microsoft Entra single sign-on is enabled on Citrix® StoreFront Cloud and the required Azure configuration has not been completed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If the **Auto client reconnect authentication** setting is enabled, single sign-on will fail. As a workaround, disable this setting on the relevant session hosts.
- If **Keep me signed in (KMSI)** is disabled in Entra ID, single sign-on fails on Linux and macOS client devices.

When single sign-on fails

If single sign-on fails when accessing virtual desktops or applications, proceed as follows:

1. Confirm that Microsoft Entra single sign-on is enabled in Citrix® StoreFront Cloud.
2. Confirm that the access method leveraged by the user is supported.
3. If the user is leveraging hybrid access, confirm that the Citrix Web Extension is installed.
4. Confirm that the client device is running the required Citrix Workspace app version.
5. Confirm that your session hosts are running the required Windows build.
6. Confirm that your session hosts are running the required VDA version.
7. Ensure that the Windows setting `Always prompt for password upon connection` is not enabled on the session hosts.

   This setting is disabled by default, and can be configured through Group Policy or Intune under `Computer Configuration\Administrative Templates\Windows Components\Remote Desktop Services\Remote Desktop Session Host\Security`.

   You can check in the registry if the setting is enabled by looking for the value `fPromptForPassword` under `HKLM\SOFTWARE\Policies\Microsoft\Windows NT\Terminal Services`. If the value is set to `1`, the setting is enabled and single sign-on will not be available. If the value is missing or set to `0`, the setting is disabled.
8. Ensure that the Windows setting `Allow Custom SSPs and APs to be loaded into LSASS` is enabled on the session hosts. This setting is enabled by default, and can be configured through Group Policy or Intune under `Computer Configuration\System\Local Security Authority`.
9. Confirm that the `AzureADJoinType` setting is configured correctly in the session hosts:
   - Key: `HKLM\SYSTEM\CurrentControlSet\Control\Citrix`
   - Value type: **DWORD**
   - Value name: `AzureADJoinType`
   - Value data: `1` (Microsoft Entra hybrid joined); `2` (Microsoft Entra joined)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

10. Ensure that the virtual desktops or applications are assigned to Microsoft Entra identities instead of Active Directory identities in Citrix Studio.
11. Confirm that the Delivery Groups' logon type is configured correctly by running the following PowerShell command:

    ```
    Get-BrokerDesktopGroup -Name <deliveryGroupName>
    ```

    For Microsoft Entra joined session hosts, `MachineLogOnType` must be set to `AzureAd`. For Microsoft Entra hybrid joined session hosts, `MachineLogOnType` must be set to `HybridAzureAd`.
12. If you are using a SAML IdP, confirm that the necessary configuration was implemented.
13. Confirm that the Citrix Resource and Client applications are registered in the Microsoft Entra tenant.
14. Confirm that the Microsoft Entra ID RDS authentication protocol is enabled on the Citrix Resource application.
15. Confirm that the Citrix Client application was added as an approved client application in the Citrix Resource application.
16. If your session hosts are Microsoft Entra hybrid joined, confirm that a Kerberos server object was created in the Active Directory domain where the user and computer accounts reside.
17. Review your Microsoft Entra Conditional Access policies. Ensure no policies are being applied to the Citrix Client application and that any policies applied to the Citrix Resource application or the session hosts are configured properly so they don't affect the single sign-on experience.

Microsoft Entra single sign-on Azure configuration

In order to leverage Microsoft Entra single sign-on, you must first allow Microsoft Entra authentication for Windows in your Microsoft Entra ID tenant, which enables issuing the required authentication tokens that allow users to sign in to the Microsoft Entra joined and Microsoft Entra hybrid joined session hosts. To achieve this, you must do the following:

1. Register the Citrix applications (Resource app and Client app) in your Microsoft Entra ID tenant.
2. Enable the Remote Desktop Security Configuration for the Citrix resource application.
3. Add the Citrix client application as an approved client for the Citrix resource application.
4. \[Optional\] Hide the user consent prompt dialog.
5. Create a Kerberos server object.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Review Microsoft Entra Conditional Access policies.

The person making the Azure configuration must be assigned one of the following Microsoft Entra built-in roles or equivalent at a minimum:

- Application Administrator
- Cloud Application Administrator

If you wish to complete the Azure configuration via PowerShell, you will need to use the Microsoft Graph PowerShell SDK. You can also leverage Microsoft Graph API with a tool like Graph Explorer.

Instructions are provided for how to complete the configuration with both PowerShell and Graph Explorer.

PowerShell configuration

If you choose to use the Microsoft Graph PowerShell SDK, please note:

- You will need to use the Azure Cloud Shell with the PowerShell terminal type, or run PowerShell 7.x on your local system, and ensure your Azure context is set to the subscription that you want to use.
- You will need to install the Microsoft Graph PowerShell SDK v1.0 module (Microsoft.Graph) and the beta application module (Microsoft.Graph.Beta.Applications).

ENABLE REMOTE DESKTOP SECURITY CONFIGURATION

After you register the Citrix applications, you must enable the Remote Desktop Security Configuration in the Citrix Resource application.

1. Import the Authentication and Application Microsoft Graph modules and connect to Microsoft Graph with the `Application.Read.All` and `Application-RemoteDesktopConfig.ReadWrite.All` scopes:

```
Import-Module Microsoft.Graph.Authentication

Import-Module Microsoft.Graph.Applications

Import-Module Microsoft.Graph.Beta.Applications

Connect-MgGraph -Scopes "Application.Read.All","Application-
RemoteDesktopConfig.ReadWrite.All"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Get the object ID for the service principals associated with the app registrations:

   Citrix Cloud US, EU, APS

   ```
   $CtxResourceSpId = (Get-MgServicePrincipal -Filter "AppId eq '3a510bb1-
   e334-4298-831e-3eac97f8b26c'").Id

   $CtxClientSpId = (Get-MgServicePrincipal -Filter "AppId eq
   '85651ebe-9a8e-49e4-aaf2-9274d9b6499f'").Id
   ```

   Citrix Cloud Japan

   ```
   $CtxResourceSpId = (Get-MgServicePrincipal -Filter "AppId eq
   '0027603f-364b-40f2-98be-8ca4bb79bf8b'").Id

   $CtxClientSpId = (Get-MgServicePrincipal -Filter "AppId eq
   '0fa97bc0-059c-4c10-8c54-845a1fd5a916'").Id
   ```

3. Set the property `isRemoteDesktopProtocolEnabled` to `true`:

   ```
   If ((Get-MgServicePrincipalRemoteDesktopSecurityConfiguration
   -ServicePrincipalId $CtxResourceSpId) -ne $true) {

       Update-MgServicePrincipalRemoteDesktopSecurityConfiguration
   -ServicePrincipalId $CtxResourceSpId -IsRemoteDesktopProtocolEnabled

   }
   ```

4. Confirm the property `isRemoteDesktopProtocolEnabled` is set to `true`:

   ```
   Get-MgServicePrincipalRemoteDesktopSecurityConfiguration
   -ServicePrincipalId $CtxResourceSpId
   ```

APPROVE THE CLIENT APPLICATION

You must explicitly add the Citrix Client application as an approved client in the Citrix Resource application.

1. Create an `approvedClientApp` object:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$acp = New-Object -TypeName
Microsoft.Graph.Beta.PowerShell.Models.MicrosoftGraphApprovedClientApp

$acp.Id = $CtxClientSpId
```

2. Add the client app to the `approvedClientApp` object:

```
New-
MgBetaServicePrincipalRemoteDesktopSecurityConfigurationApprovedClientA
pp -ServicePrincipalId $CtxResourceSpId -BodyParameter $acp
```

The output should be similar to this:

```
Id                                   DisplayName

--                                   -----------

87654321-wxyz-1a2b-3c4d-1029384756af  Citrix-Workspace
```

HIDE THE USER CONSENT PROMPT DIALOG

By default, users are prompted to allow the Remote Desktop connection when connecting to a Microsoft Entra joined or Microsoft Entra hybrid joined session host with Microsoft Entra single sign-on enabled, in which they must select Yes to allow single sign-on. Microsoft Entra will remember up to 15 unique session hosts for 30 days before prompting again.

You can hide this dialog by configuring a list of target devices. To configure the list of devices, you must create one or more groups in Microsoft Entra ID that contain the Microsoft Entra joined and/or Microsoft Entra hybrid joined session hosts and then authorize the groups in the resource application, up to a maximum of 10 groups.

NOTE

It is highly recommended to create a dynamic group to simplify the membership management for the group. While dynamic groups normally update within 5-10 minutes, large tenants can take up to 24 hours.

Dynamic groups requires the Microsoft Entra ID P1 license or Intune for Education license. For more information, see Dynamic membership rules for groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Once the groups have been created, follow these steps:

1. Get the object ID (OID) of the group that contains the session hosts for which you want to hide the Remote Desktop connection prompt.
2. Create a `targetDeviceGroup` object:

```
$tdg = New-Object -TypeName
Microsoft.Graph.PowerShell.Models.MicrosoftGraphTargetDeviceGroup

$tdg.Id = "<groupOID>"
```

3. Add the client app to the `approvedClientApp` object:

```
New-
MgServicePrincipalRemoteDesktopSecurityConfigurationTargetDeviceGroup
-ServicePrincipalId $CtxResourceSpId -BodyParameter $tdg
```

   The output should be similar to this:

```
Id                                   DisplayName

--                                   -----------

87654321-wxyz-1a2b-3c4d-1029384756af  Entra-SSO-Desktops
```

4. If you later need to remove a device group from the targetDeviceGroup object, run the following command:

```
Remove-
MgServicePrincipalRemoteDesktopSecurityConfigurationTargetDeviceGroup
-ServicePrincipalId $CtxResourceSpId -TargetDeviceGroupId "<groupOID>"
```

NOTE

You can repeat these steps to add more groups if needed, up to a maximum of 10 groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Microsoft Graph API configuration

ENABLE REMOTE DESKTOP SECURITY CONFIGURATION

After you register the Citrix applications, you must enable the Remote Desktop Security Configuration in the Citrix Resource application.

1. Get the object ID (OID) for the service principals associated with the app registrations from the Azure portal:
    a. Navigate to Microsoft Entra ID > Enterprise Applications.
    b. Remove the `Application type` filter if set so all applications are listed.
    c. Search for `Citrix-Workspace-Resource` / `Citrix-Workspace-Resource-JP` and note the associated object ID for the Resource application.
    d. Search for `Citrix-Workspace` / `Citrix-Workspace-JP` and note the associated object ID for the client application.
2. In Graph Explorer, sign in with an account from the target Azure tenant that has the required permissions.
3. Set the following query:
    - HTTP request method: PATCH
    - Microsoft Graph API Version: v1.0
    - Query:

    ```
    https://graph.microsoft.com/v1.0/servicePrincipals/<resourceAppOID>/
    remoteDesktopSecurityConfiguration
    ```

    - Request body:

    ```
    {

        "@odata.type":
    "#microsoft.graph.remoteDesktopSecurityConfiguration",

        "isRemoteDesktopProtocolEnabled": true

    }
    ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Select the **Modify Permissions** tab and ensure that you have consented to the `Application.ReadWrite.All` permission.
5. Run the query.

See remoteDesktopSecurityConfiguration resource type for reference.

APPROVE THE CLIENT APPLICATION

You must explicitly add the Citrix Client application as an approved client in the Citrix Resource application.

Set the following query and run it:

- HTTP request method: POST
- Microsoft Graph API Version: v1.0
- Query:

```
https://graph.microsoft.com/v1.0/servicePrincipals/<resourceAppOID>/
remoteDesktopSecurityConfiguration/approvedClientApps
```

- Request body:

```
{

    "@odata.type": "#microsoft.graph.approvedClientApp",

    "id": "<clientAppOID>"

}
```

HIDE THE USER CONSENT PROMPT DIALOG

By default, users are prompted to allow the Remote Desktop connection when connecting to a Microsoft Entra joined or Microsoft Entra hybrid joined session host with Microsoft Entra single sign-on enabled, in which they must select Yes to allow single sign-on. Microsoft Entra will remember up to 15 unique session hosts for 30 days before prompting again.

You can hide this dialog by configuring a list of target devices. To configure the list of devices, you must create one or more groups in Microsoft Entra ID that contain the Microsoft Entra joined and/or Microsoft Entra hybrid joined session hosts and then authorize the groups in the resource application, up to a maximum of 10 groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

It is highly recommended to create a dynamic group to simplify the membership management for the group. While dynamic groups normally update within 5-10 minutes, large tenants can take up to 24 hours.

Dynamic groups requires the Microsoft Entra ID P1 license or Intune for Education license. For more information, see Dynamic membership rules for groups.
Once the groups have been created, follow these steps:

1. Get the object ID (OID) of the group that contains the session hosts for which you want to hide the Remote Desktop connection prompt.
2. Set the following query and run it:
   - HTTP request method: POST
   - Microsoft Graph API Version: v1.0
   - Query:

     ```
     https://graph.microsoft.com/v1.0/servicePrincipals/<resourceAppOID>/
     remoteDesktopSecurityConfiguration/targetDeviceGroups
     ```

   - Request body:

     ```
     {

         "@odata.type": "#microsoft.graph.targetDeviceGroup",

         "id": "<groupOID>"

     }
     ```

NOTE

You can repeat these steps to add more groups if needed, up to a maximum of 10 groups.

If you later need to remove a device group from the targetDeviceGroup object, set the following and run the query:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- HTTP request method: DELETE
- Microsoft Graph API Version: v1.0
- Query:

```
https://graph.microsoft.com/beta/servicePrincipals/<resourceAppOID>/
remoteDesktopSecurityConfiguration/targetDeviceGroups
```

See targetDeviceGroup resource type for reference.

CREATE A KERBEROS SERVER OBJECT

If your session hosts are Microsoft Entra hybrid joined, you must configure a Kerberos server object in the Active Directory domain where the user and computer accounts reside. See Create a Kerberos Server object for details.

REVIEW MICROSOFT ENTRA CONDITIONAL ACCESS POLICIES

If you use or plan to use Microsoft Entra Conditional Access policies, review the configuration applied to the **Citrix Resource application** and the **Citrix Client application** to ensure users have the intended sign-in experience.

For detailed guidance on configuring Conditional Access when using Microsoft Entra single sign-on for DaaS, refer to the Microsoft documentation. Remember that the required Conditional Access settings must be applied to the **Citrix Resource application** or **Citrix Client application**, not the Microsoft applications.

Federated Authentication Service

Citrix Federated Authentication Service (FAS) enables single sign-on (SSO) to Citrix virtual desktops and applications in environments where users authenticate through modern identity providers such as SAML or OpenID Connect (OIDC) that don’t supply a Windows password, ensuring seamless access to session hosts joined to an Active Directory domain.

See the Federated Authentication Service documentation for more details.

Smart cards

Citrix Virtual Apps and Desktops and Citrix DaaS support smart cards both for logging into virtual desktops and applications and for use within active sessions. Smart cards provide certificate-based, two-factor authentication that strengthens security by requiring both the physical card and a PIN. This allows organizations to meet compliance requirements, protect sensitive data, and streamline access for users who already rely on smart cards for Windows logon or secure

© 1997–2026 Citrix Systems, Inc. All rights reserved.

applications. Once authenticated, users can also use their smart cards inside the session to digitally sign documents, encrypt email, or access other smart card–enabled applications, ensuring a consistent and secure experience across both local and virtual environments.

See the smart cards documentation for more details.

Web sign-in

You can use the Citrix web sign-in credential provider to enable the use of Entra ID based Windows authentication. This allows users to log into or unlock their virtual desktops using any authentication method that is enabled in Entra ID.

IMPORTANT

Web sign-in is currently in preview. This feature is provided without support and is not yet recommended for use in production environments.

System requirements

The following are the system requirements for using web sign-in:

- Virtual Delivery Agent
  - Windows: **single session** version 2607 or later
- Citrix Workspace app
  - Windows: version 2607 or later
- Session host identity: Entra joined or Entra hybrid joined
- Session host OS:
  - Windows 11, version 24H2 with 2025-09 Cumulative Updates for Windows 11 (KB5065789) or later installed (build 26100.6725)

How to configure web sign-in

Citrix web sign-in is disabled by default. To enable it, follow these steps:

1. Complete the **Azure and Microsoft Entra ID configuration** described in the Microsoft Entra single sign-on documentation. If you have Microsoft Entra single sign-on enabled in your environment, you can continue to the next step.

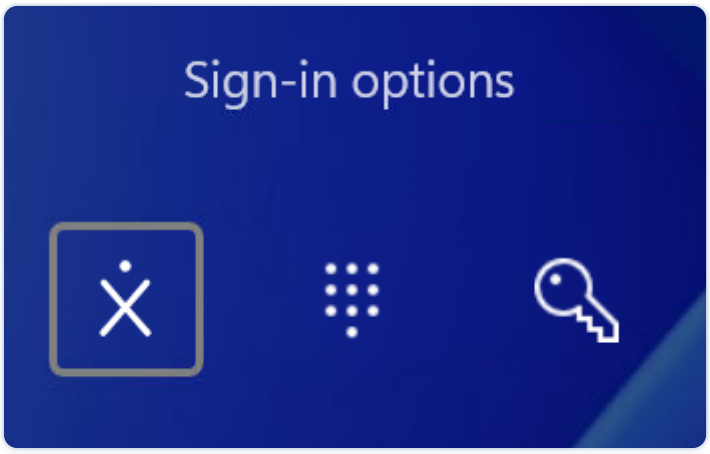
© 1997–2026 Citrix Systems, Inc. All rights reserved.

The relevant steps are:

a. Register the Citrix resource and client applications.
b. Enable the Microsoft Entra ID Remote Desktop Services authentication protocol for the Citrix resource application.
c. Hide the user consent prompt.
d. Approve the client application.
e. Create a Kerberos server object (Microsoft Entra hybrid joined environments only).
f. Review Microsoft Entra Conditional Access policies.

2. Enable the **Web sign-in** setting in a Citrix policy and apply the policy to the appropriate delivery groups.

NOTE



- It is not necessary to use Microsoft Entra single sign-on to use web sign-in.
- If the policy setting is not yet available in your tenant, you can enable web sign-in via the registry:
  - Key: HKLM\SOFTWARE\Policies\Citrix\ICAPolicies
  - Value type: DWORD
  - Value name: AllowWebSignIn
  - Value data: 1

How to use web sign-in

To use Citrix web sign-in to log in or unlock your virtual desktop:

1. Select the Citrix tile from the logon methods available.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Click on **Citrix Web Sign-in**.

3. Once the authentication prompt pops up, authenticate with the required authentication method.

NOTE

The authentication methods available to the user are determined by what is enabled in Microsoft Entra ID.

Set up resource locations

Resource locations contain the resources required to deliver applications and desktops to users. You manage the resources from Citrix Cloud. Typically, resources include:

- Hypervisors or cloud services, known as *hosts* that include:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Active Directory domain controllers.
- Virtual Delivery Agents (VDAs): VDAs are installed on a machine that delivers the applications and desktops to the users.
- Citrix Gateway (optional): To enable secure external access to the applications and desktops offered to users, add a Citrix Gateway VPX appliance to the resource location. Then, set up Citrix Gateway.
- Citrix StoreFront™ servers.
- To communicate with Citrix Cloud, every resource location must contain a Citrix Cloud Connector. A minimum of two Cloud Connectors per resource location is recommended.

A zone is equivalent to a resource location. When you create a resource location and install a Cloud Connector, a zone is automatically created for you. For more information, see Zones.

To learn more about resource types, see Connect to Citrix Cloud.

Host requirements

The hypervisor or cloud service, where you provision VMs, need unique permissions or setup.

- If the hypervisor or cloud service requires virtual networks, follow the guidance in its documentation.
- Create the appropriate Virtual Private Cloud (VPC) (for AWS or GCP) or Virtual Network (VNET) (for Azure) for the machines that you'll add to your resource location.
- Create the appropriate rules to secure inbound and outbound traffic between machines in the virtual network. For example, when using AWS, ensure that the VPC's security group has the appropriate rules configured so that machines in the VPC are accessible to only the IP addresses you specify.

The following host types are supported:

- Amazon Web Services (AWS) virtualization environments
- XenServer® virtualization environments
- Google Cloud Platform virtualization environments
- HPE Moonshot virtualization environments
- Microsoft Azure Resource Manager virtualization environments
- Microsoft System Center Virtual Machine Manager virtualization environments
- Nutanix virtualization environments

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Nutanix cloud and partner solutions
- VMware virtualization environments
- VMware cloud and partner solutions

Active Directory

Provision a Windows server, install Active Directory Domain Services (AD DS), and promote it to a Domain Controller. For guidance, see the Microsoft documentation on Active Directory Domain Services Overview.

The important considerations are:

- You must have at least one Domain Controller running Active Directory Domain Services.
- Do not install any Citrix components on a Domain Controller.

For more information, see:

- Active Directory functional levels
- Identity and access management in Citrix Cloud.
- Connect Active Directory to Citrix Cloud
- Deployment scenarios for using Connector Appliance with Active Directory

Cloud Connectors

The Cloud Connector is a group of services from Citrix Cloud that allow communication between the VDAs, StoreFront, and the cloud-based Delivery Controller. You can install Cloud Connectors interactively or from the command line.

For more information on Cloud Connectors, see:

- Citrix Cloud Connector
- Technical details
- Proxy and firewall configuration
- Installation
- Connector updates

Size and scale considerations

- When evaluating Citrix DaaS™ for sizing and scalability, consider all components.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Research and test the configuration of the Cloud Connectors and StoreFront for your specific requirements.
- Undersizing the machines can impact system performance negatively.

The article Size and scale considerations for Cloud Connectors includes:

- Size and scale testing information
- Tested maximum capacities
- Best practice recommendations for Cloud Connector machine configuration

Add a resource type

1. Sign in to Citrix Cloud.
2. In the upper left menu, select **Resource Locations**.
3. Select **+ Resource Locations** to add a resource location.
4. Enter a name for the resource location, and then click **Save**. For information about naming considerations, see Name restrictions.
5. Under the new resource location, select **+ Cloud Connectors**.
6. Download and install the Cloud Connector software on at least two servers in the domain where you have your Citrix DaaS resources.
   - During the installation, select the resource location you created in the previous steps.
   - After installation, Citrix Cloud adds the servers to the resource location, and registers the domains in which you installed the Cloud Connectors.
7. Verify that the registered domains are active:
   - From the Citrix Cloud menu, select **Identity Access Management**.
   - Select **Domains**. A list of domains where Cloud Connectors have been deployed displays.
   - Locate the domains that you are using with Citrix DaaS. Active domains display with a green bar on the left side of the domain entry.

   If your domain does not have the visual indicator, the domain is in an **unused** state. If you specify an unused domain during machine catalog setup, catalog creation fails. To ensure machine catalog setup occurs without errors, follow the steps in Activate an unused domain.

   For more information, see CTX473009: DaaS Catalog Creation Wizard: "Internal Server Error" when creating adding new machine accounts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Activate an unused domain

1. From the **Domain** tab, in **Identity and Access Management**, select **Show Unused Domains**. After you select this option, the label changes to **Hide Unused Domains**.
2. Locate the unused domain in the list. Unused domains display a gray bar on the left side of the domain entry, and a single-option ellipsis menu on the right side.
3. Select the ellipsis menu, and then select **Use domain**. The gray bar becomes green, and the ellipsis menu change to **Disable**.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For setting up resource location for specific host types:
  - AWS virtualization environments
  - Google Cloud virtualization environments
  - HPE Moonshot virtualization environments
  - Microsoft Azure Resource Manager virtualization environments
  - Microsoft System Center Virtual Machine Manager virtualization environments
  - Nutanix virtualization environments
  - Nutanix cloud and partner solutions
  - VMware virtualization environments
  - VMware cloud and partner solutions
  - XenServer virtualization environments
- For a full deployment, Create and manage connections and resources to a resource location.
- Review all the steps in the installation and configuration process

Amulet Hotkey CoreStation virtualization environments

Citrix DaaS™ manages your Amulet Hotkey CoreStation workloads through a Citrix-managed Amulet Hotkey CoreStation plug-in present in the DaaS control plane. With this plug-in, you can create connections to your Amulet Hotkey CoreStation enclosure, create catalogs, and power manage machines in the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Key steps

1. Set up your Amulet Hotkey CoreStation environment.
2. Create a connection to the Amulet Hotkey CoreStation enclosure.
3. Create a machine catalog.

   NOTE:

   Before creating a catalog, ensure to have one or more Amulet Hotkey CoreStation nodes and install VDAs on those nodes. You can consider the Amulet Hotkey CoreStation enclosure as the hypervisor and the nodes as VMs.

4. Create a delivery group.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine that will deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to Amulet Hotkey CoreStation.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

AWS virtualization environments

This article describes how to set up your AWS account as a resource location you can use with Citrix DaaS. The resource location is used for provisioning workloads in AWS EC2 and Amazon WorkSpaces Core Managed Instances. For the list of OS types supported for Amazon WorkSpace Core Managed Instances, see VDAs in Amazon WorkSpaces Core Managed Instances.

Comparison of different configurable resource locations: MCS for AWS EC2, MCS for Amazon WorkSpaces Core Managed Instances, and Quick Deploy for Amazon WorkSpaces Core Bundles.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

MCS FOR AWS EC2	MCS FOR AMAZON WORKSPACES CORE MANAGED INSTANCES	QUICK DEPLOY FOR AMAZON WORKSPACES CORE BUNDLES
Citrix® handles provisioning of VMs in your AWS account	Citrix handles provisioning of VMs in your AWS account	Amazon handles provisioning of VMs in AWS-managed WorkSpaces account
Advanced MCS workflow for VM lifecycle management	Advanced MCS workflow for VM lifecycle management	5-step quick and easy workflow
EC2 instances	WorkSpaces Core Managed Instances (utilize on-demand EC2 instances launched directly into your AWS account)	WorkSpaces Bundles, fully AWS-managed capacity (higher level abstraction)
No Microsoft 365 licensing support	BYOL Microsoft 365 support	BYOL Microsoft 365 support
Windows Server, Windows Desktop, and Linux	Windows Server, Windows Desktop, and Linux	Windows Server, Windows Desktop
Persistent and Non-persistent VMs	Persistent and Non-persistent VMs	Persistent VMs only
Pay-as-you-go only	Pay-as-you-go	Fixed price per month only
Citrix DaaS and Citrix Virtual Apps and Desktops™	Citrix DaaS and Citrix Virtual Apps and Desktops™	Citrix DaaS only

The resource location includes a basic set of components, ideal for a proof-of-concept, or other deployment that does not require resources spread over multiple availability zones.

When you complete the tasks in this article, your resource location includes the following components:

- A virtual private cloud (VPC) with public and private subnets inside a single availability zone.
- An instance that runs as both an Active Directory Domain Controller and DNS server, located in the private subnet of the VPC.
- Two domain-joined instances on which the Citrix Cloud Connector™ is installed, located in the private subnet of the VPC.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- An instance that acts as a bastion host, located in the public subnet of your VPC. This instance is used to initiate RDP connections to the instances in the private subnet for administration purposes. After you finish setting up your resource location, you can shut down this instance so it is no longer readily accessible. When you must manage other instances in the private subnet, such as VDA instances, you can restart the bastion host instance.

After you complete the tasks, you can install VDAs, provision machines, create machine catalogs, and create Delivery Groups.

Task overview

Set up a virtual private cloud (VPC) with public and private subnets. When you complete this task, AWS deploys NAT gateways with an Elastic IP address in the public subnet. This enables instances in the private subnet to access the Internet. Instances in the public subnet are accessible to inbound public traffic while instances in the private subnet are not.

Configure security groups. Security groups act as virtual firewalls that control traffic for the instances in your VPC. You add rules to your security groups that allow instances in your public subnet to communicate with instances in your private subnet. You also associate these security groups with each instance in your VPC.

Create a DHCP options set. An Amazon VPC, DHCP, and DNS services are provided by default, which affects how you configure DNS on your Active Directory Domain Controller. Amazon's DHCP cannot be disabled and Amazon's DNS can be used only for public DNS resolution, not Active Directory name resolution. To specify the domain and name servers handed to instances through DHCP, create a DHCP options set. The set assigns the Active Directory domain suffix and specifies the DNS server for all instances in your VPC. To ensure Host (A) and Reverse Lookup (PTR) records are automatically registered when instances join the domain, you configure the network adapter properties for each instance you add to the private subnet.

Add a bastion host, Domain Controller, and Cloud Connectors to the VPC. Through the bastion host, you can log on to instances in the private subnet to set up the domain, join instances to the domain, and install the Cloud Connector.

Task 1: Set up the VPC

1. From the AWS management console, select **VPC**.
2. From the VPC Dashboard, select **Create VPC**.
3. Select **VPC and more**.
4. Under NAT gateways ($), select **In 1 AZ** or **1 per AZ**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Under DNS options, leave **Enable DNS hostnames** selected.
6. Select **Create VPC**. AWS creates the public and private subnets, Internet gateway, route tables, and default security group.

NOTE:

Changing the name of an AWS Virtual Private Cloud (VPC) in the AWS console breaks the existing hosting unit in the Citrix Cloud. When the hosting unit is broken, you cannot create catalogs or add machines to existing catalogs. From Known Issue: PMCS-7701

Task 2: Configure security groups

This task creates and configures the following security groups for your VPC:

- A public security group to associate with the instances in your Public subnet.
- A private security group to associate with the instances in your Private subnet.

To create the security groups:

1. In the VPC Dashboard, select **Security Groups**.
2. Create a security group for the public security group. Select **Create Security Group** and enter a name tag and description for the group. In VPC, select the VPC you created earlier. Select **Yes, Create**.

Configure the Public security group

1. From the security group list, select the Public security group.
2. Select the **Inbound Rules** tab and select Edit to create the following rules:

TYPE	SOURCE
ALL Traffic	Select the Private security group.
ALL Traffic	Select the Public security group.
ICMP	0.0.0.0/0
22 (SSH)	0.0.0.0/0
80 (HTTP)	0.0.0.0/0

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TYPE	SOURCE
443 (HTTPS)	0.0.0.0/0
1494 (ICA/HDX)	0.0.0.0/0
2598 (Session Reliability)	0.0.0.0/0
3389 (RDP)	0.0.0.0/0

3. When finished, select **Save**.
4. Select the **Outbound Rules** tab and select **Edit** to create the following rules.

TYPE	DESTINATION
ALL Traffic	0.0.0.0/0

5. When finished, select **Save**.

Configure the private security group

1. From the security group list, select the Private security group.
2. If you have not yet setup traffic from the public security group, you must set TCP ports. Select the **Inbound Rules** tab and select **Edit** to create the following rules:

TYPE	SOURCE
ICMP	Select the Public security group.
TCP 53 (DNS)	Select the Public security group.
UDP 53 (DNS)	Select the Public security group.
80 (HTTP)	Select the Public security group.
TCP 135	Select the Public security group.
TCP 389	Select the Public security group.
UDP 389	Select the Public security group.
443 (HTTPS)	Select the Public security group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TYPE	SOURCE
TCP 1494 (ICA/HDX)	Select the Public security group.
TCP 2598 (Session Reliability)	Select the Public security group.
3389 (RDP)	Select the Public security group.
TCP 49152–65535	Select the Public security group.

3. When finished, select **Save.**
4. Select the **Outbound Rules** tab and select **Edit** to create the following rules.

TYPE	DESTINATION
ALL Traffic	Select the Private security group.
ALL Traffic	0.0.0.0/0

5. When finished, select **Save**.

Task 3: Launch instances

Do the following steps to create four EC2 instances and decrypt the default Administrator password that Amazon generates:

1. From the AWS management console, select **EC2**.
2. From the EC2 Dashboard, select **Launch Instance**.
3. Select a Windows Server machine image and instance type.
4. On the **Configure Instance Details** page, enter a name for the instance and select the VPC that you had set up earlier.
5. In **Subnet**, make the following selections for each instance:
    - Bastion host: Select the Public subnet
    - Domain controller and Connectors: Select the Private subnet
6. In **Auto-assign Public IP address**, make the following selections for each instance:
    - Bastion host: Select **Enable**
    - Domain controller and Connectors: Select **Use default setting** or **Disable**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. In **Network Interfaces**, enter a primary IP address within the IP range of your private subnet for the Domain Controller and Cloud Connector instances.
8. If necessary, on the **Add Storage** page, modify the disk size.
9. On the **Tag Instance** page, enter a friendly name for each instance.
10. On the **Configure Security Groups** page, select **Select an existing security group** and then make the following selections for each instance:
    - Bastion host: Select the Public security group.
    - Domain controller and Cloud Connectors: Select the Private security group.
11. Review your selections and then select **Launch**.
12. Create a new key pair or select an existing one. If you create a new key pair, then download your private key (`.pem`) file and keep it in a safe place. You must supply your private key when you acquire the default Administrator password for the instance.
13. Select **Launch Instances**. Select **View Instances** to display a list of your instances. Wait until the newly launched instance has passed all status checks before accessing it.
14. Acquire the default Administrator password for each instance.
    a. From the instance list, select the instance and then select **Connect**.
    b. Go to the **RDP client** tab, select **Get Password**, and upload your private key (`.pem`) file when prompted.
    c. Select **Decrypt Password** to get the human readable password. AWS displays the default password.
15. Repeat all the steps from step 2 until you have created four instances:
    - One bastion host instance in your public subnet
    - Three instances in your private subnet to be used as:
        - One as a Domain Controller
        - Two as Cloud Connectors

Task 4: Create a DHCP options set

1. From the VPC Dashboard, select **DHCP Options Sets**.
2. Enter the following information:
    - Name tag: Enter a friendly name for the set.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Domain name: Enter the fully qualified domain name that you use when you configure the Domain Controller instance.
- Domain name servers: Enter the private IP address you assigned to the Domain Controller instance and the string **AmazonProvidedDNS**, separated by commas.
- NTP servers: Leave this field blank.
- NetBIOS name servers: Enter the private IP address of the Domain Controller instance.
- NetBIOS node type: Enter **2**.

3. Select **Yes, Create.**
4. Associate the new set with your VPC:

   a. From the VPC Dashboard, select **Your VPCs** and then select the VPC you set up earlier.

   b. Select **Actions > Edit DHCP Options Set**.

   c. When prompted, select the new set you created, and then select **Save**.

Task 5: Configure the instances

1. Using an RDP client, connect to the public IP address of the bastion host instance. When prompted, enter the credentials for the Administrator account.
2. From the bastion host instance, launch **Remote Desktop Connection** and connect to the private IP address of the instance you want to configure. When prompted, enter the Administrator credentials for the instance.
3. For all instances in the private subnet, configure the DNS settings:

   a. Select **Start > Control Panel > Network and Internet > Network and Sharing Center > Change adapter settings**. Double-click the network connection displayed.

   b. Select **Properties > Internet Protocol Version 4 (TCP/IPv4) > Properties**.

   c. Select **Advanced > DNS**. Ensure that the following settings are enabled, and then select **OK**:

      - **Register this connection's addresses in DNS**
      - **Use this connection's DNS suffix in DNS registration**

4. Configure the Domain Controller:

   a. Using Server Manager, add the Active Directory Domain Services role with all default features.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. Promote the instance to a Domain Controller. During promotion, enable DNS and use the domain name you specified when you created the DHCP options set. Restart the instance when prompted.

5. Configure the first Cloud Connector:

   a. Join the instance to the domain and restart when prompted. From the bastion host instance, reconnect to the instance using RDP.

   b. Sign in to Citrix Cloud. Select **Resource Locations** from the upper left menu.

   c. Download the Cloud Connector.

   d. When prompted, run the `cwcconnector.exe` file and supply your Citrix Cloud credentials. Follow the wizard.

   e. Once complete, select **Refresh** to display the **Resource Locations** page. When the Cloud Connector is registered, the instance appears on the page.

6. Repeat the steps to configure the Cloud Connector to configure the second Cloud Connector.

7. Attach an IAM Policy to the Cloud Connectors to support AWS hosting connections with role-based authorization. You must have the same IAM Policy attached to all the Cloud Connectors in a resource location. For information about AWS permissions, see Required AWS permissions-Amazon EC2 and Required AWS permissions-Amazon WorkSpaces Core Managed Instances.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see:
  - Connection to AWS
  - Connection to Amazon WorkSpaces Core Managed Instances
- Review all the steps in the installation and configuration process

More information

- Create and manage connections and resources
- Create machine catalogs

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Google Cloud virtualization environments

Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) lets you provision and manage machines on Google Cloud.

Prerequisites

Before you start provisioning the VMs to Google Cloud Platform (GCP), you must make sure the following prerequisites are met.

1. The Citrix subscription must include support for Hybrid Multi-Cloud workloads. For more information, see Compare Citrix subscription features.
2. The admin account must have sufficient permissions to create host connections, machine catalogs, and delivery groups. For more information, see Configure Delegated Administration.
3. Identify a Google Cloud project, in which all compute resources associated with the machine catalog are stored. It can be an existing project or a new one. For more information, see Google Cloud projects.
4. Enable the Google Cloud APIs required for the integration with Citrix DaaS. For more information, see Enable Google Cloud APIs.
5. Create the service accounts in Google Cloud and grant the appropriate permissions. For more information, see Configure and update service accounts.
6. Download the key file for the Citrix Cloud Service Account. For more information, see Citrix Cloud Service Account key.
7. The virtual machines must have access to the Google APIs without a public IP address. For more information, see Enable Private Google Access.

Google Cloud projects

There are basically two types of Google Cloud projects:

- Provisioning project: In this case, the current admin account owns the provisioned machines in the project. This project is also referred to as a local project.
- Shared VPC project: Project in which machines created in the provisioning project use the VPC from the Shared VPC project. The admin account used for provisioning projects has limited permissions in this project, specifically, only permissions to use the VPC.

Service endpoint URLs

You must have access to the following URLs:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `https://oauth2.googleapis.com`
- `https://cloudresourcemanager.googleapis.com`
- `https://compute.googleapis.com`
- `https://storage.googleapis.com`
- `https://cloudbuild.googleapis.com`

Enable Google Cloud APIs

To use the Google Cloud functionality through Studio, enable these APIs in your Google Cloud project:

- Compute Engine API
- Cloud Resource Manager API
- Identity and Access Management (IAM) API
- Cloud Build API

From the Google Cloud console, complete these steps:

1. In the upper left menu, select **APIs and Services > Enabled APIs & services**.
2. On the **Enabled APIs & services** screen, ensure that the Compute Engine API is enabled. If not, follow these steps:
    a. Navigate to **APIs and Services > Library**.
    b. In the search box, type *Compute Engine*.
    c. From the search results, select **Compute Engine API**.
    d. On the **Compute Engine API** page, select **Enable**.
3. Enable Cloud Resource Manager API.
    a. Navigate to **APIs and Services > Library**.
    b. In the search box, type *Cloud Resource Manager*.
    c. From the search results, select **Cloud Resource Manager API**.
    d. On the **Cloud Resource Manager API** page, select **Enable**. The status of the API appears.
4. Similarly, enable **Identity and Access Management (IAM) API** and **Cloud Build API**, and **Cloud Key Management Service (KMS) API**.

You can also use Google Cloud Shell to enable the APIs. To do this:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open the Google Console and load the Cloud Shell.
2. Run the following four commands in the Cloud Shell:
   - gcloud services enable compute.googleapis.com
   - gcloud services enable cloudresourcemanager.googleapis.com
   - gcloud services enable iam.googleapis.com
   - gcloud services enable cloudbuild.googleapis.com
   - gcloud services enable cloudkms.googleapis.com
3. Click **Authorize** when the Cloud Shell prompts.

Configure and update service accounts

NOTE:

GCP is introducing changes to Cloud Build Service's default behavior and use of service accounts after April 29, 2024. For more information, see Cloud Build Service Account Change. Your existing Google projects with Cloud Build API enabled before April 29, 2024 are not affected by this change. However, if you want to have existing Cloud Build Service behavior after April 29, you can create or apply the organization policy to disable the constraint enforcement before you enable the Cloud Build API. As a result, the following content is divided into two: Before April 29, 2024 and After April 29, 2024. If you set the new organization policy, follow the section Before April 29, 2024.

Before April 29, 2024

Citrix Cloud™ uses three separate service accounts within the Google Cloud project:

- *Citrix Cloud Service Account*: This service account enables Citrix Cloud to access the Google project, provision, and manage machines. This service account authenticates to Google Cloud using a key generated by Google Cloud.

  You must create this service account manually as outlined here. For more information, see Create a Citrix Cloud Service Account.

  You can identify this service account with an email address. For example, `<my-service-account>@<project-id>.iam.gserviceaccount.com`.

- *Cloud Build Service Account*: This service account is provisioned automatically after you enable all the APIs mentioned in Enable Google Cloud APIs. To view all automatically created service

© 1997–2026 Citrix Systems, Inc. All rights reserved.

accounts, navigate to **IAM & Admin > IAM** in the **Google Cloud** console and select the **Include Google-provided role grants** checkbox.

You can identify this service account by an email address that begins with the **Project ID** and the word **cloudbuild**. For example, `<project-id>@cloudbuild.gserviceaccount.com`

Verify if the service account has been granted the following roles. If you must add roles, follow the steps outlined in Add roles to the Cloud Build Service Account.

- Cloud Build Service Account
- Compute Instance Admin
- Service Account User

- *Cloud Compute Service Account*: This service account is added by Google Cloud to instances created in Google Cloud once the Compute API is activated. This account has the IAM basic editor role to do the operations. However, if you delete the default permission to have more granular control, you must add a **Storage Admin** role that requires the following permissions:
  - resourcemanager.projects.get
  - storage.objects.create
  - storage.objects.get
  - storage.objects.list

You can identify this service account by an email address that begins with the **Project ID** and the word **compute**. For example, `<project-id>-compute@developer.gserviceaccount.com`.

CREATE A CITRIX CLOUD SERVICE ACCOUNT

To create a Citrix Cloud Service Account, follow these steps:

1. In the Google Cloud console, navigate to **IAM & Admin > Service accounts**.
2. On the **Service accounts** page, select **CREATE SERVICE ACCOUNT**.
3. On the **Create service account** page, enter the required information, and then select **CREATE AND CONTINUE**.
4. On the **Grant this service account access to project** page, click the **Select a role** drop-down menu and select the required roles. Click **+ADD ANOTHER ROLE** if you want to add more roles.

   Each account (personal or service) has various roles defining the management of the project. Grant the following roles to this service account:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Compute Admin
- Storage Admin
- Cloud Build Editor
- Service Account User
- Cloud Datastore User
- Cloud KMS Crypto Operator

The Cloud KMS Crypto Operator requires the following permissions:

- cloudkms.cryptoKeys.get
- cloudkms.cryptoKeys.list
- cloudkms.keyRings.get
- cloudkms.keyRings.list
- cloudkms.cryptoKeyVersions.useToDecrypt
- cloudkms.cryptoKeyVersions.useToEncrypt

NOTE:

Enable all the APIs to get the complete list of roles available while creating a new service account.

5. Click **CONTINUE**
6. On the **Grant users access to this service account** page, add users or groups to grant them access to perform actions in this service account.
7. Click **DONE**.
8. Navigate to the IAM main console.
9. Identify the service account created.
10. Validate the roles are assigned successfully.

Considerations:

When creating the service account, consider the following:

- The steps **Grant this service account access to project** and **Grant users access to this service account** are optional. If you choose to skip these optional configuration steps, the newly created service account does not display in the **IAM & Admin > IAM** page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To display roles associated with a service account, add the roles without skipping the optional steps. This process ensures that roles appear for the configured service account.

CITRIX CLOUD SERVICE ACCOUNT KEY

The Citrix Cloud Service Account key is required for creating a connection in Citrix DaaS. The key is contained in a credential file (.json). The file is automatically downloaded and saved to the **Downloads** folder after you create the key. When you create the key, be sure to set the key type to JSON. Otherwise, Studio cannot parse it.

To create a Service Account Key, navigate to **IAM & Admin > Service accounts** and click the email address of the Citrix Cloud Service Account. Switch to the **Keys** tab and select **Add Key > Create new key**. Make sure to select **JSON** as the key type.

TIP:

Create keys using the **Service accounts** page in the Google Cloud console. We recommend that you change keys regularly for security purposes. You can provide new keys to the Citrix Virtual Apps and Desktops application by editing an existing Google Cloud connection.

ADD ROLES TO THE CITRIX CLOUD SERVICE ACCOUNT

To add roles to the Citrix Cloud Service Account:

1. In the Google Cloud console, navigate to **IAM & Admin > IAM**.
2. On the **IAM > PERMISSIONS** page, locate the service account you created, identifiable with an email address.

   For example, `<my-service-account>@<project-id>.iam.gserviceaccount.com`
3. Select the pencil icon to edit the access to the principal of the service account.
4. On the **Edit access to "project-id"** page for the selected principal option, select **ADD ANOTHER ROLE** to add the required roles to your service account one by one and then select **SAVE**.

ADD ROLES TO THE CLOUD BUILD SERVICE ACCOUNT

To add roles to the Cloud Build Service Account:

1. In the Google Cloud console, navigate to **IAM & Admin > IAM**.
2. On the **IAM** page, locate the Cloud Build service account, identifiable with an email address that begins with the **Project ID** and the word **cloudbuild**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example, `<project-id>@cloudbuild.gserviceaccount.com`

3. Select the pencil icon to edit the Cloud Build account roles.
4. On the **Edit access to "project-id" page** for the selected principal option, select **ADD ANOTHER ROLE** to add the required roles to your Cloud Build service account one by one and then select **SAVE**.

> **NOTE:**
>
> Enable all the APIs to get the complete list of roles.

After April 29, 2024

Citrix Cloud uses two separate service accounts within the Google Cloud project:

- *Citrix Cloud Service Account*: This service account enables Citrix Cloud to access the Google project, provision, and manage machines. This service account authenticates to Google Cloud using a key generated by Google Cloud.

  You must create this service account manually.

  You can identify this service account with an email address. For example, `<my-service-account>@<project-id>.iam.gserviceaccount.com`.
- *Cloud Compute Service Account*: This service account is provisioned automatically after you enable all the APIs mentioned in Enable Google Cloud APIs. To view all automatically created service accounts, navigate to **IAM & Admin > IAM** in the **Google Cloud** console and select the **Include Google-provided role grants** checkbox. This account has the IAM basic editor role to do the operations. However, if you delete the default permission to have more granular control, you must add **Storage Admin** role that requires the following permissions:

  - resourcemanager.projects.get
  - storage.objects.create
  - storage.objects.get
  - storage.objects.list

  You can identify this service account by an email address that begins with the **Project ID** and the word **compute**. For example, `<project-id>-compute@developer.gserviceaccount.com.`

  Verify if the service account has been granted the following roles.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Cloud Build Service Account
- Compute Instance Admin
- Service Account User

CREATE A CITRIX CLOUD SERVICE ACCOUNT

To create a Citrix Cloud Service Account, follow these steps:

1. In the Google Cloud console, navigate to **IAM & Admin > Service accounts**.
2. On the **Service accounts** page, select **CREATE SERVICE ACCOUNT**.
3. On the **Create service account** page, enter the required information, and then select **CREATE AND CONTINUE**.
4. On the **Grant this service account access to project** page, click the **Select a role** drop-down menu and select the required roles. Click **+ADD ANOTHER ROLE** if you want to add more roles.

   Each account (personal or service) has various roles defining the management of the project. Grant the following roles to this service account:

   - Compute Admin
   - Storage Admin
   - Cloud Build Editor
   - Service Account User
   - Cloud Datastore User
   - Cloud KMS Crypto Operator

   The Cloud KMS Crypto Operator requires the following permissions:

   - cloudkms.cryptoKeys.get
   - cloudkms.cryptoKeys.list
   - cloudkms.keyRings.get
   - cloudkms.keyRings.list

   NOTE:

   Enable all the APIs to get the complete list of roles available while creating a new service account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Click **CONTINUE**
6. On the **Grant users access to this service account** page, add users or groups to grant them access to perform actions in this service account.
7. Click **DONE**.
8. Navigate to the IAM main console.
9. Identify the service account created.
10. Validate the roles are assigned successfully.

Considerations:

When creating the service account, consider the following:

- The steps **Grant this service account access to project** and **Grant users access to this service account** are optional. If you choose to skip these optional configuration steps, the newly created service account does not display in the **IAM & Admin > IAM** page.
- To display roles associated with a service account, add the roles without skipping the optional steps. This process ensures that roles appear for the configured service account.

CITRIX CLOUD SERVICE ACCOUNT KEY

The Citrix Cloud Service Account key is required for creating a connection in Citrix DaaS. The key is contained in a credential file (.json). The file is automatically downloaded and saved to the **Downloads** folder after you create the key. When you create the key, be sure to set the key type to JSON. Otherwise, Studio cannot parse it.

To create a Service Account Key, navigate to **IAM & Admin > Service accounts** and click the email address of the Citrix Cloud Service Account. Switch to the **Keys** tab and select **Add Key > Create new key**. Make sure to select **JSON** as the key type.

TIP:

Create keys using the **Service accounts** page in the Google Cloud console. We recommend that you change keys regularly for security purposes. You can provide new keys to the Citrix Virtual Apps and Desktops application by editing an existing Google Cloud connection.

ADD ROLES TO THE CITRIX CLOUD SERVICE ACCOUNT

To add roles to the Citrix Cloud Service Account:

1. In the Google Cloud console, navigate to **IAM & Admin > IAM**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **IAM > PERMISSIONS** page, locate the service account you created, identifiable with an email address.

   For example, `<my-service-account>@<project-id>.iam.gserviceaccount.com`

3. Select the pencil icon to edit the access to the principal of the service account.
4. On the **Edit access to "project-id"** page for the selected principal option, select **ADD ANOTHER ROLE** to add the required roles to your service account one by one and then select **SAVE**.

ADD ROLES TO THE CLOUD COMPUTE SERVICE ACCOUNT

To add roles to the Cloud Compute Service Account:

1. In the Google Cloud console, navigate to **IAM & Admin > IAM**.
2. On the **IAM** page, locate the Cloud Compute Service Account, identifiable with an email address that begins with the **Project ID** and the word **compute**.

   For example, `<project-id>-compute@developer.gserviceaccount.com`

3. Select the pencil icon to edit the Cloud Build account roles.
4. On the **Edit access to "project-id" page** for the selected principal option, select **ADD ANOTHER ROLE** to add the required roles to your Cloud Build service account one by one and then select **SAVE**.

   NOTE:

   Enable all the APIs to get the complete list of roles.

Storage permissions and bucket management

Citrix DaaS improves the process of reporting cloud build failures for the Google Cloud service. This service runs builds on the Google Cloud. Citrix DaaS creates a storage bucket named `citrix-mcs-cloud-build-logs-{region}-{5 random characters}` where the Google Cloud services captures build log information. An option is set on this bucket that deletes the contents after a period of 30 days. This process requires that the service account used for the connection has Google Cloud permissions set to `storage.buckets.update`. If the service account does not have this permission, Citrix DaaS ignores errors and proceeds with the catalog creation process. Without this permission, the size of the build logs increases and requires manual cleanup.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable private Google access

When a VM lacks an external IP address assigned to its network interface, packets are only sent to other internal IP addresses destinations. When you enable private access, the VM connects to the set of external IP addresses used by the Google API and associated services.

NOTE:

Whether private Google access is enabled, all VMs that are with and without public IP addresses, must be able to access Google Public APIs, especially if third-party networking appliances have been installed in the environment.

To ensure that a VM in your subnet can access the Google APIs without a public IP address for MCS provisioning:

1. In Google Cloud, access the **VPC network configuration**.
2. Identify the subnets used or the Citrix® environment in the **Subnets in current project** tab.
3. Click the name of the subnets and enable **Private Google Access**.

For more information, see Configuring Private Google Access.

IMPORTANT:

If your network is configured to prevent VM access to the internet, ensure that your organization assumes the risks associated with enabling Private Google access for the subnet to which the VM is connected.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to Google cloud environments.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

© 1997–2026 Citrix Systems, Inc. All rights reserved.

HPE Moonshot virtualization environments

Citrix DaaS™ manages your HPE Moonshot workloads through a Citrix-managed HPE Moonshot plug-in present in the DaaS control plane. With this plug-in, you can create connections to your HPE Moonshot chassis, create catalogs, and power manage machines in the catalog.

Key steps

1. Set up your HPE environments.
2. Create a connection to the HPE Moonshot chassis.
3. Create a machine catalog.

   NOTE:

   Before creating a catalog, ensure to have one or more HPE Moonshot cartridge nodes and install VDAs on those nodes. You can consider the HPE Moonshot chassis as the hypervisor and the cartridge nodes as VMs.

4. Create a delivery group.
5. Migrate the rest of unmanaged HPE Moonshot nodes to the managed catalog or delivery group.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine that will deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to HPE Moonshot.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

Microsoft Azure Resource Manager virtualization environments

When using the Microsoft Azure Resource Manager to provision virtual machines in your Citrix DaaS™ deployment, get familiar with the following:

- What is Microsoft Entra ID?

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Integrating Microsoft Entra ID with applications getting started guide
- Application and service principal objects in Microsoft Entra ID
- Managed identities for Azure resources

To set up your Microsoft Azure Resource Manager, see Set up resource location.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to Microsoft Azure.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs
- CTX219211: Set up a Microsoft Entra ID account
- CTX219243: Grant XenApp and XenDesktop access to your Azure subscription
- CTX219271: Deploy hybrid cloud using site-to-site VPN

Microsoft SCVMM virtualization environments

Follow this guidance if you use Hyper-V with the Microsoft System Center Virtual Machine Manager (VMM) to provide virtual machines.

See System requirements for a list of supported VMM versions.

You can use Machine Creation Services™ or Citrix Provisioning (formerly Provisioning Services) to provision:

- Generation 1 Desktop or Server OS VMs
- Generation 2 Windows Server 2016, Windows Server 2019, Windows Server 2022, Windows 10, and Windows 11 VMs (with or without secure boot)

Install and configure a hypervisor

Install the Microsoft Hyper-V role and VMM on your servers.

Verify the following account information:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In Studio, the account you specify when creating a connection must be a VMM administrator or VMM delegated administrator for the relevant Hyper-V machines. If this account has only the delegated administrator role in VMM, the storage data is not listed in Studio during the connection creation process.

Your user account must also be a member of the administrators local security group on each Hyper-V server to support VM lifecycle management (such as VM creation, update, and deletion).

In large deployments where a single SCVMM manages multiple clusters in different data centers, you can limit the host groups scope of the admins.

To limit the host groups scope, use the delegated admin role in the Microsoft System Center Virtual Machine Manager (VMM) console.

1. On **Create User Roles Wizard**, select **Fabric Administrator** (delegated administrator) as a user role.
2. In **Members**, add the user account in the Active Directory that you want to use as delegated admin.
3. In **Scope**, select the host groups you want the delegated admin to have access to.
4. Create a new **Run As Account** using delegated admin user credentials. Use these credentials to create a hypervisor connection later. Do not use the main administrator role accounts.

Install the VMM console

Install a System Center Virtual Machine Manager console on each server having a Citrix Cloud Connector.

The console version must match the management server version. Although an earlier console can connect to the management server, provisioning VDAs fails if the versions differ.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to Microsoft System Center Virtual Machine Manager.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create machine catalogs

Nutanix virtualization environments

Connect Citrix DaaS™ to Nutanix AHV clusters through Nutanix Prism Central using Nutanix AHV Prism Central host connection. This host connection:

- Supports machine catalogs with both power managed and MCS provisioned VDAs.
- Enables MCS master image sharing across AHV clusters using template versions.
- Simplifies certificate trust on host connection.
- Eliminates the need of Nutanix plug-in installation on Cloud Connectors.

See Nutanix Prism Central on AHV.

You can also use Nutanix Prism Element on AHV using Nutanix Acropolis as the host connection to provide VMs in your Citrix DaaS deployment. However, this setup process requires installing and registering the Nutanix plug-in in your Citrix DaaS environment. See Nutanix Prism Element on AHV.

For more information on the Nutanix Acropolis MCS plug-in Installation guide, see Nutanix Support Portal.

Nutanix Prism Central on AHV

Citrix has developed and maintains a plug-in that integrates Citrix with Nutanix Prism Central on AHV. This plug-in is integrated with Citrix Delivery Controllers, eliminating the need for separate plug-in installations.

The Nutanix AHV Prism Central plug-in is pre-installed on Delivery Controllers managed by Citrix in Citrix DaaS, eliminating the need for separate installation on Cloud Connectors. For information on Citrix-managed components and services, see Components and services managed by Citrix.

Prerequisites

You need the following for Nutanix AHV Prism Central:

- Prism Central version pc.2025.2 or later. Refer to Supported Hypervisors for Citrix Virtual Apps and Desktops (MCS) and Citrix Provisioning (PVS) for detailed supported Prism Central versions.
- AOS version 7.3 or later for the Nutanix AHV clusters.
- Nutanix AHV clusters must register to the Prism Central.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The Citrix administrator account must have sufficient permissions to create host connections, machine catalogs, and delivery groups. For more information, see Configure Delegated Administration.
- Citrix Cloud™ communicates with Nutanix Prism Central through the Cloud Connector. Therefore, the Nutanix Prism Central instance must be accessible from the Cloud Connector.

Limitations in the feature

Due to Nutanix Prism and API limitation, power actions like Guest Reboot or Guest Shutdown might fail for a Windows VM. To resolve this issue, we recommend following Nutanix instructions in the document Power actions initiated from Prism or API might fail for Windows VMs to apply settings on VDAs.

Key steps

1. Set up your Nutanix virtualization environments. For information, see Add a resource type or Activate an unused domain.
2. Create a connection to the Nutanix AHV Prism Central
3. Create a machine catalog using Nutanix machine template version.

Nutanix Prism Element on AHV

Nutanix Prism Element on AHV requires installing the Nutanix plug-in on all Cloud Connectors where Citrix DaaS must create a host connection to the resource location that has a Nutanix hypervisor.

Key steps

1. Install and register the Nutanix plug-in.
2. Set up your Nutanix virtualization environments. For information, see Add a resource type or Activate an unused domain.
3. Create a connection.
4. Create a machine catalog.

Install and register the Nutanix plug-in

Complete the procedure to install and register the Nutanix plug-in on all your Cloud Connectors. For information about installing the Nutanix plug-in, see the Nutanix Documentation site.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing a connection, see Connection to Nutanix.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

Nutanix cloud and partner solutions

Nutanix AHV Prism Central

Citrix DaaS™ supports Nutanix Cloud Clusters (NC2) in the following cloud hypervisors for Citrix-managed Nutanix AHV Prism Central plug-in.

- Amazon Web Services (AWS)
- Microsoft Azure

Nutanix Cloud Clusters

Citrix DaaS supports Nutanix Cloud Clusters on AWS and Azure. Nutanix clusters simplify how applications are run on private or multiple public clouds.

For more information on setting up NC2, see:

- Nutanix Cloud Clusters on AWS Deployment and User Guide
- Nutanix Cloud Clusters on Azure Deployment and User Guide.

Requirements

You need the following accounts to use NC2:

- A Nutanix account
- For AWS: An AWS account with the following permissions.
  - IAMFullAccess
  - AWSConfigRole
  - AWSCloudFormationFullAccess

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For Azure:
  - A valid “NC2 on Azure” license
  - An Azure account that includes one of the following roles:
    - Global Administrator
    - Cloud Application Administrator
    - Application Administrator
    - all the permissions

Permissions for NC2 on Azure

Create a Nutanix Cluster

1. Log in to your Nutanix account.
2. Navigate to the Nutanix cluster option, and click **Launch**. The **Nutanix Console** opens. For more information:
   - Get Started with Nutanix Cluster on AWS
   - Nutanix Cloud Clusters on Microsoft Azure
3. Select the option to create a new VPC.

Once the cluster is created, retrieve the address of the Nutanix Prism.

TROUBLESHOOTING

The cluster creation process might fail with the following errors:

- **Cluster failed to create within a given time. Deleting cluster**
- **Host Nutanix Cluster - Node XXXXXXXXXXX: Instance i-xxxxxxxxxxxxx: disable network interface source/dest check error**.
- **Host Nutanix Cluster - Node XXXXXXXXXXX: Unable to obtain instance i-xxxxxxxxxxxxx network interface info**

If the cluster fails to create, then try to recreate one in a different region. Make sure to delete the Nutanix CloudFormation Stack (CFS) before retrying.

NOTE:

In addition to other resources, the Nutanix CFS creates:

- One VPC named Nutanix Cluster xxxxxxxxxxxx 10.0.0.0/16
- Two subnets 10.0.128.0/24 and 10.0.129.0/24
- One Internet gateway
- One NAT gateway

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Retrieve the Prism server address

1. Register the NC2 cluster with the Prism Central server. See Registering a Cluster with Prism Central.
2. Use the host name or IP address of the Prism Central server as the address.

NC2 for Nutanix Prism Element

Citrix DaaS supports Nutanix Cloud Clusters (NC2) in the following cloud hypervisor for the Nutanix Prism Element plug-in.

- Amazon Web Services (AWS)

Nutanix Cloud Clusters on AWS

For more information on Nutanix Cloud Clusters on AWS, see Nutanix Cloud Clusters on AWS Deployment and User Guide.

TIP:

This support provides the same functionality as a Nutanix on-premises cluster. Only a single cluster is supported, the *Prism Element*. For more information, see here.

You need the following accounts to use NC2 on AWS:

- A Nutanix account
- An AWS account with the following permissions:
  - IAMFullAccess
  - AWSConfigRole
  - AWSCloudFormationFullAccess

For creating a Nutanix Cluster and troubleshooting if cluster creation fails, see Create a Nutanix Cluster and Troubleshooting.

Once the cluster is created, retrieve the address of the **Nutanix Prism**:

Retrieve the prism server address

1. Go to the **Nutanix Console**.
2. In the upper right on the console, hover over the link **Launch Prism Element** and copy the URL.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to Nutanix cloud and partner solutions.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

Red Hat OpenShift virtualization environments

Citrix® manages your Red Hat OpenShift workloads through a Citrix-managed OpenShift plug-in. With this plug-in, you can create hosting connections and hosting units to your OpenShift cluster, create catalogs, and power manage machines in the catalog.

The following configurations are supported:

- Networking options:
  - Linux Bridge and OVS Bridge: Available for cluster networking.
- Storage options:
  - Local storage: Supported for on-node persistent storage.
  - NetApp storage: Supported for enterprise-grade external storage integration.

Key steps

- Set up your Red Hat OpenShift environment.
- Create a connection and a resource to the OpenShift cluster.
- Create a machine catalog.
- Create a delivery group.

Set up your Red Hat OpenShift environment

1. *Create an OpenShift cluster and obtain the cluster API address*: In the OpenShift console, after setting up a cluster, navigate to **Home > Overview > Details**, and get the cluster API address.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. *Create a service account and obtain the service account token using the OpenShift command-line interface (CLI) (oc command)*: The service account token is the authentication credential associated with the service account. The service account is used to authenticate the OpenShift plug-in with OpenShift. Each service account is associated with one namespace.
3. *Configure permissions for the service account*: A service account can have multiple roles, and each role consists of permissions that define what actions the OpenShift Plugin can perform on which resources. The roles are bound through **Role Bindings**, and there are two types of **Role Bindings**:
    a. **Cluster-wide Role Binding**: used for receiving events from OpenShift. Namespace-bound Role Binding: used for managing VMs in a specific namespace.
    b. **Namespace-bound Role Binding**: used for managing VMs in a specific namespace.
4. *Create a namespace (Project)*: Namespace in OpenShift is an isolated environment that groups resources like VMs or networks, allowing better organization and access control. **Namespace** is the Kubernetes term, while **Project** is the OpenShift term. From the OpenShift Plugin perspective, they are the same. A namespace is required to deploy the VMs. Use the OpenShift console or OpenShift Container Platform CLI to create the name space.
5. *Create one network attachment definition under the target namespace*: Network attachment definitions specify the networking configuration for VMs running in OpenShift. Under **Networking > NetworkAttachmentDefinitions**, you can see the Network Attachment Definitions for each Namespace.
6. *Configure the storage classes*: Storage classes define how VM storage is allocated. Under **Storage > StorageClass**, you can configure and see the list of storage providers.

Create a service account

1. Download and unzip oc Command Line Tool.
2. Access the OpenShift Console using your login ID.
3. Click your user profile and click **Copy login command**.
4. Click **Display Token** and copy the token.
5. Run the login command using oc Command Line. Example:

```
.\oc.exe login --token=<token> --server=<server address>
```

6. Create a service account.
    - If you want to create the service account under the default namespace, run:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
.\oc.exe create sa <service account name>
```

- If you want to create the service account under your own namespace, run:

```
.\oc.exe create sa <service account name> -n mynamespace
```

7. Create a `YAML` file for secret. Example:

- If you create the service account under the default namespace:

```
apiVersion: v1

kind: Secret

metadata:

name: service account name

annotations:

kubernetes.io/service-account.name: service account name

type: kubernetes.io/service-account-token
```

- If you create the service account under your own namespace:

```
apiVersion: v1

kind: Secret

metadata:

name: service account name

namespace: mynamespace

annotations:

kubernetes.io/service-account.name: service account name
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
type: kubernetes.io/service-account-token
```

8. Apply the YAML.

```
.\oc.exe apply -f <yamlFile.yaml>
```

NOTE:

The `oc` describes the secret to get the token. The token is used as a password.

Create roles and role bindings for the service account

With the cluster-wide role binding, the service account has permissions to read all VM events across the cluster, allowing the OpenShift plug-in to maintain a single event watcher for all VM-related events. With the namespace role binding the service account has permissions to manage VMs in the target namespace. You can use a script to create roles and bind them to a service account. See `<https://github.com/citrix/citrix-mcs-sdk-samples/tree/main/OpenShift/Hosting%20Connection/Role/>`.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine that will deliver apps or a desktop to your users.
- For creating and managing a connection, see Connection to Red Hat OpenShift

More information

- Create and manage connections and resources
- Create machine catalogs

VMware virtualization environments

Follow this guidance if you use VMware to provide virtual machines.

Install vCenter Server and the appropriate management tools. (No support is provided for vSphere vCenter Linked Mode operation.)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

No support is provided for vSphere vCenter Linked Mode operation.

If you plan to use Machine Creation Services™ (MCS), do not disable the Datastore Browser feature in vCenter Server. If you disable this feature, MCS does not work correctly.

To set up your VMware virtualization environments, see Add a resource type or activate an unused domain in Citrix Cloud.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to VMware.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

VMware cloud and partner solutions

Citrix DaaS (formerly Citrix Virtual Apps and Desktops™ service) supports the following VMware cloud and partner solutions:

- Azure VMware Solution (AVS)
- Google Cloud VMware Engine
- VMware Cloud on Amazon Web Services (AWS)

Use Citrix DaaS™ to migrate VMware based on-premises Citrix workloads to the respective VMware partner solutions.

Azure VMware Solution (AVS) integration

Citrix DaaS supports AVS. AVS provides cloud infrastructure containing vSphere clusters created by Azure infrastructure. Leverage DaaS to use AVS for provisioning your VDA workload in the same way that you would using vSphere in on-premises environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Set up the AVS cluster

To enable Citrix DaaS to use AVS, do the following steps in Azure:

- Request a host quota
- Register the `Microsoft.AVS` resource provider
- Verify networking planning checklist
- Network Checklist
- Create an AVS private cloud
- Access the AVS private cloud
- Configure networking for your VMware private cloud in Azure
- Configure DHCP for AVS
- Add a network segment in AVS
- Verify the AVS environment

REQUEST HOST QUOTA FOR AZURE ENTERPRISE AGREEMENT CUSTOMERS

In the Azure portal's **Help + Support** page select **New support request**, and include the following information:

- Issue type: Technical
- Subscription: Select your subscription
- Service:**All services > Azure VMware Solution**
- Resource: General question
- Summary: Need capacity
- Problem type: Capacity Management Issues
- Problem subtype: Customer Request for Additional Host Quota/Capacity

In the **Description** of the support ticket, include the following information in the **Details** tab:

- POC or Production
- Region Name
- Number of hosts
- Any other details

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

AVS requires a minimum of three hosts, and recommends that you use redundancy of N+1 hosts.

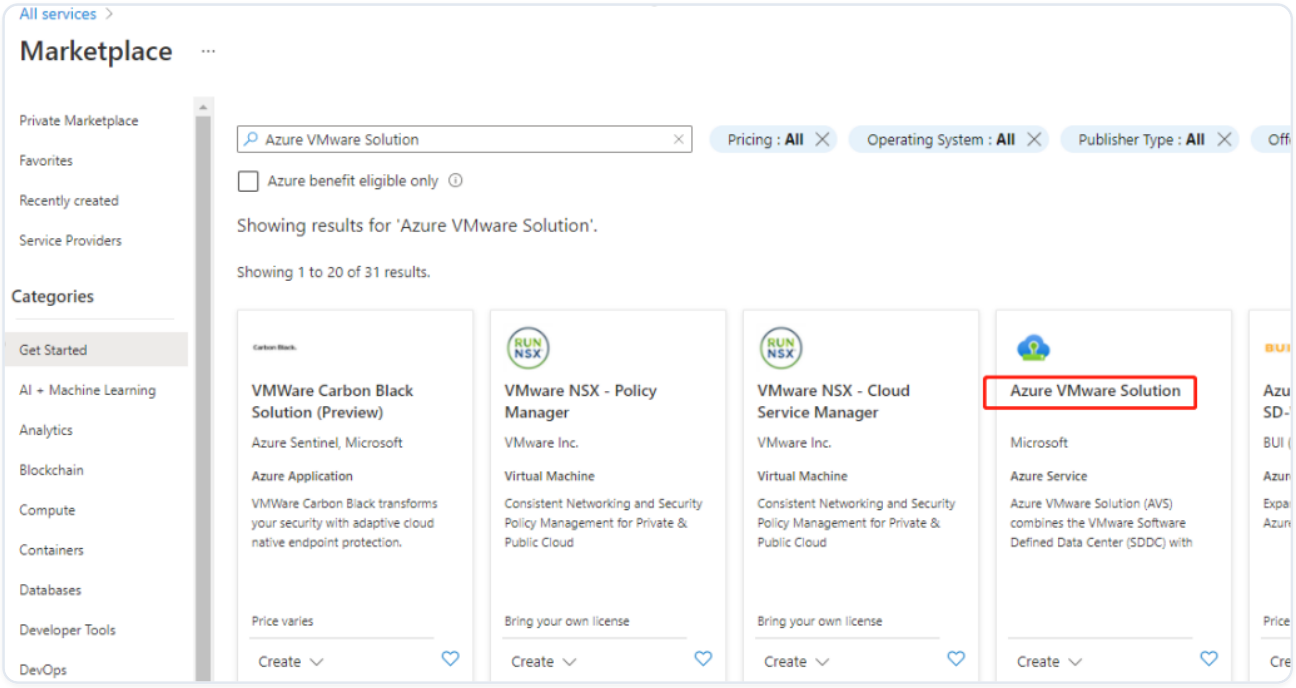
After specifying details for the support ticket, select **Review + Create** to submit the request to Azure.

REGISTER THE MICROSOFT.AVS RESOURCE PROVIDER

After requesting the host quota, register the resource provider:

1. Sign in to the Azure portal.
2. On the Azure portal menu, select **All services**.
3. In the **All services** menu, enter the subscription, and select **Subscriptions**.
4. Select the subscription from the subscription list.
5. Select **Resource providers** and enter **Microsoft.AVS** in the search bar.
6. If the resource provider is not registered, select **Register**.

NETWORKING CONSIDERATIONS



AVS offers networking services requiring specific network address ranges and firewall ports. See Networking planning checklist for Azure VMware Solution for more information.

CREATE AN AVS PRIVATE CLOUD

After considering network requirements for your environment, create an ASV private cloud:

1. Sign in to the Azure portal.
2. Select **Create a new resource**.
3. In the **Search the Marketplace** text box type, *Azure VMware Solution*, and select **Azure VMware Solution** from the list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In the **Azure VMware Solution** window:

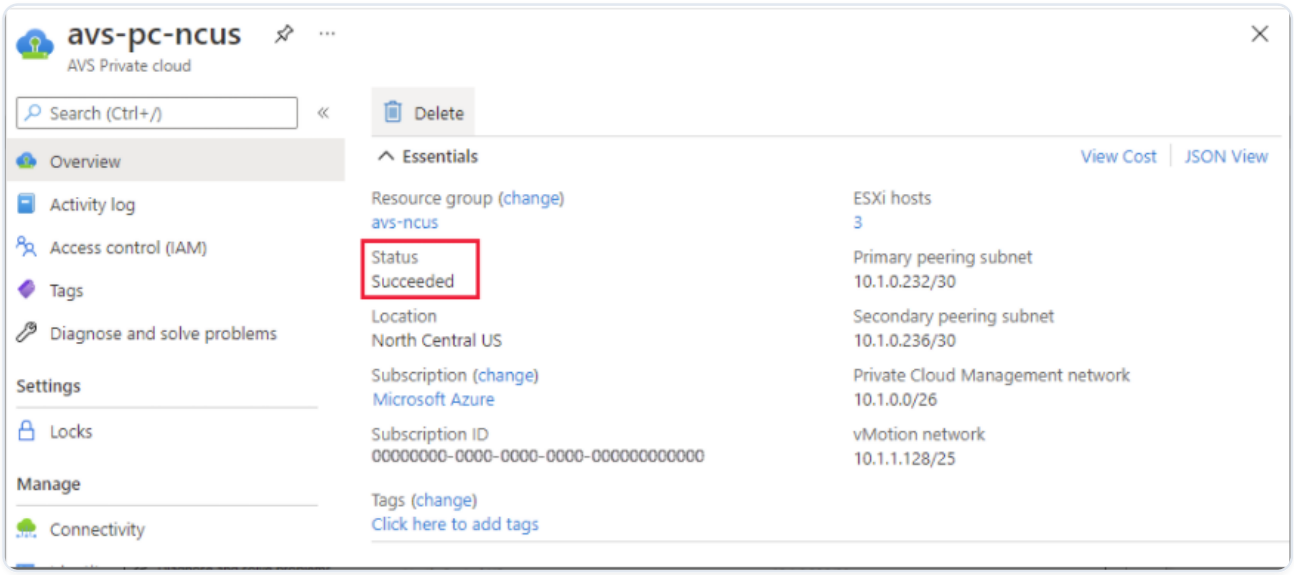
1. Select **Create**.
2. Go to the **Basics** tab.
3. Enter the values for the fields, using the information in the table below:

FIELD	VALUE
Subscription	Select the subscription that you plan to use for the deployment. All resources in an Azure subscription are billed together.
Resource group	Select the resource group for your private cloud. An Azure resource group is a logical container into which Azure resources are deployed and managed. Alternatively, you can create a new resource group for your private cloud.
Location	Select a location, such as east us. This is the region you defined during the planning phase.
Resource name	Provide the name of your Azure VMware Solution private cloud.
Size of host	Select the size as per your need.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

FIELD	VALUE
Number of hosts	Shows the number of hosts allocated for the private cloud cluster. The default value is 3, which can be raised or lowered after deployment.
Address block for private cloud	Provide an IP address block for the private cloud. The CIDR represents the private cloud management network and will be used for the cluster management services, such as vCenter Server and NSX-T Manager. Use /22 address space, for example, 10.175.0.0/22. The address should be unique and not overlap with other Azure Virtual Networks and with on-premises networks.

In the **Create a private cloud** screen:



1. In the **Location** field, select the region that has the AVS. The resource group region is the same as the AVS region.
2. In the **Size of host** field, select a size as per your need.
3. Specify an IP address in the **Address Block for private cloud** field. For example, 10.15.0.0/22.
4. Select **Review + Create**.
5. After reviewing the information, click **Create**.

TIP:

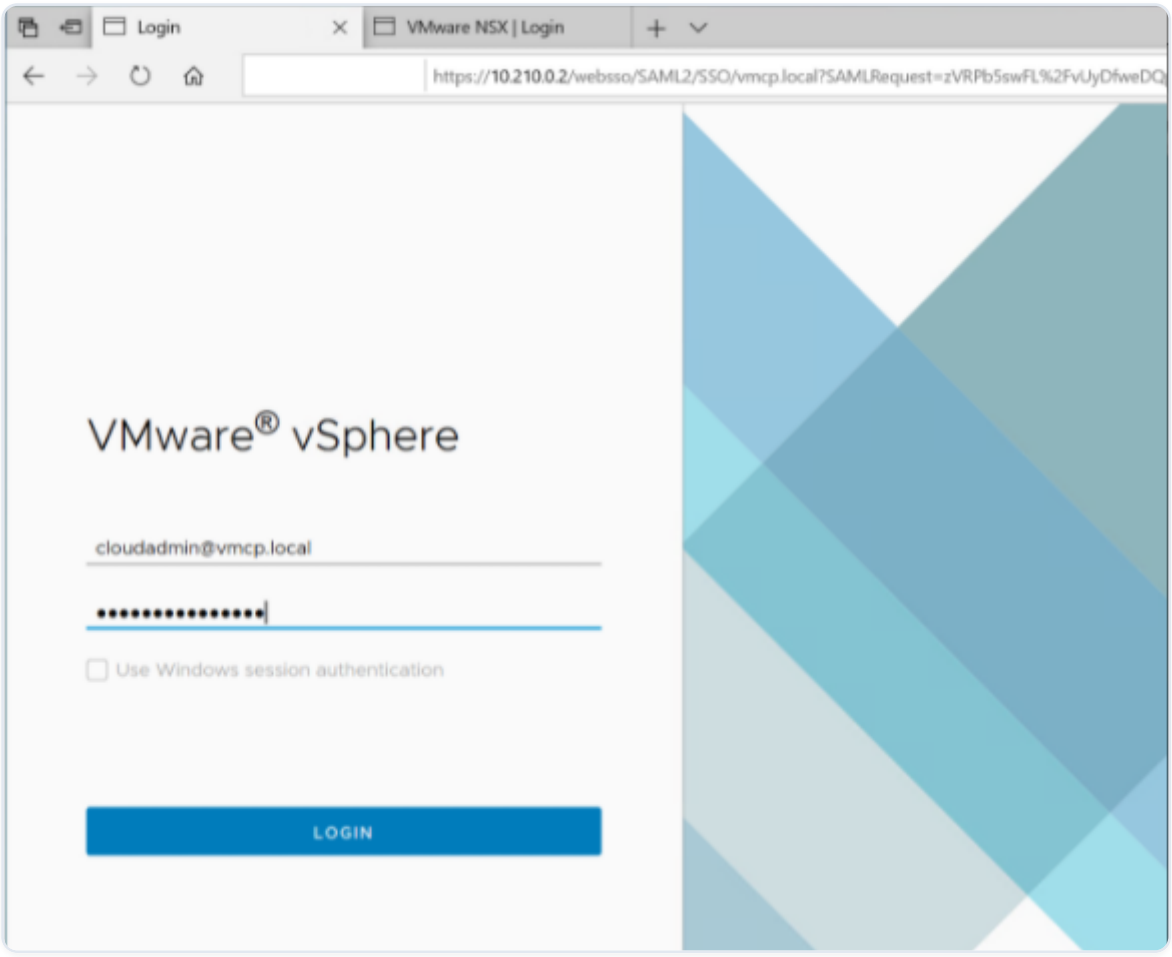
Creating a private cloud can take 3–4 hours. Adding a single host to the cluster can take 30–45 minutes.

Verify that the deployment was successful. Navigate to the resource group that you created and select your private cloud. Once the **Status** is **Succeeded** the deployment is complete.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ACCESS THE AVS PRIVATE CLOUD

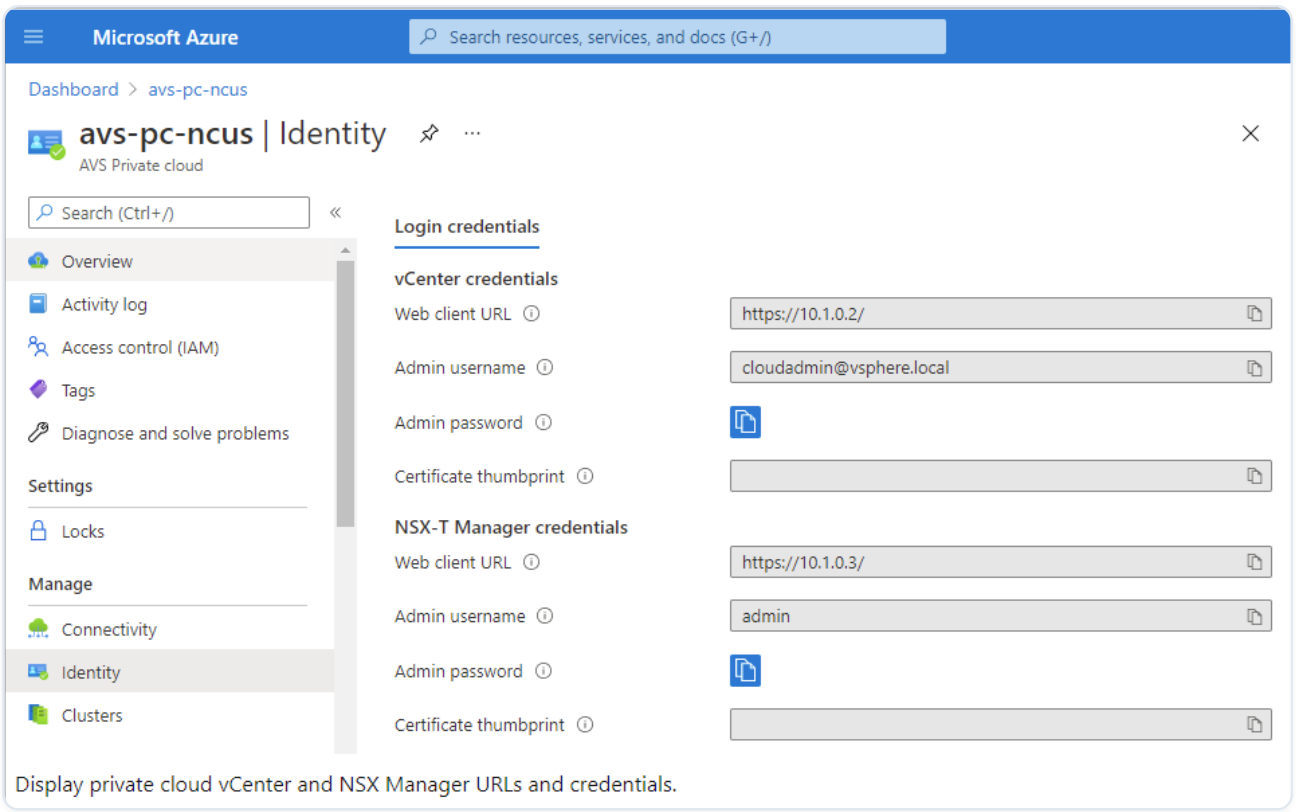
Once you have created a private cloud, create a Windows VM and connect to the local vCenter of your private cloud.



Create a new Windows virtual machine

1. In the resource group, select **+ Add** then search and select **Microsoft Windows 10/11 or Windows Server 2016/2019**.
2. Enter the required information, then select **Review + Create**.
3. Once validation passes, select **Create** to start the virtual machine creation process.

Connect to the local vCenter of your private cloud



1. Sign in to **vSphere Client with VMware vCenter SSO** as a cloud administrator.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. In the Azure portal, select your private cloud, and then **Manage> Identity**.

The URLs and user credentials for private cloud vCenter and NSX-T Manager appear:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

After confirming URLs and user credentials:

1. Navigate to the VM that you created in the preceding step and connect to the virtual machine.
2. In the Windows VM, open a browser and navigate to the vCenter and NSX-T Manager URLs in two browser tabs. In the vCenter tab, enter the mailto:cloudadmin@vmcp.local user credentials from the previous step.

CONFIGURE NETWORKING FOR YOUR VMWARE PRIVATE CLOUD IN AZURE

After accessing an ASV private cloud, configure networking by creating a virtual network and gateway.

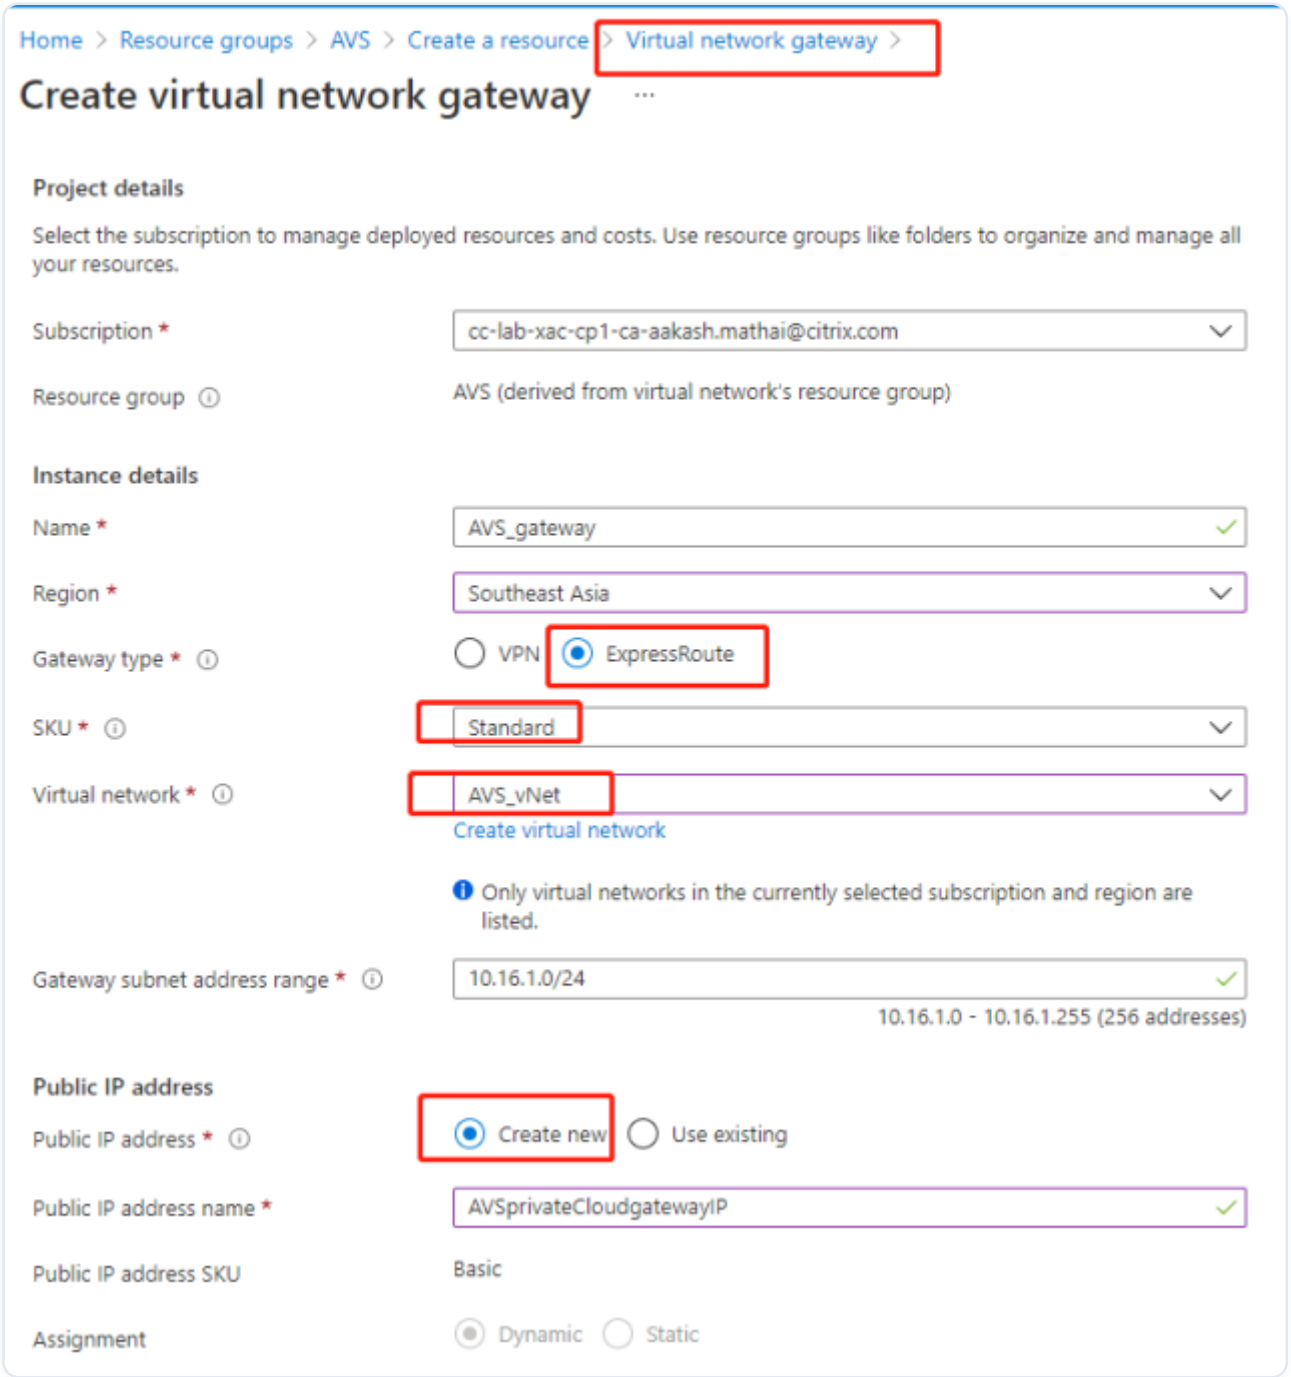
Create a virtual network

1. Sign in to the Azure portal.
2. Navigate to the previously created resource group.
3. Select **+ Add** to define a new resource.
4. In the **Search the Marketplace** text box, type *virtual network*. Find the virtual network resource and select it.
5. On the **Virtual Network** page, select **Create** to set up the virtual network for your private cloud.
6. On the **Create Virtual Network** page, enter the details for your virtual network.
7. On the **Basics** tab, enter a name for the virtual network, select the appropriate region, and click **Next : IP Addresses.**
8. On the **IP Addresses** tab, under IPv4 address space, enter the previously created address.

IMPORTANT:

Use an address that does not overlap with the address space you used when you created your private cloud.

After entering the address space:



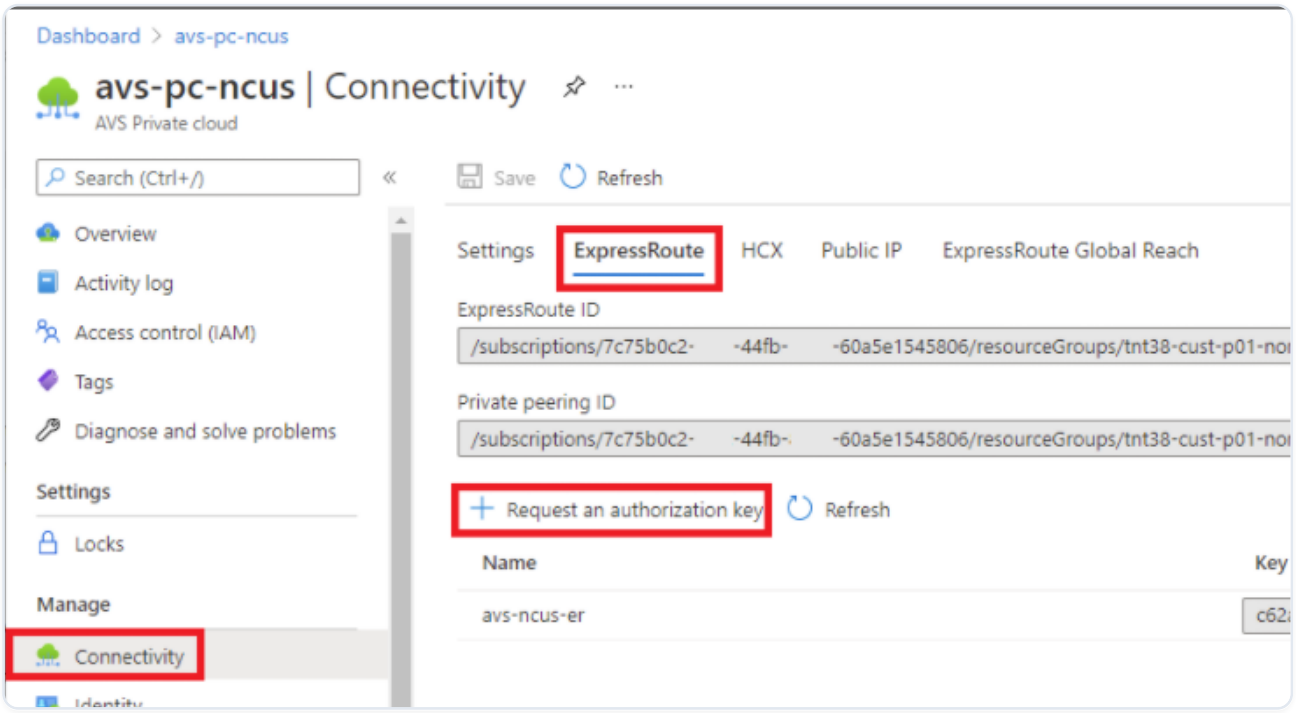
1. Select **+ Add subnet**.
2. On the **Add subnet** page, give the subnet a name and appropriate address range.
3. Click **Add.**
4. Select **Review + create**.
5. Verify the information and click **Create**. Once the deployment is complete, the virtual network appears in the resource group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a virtual network gateway

After creating a virtual network, create a virtual network gateway.

1. In your resource group, select **+ Add** to add a new resource.
2. In the **Search the Marketplace** text box, type *virtual network gateway*. Find the virtual network resource and select it.
3. On the **Virtual Network gateway** page, click **Create**.
4. On the **Basics** tab in the **Create virtual network gateway** page, provide values for the fields.
5. Click **Review + create**.

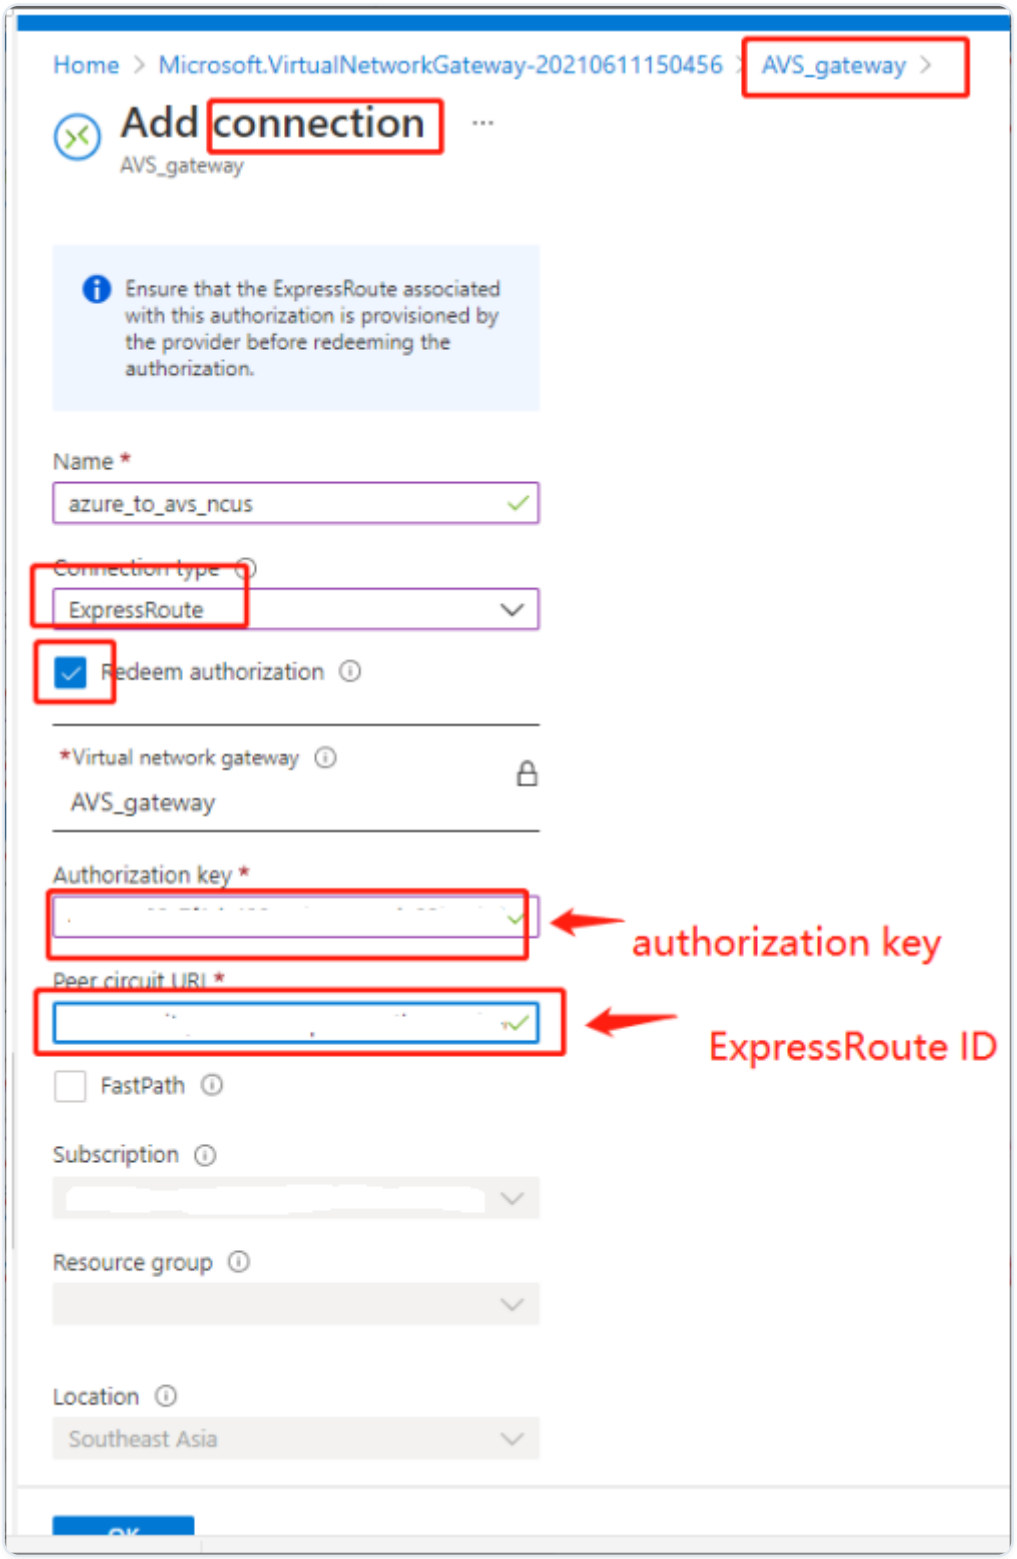


© 1997–2026 Citrix Systems, Inc. All rights reserved.

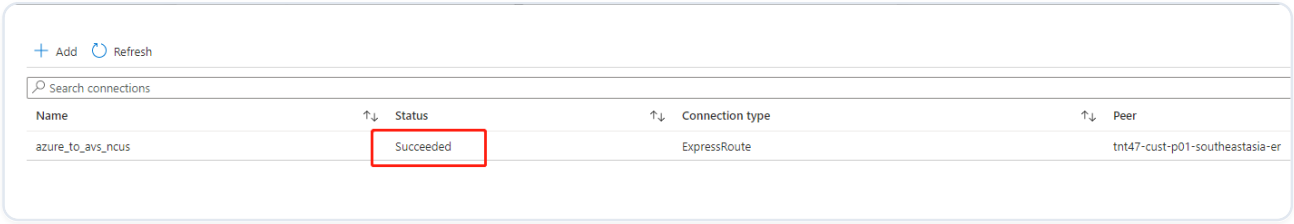
After reviewing the virtual network gateway configuration, click **Create** to deploy your virtual network gateway. Once the deployment completes, connect your **ExpressRoute** connection to the virtual network gateway containing your Azure AVS private cloud.

CONNECT EXPRESSROUTE TO THE VIRTUAL NETWORK GATEWAY

After deploying a virtual network gateway, add a connection between it and your Azure AVS private cloud:



1. Request an ExpressRoute authorization key.
2. In the Azure portal, navigate to the **Azure VMware Solution private cloud**. Select **Manage> Connectivity > ExpressRoute** and then select **+ Request an authorization key.**



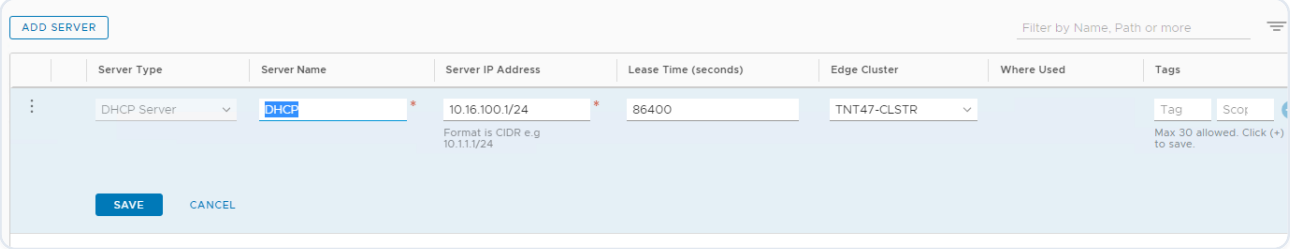
After requesting an authorization key:

1. Enter a name for the key and click **Create**. It may take about 30 seconds to create the key. Once created, the new key appears in the list of authorization keys for the private cloud.
2. Copy the **authorization key** and **ExpressRoute ID**. You'll need them to complete the peering process. The authorization key disappears after some time, so copy it when it appears.
3. Navigate to the **virtual network gateway** you plan to use and select **Connections> + Add**.
4. On the **Add connection** page, provide values for the fields, and select **OK.**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The connection is established between your ExpressRoute circuit and your virtual network:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

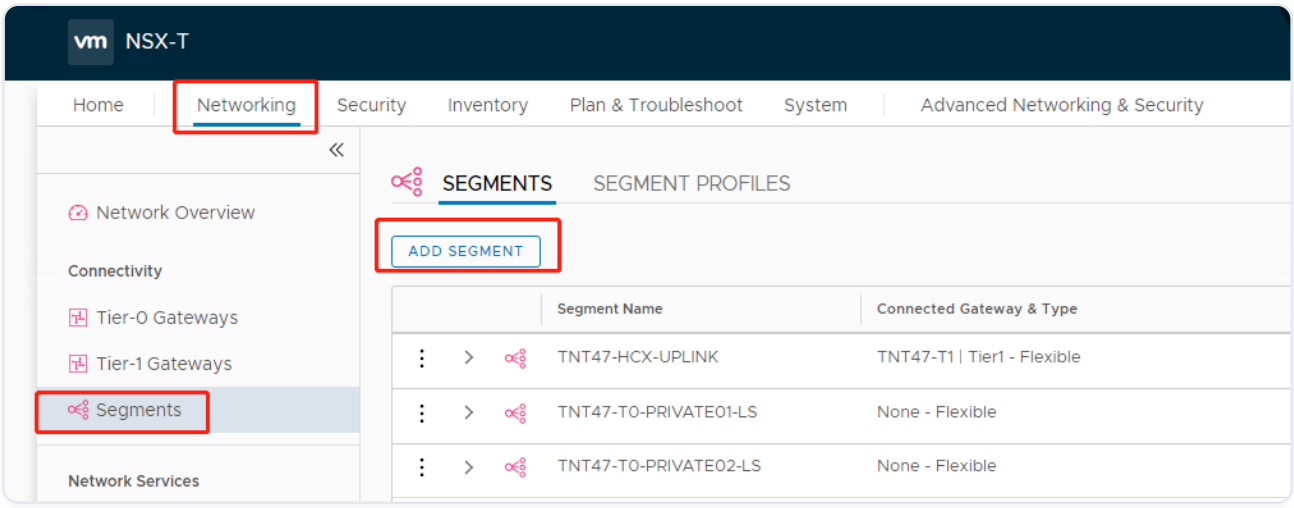


CONFIGURE DHCP FOR AZURE VMWARE SOLUTION

After connecting ExpressRoute to the virtual gateway, configure DHCP.

Use NSX-T to host your DHCP server

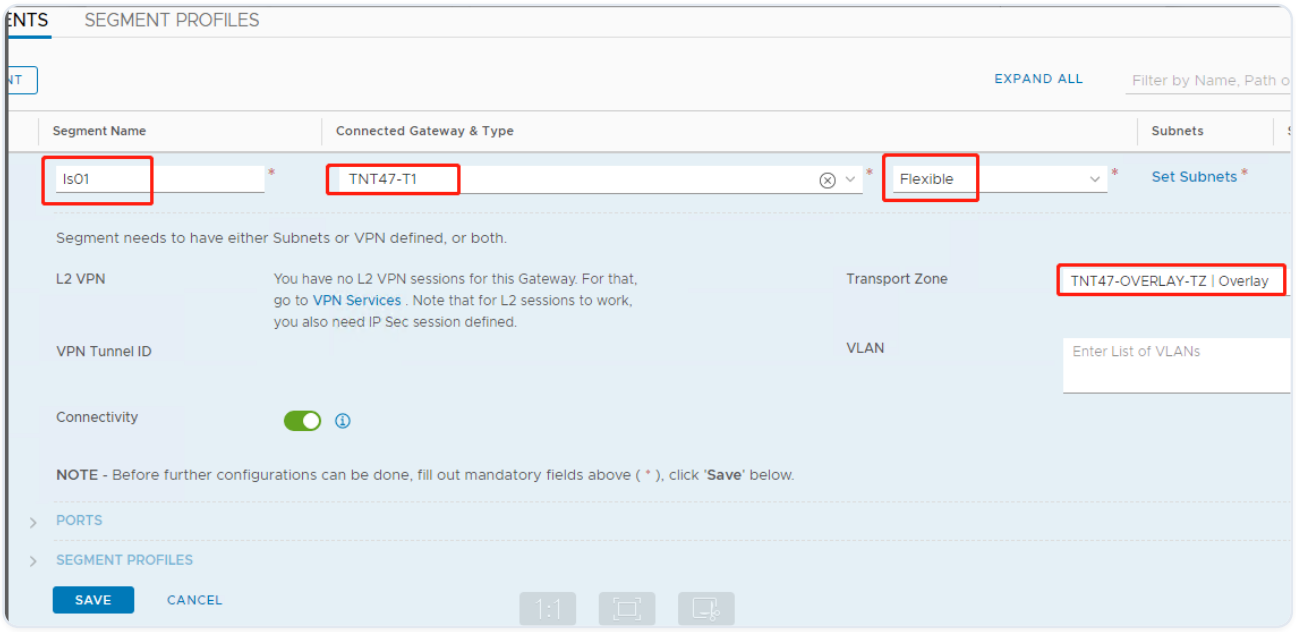
In NSX-T Manager:



1. Select **Networking> DHCP**, and then select **Add Server**.
2. Select **DHCP** for the **Server Type**, provide the server name and IP address.
3. Click **Save**.
4. Select **Tier 1 Gateways**, select the vertical ellipsis on the Tier-1 gateway, and then select **Edit**.
5. Select **No IP Allocation Set** to add a subnet.
6. Select **DHCP Local Server** for the **Type**.
7. For the **DHCP Server**, select **Default DHCP**, and then click **Save**.
8. Click **Save** again and then select **Close Editing**.

ADD A NETWORK SEGMENT IN THE AZURE VMWARE SOLUTION

After setting up DHCP, add a network segment.



To add a network segment, in NSX-T Manager, select **Networking> Segments**, and then click **Add Segment**.

In the **Segments profile** screen:

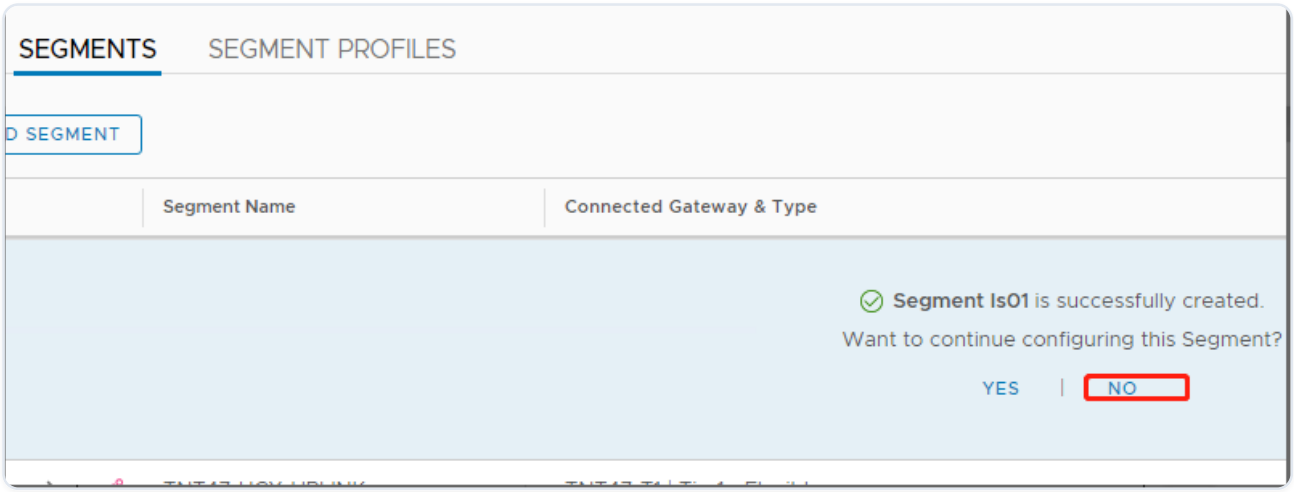
© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Enter a **name** for the segment.
2. Select the **Tier-1 Gateway (TNTxx-T1)** as the **Connected Gateway** and leave the **Type** as **Flexible**.
3. Select the pre-configured overlay **Transport Zone(TNTxx-OVERLAY-TZ)**.
4. Click **Set Subnets**.

In the **Subnets** section:

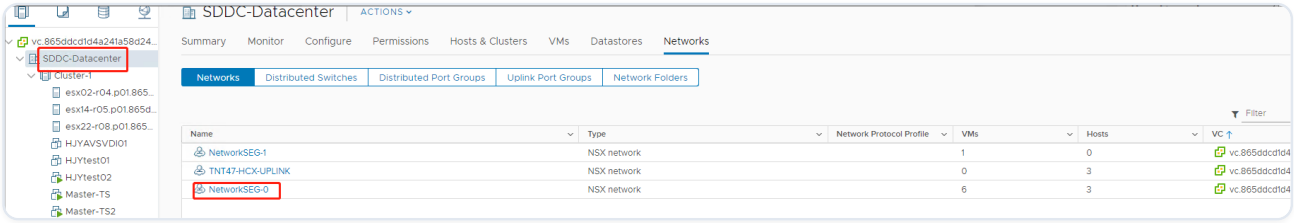
1. Enter the gateway IP address.
2. Select **Add**.

IMPORTANT:



This segment IP address must belong to the Azure gateway IP address, 10.15.0.0/22.

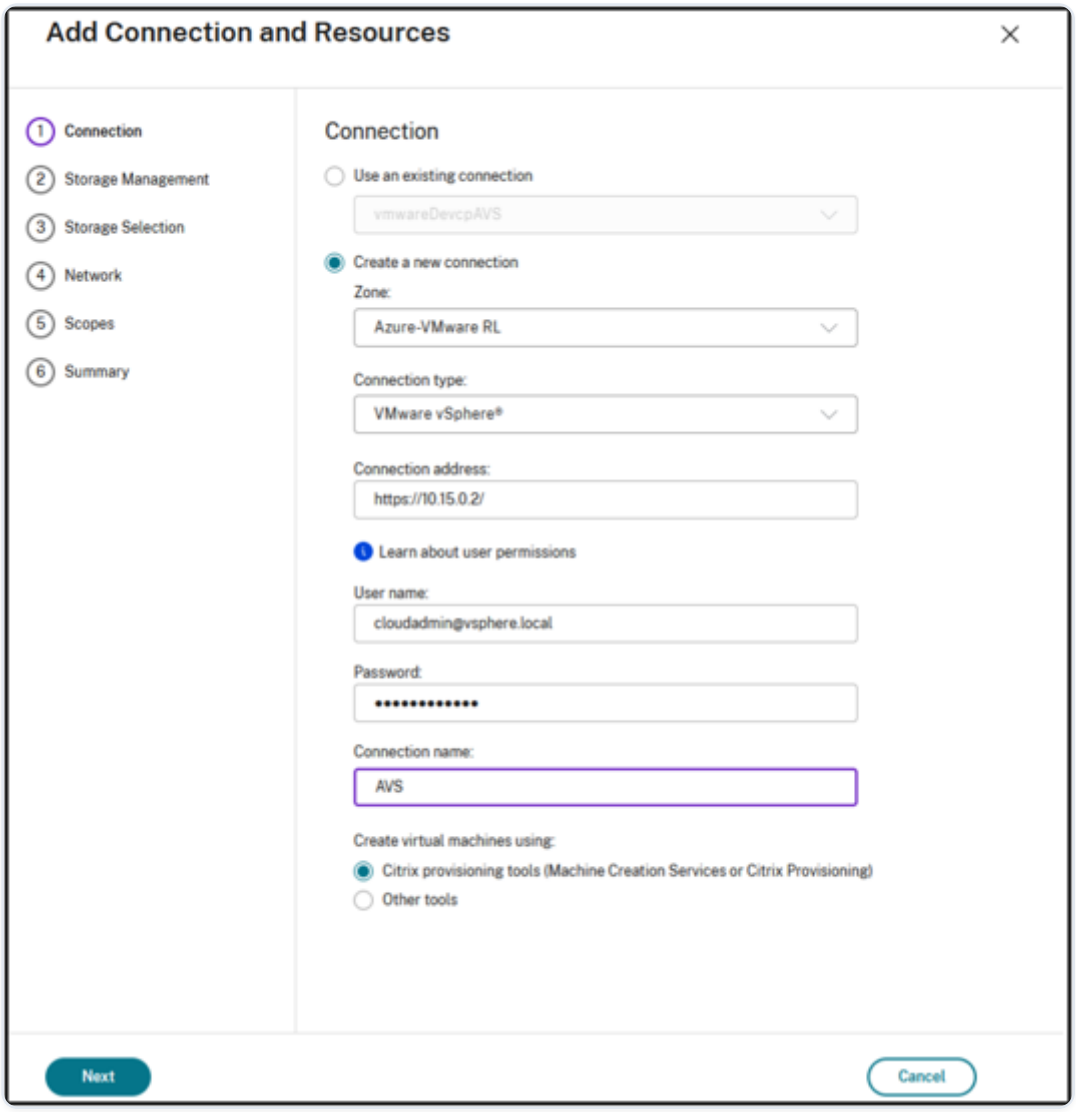
DHCP range must belong to segment IP address:



Select **No** to decline the option to continue configuring the segment:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In vCenter, select **Networking > SDDC-Datacenter**:



VERIFY THE AVS ENVIRONMENT

Set up resource location for the AVS private cloud and install a pair of cloud connectors.

CREATE THE AVS CONNECTION IN CITRIX STUDIO

1. Create a machine in vCenter and install a pair of Cloud Connectors in the machine. See Configure the instances.
2. From Studio, select Hosting in the left pane.
3. Select the hosting node, and click **Add Connection and Resources**.
4. On the **Connection** screen, select **Create a new Connection**, and the following details:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Select **Connection type** as **VMware vSphere**.

b. In the **Connection address**, enter the vCenter private IP address.

c. Enter the vCenter credentials.

d. Enter a connection name.

e. Choose the tool to create virtual machines.

5. On the **Network** screen, select the subnet created in the NSX-T server.

6. Complete the wizard.

Google Cloud VMware Engine

Citrix DaaS lets you migrate VMware-based on-premises Citrix workloads to Google Cloud VMware Engine.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure Google Cloud VMware Engine

The following procedure describes how to acquire and set up cluster on Google Cloud VMware Engine.

ACCESS THE VMWARE ENGINE PORTAL

1. In the **Google Cloud Console**, click the navigation menu.
2. In the **Compute** section, click **VMware Engine** to open VMware Engine in a new browser tab.

REQUIREMENTS TO CREATE FIRST PRIVATE CLOUD

You must have access to Google Cloud VMware Engine, available VMware Engine node quota, and an appropriate IAM role. Set up the following requirements before you continue to create your private cloud:

1. Request API access and node quota. For more information, see Requesting API access and quota.
2. Note the address ranges you want to use for VMware management appliances and the HCX deployment network. For more information, see Networking requirements.

   NOTE:

   The HCX deployment is only applicable to IP Plan version 1.0.

3. Get the VMware Engine Service Admin IAM role.

CREATE YOUR FIRST PRIVATE CLOUD

1. Access the VMware Engine portal.
2. On the VMware Engine Home page, click **Create a private cloud**. The hosting location and hardware node types are listed.
3. Select the number of nodes for the private cloud. At least three nodes are required.
4. Enter a Classless Inter-Domain Routing (CIDR) range for the VMware management network.
5. Enter a CIDR range for the HCX deployment network.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT:

- The CIDR range must not overlap with any of your on-premises or cloud subnets. The CIDR range must be /27 or higher.
- The HCX deployment is only applicable to IP Plan version 1.0.

6. Select **Review and create**.
7. Review the settings. To change any settings, click **Back**.
8. Click **Create** to begin creating the private cloud.

As VMware Engine creates your new private cloud, it deploys several VMware components and sets up initial Autoscale™ policies for clusters in the private cloud. Private cloud creation can take 30 minutes to 2 hours. After the provisioning is complete, you receive an email.

SET UP GOOGLE CLOUD VMWARE ENGINE VPN GATEWAY

To establish an initial connectivity to Google Cloud VMware Engine, you can use a VPN gateway. This is an OpenVPN-based client VPN using which you can connect to your VMware Software Defined Data Center (SDDC) vCenter and do any initial configuration required.

Before deploying a VPN gateway, configure the **Edge Services** range for the region where your SDDC is deployed. To do this:

1. Log on to the **Google Cloud VMware Engine** portal, and go to **Network > Regional Settings**. Click **Add Region**.
2. Choose the region where your SDDC is deployed and enable **Internet Access** and **Public IP Service**.
3. Supply the Edge Services range noted during planning and click **Submit**. Enabling these services take 10–15 minutes.

   Once complete, the Edge Services show as **Enabled** on the Regional Settings page. Enabling these settings allow Public IPs to be allocated to your SDDC, which is a requirement for deploying a VPN gateway.

Deploy a VPN gateway

1. In the **Google Cloud VMware Engine** portal, go to **Network > VPN Gateways**. Click **Create New VPN Gateway**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Supply the name for the VPN gateway and the client subnet reserved during planning. The location of the VPN must be the same as the private cloud region. Click **Next**.
3. Select users to grant VPN access. Click **Next**.
4. Specify the networks that must be accessible over VPN. Click **Next**.
5. A summary screen is displayed. Verify the selections, and click **Submit** to create the VPN Gateway. The VPN Gateways page is displayed with the status of the new VPN gateway as **Creating**.
6. After the status changes to **Operational**, click the new VPN gateway.
7. Click **Download my VPN configuration** to download a ZIP file containing pre-configured OpenVPN profiles for the VPN gateway. Profiles for connecting through UDP/1194 and TCP/443 are available. Choose your preference and import it into Open VPN, and then connect.
8. Go to **Resources** and select your SDDC.

CONNECT THE VPN

1. Establish a point-to-site connection between your on-premises network and the private cloud through the VPN Gateway setup. See Set up Google Cloud VMware Engine VPN Gateway.
2. Upload the VPN configuration downloaded in Set up Google Cloud VMware Engine VPN Gateway.
3. Import to your VPN client, for example, OpenVPN Connect.

For more information, see Connecting using VPN.

CREATE FIRST SUBNET

Access NSX-T Manager from the VMware Engine portal
The process of creating a subnet happens in NSX-T, which you access through VMware Engine. Do the following to access NSX-T Manager.

1. Log on to the **Google Cloud VMware Engine** portal.
2. From the main navigation, go to **Resources**.
3. Click the **Private cloud name** corresponding to the private cloud where you want to create the subnet.
4. On the details page of your private cloud, click the **vSphere Management Network** tab.
5. Click the **FQDN** corresponding to the NSX-T Manager.
6. When prompted, enter your sign-in credentials. If you have set up vIDM and connected it to an identity source, such as Active Directory, use your identity source credentials instead.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

REMINDER:

You can retrieve generated credentials from the private cloud details page.

Set up DHCP service for the subnet

Before you can create a subnet, set up a DHCP service:

In NSX-T Manager:

1. Go to **Networking > DHCP**. The networking dashboard shows that the DHCP service creates one Tier-0 and one Tier-1 gateway.
2. To begin provisioning a DHCP server, click **Add Server**.
3. Select **DHCP** for the **Server Type**, provide the server name and IP address.
4. Click **Save** to create the DHCP service.

Do the following to attach this DHCP service to the relevant Tier-1 gateway. A default Tier-1 gateway is already provisioned by the DHCP service:

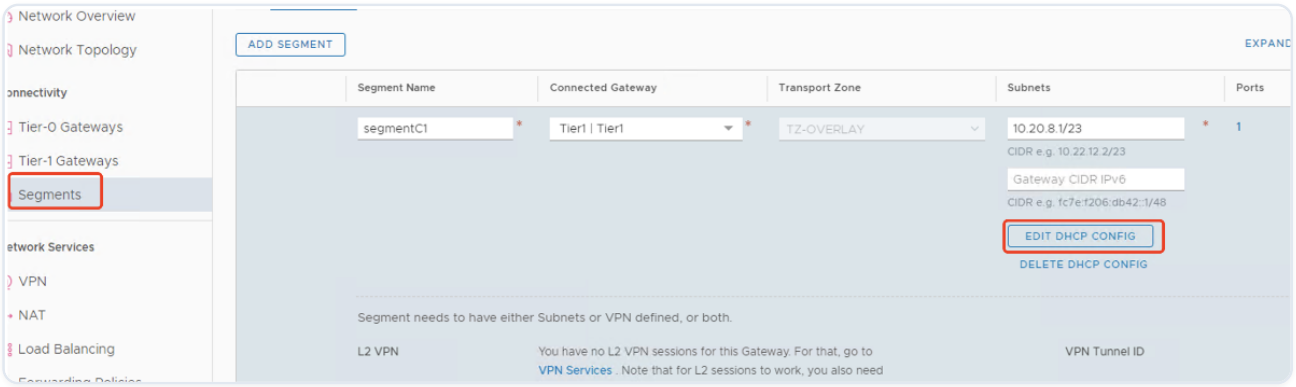
1. Select **Tier 1 Gateways**, select the vertical ellipsis on the Tier-1 gateway, and then select **Edit**.
2. In the **IP Address Management** field, select **No IP Allocation Set**.
3. Select **DHCP Local Server** for the **Type**.
4. Select the DHCP server that you created for the **DHCP Server**.
5. Click **Save**.
6. Click **Close Editing**.

You can now create a network segment in NSX-T. For more information about DHCP in NSX-T, see the VMware documentation for DHCP.

Create a network segment in NSX-T

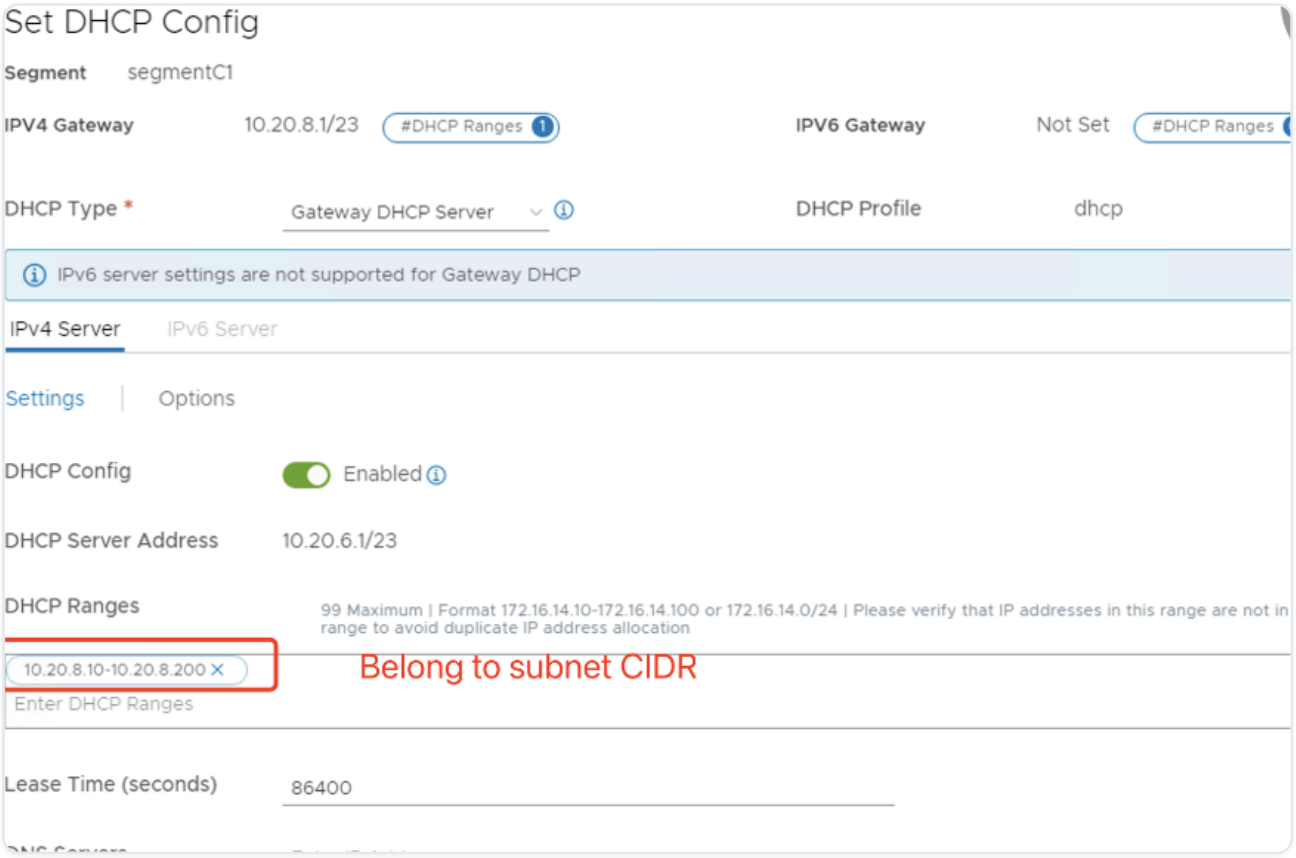
For workload VMs, you create subnets as NSX-T network segments for your private cloud:

1. In NSX-T Manager, go to **Networking > Segments**.
2. Click **Add Segment**.
3. Enter a name for the segment.
4. Select the **Tier-1** as the **Connected Gateway** and leave the Type as **Flexible**.
5. Click **Set Subnets**.
6. Click **Add Subnets**.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

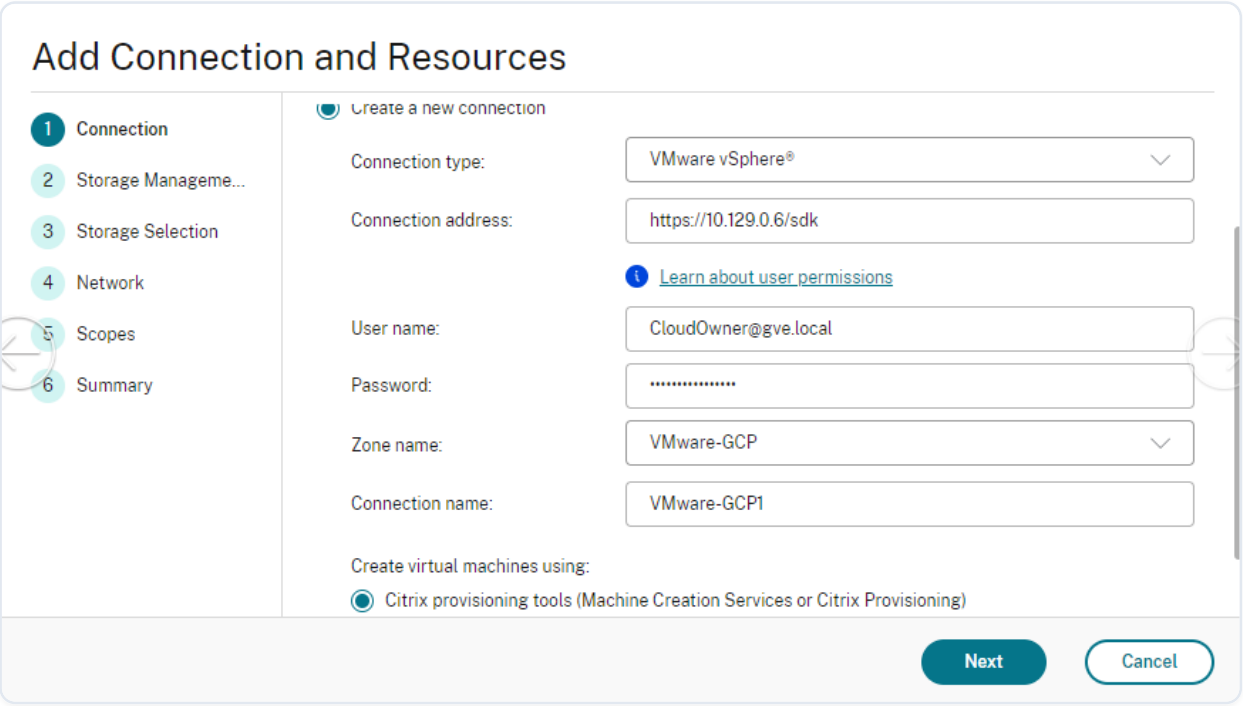
7. Enter the subnet range in the **Gateway IP/Prefix Length**. Specify the subnet range with **.1** as the last octet. For example, **10.12.2.1/24**.
8. Specify the DHCP Ranges and click **ADD**.
9. In **Transport Zone**, select **TZ-OVERLAY** from the drop-down list.
10. Click **Save**. You can now select this network segment in vCenter when creating a VM.



In a given region, you can set up at most 100 unique routes from VMware Engine to your VPC network using private services access. This includes, for example, private cloud management IP address ranges, NSX-T workload network segments, and HCX network IP address ranges. This limit includes all private clouds in the region.

NOTE:

There is a Google Cloud configuration issue because of which you need to configure DHCP range setting several times. Therefore, make sure to configure the DHCP range setting after Google Cloud configuration. Click **EDIT DHCP CONFIG** to configure the DHCP ranges.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE THE GOOGLE CLOUD VMWARE CONNECTION IN CITRIX STUDIO

1. Create a machine in vCenter and install a pair of Cloud Connectors in the machine. See Configure the instances.
2. Launch the Citrix Studio.
3. Select the hosting node, and click **Add Connection and Resources**.
4. On the **Connection** screen, select **Create a new Connection**, and the following details:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Select **Connection type** as **VMware vSphere**.

b. In the **Connection address**, enter the vCenter private IP address.

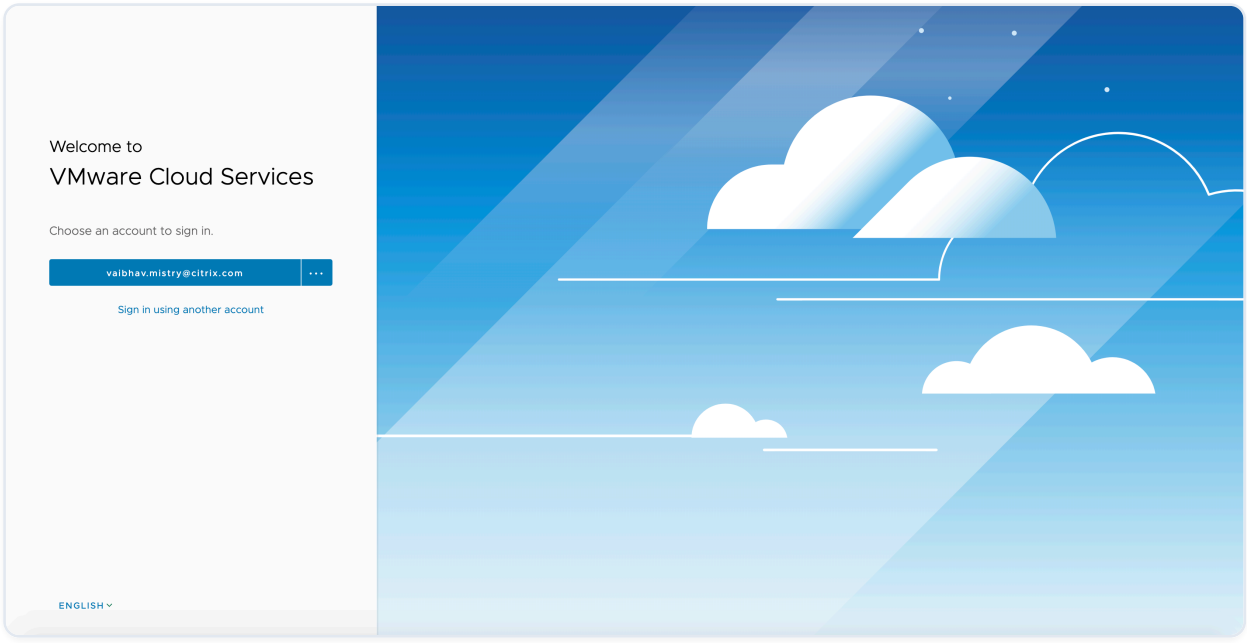
c. Enter the vCenter credentials.

d. Enter a connection name.

e. Choose the tool to create virtual machines.

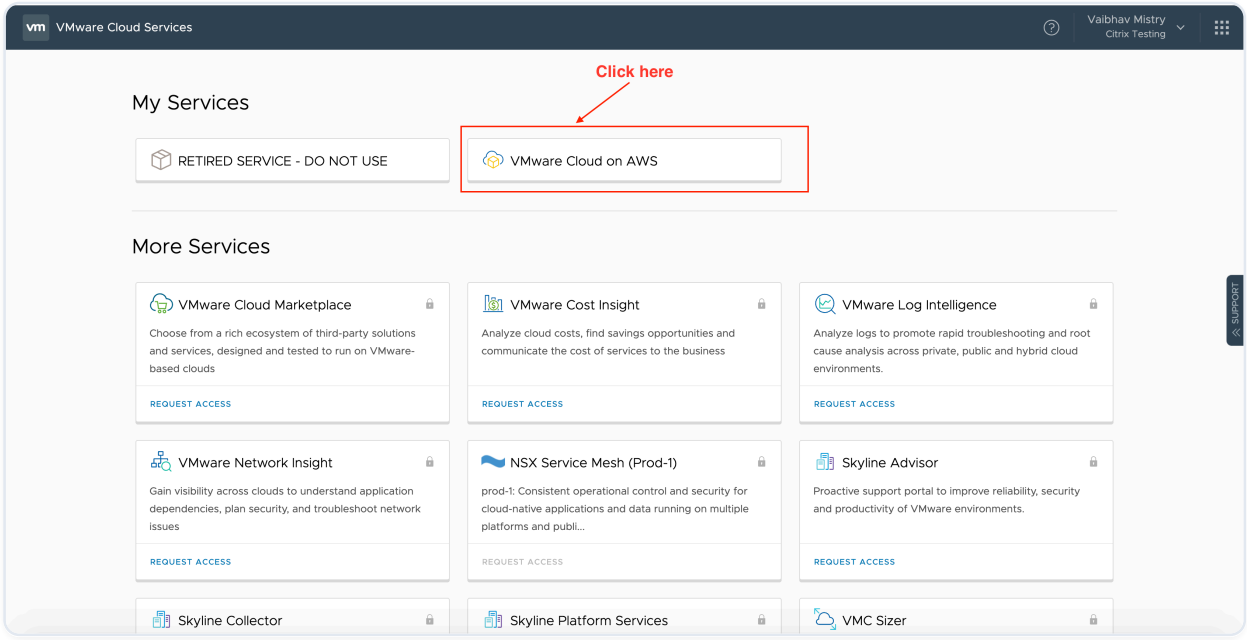
5. On the **Network** screen, select the subnet created in the NSX-T server.
6. Complete the wizard.

VMware cloud on Amazon Web Services (AWS)



VMware cloud on Amazon Web Services (AWS) enables you to migrate VMware based on-premises Citrix workloads to AWS Cloud and your core Citrix Virtual Apps and Desktops environment to Citrix DaaS.

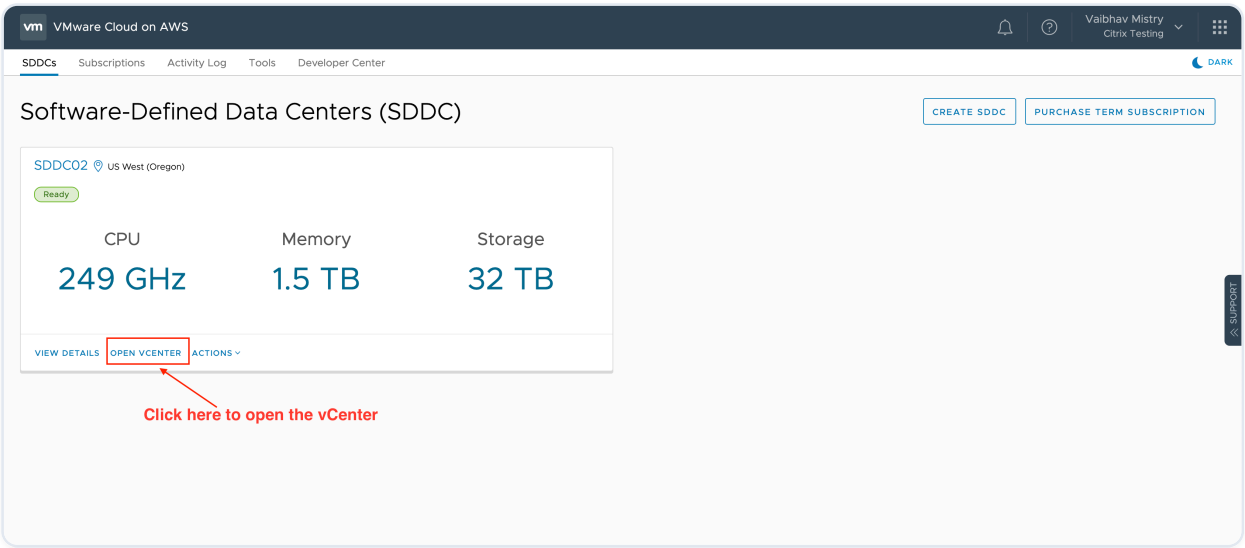
This article describes the procedure to set up a VMware cloud on AWS.

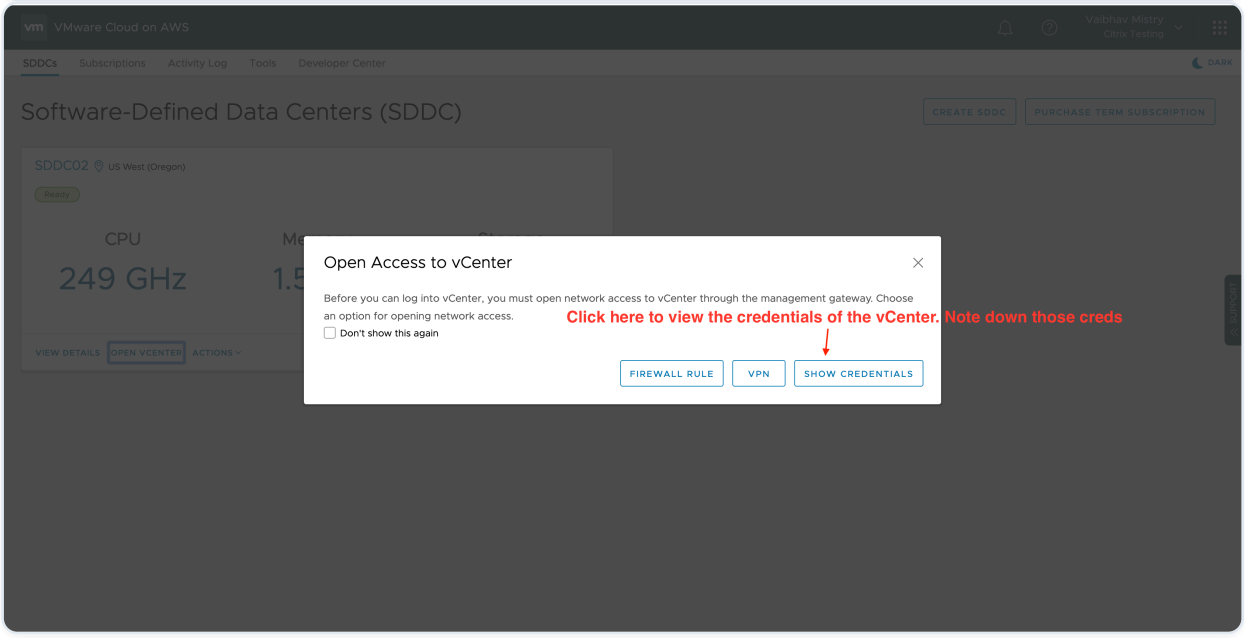


Access the VMware cloud environment

1. Log in to VMware cloud services using the URL `<https://console.cloud.vmware.com/>`.

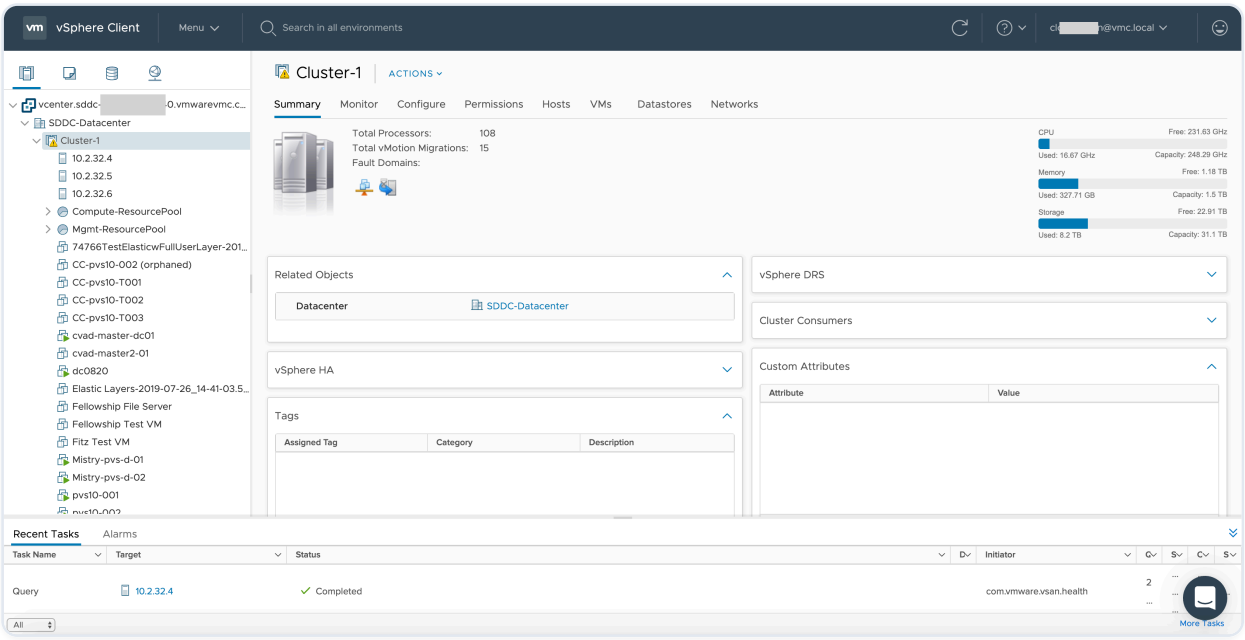
© 1997–2026 Citrix Systems, Inc. All rights reserved.





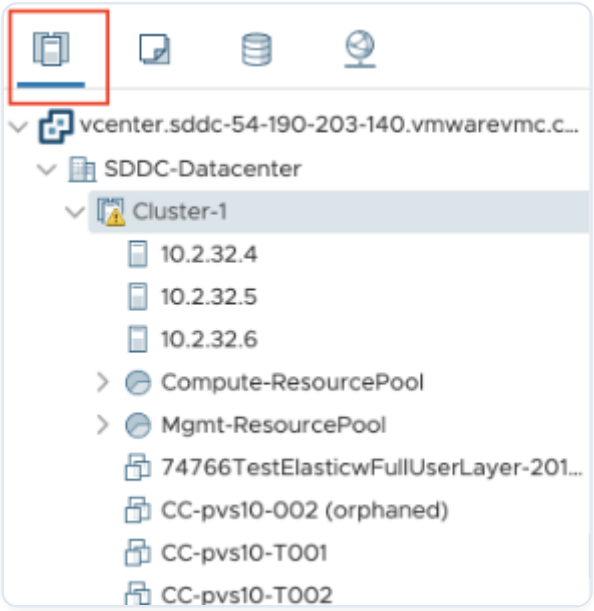
2. Click **VMware Cloud on AWS**. The page Software-Defined Data Centers (SDDC) appears.

3. Click **OPEN VCENTER**, and then click **SHOW CREDENTIALS**. Note the credentials for later use.



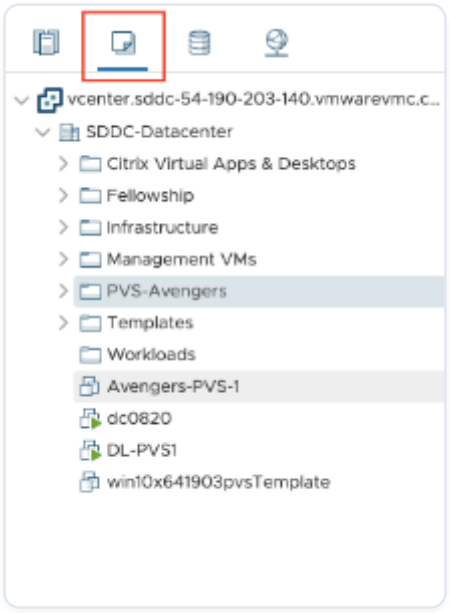
© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Open a Web browser and enter the URL for the vSphere Web Client.
5. Enter the credentials as noted and click **Login**. The vSphere client webpage is similar to the on-premises environment.



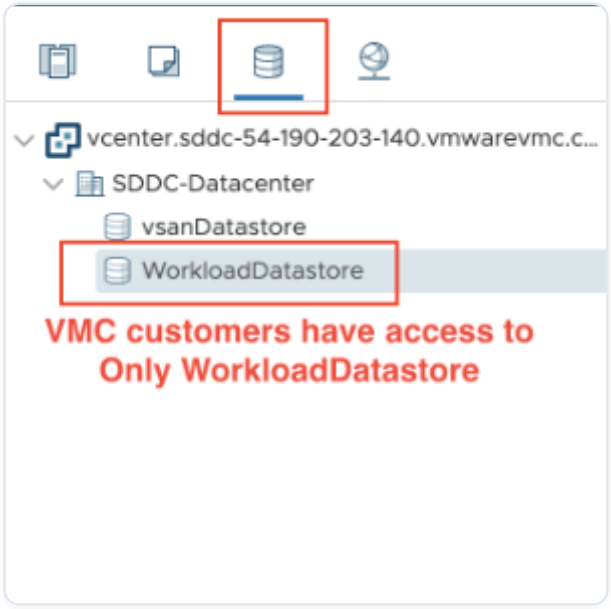
© 1997–2026 Citrix Systems, Inc. All rights reserved.

About VMware cloud environment



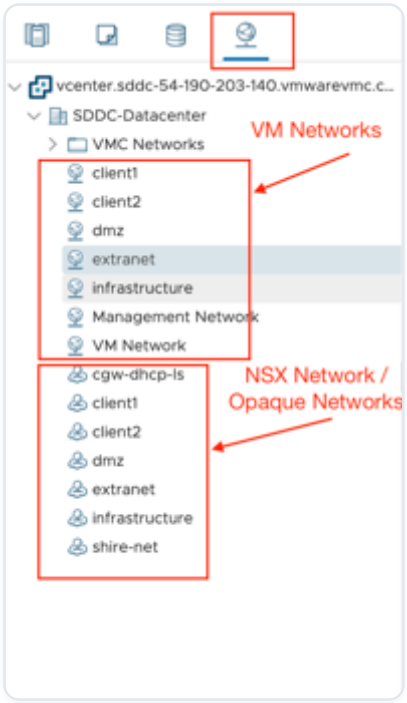
There are four views on the vSphere client webpage.

- Host and Cluster view: You cannot create a new Cluster, but the cloud admin can create multiple resource pools.



- VM and Template view: Cloud admin can create many folders.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- Storage View: Select **WorkloadDatastore** storage when you add hosting unit in the Citrix Studio because you have access to only Workload Datastore.

- Network View: The icons are different for VMware cloud networks and opaque networks.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

After you set up the cluster, refer to VMware virtualization environments for adding connections and resources.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing a connection, see Connection to VMware cloud and partner solutions.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

XenServer® virtualization environments

XenServer simplifies your operational management while ensuring a high definition user experience for intensive workloads.

To set up your XenServer, see Add a resource type.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- For a simple proof-of-concept deployment, install a VDA on a machine designated to deliver apps or a desktop to your users.
- For creating and managing connections, see Connection to XenServer.
- Review all the steps in the installation and configuration process.

More information

- Create and manage connections and resources
- Create machine catalogs

Size and scale considerations for Cloud Connectors

When evaluating Citrix DaaS for sizing and scalability, consider all the components. Research and test the configuration of Citrix Cloud™ Connectors and StoreFront for your specific requirements. Providing insufficient resources for sizing and scalability negatively affects the performance of your deployment.

NOTE:

- These recommendations apply to Citrix DaaS Standard for Azure in addition to Citrix DaaS.
- The tests and recommendations given in this article are guidelines to help you start your testing. We recommend that you perform the testing in your environment to validate the correct connector sizing.
- For sizing and scale considerations for HDX proxy, see Cloud Connector sizing and scale considerations for HDX proxy.

This article provides details of the tested maximum capacities and best practice recommendations for Cloud Connector machine configuration. Tests were performed on deployments configured with StoreFront™ and Local Host Cache (LHC).

The information provided applies to deployments in which each resource location contains both VDI workloads and RDS workloads.

The Cloud Connector links your workloads to Citrix DaaS™ in the following ways:

- Provides a proxy for communication between your VDAs and Citrix DaaS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Provides a proxy for communication between Citrix DaaS and your Active Directory (AD) and hypervisors.
- In deployments that include StoreFront servers, the Cloud Connector serves as a temporary session broker during cloud outages, providing users with continued access to resources.

It is important to have your Cloud Connectors properly sized and configured to meet your specific needs. While tests were run with two Cloud Connectors, only one Cloud Connector is available during Cloud Connector upgrades. To ensure high availability during Cloud Connector upgrades, some customers have opted to deploy three Cloud Connectors.

Each set of Cloud Connectors is assigned to a resource location (also known as a zone in Studio). A resource location is a logical separation that specifies which resources communicate with that set of Cloud Connectors. At least one resource location is required per domain to communicate with the Active Directory (AD).

Each machine catalog and hosting connection is assigned to a resource location.

For deployments with more than one resource location, assign machine catalogs and VDAs to the resource locations to optimize the ability of LHC to broker connections during outages. For more information on creating and managing resource locations, see Connect to Citrix Cloud. For optimum performance, configure your Cloud Connectors on low-latency connections to VDAs, AD servers, and hypervisors.

Recommended processors and storage

For performance similar to that seen in these tests, use modern processors that support SHA extensions. SHA extensions reduce the cryptographic load on the CPU. Recommended processors include:

- Advanced Micro Devices (AMD) Zen and newer processors
- Intel Ice Lake and newer processors

The recommended processors run efficiently. You can use older processors, however, it might lead to a higher CPU load. We recommend increasing your vCPU count to offset this behavior.

The tests described in this article were performed with AMD EPYC and Intel Cascade Lake processors.

Cloud Connectors have a heavy cryptographic load while communicating with the cloud. Cloud Connectors using processors with SHA extensions experience lower load on their CPU which is

© 1997–2026 Citrix Systems, Inc. All rights reserved.

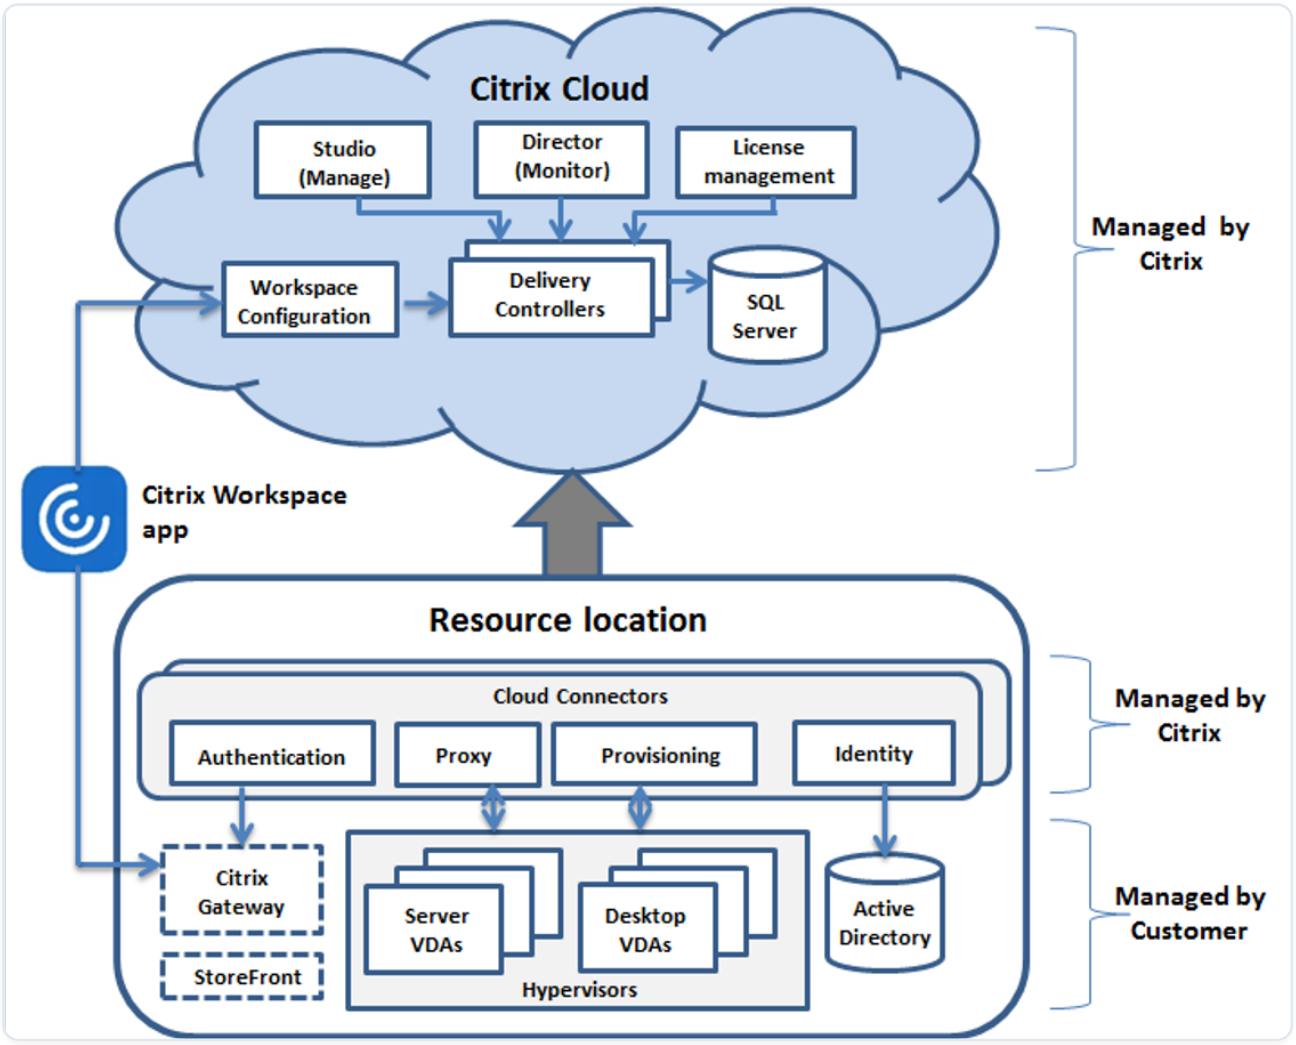
expressed by lower CPU usage by the Windows Local Security Authority Subsystem Service (LSASS).

Citrix recommends using modern storage with adequate I/O operations per second (IOPS), especially for deployments that use LHC. Solid state drives (SSDs) are suggested but premium cloud storage tiers are not needed. Higher IOPS are needed for LHC scenarios where the Cloud Connector runs a small copy of the database. This database is updated with site configuration changes regularly and provides brokering capabilities to the resource location in times of Citrix Cloud outages.

Recommended compute configuration for Local Host Cache

Local Host Cache (LHC) provides high availability by enabling connection brokering operations in a deployment to continue when a Cloud Connector cannot communicate with Citrix Cloud.

Cloud Connectors run Microsoft SQL Express Server LocalDB, which is automatically installed when you install the Cloud Connector. The CPU configuration of the Cloud Connector, especially the number of cores available to SQL Express Server LocalDB, directly affects LHC performance. The number of CPU cores available to SQL Server Express Server LocalDB affects LHC performance even more than memory allocation does. This CPU overhead is observed only when in LHC mode when Citrix DaaS is not reachable, and the LHC broker is active. For any deployment using LHC, Citrix recommends four cores per socket, with a minimum of four CPU cores per Cloud Connector. For information on configuring compute resources for SQL Express Server LocalDB, see Compute capacity limits by edition of SQL Server.



If compute resources available to the SQL Express Server LocalDB are misconfigured, configuration synchronization times might be increased and performance during outages might be reduced. In some virtualized environments, compute capacity might depend on the number of logical processors and not CPU cores.

Summary of test findings

All results in this summary are based on the findings from a test environment as configured in the detailed sections of this article. The results shown here are for a single resource location. Different system configurations might yield different results.

This illustration gives a graphical overview of the tested configuration.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following table shows the minimum recommended Cloud Connector CPU and memory configurations for sites of various sizes. Results of testing with these configurations are shown below. See Limits for more information on the resource location limits.

	MEDIUM	LARGE	MAXIMUM
Connectors for HA	2	2	3
VDAs	Up to 1000	1001 - 5000	5001 - 10,000
Sessions	Up to 2500	Up to 10,000	Up to 25,000
Hosting connections	Up to 20	Up to 40	Up to 40
CPUs for Cloud Connectors	4vCPU	4vCPU	8vCPU
Memory for Cloud Connectors	6 GB	8 GB	10 GB

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If your deployment exceeds 5000 VDAs, you must use three Cloud Connectors for high availability and scalability.

Test methodology

Tests were conducted to add load and to measure the performance of the environment components. The components were monitored by collecting performance data and procedure timing, such as logon time and registration time. Sometimes, proprietary Citrix simulation tools are used to simulate VDAs and sessions. These tools are designed to exercise Citrix components the same way that traditional VDAs and sessions do, without the same resource requirements to host real sessions and VDAs. Tests were conducted in both cloud brokering and LHC mode for scenarios with Citrix StoreFront.

Recommendations for Cloud Connector sizing in this article are based on data gathered from these tests.

The following tests were run:

- **Session logon/launch storm:** a test that simulates high-volume logon periods.
- **VDA registration storm:** a test that simulates high-volume VDA registration periods. For example, following an upgrade cycle or transitioning between cloud brokering and Local Host Cache mode.
- **VDA power action storm:** a test that simulates high-volume of VDA power actions.

Test scenarios and conditions

These tests were performed with LHC configured. For more information about using LHC, see the Local Host Cache article. LHC requires an on-premises StoreFront server. For detailed information about StoreFront, see the StoreFront product documentation.

Recommendations for StoreFront configurations:

- If you have multiple resource locations with a single StoreFront server or server group, enable the advanced health check option for the StoreFront store. See StoreFront requirement in the Local Host Cache article.
- For higher session launch rates, use a StoreFront server group. See Configure server groups in the StoreFront product documentation.

Test conditions:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- CPU and memory requirements are for the base OS and Citrix services only. Third-party apps and services might require additional resources.
- VDAs are any virtual or physical machines running Citrix Virtual Delivery Agent.
- Tests are performed using Windows VDAs only.
- All VDAs tested were power-managed using Citrix DaaS.
- Session were launched at a sustained rate of 1,000 per minute.
- Workloads of 1,000 to 10,000 VDI and 500–10,000 RDS servers with 1,000-25,000 sessions were tested.
- RDS sessions were tested up to 25,000 per resource location.
- Tests were performed using two Cloud Connectors in both normal operations and during outage. Citrix recommends using at least two Cloud Connectors for high availability, and three Cloud Connectors for maximum and large sized resource locations. When in outage mode, only one of the Cloud Connectors is used for VDA registrations and brokering. While tests were run with two Cloud Connectors, only one Cloud Connector is available during upgrades. To ensure high availability during upgrades, some customers have opted to run with three Cloud Connectors.
- Tests were performed with the Cloud Connector configured with Intel Cascade Lake processors.
- Sessions were launched via a single Citrix StoreFront server.
- LHC outage sessions launch tests conducted after machines had re-registered.

RDS session counts are a recommendation and not a limit. Test your own RDS session limit in your environment.

NOTE:

Session count and launch rate are more important for RDS than the VDA count.

Medium workloads

These workloads were tested with 4 vCPUs and 6 GB memory.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
1000 VDI	Online	5 minutes	CPU maximum = 36%, CPU average = 33%, memory maximum = 5.3 GB	2 minutes	CPU maximum = 29%, CPU average = 27%, memory maximum = 3.7 GB	500 per minute
1000 VDI	Outage	4 minutes	CPU maximum = 11%, CPU average = 10%, memory maximum = 4.5 GB	2 minutes	CPU maximum = 42%, CPU average = 28%, memory maximum = 4.0 GB	500 per minute
250 RDS, 5000 sessions	Online	3 minutes	CPU maximum = 14%, CPU average = 4%, memory maximum = 3.5 GB	9 minutes	CPU maximum = 46%, CPU average = 21%, memory maximum = 3.7 GB	555 per minute
250 RDS, 5000 sessions	Outage	3 minutes	CPU maximum = 15%, CPU average = 5%, memory	9 minutes	CPU maximum = 51%, CPU average = 32%, memory	555 per minute

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
			maximum = 3.7		maximum = 4.2 GB	

Large workloads

These workloads were tested with 4 vCPUs and 8 GB memory.

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
5000 VDI	Online	3–4 minutes	CPU maximum = 45%, CPU average = 25%, memory maximum = 7.0 GB	5 minutes	CPU maximum = 75%, CPU average = 55%, memory maximum = 7.0 GB	1000 per minute
5000 VDI	Outage	4–6 minutes	CPU maximum = 15%, CPU average = 5%, memory maximum = 7.5 GB	5 minutes	CPU maximum = 45%, CPU average = 40%, memory maximum = 7.5 GB	1000 per minute
500 RDS, 10,000 sessions	Online	3 minutes	CPU maximum = 45%, CPU average =	10 minutes	CPU maximum = 75%, CPU average =	1000 per minute

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
			25%, memory maximum = 7.0 GB		55%, memory maximum = 7.0 GB	
500 RDS, 10,000 sessions	Outage	3 minutes	CPU maximum = 15%, CPU average = 5%, memory maximum = 7.5	10 minutes	CPU maximum = 45%, CPU average = 40%, memory maximum = 7.5 GB	1000 per minute

Maximum workloads

These workloads were tested with 8 vCPUs and 10 GB memory.

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
10,000 VDI	Online	3–4 minutes	CPU maximum = 85%, CPU average = 10%, memory maximum = 8.5 GB	7 minutes	CPU maximum = 66%, CPU average = 28%, memory maximum = 7.0 GB	1400 per minute
10,000 VDI	Outage	4–5 minutes	CPU maximum = 90%,	5 minutes	CPU maximum = 90%,	2000 per minute

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TEST WORKLOADS	SITE CONDITION	VDA REGISTRATION TIME	REGISTRATION CPU AND MEMORY USAGE	LAUNCH TEST LENGTH	SESSION LAUNCH CPU AND MEMORY USAGE	LAUNCH RATE
			CPU average = 17%, memory maximum = 8.2 GB		CPU average = 45%, memory maximum = 8.5 GB	
1000 RDS, 20,000 sessions	Online	1–2 minutes	CPU maximum = 60%, CPU average = 20%, memory maximum = 8.6 GB	17 minutes	CPU maximum = 66%, CPU average = 25%, memory maximum = 6.8 GB	1200 per minute
1000 RDS, 20,000 sessions	Outage	3–4 minutes	CPU maximum = 22%, CPU average = 10%, memory maximum = 8.5	21 minutes	CPU maximum = 90%, CPU average = 50%, memory maximum = 7.5 GB	1000 per minute

NOTE:

The workloads shown here are the maximum recommended workloads for one resource location. To support larger workloads, add more resource locations.

Configuration synchronization resource usages

The configuration synchronization process keeps the Cloud Connectors up to date with Citrix DaaS. Updates are automatically sent to the Cloud Connectors to make sure that the Cloud Connectors are ready to take over brokering if an outage occurs. The configuration synchronization

© 1997–2026 Citrix Systems, Inc. All rights reserved.

updates the LHC database, SQL Express Server LocalDB. The process imports the data to a temporary database then switches to that database once imported. This ensures that there is always an LHC database ready to take over.

The CPU, memory, and disk usage are temporarily increased while data is imported to the temporary database.

Test conditions:

- Tested on an 8 vCPU AMD EPYC
- The imported site configuration database was for an environment with site-wide total of 80,000 VDAs and 300,000 users (three shifts of 100,000 users)
- Data import time was tested on a resource location with 10,000 VDI

Test results:

- **Data import time:** 7–10 minutes
- **CPU usage:**
  - maximum = 25%
  - average = 15%
- **Memory usage:**
  - increase of approximately 2 GB to 3 GB
- **Disk usage:**
  - 4 MB/s disk read spike
  - 18 MB/s disk write spike
  - 70 MB/s disk write spike during downloading and writing of xml config files
  - 4 MB/s disk read spike at the completion of import
- **LHC database size:**
  - 400–500 MB database file
  - 200–300 MB log database

Additional resource usage considerations:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- During import the full site configuration data is downloaded. This download might cause a memory spike, depending on the site size. If memory spikes are occurring during configuration syncs, consider increasing the size of the Cloud Connectors.
- The tested site used approximately 800 MB for the database and database log files combined. During a configuration synchronization, these files are duplicated with a maximum combined size of approximately 1600 MB. Ensure that your Cloud Connector has enough disk space for the duplicated files. The configuration synchronization process fails if the disk is full.

Install VDAs

Introduction

This article begins with a description of Windows VDAs and the available VDA installers. The remainder of the article describes the steps in the VDA installation wizard. Command-line equivalents are provided. For details, see Install VDAs using the command line.

For information about Linux VDAs, see Linux Virtual Delivery Agent.

View an introduction to VDAs.

Installation considerations

The Citrix DaaS article describes what VDAs are and what they do. Here's more information.

- **Analytics collection:** Analytics are collected automatically when you install or upgrade components. By default, that data is uploaded to Citrix automatically when the installation completes. Also, when you install components, you are automatically enrolled in the Citrix Customer Experience Improvement Program (CEIP), which uploads anonymous data. Also, during an installation or upgrade, you're offered the opportunity to enroll in Call Home.

  If a VDA installation fails, an MSI analyzer parses the failing MSI log, displaying the exact error code. The analyzer suggests a CTX article, if it is a known issue. The analyzer also collects anonymized data about the failure error code. This data is included with other data collected by CEIP. If you end enrollment in CEIP, the collected MSI analyzer data is no longer sent to Citrix.

  For information about these programs, see Citrix Insight Services.
- **Citrix Workspace™ app:** Citrix Workspace app for Windows is not installed by default when you install a VDA. You can download and install or upgrade Citrix Workspace app for Windows

© 1997–2026 Citrix Systems, Inc. All rights reserved.

and other Citrix Workspace apps from the Citrix website. Alternatively, you can make those Citrix Workspace apps available from the Workspace or a StoreFront™ server.

- **Print Spooler Service:** The Microsoft Print Spooler Service must be enabled. You cannot successfully install a VDA if that service is disabled.
- **Microsoft Media Foundation:** Most supported Windows editions come with Media Foundation already installed. If the machine on which you're installing a VDA does not have Microsoft Media Foundation (such as N editions), several multimedia features are not installed and do not work.
  - Flash Redirection
  - Windows Media Redirection
  - HTML5 Video Redirection
  - HDX™ RealTime Webcam Redirection

  You can acknowledge the limitation, or end the VDA installation and restart it later, after installing Media Foundation. In the graphical interface, this choice is presented in a message. In the command line, you can use the `/no_mediafoundation_ack` option to acknowledge the limitation.
- **Local user group:** When you install the VDA, a new local user group called Direct Access Users is created automatically. For a single-session OS VDA, this group applies only to RDP connections. For a multi-session OS VDA, this group applies to ICA® and RDP connections.
- **Cloud Connector address requirement:** The VDA must have at least one valid Cloud Connector address (in the same resource location) with which to communicate. Otherwise, sessions cannot be established. You specify Cloud Connector addresses when you install the VDA. For information about other ways to specify Cloud Connector addresses where VDAs can register, see VDA registration.
- **Operating system considerations:**
  - Review the System requirements for supported platforms, operating systems, and versions.
  - Ensure that each operating system maintains the latest updates.
  - Ensure that VDAs have synchronized system clocks. The Kerberos infrastructure that secures communication between the machines requires synchronization.
  - Optimization guidance for Windows 10 machines is available in CTX216252.
  - If you try to install (or upgrade to) a Windows VDA on an OS that is not supported for that VDA version, a message describes your options. For more information, see System requirements and Earlier operating systems.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Installed MSIs:** Several MSIs are installed automatically when you install a VDA. You can prevent the installation of some MSIs on the **Additional Components** page of the graphical interface or with the `/exclude` option in the CLI. For others, the only way to prevent their installation is with the `/exclude` CLI option.
- **Domain-joined:** Ensure that the machine is domain-joined before installing the VDA software.

Restarts during VDA installation

A restart is required at the end of the VDA installation. That restart occurs automatically by default.

To minimize the number of other restarts needed during VDA installation:

- Ensure that a supported Microsoft .NET Framework version is installed before beginning the VDA installation.
- For Windows multi-session OS machines, install and enable the RDS role services before installing the VDA.

If you do not install those prerequisites before installing the VDA:

- If you are using the graphical interface or the command line interface without the `/noreboot` option, the machine restarts automatically after installing the prerequisite.
- If you are using the command line interface with the `/noreboot` option, you must initiate the restart.

After each restart, the VDA installation continues. If you're installing from the command line, you can prevent the automatic resumption with the `/noresume` option.

When upgrading a VDA to version 7.17 or a later supported version, a restart occurs during the upgrade. This restart cannot be avoided.

Restore on install or upgrade failure

NOTE:

This feature is available only for single-session VDAs.

If a single-session VDA installation or upgrade fails, and the "restore on failure" feature is enabled, the machine is returned to a restore point that was set before the installation or upgrade began.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

When a single-session VDA installation or upgrade starts with this feature enabled, the installer creates a system restore point before beginning the actual install or upgrade. If the VDA installation or upgrade fails, the machine is returned to the restore point state. The `%temp%/Citrix` folder contains deployment logs and other information about the restore.

By default, this feature is disabled.

If you plan to enable this feature, make sure that system restore is not disabled through a GPO setting (`Computer Configuration > Administrative Templates > System > System Restore`).

To enable this feature when installing or upgrading a single-session VDA:

- When using a VDA installer's graphical interface (such as using **Autostart** or the `XenDesktopVDASetup.exe` command without any restore or quiet options), select the **Enable automatic restore if update fails** check box on the **Summary** page.

  If the install/upgrade completes successfully, the restore point is not used, but is retained.
- Run a VDA installer with either the `/enablerestore` or `/enablerestorecleanup` option.
  - If you use the `/enablerestorecleanup` option, and the install/upgrade completes successfully, the restore point is removed automatically.
  - If you use the `/enablerestore` option, and the install/upgrade completes successfully, the restore point is not used, but is retained.

VDA installers

VDA installers can be downloaded directly from the Citrix Cloud™ console.

By default, files in the self-extracting installers are extracted to the `Temp` folder. The files extracted to the `Temp` folder are automatically deleted after the installation completes. Alternatively, you can use the `/extract` command with an absolute path.

Three standalone VDA installers are available for download.

VDAServerSetup.exe Installs a multi-session OS VDA.

VDAWorkstationSetup.exe Installs a single-session OS VDA.

VDAWorkstationCoreSetup.exe Installs a single-session OS VDA that is optimized for Remote PC Access deployments or core VDI installations. Remote PC Access uses physical machines. Core VDI installations are VMs that are not being used as an image. This installer deploys only the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

core services necessary for VDA connections. Therefore, it supports only a subset of the options that are valid with the VDAWorkstationSetup installer.

For more information, see Install VDA for your respective versions.

Troubleshoot

In the Studio display for a delivery group, the **Installed VDA version** entry on the Details pane mightn't be the version installed on the machines. The machine's Windows Programs and Features display shows the actual VDA version.

Citrix Optimizer

Citrix Optimizer is a tool for Windows OS that helps Citrix administrators optimize VDAs by removing and optimizing various components.

After installing a VDA and completing the final restart, download and install Citrix Optimizer. See CTX224676. The CTX article contains the download package, plus instructions about installing and using Citrix Optimizer.

Customize a VDA

Later, to customize (change information for) an installed VDA:

1. From the Windows feature for removing or changing programs, select **Citrix Virtual Delivery Agent** or **Citrix Remote PC Access/VDI Core Services VDA**. Then right-click and select **Change**.
2. Select **Customize Virtual Delivery Agent Settings**.

When the installer launches, change any available settings.

Customize the port for communicating with Cloud Connectors

You can customize the port that VDAs use to communicate with Cloud Connectors based on your specific security requirements. This feature is useful if your security team doesn't allow the default port (port 80) to be open or if the default port is already in use.

NOTE:

When changing the default port number, only values within the range 1024–65535 are supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To customize the port, complete the following steps:

1. Add the VDA port number on Citrix Cloud Connectors
2. Additional Citrix Cloud Connector™ configuration when using Rendezvous V1
3. Add the VDA port number on VDAs

Add the VDA port number on Citrix Cloud Connectors

Go to the Citrix Cloud Connector and run the following two PowerShell commands:

- `PS C:\> & 'C:\Program Files\Citrix\XaXdCloudProxy\XaXdCloudProxy.exe' -VdaPort <port number>`
- `PS C:\> & 'C:\Program Files\Citrix\Broker\Service\HighAvailabilityService.exe' -VdaPort <port number> -ConfigureFirewall`

Example:

- `PS C:\> & 'C:\Program Files\Citrix\XaXdCloudProxy\XaXdCloudProxy.exe' -VdaPort 18000`
- `PS C:\> & 'C:\Program Files\Citrix\Broker\Service\HighAvailabilityService.exe' -VdaPort 18000 -ConfigureFirewall`

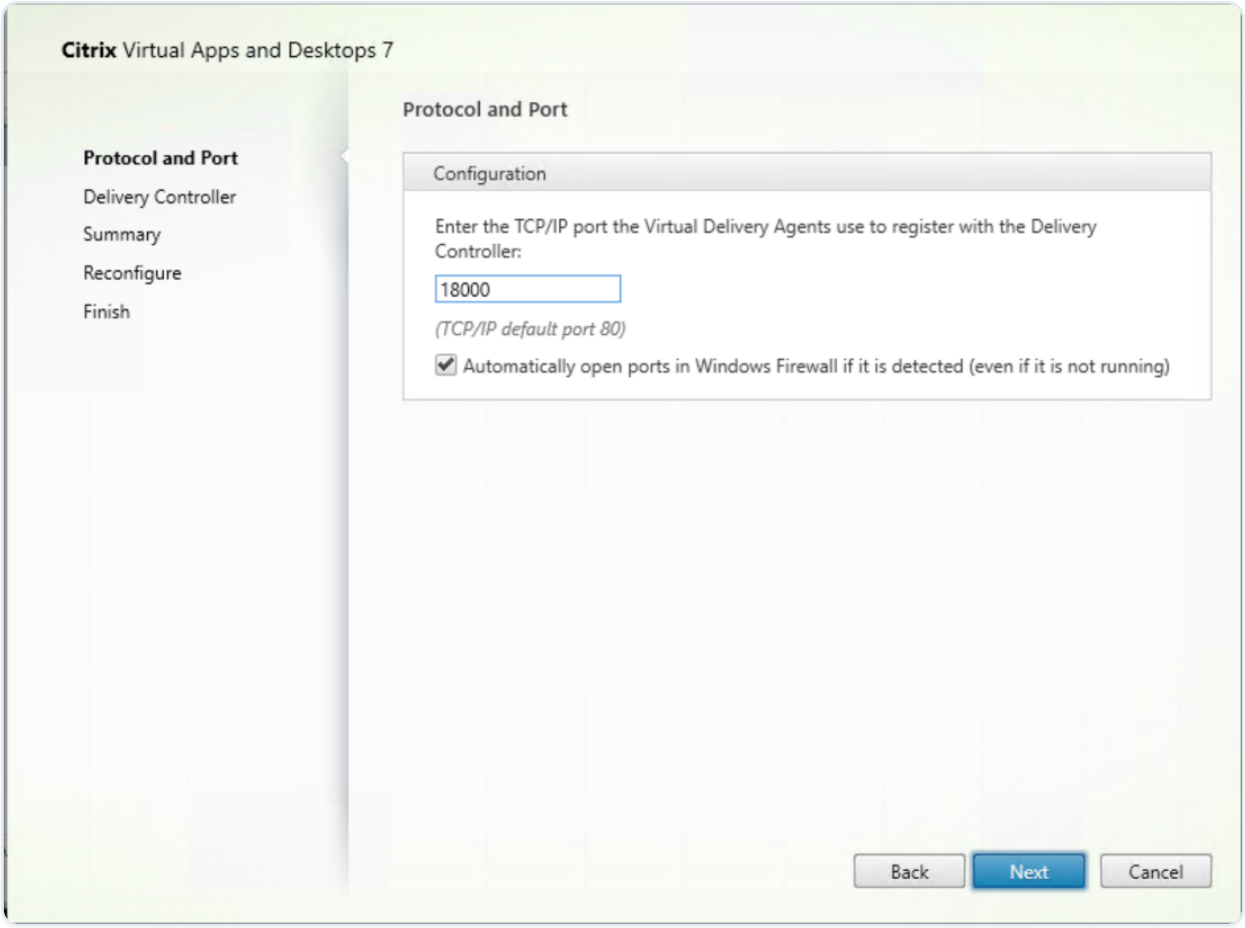
When customizing the port, consider the following:

- You must use the same port number in both commands.
- You must run both commands *on all Cloud Connectors*.
- To successfully communicate with Cloud Connectors, ensure that all VDAs use the same port number.
- The port you configure persists across connector updates.

Additional Citrix Cloud Connector configuration when using Rendezvous V1

Set the following registry key on each Citrix Cloud Connector:

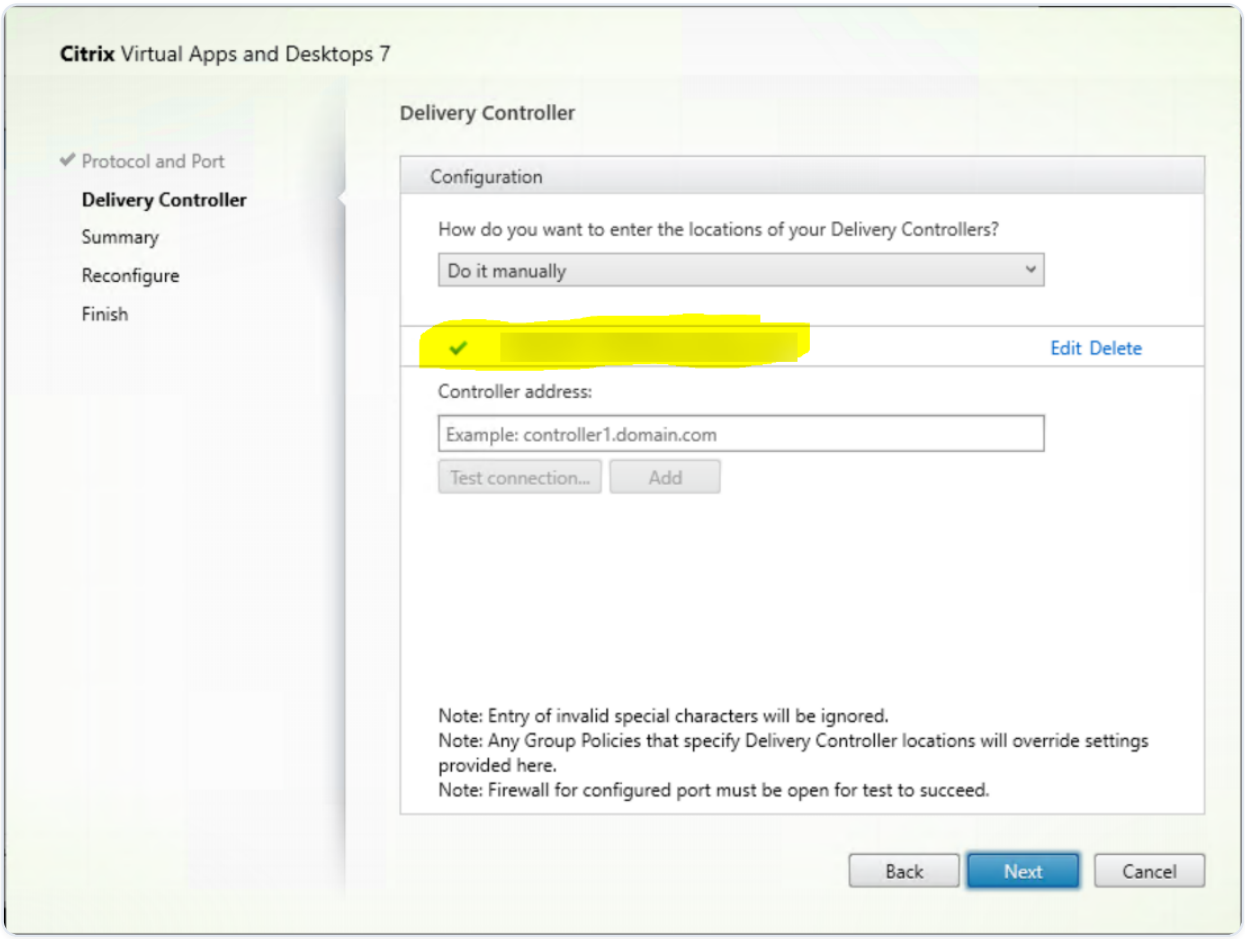
`HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\XaXdCloudProxyPersist`



Name: `WorkerPortNumber` Type: `REG_DWORD` Value: `<port number>`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add the VDA port number on VDAs



Install the VDA with default settings and configure as follows. If the VDA is already installed, continue with the steps below.

1. On the VDA, open **XenDesktopVdaSetup.exe**, which is located at `C:\Program Files\Citrix\XenDesktopVdaSetup\XenDesktopVdaSetup.exe`.
2. On the **Protocol and Port** page, add the custom port number.

3. On the **Delivery Controller™** page, enter the FQDN of the Controller.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Click **Next** to proceed through the wizard to complete the configuration.

The port numbers are then reconfigured successfully.

NOTE:

You might see the following error message when you test a Controller connection: No running instance of a Controller found on < the Controller address you entered >. If the address is correct, you can dismiss the message.

Troubleshooting

To check whether the custom ports are configured correctly, go to the Cloud Connector and perform the following troubleshooting steps:

1. Verify that the following two registry keys exist.

   HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\XaXdCloudProxyPersist Name: CustomVDAPortNumber Type: REG_DWORD Data: 18000

© 1997–2026 Citrix Systems, Inc. All rights reserved.

HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\XaXdCloudProxyPersist Name: CustomVDAPortNumberHA Type: REG_DWORD Data: 18000

2. Run the following command to create a .txt file.

   - `netsh http show urlacl > <filepath>.txt`

   Example:

   - `netsh http show urlacl > c:\reservations.txt`

3. Open the .txt file and check the following four URLs to verify that the correct port is used.

   - `http://+:18000/Citrix/CdsController/IRegistrar/`
   - `http://+:18000/Citrix/CdsController/ITicketing/`
   - `http://+:18000/Citrix/CdsController/IDynamicDataSink/`
   - `http://+:18000/Citrix/CdsController/INotifyBroker/`

4. Verify that the following two firewall rules are created and required ports are open.

   - Citrix XaXdProxy
   - Citrix Broker Service (TCP-In)

Other information

- After you install a VDA, you can check the health and availability of the site and its components with a Cloud Health check.

Where to go next

Create machine catalogs.

To review the entire configuration process, see Plan and build a deployment.

Install VDAs using the command line

Introduction

This article applies to installing, upgrading, and customizing Virtual Delivery Agents (VDAs) on machines with Windows operating systems.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This article describes how to issue VDA installation commands. Before beginning an installation, review Install VDAs to learn about installation considerations, installers, and what you specify during installation.

Install a VDA from the command line

To install a VDA (and see command execution progress and return values), you must have elevated administrative permissions or use **Run as administrator**.

1. On the machine where you're installing the VDA, sign to Citrix Cloud.
2. In the upper left menu, select **Solutions > DaaS**.
3. On the upper right side, click **Downloads** and select **Download VDA**. You're redirected to the VDA download page. Find the VDA installer that you want and click **Download File**.
4. After the download completes, run its name. Use the options described in this article.
    - For the multi-session OS Virtual Delivery Agent, run `VDAServerSetup.exe`
    - For the single-session OS Virtual Delivery Agent, run `VDAWorkstationSetup.exe`
    - For the single-session OS Core Services Virtual Delivery Agent, run `VDAWorkstationCoreSetup.exe`

To extract the files before installing them, use `/extract` with the absolute path, for example `.\VDAWorkstationCoreSetup.exe /extract %temp%\CitrixVDAInstallMedia`. (The directory must exist. Otherwise, the extract fails.) Then in a separate command, run the appropriate command, using the valid options listed in this article.

- For `VDAServerSetup_XXXX.exe`, run `<extract folder>\Extract\Image-Full\x64\XenDesktop Setup\XenDesktopVDASetup.exe`
- For `VDAWorkstationCoreSetup_XXXX.exe`, run `<extract folder>\Extract\Image-Full\x64\XenDesktop Setup\XenDesktopRemotePCSetup.exe`
- For `VDAWorkstationSetup_XXXX.exe`, run `<extract folder>\Extract\Image-Full\x64\XenDesktop Setup\XenDesktopVDASetup.exe`

Command-line options to install a VDA

The following options are valid with one or more of the commands: `VDAServerSetup.exe`, `VDAWorkstationSetup.exe`, and `VDAWorkstationCoreSetup.exe`.

- **/components** *component*\[,*component*\]

  Comma-separated list of components to install or remove. Valid values are:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - **VDA:** Virtual Delivery Agent
  - **PLUGINS:** Citrix Workspace™ app for Windows

  To install the VDA and Citrix Workspace app, specify `/components vda,plugins`.

  If the `plugins` option is left out, only the VDA is installed (not the Citrix Workspace app).

  This option is not valid when using the `VDAWorkstationCoreSetup.exe` installer. That installer cannot install Citrix Workspace app.

- **/controllers** "*controller* ..."

  Space-separated FQDNs of Citrix Cloud Connectors with which the VDA can communicate, enclosed in straight quotation marks. Do not specify both the `/site_guid` and `/controllers` options.

- **/disableexperiencemetrics**

  Prevents the automatic upload of analytics collected during installation, upgrade, or removal to Citrix.

- **/enable_hdx_ports**

  Opens ports in the Windows firewall required by the VDA and enabled features (except Windows Remote Assistance), if the Windows Firewall Service is detected, even if the firewall is not enabled. If you are using a different firewall or no firewall, you must configure the firewall manually. For port information, see Network ports.

  To open the UDP ports that HDX adaptive transport, specify the `/enable_hdx_udp_ports` option, in addition to the `/enable_hdx_ports` option.

- **/enable_hdx_udp_ports**

  Opens UDP ports in the Windows firewall that HDX adaptive transport requires, if the Windows Firewall Service is detected, even if the firewall is not enabled. If you are using a different firewall or no firewall, you must configure the firewall manually. For port information, see Network ports.

  To open the ports that the VDA uses, specify the `/enable_hdx_ports` option, in addition to the `/enable_hdx_udp_ports` option.

- **/enable_real_time_transport**

  Enables or disables use of UDP for audio packets (RealTime Audio Transport for audio). Enabling this feature can improve audio performance. Include the `/enable_hdx_ports`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

option if you want the UDP ports opened automatically when the Windows Firewall Service is detected.

- **/enable_remote_assistance**

  Enables the shadowing feature in Windows Remote Assistance for use with the **Monitor** functions. If you specify this option, Windows Remote Assistance opens the dynamic ports in the firewall.

- **/enablerestore** or **/enablerestorecleanup**

  (Valid only for single-session VDAs) Enables automatic return to the restore point, if the VDA install or upgrade fails.

  If the install/upgrade completes successfully:

  - `/enablerestorecleanup` instructs the installer to remove the restore point.
  - `/enablerestore` instructs the installer to keep the restore point, even though it was not used.

  For details, see Restore on install or upgrade failure.

- **/enable_ss_ports**

  Opens ports in the Windows Firewall that are required for screen sharing, if the Windows Firewall Service is detected, even if the firewall is not enabled. If you are using a different firewall or no firewall, you must configure the firewall manually.

- **/exclude** "*component*"\[,"*component*"\]

  Prevents installation of one or more comma-separated optional components, each enclosed in straight quotation marks. For example, installing or upgrading a VDA on an MCS-managed image needs the Machine Identity Service component. Valid values are:

  - Machine Identity Service
  - Citrix Profile Management
  - Citrix Profile Management WMI Plug-in
  - Citrix Personalization for App-V - VDA
  - Citrix MCS IODriver
  - Citrix VDA Upgrade Agent
  - Citrix Rendezvous V2

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Excluding Citrix Profile Management from the installation (`/exclude "Citrix Profile Management"`) affects monitoring and troubleshooting of VDAs from the **Monitor** console. On the **User details** and **EndPoint** pages, the Personalization panel and the Logon Duration panel fail. On the **Dashboard** and **Trends** pages, the Average Logon Duration panel display data only for machines that have Profile Management installed.

Even if you are using a third-party Profile Management solution, Citrix recommends that you install and run the Citrix Profile Management Service. Enabling the Citrix Profile Management Service is not required.

If you plan to use MCS to provision VMs, do not exclude the Machine Identity Service.

If you specify both `/exclude` and `/includeadditional` with the same component name, the component isn't installed.

This option is not valid when using the `VDAWorkstationCoreSetup.exe` installer. That installer automatically excludes many of these items.

- **/h** or **/help**

  Displays command help.

- **/includeadditional** "*component*"\[,"*component*"\] ...

  Includes installation of one or more comma-separated optional components, each enclosed in straight quotation marks. The component names are case-sensitive.

  This option can be helpful when you are creating a Remote PC Access deployment, and want to install components that are not included by default. Valid values are:

  - Citrix Profile Management
  - Citrix Profile Management WMI Plug-in
  - Citrix Personalization for App-V - VDA
  - Citrix MCS IODriver
  - Citrix VDA Upgrade Agent
  - Citrix Rendezvous V2
  - User personalization layer
  - Citrix Web Socket VDA Registration Tool

  If you specify both `/exclude` and `/includeadditional` with the same component name, that component isn't installed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **/installdir** *directory*

  Existing empty directory where components will be installed. Default = c:\Program Files\Citrix.

- **/install_mcsio_driver**

  Do not use. Instead, use `/includeadditional "Citrix MCS IODriver"` or `/exclude "Citrix MCS IODriver"`

- **/logpath** *path*

  Log file location. The specified folder must exist. The installer does not create it. Default = "%TEMP%\Citrix\XenDesktop Installer"

  This option isn't available in the graphical interface.

- **/masterimage**

  Valid only when installing a VDA on a VM. Sets up the VDA as an image. This option is equivalent to `/mastermcsimage`.

  This option is not valid when using the `VDAWorkstationCoreSetup.exe` installer.

- **/mastermcsimage**

  Specifies that this machine will be used as an image with Machine Creation Services. This option is equivalent to `/masterimage`.

- **/masterpvsimage**

  Specifies that this machine will be used as an image with either Citrix Provisioning™ or a third-party provisioning tool (such as Microsoft System Center Configuration Manager).

- **/no_mediafoundation_ack**

  Acknowledges that Microsoft Media Foundation is not installed, and several HDX™ multimedia features are not installed and do not work. If this option is omitted and Media Foundation is not installed, the VDA installation fails. Most supported Windows editions come with Media Foundation already installed, except N editions.

- **/nodesktopexperience**

  Valid only when installing a multi-session OS VDA. Prevents enabling of the Enhanced Desktop Experience feature. This feature is also controlled with the Enhanced Desktop Experience Citrix policy setting.

- **/noreboot**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prevents a restart after installation. The VDA cannot be used until after a restart.

- **/noresume**

  By default, when a machine restart is needed during an installation, the installer resumes automatically after the restart completes. To override the default, specify `/noresume`. This can be helpful if you must remount the media or want to capture information during an automated installation.

- **/portnumber** *port*

  Valid only when the `/reconfig` option is specified. Port number to enable for communications between the VDA and the Controller. The previously configured port is disabled, unless it is port 80.

- **/proxyconfig** "*address or PAC file path*"

  Valid only if command contains `/includeadditional "Citrix Rendezvous V2"`. The address or PAC file path of the proxy for use with the Rendezvous protocol. For feature details, see Rendezvous protocol.

  - Proxy address format: `http://<url-or-ip>:<port>`
  - PAC file format: `http://<url-or-ip>:<port>/<path>/<filename>.pac`

- **/quiet** or **/passive**

  No user interface appears during the installation. The only evidence of the installation and configuration process is in Windows Task Manager. If this option is omitted, the graphical interface launches.

- **/reconfigure**

  Customizes previously configured VDA settings when used with the `/portnumber`, `/controllers`, or `/enable_hdx_ports` options. If you specify this option without also specifying the `/quiet` option, the graphical interface for customizing the VDA launches.

- **/remotepc**

  Valid only for Remote PC Access deployments (single-session OS) or brokered connections (multi-session OS).

  This option is not valid when using the `VDAWorkstationCoreSetup.exe` installer. That installer automatically excludes installation of these components.

- **/remove_appdisk_ack**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Authorizes the VDA installer to uninstall the AppDisks™ VDA plug-in if it's installed.

- **/remove_pvd_ack**

  Authorizes the VDA installer to uninstall Personal vDisk if it's installed.

- **/remove**

  Removes the components specified with the `/components` option.

- **/removeall**

  Removes the VDA. It does not remove the Citrix Workspace app (if installed).

- **/sendexperiencemetrics**

  Automatically sends analytics collected during the installation, upgrade, or removal to Citrix. If this option is omitted (or the `/disableexperiencemetrics` option is specified), analytics are collected locally, but not sent automatically.

- **/servervdi**

  Installs a single-session OS VDA on a supported Windows server. Omit this option when installing a multi-session VDA on a Windows server. Before using this option, see Server VDI.

- **/site_guid** *guid*

  Globally Unique Identifier of the site Active Directory Organizational Unit (OU). This associates a virtual desktop with a site when you are using Active Directory for discovery (auto-update is the recommended and default discovery method). The site GUID is a site property displayed in Studio. Do not specify both the `/site_guid` and `/controllers` options.

- **/tempdir** *directory*

  Directory to hold temporary files during installation. Default = c:\Windows\Temp.

  This option is not available in the graphical interface.

- **/virtualmachine**

  Valid only when installing a VDA on a VM. Overrides detection by the installer of a physical machine, where BIOS information passed to VMs makes them appear as physical machines.

  This option is not available in the graphical interface.

- **/xendesktopcloud**

  Indicates that the VDA is installed in a Citrix DaaS (Citrix Cloud™) deployment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Examples: Install a VDA

- **Install a VDA on a multi-session OS.** The following command installs a VDA on a multi-session OS.

  ```
  VDAServerSetup.exe /quiet /controllers "Contr-East.domain.com" /
  enable_hdx_ports /masterimage
  ```

  The VDA will be used as an image.

- **Install a multi-session OS VDA or single-session OS VDA.** The following command installs a multi-session OS VDA or a single-session OS VDA.

  ```
  VDAServerSetup_XXXX.exe /quiet /controllers "ddc1.abc.com","ddc2.abc.com" /
  enable_hdx_ports /enable_Remote_Assistance /enable_real_time_transport /
  enable_ss_ports /noreboot
  ```

  Separate each delivery controller™ FQDN by a comma. Note that `XXXX` represents the VDA version.

- **Install a Core Services VDA on a single-session OS.** The following command installs a Core Services VDA on a single session OS for use in a Remote PC Access or VDA deployment.

  ```
  VDAWorkstationCoreSetup.exe /quiet /controllers "Contr-East.domain.com" /
  enable_hdx_ports /noreboot
  ```

  Citrix Workspace app and other non-core services are not installed. The address of a Cloud Connector is specified, and ports in the Windows Firewall Service are automatically opened. The administrator handles restarts.

Customize a VDA using the command line

After you install a VDA, you can customize several settings. Run `XenDesktopVDASetup.exe`, using one or more of the following options.

- `/reconfigure` (required when customizing a VDA)
- `/h` or `/help`
- `/quiet`
- `/noreboot`
- `/controllers`
- `/portnumber port`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `/enable_hdx_ports`

Where to go next

- Create machine catalogs
- To review the entire configuration process, see Plan and build a deployment.

WebSocket communication between VDA and Delivery Controller™

This article describes how to set up a WebSocket connection for communication between VDAs and Delivery controllers as an alternative to using WCF communication. It provides the benefit that only the TLS port 443 for communication from the VDA to the Delivery Controller.

Currently this is only available for MCS provisioned machines.

How it works

The following section describes the workflow for the WebSocket connection between a Delivery Controller and a VDA:

1. The admins initiate the process by provisioning VDAs using the Machine Creation Service (MCS).
2. During the MCS provisioning process, MCS generates public-private key pairs for each VDA and registers the public keys with the FMA trust service on the Delivery Controller. MCS saves the public-private key pair as a file under the identity disk on the VDAs.
3. When the VDA machine boots up, the MCS agent installed on the VDA machine reads the key pair from the identity disk and writes this information to the VDA registry location.
4. The broker agent installed on the VDA reads the key pairs from the registry and generates an SSL-enabled WebSocket request to the Delivery Controller with a service key authentication header signed by the private key.
5. The delivery controller verifies the signed service key authentication header with the public key from the FMA trust service.
6. Once the verification is complete, the system establishes the WebSocket connection between the VDA and the Delivery Controller.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

WebSocket support

Procedure

Follow the instructions to set up a WebSocket connection:

1. Create a machine catalog for AD-joined VDAs with MCS provisioning. For more information, see Create machine catalog.
2. Create a delivery group and add your VDA to it. For more information, see Create delivery groups.
3. Enable a WebSocket connection on the VDA. Run the following PowerShell command on the VDA:

   ```
   New-ItemProperty
   "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CitrixBrokerAgent
   \WebSocket" -Name "Enabled" -PropertyType "DWord" -Value 1 -Force
   ```

   - To check if WebSocket is enabled, check the following registry key value. The value of `Enabled` must be 1.

     Key:

     ```
     HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CitrixBrokerAge
     nt\WebSocket
     ```

     Name: Enabled

     Type: REG_DWORD

     Value: 1

Create and manage connections

Introduction

Configuring a connection involves selecting the connection type from the list of supported hypervisors and cloud services, and choosing the appropriate storage and network resources for that connection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

You must have Full Administrator privileges to perform tasks related to connection and resource management.

Where to find information about connection types

System requirements provide a list of supported hypervisors and cloud service versions, along with links to articles for each specific host.

Host storage

A storage product is supported if it is manageable through a supported hypervisor. Citrix Support assists only those storage product vendors in troubleshooting and resolving issues, and documenting these issues and solutions in the Knowledge Center as necessary.

When provisioning machines, data is classified by type:

- Operating system (OS): includes images
- Temporary data: include all non-persistent data written to MCS-provisioned machines, Windows page files, and any data that is synchronized with ShareFile. This data is discarded each time a machine restarts. If the base image includes user profile data, this data remain persistent. If a centralized user profile solution is in use, the user profile data is synchronized with the external profile store. The locally cached user profile data is discarded upon each machine restart.

Allocating distinct storage resources for different types of data can minimize system load and enhance IOPS (Input/Output Operations Per Second) performance on each storage device. This strategic allocation makes optimal use of the host's available resources. Also, it allows for the selection of the most suitable storage medium based on the specific needs of each data type, such as greater persistence or resilience for certain kinds of data.

- Shared and local storage options: Storage resources can either be centralized that is, separate from any host and used by all hosts, or localized to a specific hypervisor. Centralized options include Windows cluster shared volumes, which might or might not have additional attached storage, or appliances from storage vendors. Centralized storage solutions might offer advanced features for optimizations, for example, hypervisor-specific storage control paths, and direct plug-in access.
- Local storage benefits and trade-offs: Storing temporary data locally avoids going to the network to access shared storage, thereby reduces IOPS load on the shared resources. While

© 1997–2026 Citrix Systems, Inc. All rights reserved.

centralized storage can be more expensive, using local storage can be a cost-effective alternative. However, these benefits can be weighed against the availability of sufficient storage on the hypervisor servers.

Storage shared by hypervisors

The storage shared by hypervisors method stores data that needs longer-term persistence centrally, providing centralized backup, and management. That storage holds the OS disks.

When you select this method, you can choose whether to use local storage (on servers in the same hypervisor pool) for temporary machine data. This data does not require persistence or as much resilience as the data in the shared storage. This is called the *temporary data cache*. The local disk helps reduce traffic to the main OS storage. This disk is cleared after every machine restart. The disk is accessed through a write-through memory cache. Keep in mind that if you use local storage for temporary data, the provisioned VDA is tied to a specific hypervisor host. If that host fails, the VM cannot start.

Exception: If you use Clustered Storage Volumes (CSV), Microsoft System Center Virtual Machine Manager does not allow temporary data cache disks to be created on local storage.

If you store temporary data locally, you can then enable and configure non-default values for each VM's cache disk and memory size when you create a machine catalog that uses that connection. However, the default values are as per the connection type, and are sufficient for most cases.

The hypervisor can also provide optimization technologies through in-memory read-caching of the disk images locally. For example, XenServer offers IntelliCache. This can also reduce network traffic to the central storage.

Storage local to the hypervisor

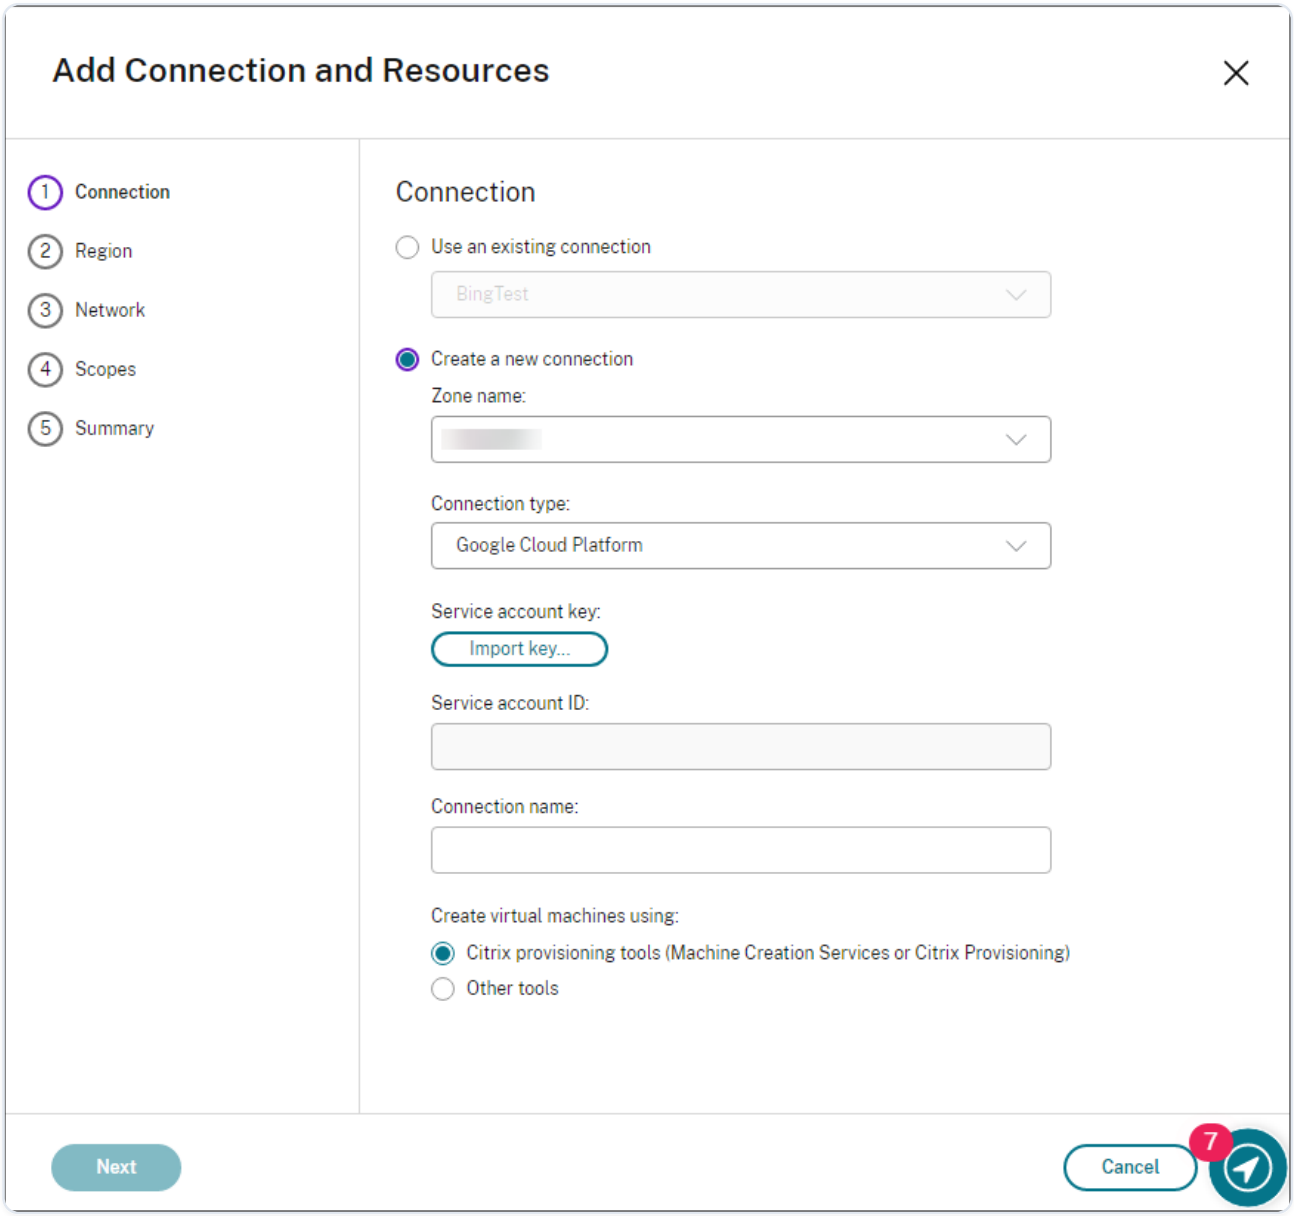
The storage local to the hypervisor method stores data locally on the hypervisor. With this method, images and other OS data are transferred to all the hypervisors used in the site, both for initial machine creation and future image updates. This results in significant traffic on the management network. Image transfers are also time-consuming, and the images become available to each host at a different time.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a connection and resources

IMPORTANT:

The host resources (storage and network) in your resource location must be available before you create a connection.



1. Sign in to Citrix Cloud.
2. In the **DaaS** tile, click **Manage** to open Studio.
3. Select **Hosting** in the left pane.
4. Click **Add Connections and Resources** in the action bar.
5. The wizard guides you through the configuration process described in the following steps. Specific page content depends on the selected connection type. After completing the steps on each page, select **Next** until you reach the **Summary** page.

NOTE:

The content of each page within the wizard varies based on the type of connection that you've selected.

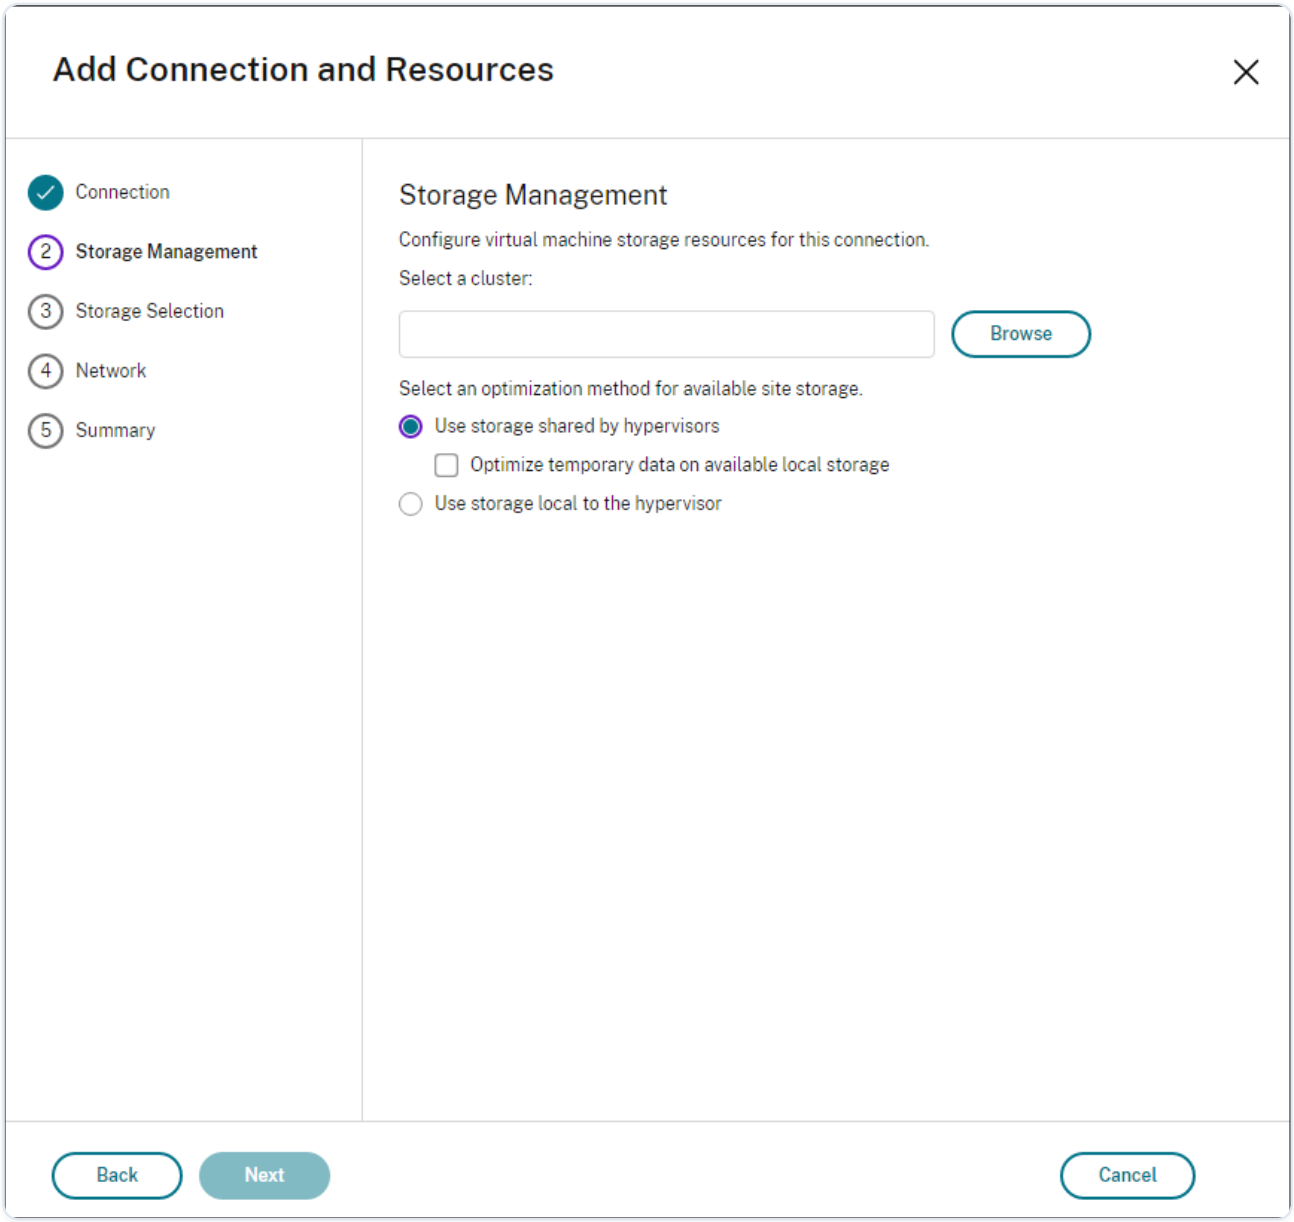
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Step 1. Connection

On the **Connection** page:

- To create a new connection, select **Create a new Connection**. To create a resource for an existing connection, select **Use an existing Connection**, and then choose the relevant connection.
- Select a zone in the **Zone name** field. The options are all resource locations you configured.
- Select a hypervisor or cloud service in the **Connection type** field. The options include all Citrix-supported hypervisors and cloud services:
  - For a resource location without accessible Cloud Connectors, only hypervisors and cloud services that support connectorless deployments are available.
  - For a resource location with accessible Cloud Connectors, only hypervisors and cloud services that have their plug-ins properly installed on those connectors are available.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Alternatively, you can use the PowerShell command `Get-HypHypervisorPlugin [-ZoneUid] $rluid [-IncludeUnavailable]` false or true to get the list of available hypervisors and Cloud services.

- Enter a connection name. This name appears in the **Hosting** display.
- Choose a tool to create virtual machines.

NOTE:

Information on the **Connection** page differs depending on the host or connection type that you're using. For example, when using Azure Resource Manager, you can use choose either a service principal or managed identity. For details, see Connection to Microsoft Azure.

Step 2. Storage management

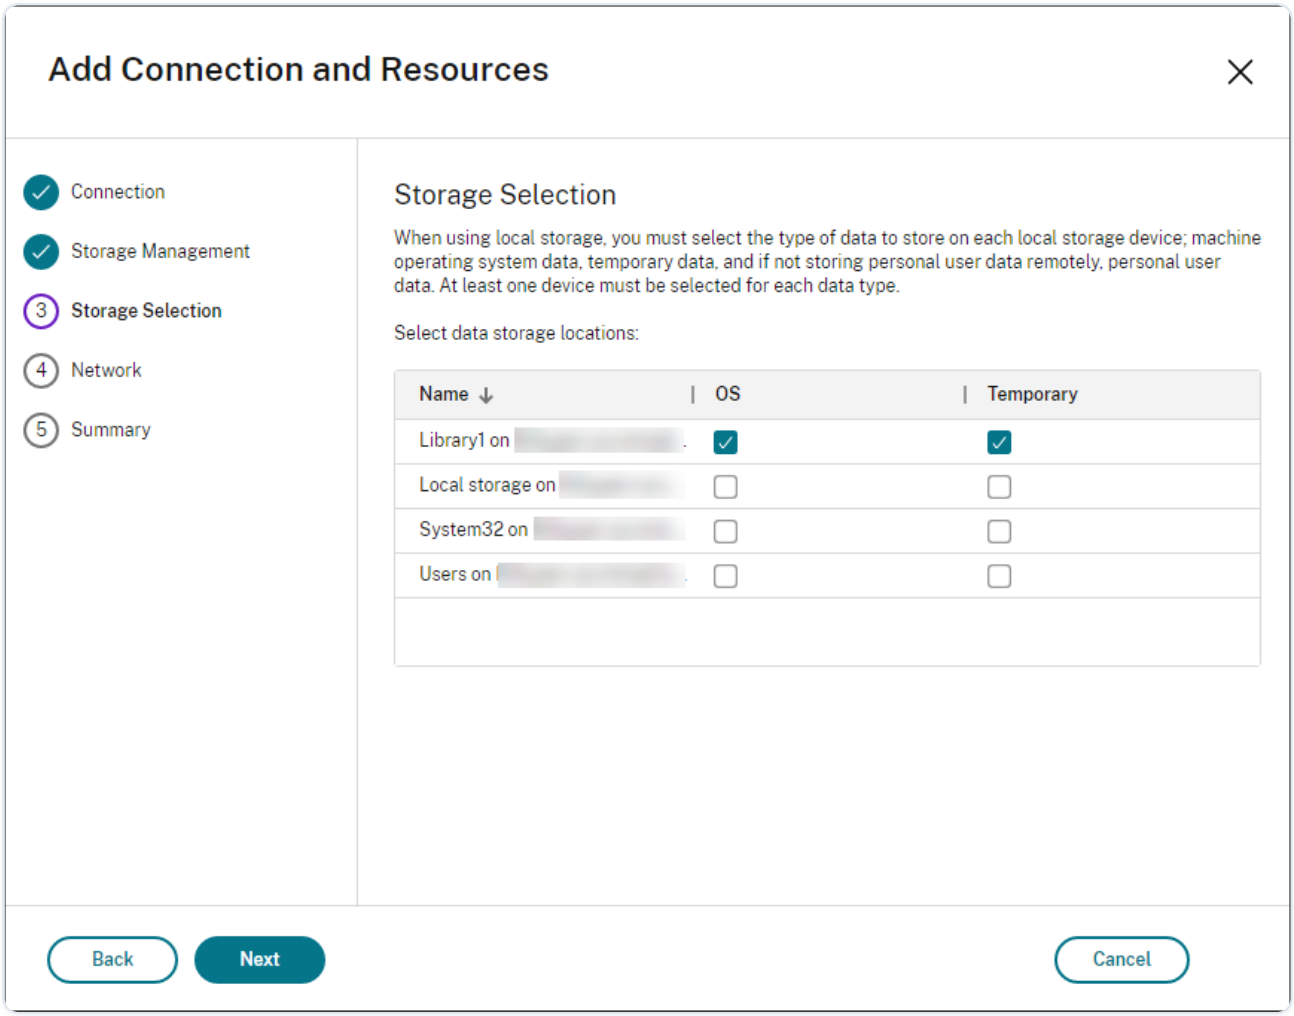
© 1997–2026 Citrix Systems, Inc. All rights reserved.

For information about storage management types and methods, see Host storage.

If you are configuring a connection to a Hyper-V or VMware host, browse to and then select a cluster name. Other connection types do not request a cluster name.

Select a storage management method: storage shared by hypervisors or storage local to the hypervisor.

For more information, see Storage shared by hypervisors and Storage local to the hypervisor.



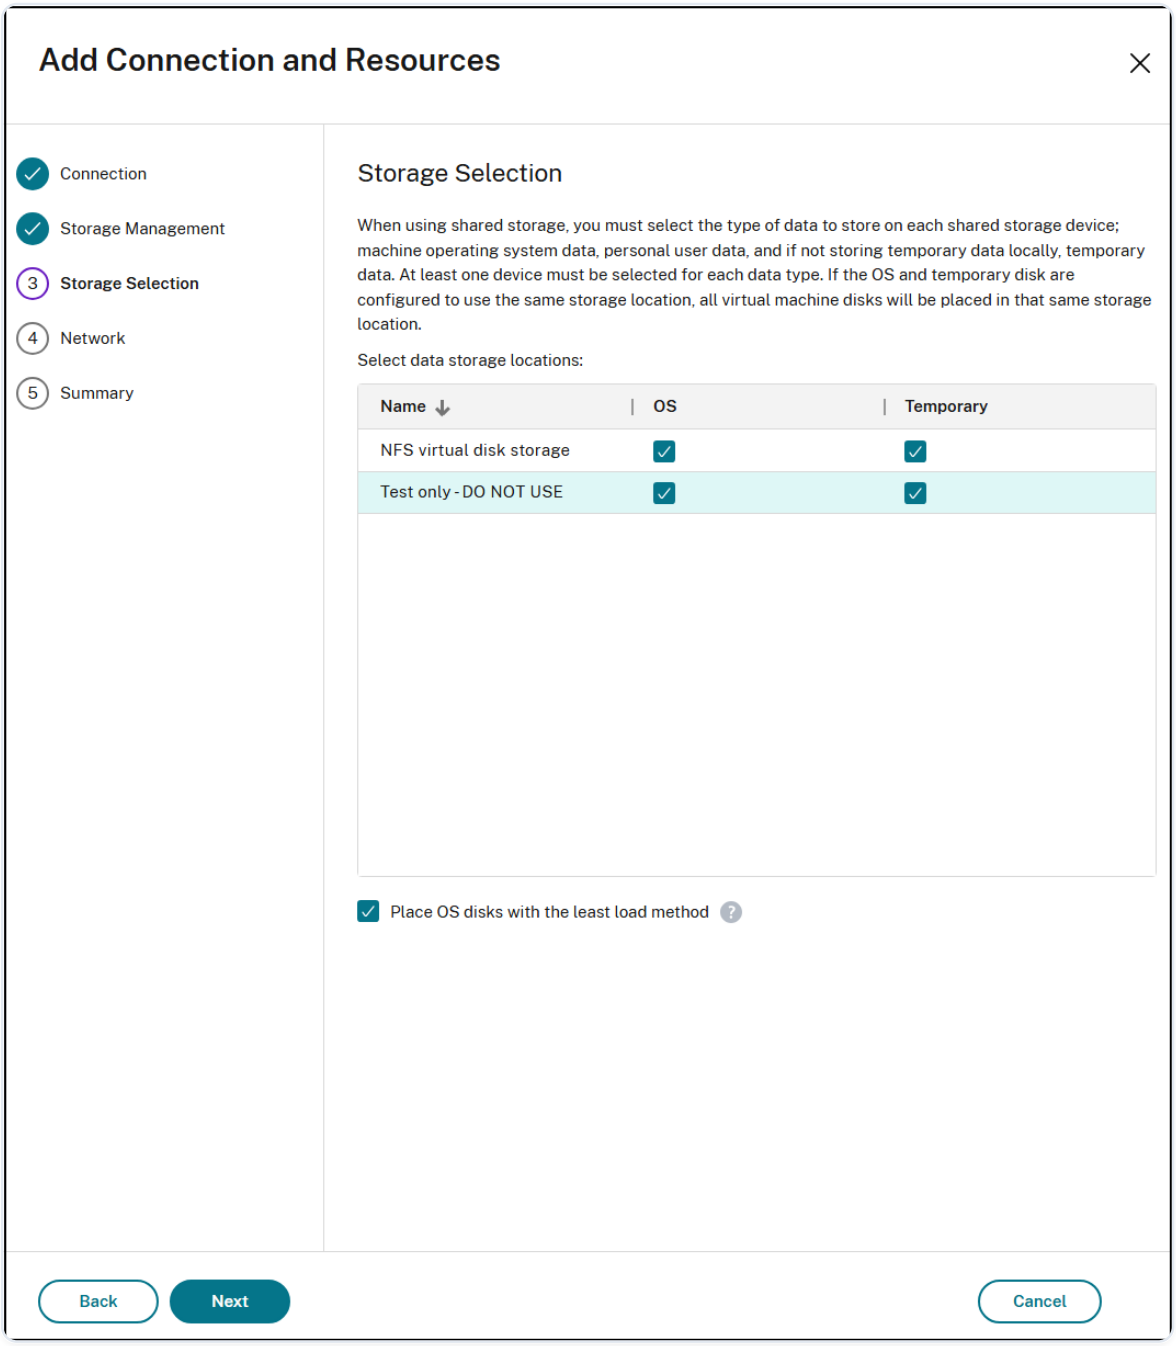
If you use shared storage on a XenServer pool, indicate if you want to use IntelliCache to reduce the load on the shared storage device. See Use IntelliCache for XenServer connections.

NOTE:

In XenServer®, VMware, and SCVMM virtualization environments, you can have Write-back cache (WBC) disk on the same storage location as OS disk. For this, do not select **Optimize temporary data on available local storage**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Step 3. Storage selection



For more information about storage selection, see Host storage.

Select at least one host storage device for each available data type. The storage management method that you selected on the previous page affects which data types are available for selection on this page. You must select at least one storage device for each supported data type before you can proceed to the next page in the wizard.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- In XenServer, VMware, and SCVMM virtualization environments, MCS places Write-back cache (WBC) disk on the same storage location as OS disk if you configure the available OS storage list the same as the available temporary storage list.
- If you select at least two or more OS data storage locations, the **Optimize storage load balancing with least load method option** appears. This option allows you to choose the least loaded storage repository for disk allocation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The **Summary** page indicates whether the option is **Enabled** or **Disabled**, depending on your selection. The **Details** panel displays changes to the storage allocation method. You can adjust it using the **Edit storage** option on the **OS Storage** page.

You can get more configuration options on **Storage Selection** page if you choose **Use storage shared by hypervisors** and select **Optimize temporary data on available local storage** on **Storage Management** page. For example, you can select which local storage devices (in the same hypervisor pool) to use for temporary data.

The number of currently selected storage devices is shown (in the graphic, "1 storage device selected"). When you hover over that entry, the selected device names appear (unless no devices are configured).

1. Select **Select** to change the storage devices to use.
2. In the **Select Storage** dialog box, select or clear the storage device checkboxes, and then select **OK**.

Step 4. Region

NOTE:

The **Region** page appears only for some host types.

The region selection indicates where VMs will be deployed. Ideally, choose a region close to where users will access their applications.

Step 5. Network

Enter a name for the resources. This name identifies the storage and network combination associated with the connection.

Select one or more networks that the VMs will use.

Some connection types (such as Azure Resource Manager) also list subnets that VMs will use. Select one or more subnets.

Step 6. Summary

Review your selections. If you want to make changes, return to the previous wizard pages. When you complete your review, select **Finish**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- If you store temporary data locally, you can configure non-default values for temporary data storage when you create the catalog containing machines that use this connection.
- A scope is not shown for Full access administrators. For more information, see Administrators, roles, and scopes.

Edit connection settings

You cannot use this procedure to:

- Rename a connection or create a new connection.
- Change the GPU settings for a connection. Catalogs accessing this resource must use an appropriate GPU-specific image. Therefore, if you want to change the GCP settings, create a new connection instead of editing an existing connection.

Edit a connection

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **Edit Connection** in the action bar.
3. Use the **Connection Properties** page to change the connection address and credentials. Change the address only if the current host machine has a new address. Entering an address to a different machine breaks the connection's machine catalogs.
    - Select **Edit settings…**, and then enter the new information.
    - To specify the high-availability servers for a XenServer connection, select **Edit servers...** and select the servers. Citrix recommends that you select all servers in the pool to allow communication with XenServer if the pool master fails.

    NOTE:

    If you are using HTTPS and want to configure high-availability servers, do not install a wildcard certificate for all servers in a pool. An individual certificate for each server is required. For more information, see Create a connection to XenServer.
4. Use the **Advanced** page to edit the settings to specify a maximum number of simultaneous actions (or concurrent machines) per hosting connection. These settings can help when power

© 1997–2026 Citrix Systems, Inc. All rights reserved.

management settings allow too many or too few machines to start at the same time. Each connection type has specific default values that are appropriate for most cases. Usually, they do not need to be changed.

- The **Simultaneous actions (all types)** and **Simultaneous Personal vDisk inventory updates** settings specify two values: a maximum absolute number that can occur simultaneously on this connection, and a maximum percentage of all machines that use this connection. You must specify both absolute and percentage values. The actual limit applied is the lower of the values.

  For example, in a deployment with 34 machines, if **Simultaneous actions (all types)** is set to an absolute value of 10 and a percentage value of 10, the actual limit applied is 3 (that is, 10 percent of 34 rounded to the nearest whole number, which is less than the absolute value of 10 machines).
- The **Maximum new actions per minute** is an absolute number. There is no percentage value.
- Enter information in **Connection options** only under the guidance of a Citrix Support representative.

5. Use the **Scopes** page to select one or more scopes for this host.

   NOTE:

   A scope is not shown for Full access administrators. By definition, those administrators can access all customer-managed Citrix Cloud and subscribed services objects.

   For more information, see Administrators, roles, and scopes.
6. Use the **Shared Tenants** page to add tenants and subscriptions that share the Azure Compute Gallery with the subscription of this connection.

   a. Enter the **Application secret** for the application associated with this connection. With this information, you can authenticate to Azure. We recommend that you change keys regularly to ensure security.

   b. Add shared tenants and subscriptions. You can add up to eight shared tenants. For each tenant, you can add up to eight subscriptions.
7. Click **Save** and **Apply** to apply any changes you made and keep the window open, or select **OK** to apply changes and close the window.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Turn maintenance mode on or off for a connection

Turning on maintenance mode for a connection prevents any new power action from affecting any machine stored on the connection. Users cannot connect to a machine when it is in maintenance mode. If users are already connected, maintenance mode takes effect when they log off.

1. From Studio, select **Hosting** in the left pane.
2. Select the connection. To turn maintenance mode on, select **Turn On Maintenance Mode** in the action bar. To turn maintenance mode off, select **Turn Off Maintenance Mode**.

You can also turn the maintenance mode on or off for individual machines. You can turn maintenance mode on or off for machines in machine catalogs or delivery groups.

Delete a connection

CAUTION:

Deleting a connection can result in the deletion of large numbers of machines and loss of data. Ensure that user data on affected machines is backed up or no longer required.

Before deleting a connection, ensure that:

- All users are logged off from the machines stored on the connection.
- No disconnected user sessions are running.
- Maintenance mode is turned on for pooled and dedicated machines.
- All machines in machine catalogs used by the connection are powered off.

A machine catalog becomes unusable when you delete a connection that the catalog references. If this connection is referenced by a catalog, you can delete the catalog. Before you delete a catalog, make sure it is not used by other connections.

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **Delete Connection** in the action bar.
3. If this connection has machines stored on it, you are asked whether to delete the machines. If they are to be deleted, specify what to do with the associated Active Directory computer accounts.

Rename a connection

1. From Studio, select **Hosting** in the left pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Select the connection and then select **Rename Connection**.

Test a connection

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **Test Connection**.

Test TLS Certificate

1. From Studio, select **Hosting** in the left pane.
2. Right-click the connection for which you want to re-trust the certificate with a warning symbol and select **Test TLS Certificate Trust**.
3. Input the password in the subsequent window and click **Save**.
    a. If the certificate needs to be re-trusted, a warning dialog box pops up with an option to trust the certificate.
    b. If the certificate is already trusted, a successful dialog box pops up that says the certificate is trusted.

View machine details on a connection

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **View Machines** in the action bar.

The upper pane lists the machines accessed through the connection. Select a machine to view its details in the lower pane. Session details are also provided for open sessions.

Use the search feature to find machines quickly. Either select a saved search from the list at the top of the window, or create a new search. You can either search by typing all or part of the machine name, or you can build an expression to use for an advanced search. To build an expression, select **Unfold**, and then select from the lists of properties and operators.

Manage machines on a connection

1. From Studio, select **Hosting** in the left pane.
2. Select a connection and then select **View Machines** in the action bar.
3. Select one of the following in the action bar. Some actions might not be available, depending on the machine state and the host connection type.
    - **Start:** Starts the machine if it is powered off or suspended.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Suspend:** Pauses the machine without shutting it down, and refreshes the list of machines.
- **Shut down:** Requests the operating system to shut down.
- **Force shut down:** Forcibly powers off the machine, and refreshes the list of machines.
- **Restart:** Requests the operating system to shut down and then start the machine again. If the operating system cannot comply, the desktop remains in its current state.
- **Enable maintenance mode:** Temporarily stops connections to a machine. Users cannot connect to a machine in this state. If users are connected, maintenance mode takes effect when they log off. (You can also turn maintenance mode on or off for all machines accessed through a connection, as described earlier.)
- **Remove from Delivery Group:** Removing a machine from a Delivery Group does not delete it from the machine catalog that the Delivery Group uses. You can remove a machine only when no user is connected to it. Turn on maintenance mode to temporarily prevent users from connecting while you are removing the machine.
- **Delete:** When you delete a machine, users no longer have access to it, and the machine is deleted from the machine catalog. Before deleting a machine, ensure that all user data is backed up or no longer required. You can delete a machine only when no user is connected to it. Turn on maintenance mode to temporarily stop users from connecting while you are deleting the machine.

For actions that involve machine shutdown, if the machine does not shut down within 10 minutes, it is powered off. If Windows attempts to install updates during shutdown, there is a risk that the machine will be powered off before the updates are completed.

Edit storage

You can display the status of servers that are used to store the operating system, temporary, and personal (PvD) data for VMs that use a connection. You can also specify which servers to use for storage of each data type.

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **Edit Storage** in the action bar.
3. In the left pane, select the data type: operating system or temporary.
4. Select or clear the checkboxes for one or more storage devices for the selected data type.
5. Select **OK**.

Each storage device in the list includes its name and storage status. Valid storage status values are:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **In use**: The storage is being used for creating machines.
- **Superseded**: The storage is being used only for existing machines. No new machines are added to this storage.
- **Not in use**: The storage is not being used for creating machines.

If you clear the checkbox for a device that is currently **In use**, its status changes to **Superseded**. Existing machines will continue to use that storage device (and can write data to it). So, that location can become full even after it stops being used for creating machines.

Detect Orphaned Azure resources

Orphaned resources are unused resources present in the system and they can lead to unnecessary expenses.

Apart from Cloud administrators, any newly created roles with **Use Host Connection to Detect Orphaned Resources in Hypervisor** permission under **Hosts** will be able to detect orphaned resources.

This feature allows you to detect the orphaned Azure resources in the hosts on your cloud site.

Follow the steps on Citrix DaaS™:

1. From Studio, select **Hosting** in the left pane.
2. Select a connection, and then select **Detect Orphaned Resources** in the action bar. The **Detect Orphaned Resources** dialog box displays the orphaned resource report.
3. To view the orphaned resource report, select **View Report**.

Alternatively, you can detect orphaned Azure resources using PowerShell. For more information, see Retrieve a list of orphaned resources.

To understand the reasons behind the orphaned resources, and to learn how to proceed further, see Efficiently manage Orphaned Azure resources with Citrix.

Connection timers

You can use Citrix policy settings to configure three connection timers:

- **Maximum connection timer:** Determines the maximum duration of an uninterrupted connection between a user device and a virtual desktop. Use the **Session connection timer** and **Session connection timer interval** policy settings.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Connection idle timer:** Determines how long an uninterrupted user device connection to a virtual desktop is maintained if there is no input from the user. Use the **Session idle timer** and **Session idle timer interval** policy settings.
- **Disconnect timer**: Determines how long a disconnected, locked virtual desktop can remain locked before the session is logged off. Use the **Disconnected session timer** and **Disconnected session timer interval** policy settings.

When you update any of these settings, ensure they are consistent across your deployment.

See the policy settings documentation for more information.

Edit networks of resources

You can change networks for a connection. Do the following:

1. Go to **Hosting**.
2. Select the target resources under the connection and then select **Edit Network** in the action bar.
3. Select one or more networks for the virtual machines to use.
4. Click **Save** to save your changes and exit.

Delete, rename, or test resources

1. From Studio, select **Hosting** in the left pane.
2. Select the target resources under the connection, and then select the appropriate entry in the action bar:
    - **Delete Resources**
    - **Rename Resources**
    - **Test Resources**

Flexible storage location option for VMs

The VMs in a machine catalog are allocated various storage services (SR). To balance the VM allocation in different storage, you have two options:

- **Enhanced current round robin allocation method**: Instead of always starting from the same fixed SR, MCS begins the allocation from the SR right after the last used SR.
- **Least load-based allocation method**: Places the VMs on the least current load, determined by comparing the total number of VMs on each SR within the same machine catalog. For

© 1997–2026 Citrix Systems, Inc. All rights reserved.

example, if a machine catalog contains 100 VMs distributed as follows: 20 VMs on SR1, 30 VMs on SR2, and 50 VMs on SR3, the new VMs are allocated to SR1 first. This method ensures that the load across SR1, SR2, and SR3 is balanced.

This feature is:

- Applicable to all on-premises hypervisors (VMware, XenServer, and Hyper-V)
- Applicable to only OS disk storage.
- Not applicable to the existing VMs

To implement the load-based allocation option, add the custom property `Name="StorageBalanceType"` `Value="VMCountBasedLeastLoad` while creating or updating a host connection. If you don't use this custom property and value, then by default the enhanced round robin method is applied.

For example:

- While creating a host connection:

```
New-Item -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property
xsi:type=`"StringProperty`" Name=`"StorageBalanceType`"
Value=`"VMCountBasedLeastLoad`" /></CustomProperties>"
-HypervisorConnectionName "Xen-Connection" -NetworkPath @("XDHyp:
\Connections\Xen-Connection\Network 0.network") -Path @("XDHyp:
\HostingUnits\XS-Network") -PersonalvDiskStoragePath @() -RootPath
"XDHyp:\Connections\Xen-Connection\" -StoragePath @("XDHyp:
\Connections\Xen-Connection\NFS virtual disk storage.storage")
```

- While updating a host connection:

```
Set-Item  -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property
xsi:type=`"StringProperty`" Name=`"StorageBalanceType`"
Value=`"VMCountBasedLeastLoad`" /></CustomProperties>" -Path @("XDHyp:
\HostingUnits\XS-Network")
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Retrieve a list of orphaned resources

You can get a list of orphaned resources that are created by MCS but are no longer tracked by MCS. This is currently applicable to Azure environments. To get the list, you can use PowerShell commands. You can filter using connections.

By default, the **Full Administrator** and **Cloud Administrator** roles have this permission assigned. To allow other roles to perform this action, assign them the **Use Host Connection to Detect Orphaned Resources in Hypervisor** permission under **Hosts**. For more information, seeCreate and manage roles.

NOTE:

The PowerShell command is rejected if any provisioning or image update is in progress.

Limitations

- To avoid incorrect recognition of orphaned resources, do not power on VMs while you are filtering orphaned resources.
- Around 2,000 records are displayed as orphaned if there is possible heavy workload.

Display the list of orphaned resources

To display the list of orphaned resources

1. Open a **PowerShell** window.
2. Run `asnp citrix*`.
3. Run the following commands:

    a. Get the connection uid. The connection uid is the value of the HypervisorConnectionUid attribute.

    ```
    Get-ChildItem xdhyp:\connections | where { $_.PluginId -like
    'Azure*' }"
    ```

    b. Get the list of orphaned resources.

    ```
    get-provorphanedresource

    -HypervisorConnectionUid <connection uid>
    ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Display the list of orphaned resources from a subscription id

To display the list of orphaned resources from a subscription id:

1. Open a **PowerShell** window.
2. Run `asnp citrix*`.
3. Run the following commands:

    a. Find the connection uid using the subscription ID. The connection uid is the value of the HypervisorConnectionUid attribute.

    ```
    Get-ChildItem xdhyp:\connections | where { $_.CustomProperties
    -match '<subscriptionId>' }
    ```

    b. Get the list of orphaned resources.

    ```
    get-provorphanedresource -HypervisorConnectionUid <connection uid>
    ```

NOTE:

Check the resources carefully before deleting.

Use WinHttp (netsh) proxy server settings for hosting connection

This feature enhancement allows hosting connections to use the WinHttp (netsh) proxy server settings to be used with the hosting connection. This allows simpler proxy setup and also ensures consistent proxy usage between the Cloud Connector and host connections.

This feature is applicable to the following virtualization environments:

- Nutanix
- HPE Moonshot
- Red Hat OpenShift

Use cases

- Example 1: No custom property is set on the hosting connection

  The hosting connection will not read any proxy configuration settings on the machine and will attempt to connect to the hypervisor without a proxy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Example 2: Custom property is set on the hosting connection with value = True

  The hosting connection will only read the WinHttp proxy settings and use the proxy settings if present. If not present, no proxy settings will be used for the hosting connection.

- Example 3: Custom property is set on the hosting connection with value = False

  The hosting connection will not read any proxy configuration settings on the machine and will attempt to connect to the hypervisor without a proxy.

Changes to the existing workflow or process

- To use the WinHttp (netsh) proxy server configured on the Cloud Connectors for the hosting connection, you can now include this custom property with the hosting connection.

  ```
  <Property xsi:type="StringProperty"
  Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />
  ```

- When this custom property is set to `True`, the API calls to the hypervisor are routed through the WinHttp proxy server set on the machine through netsh winhttp set proxy command.
- When this custom property is set to `False`, or this custom property is not set, the API calls will ignore all the proxy servers (including the WinINet proxy and .net proxy) configured on the Cloud Connectors.

Prerequisite

Before setting the custom property while creating the host connection using PowerShell, make sure that you configure the WinHTTP proxy on all the Citrix Cloud Connectors in the Resource Location.

Configuration steps

To create a new hosting connection to use the WinHttp proxy settings through CLI:

```
$CustomProperties = "<CustomProperties  xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`">

<!-- Include any other hypervisor specific custom properties here -->

<Property xsi:type=`"StringProperty`"
Name=`"UseSystemProxyForHypervisorTrafficOnConnectors`" Value=`"True`" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>"

New-Item -ConnectionType $ConnectionType -HypervisorAddress @('https://
hypervisorhost1.example.com') -Path @('XDHyp:\Connections\
$ConnectionName') -Password $Password -UserName $User -CustomProperties
$CustomProperties
```

To set the custom property on an existing hosting connection:

1. Copy the existing custom properties from the host connection if any present.

   ```
   dir XDHyp:\Connections
   ```

2. Copy the custom properties for your host connection and add the following, and save it to a variable.

   ```
   $CustomProperties

   <Property xsi:type=`"StringProperty`"
   Name=`"UseWinHttpProxyForHypervisorTraffic`" Value=`"True`" />
   ```

   Example:

   ```
   $CustomProperties = "<CustomProperties xmlns=`"http://
   schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
   www.w3.org/2001/XMLSchema-instance`">

   <Property xsi:type=`"IntProperty`"
   Name=`"MaximumConcurrentProvisioningOperations`" Value=`"100`"/
   ><Property xsi:type=`"StringProperty`"
   Name=`"UseSystemProxyForHypervisorTrafficOnConnectors`"
   Value=`"True`" />

   </CustomProperties>"
   ```

   If existing custom property was empty, set the custom property:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$CustomProperties = "<CustomProperties  xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`">

<Property xsi:type=`"StringProperty`"
Name=`"UseSystemProxyForHypervisorTrafficOnConnectors`"
Value=`"True`" />

</CustomProperties>"
```

3. Run `Set-Item` command to update the existing hosting connection.

```
Set-Item -CustomProperties $CustomProperties -LiteralPath @("XDHyp:
\Connections\$ConnectionName") -PassThru -UserName $User
-SecurePassword $Password
```

Where to go next

- For information on connection to specific host types, see:
  - Connection to AWS
  - Connection to Google cloud environments
  - Connection to Microsoft Azure
  - Connection to Microsoft System Center Virtual Machine Manager
  - Connection to Nutanix
  - Connection to Nutanix cloud and partner solutions
  - Connection to VMware
  - Connection to VMware cloud and partner solutions
  - Connection to XenServer

If you're in the initial deployment process, create a machine catalog.

Connection to Amulet Hotkey CoreStation

Create and manage connections and resources describes the general wizards for creating a connection. The following information covers details specific to Amulet Hotkey CoreStation. You can currently create a connection to the Amulet Hotkey CoreStation using PowerShell commands.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Before creating a connection to Amulet Hotkey CoreStation, you need to first finish setting up your Amulet Hotkey CoreStation account. See Amulet Hotkey CoreStation virtualization environments

Create a connection

You can create a connection to Amulet Hotkey CoreStation using:

- Studio
- PowerShell commands

Create a connection using Studio

1. In the **Add Connection and Resources** page, select **Amulet Hotkey CoreStation** as the connection type.
2. Enter the connection address of your Amulet Hotkey CoreStation enclosure Manager. You can use an IP address, host name, or FQDN for the address.
3. Enter your enclosure administrative credentials and a friendly connection name.

   Connection setup stops when either of the situations occurs:

   - DaaS receives a public CA-signed certificate with errors: An error message appears. Follow the on-screen instructions to fix the issue. Otherwise, you can't proceed with connection creation.
   - DaaS receives a private CA-signed certificate: A warning page appears. Compare the received thumbprint with the server's for the certificate validity. If it's valid, select Trust certificate and click OK to proceed with connection creation. DaaS will then trust the certificate and store the thumbprint for future validation.

Create a connection using PowerShell commands

When you create a connection using PowerShell command, provide the following information:

- IP: Amulet Hotkey CoreStation IP Address
- Username: Amulet Hotkey CoreStation username
- Password: Amulet Hotkey CoreStation password

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-ConfigZone

Get-HypHypervisorPlugin

New-Item `

    -ConnectionType "Custom" `

    -HypervisorAddress $IP `

    -Metadata
@{"Citrix_Orchestration_Hypervisor_Secret_Allow_Edit"="false"} `

    -Path @("XDHyp:\Connections\$connectionName") `

    -Persist `

    -PluginId "AmuletHotkeyCoreStationFactory" `

    -Scope @() `

    -SecurePassword $Password `

    -UserName $UserName `

    -ZoneUid $ZoneUid `

    -SslThumbprint $SslThumbprint

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$HypervisorConnectionID
```

NOTE:

The `-SslThumbprint` parameter is required only for private CA-signed certificates.

Certificate and thumbprint validation

For creating a successful connection to Amulet Hotkey CoreStation, the certificate must not have errors and the thumbprint must have a correct value. Following are the use cases related to the certificate and thumbprint validation:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SCENARIO	RESULT
Public CA-signed certificate has errors.	The connection is not created successfully. See the error details and resolve the issue.
Public CA-signed certificate without errors.	The connection is created successfully, and the `SslThumbprints` value is `Null`.
Private CA-signed certificate without errors and a `sslthumbprint` value.	The connection is created successfully with a correct `SslThumbprints` value.
Private CA-signed Certificate with an incorrect thumbprint value.	The connection is not created successfully.
Private CA-signed Certificate without errors. (no thumbprint provided)	The connection is created successfully. The `SSlThumbprints` is `Null` when creating the connection. The `SSlThumbprints` value is updated to a value by the site service.

Manage connections

Fix certificate issues

Citrix DaaS blocks an Amulet Hotkey CoreStation connection when certificate issues arise, preventing you from delivering and managing workloads on associated Amulet Hotkey CoreStation nodes. You'll see an error icon next to the connection in the **Host connections** list.

See the following table for specific issues and solutions.

ISSUE	SOLUTION
A certificate error occurs to the public CA-signed certificate.	Click the connection and select the **Troubleshoot** tab. View the error details and resolve the issue.
The received certificate is private CA-signed or expired.	Edit the host connection to update the certificate thumbprint. Details steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ISSUE	SOLUTION	
	1. Select the connection and click **Edit Connection**. 2. On the **Connection Properties** page, click **Edit settings**. 3. Enter the password to connect to the Amulet Hotkey CoreStation enclosure, and then click **Save**. 4. On the **Warning** page that appears, compare the received thumbprint with the server's for certificate validity. 5. If they are the same, select **Trust certificate** and then click **OK**.	

Update thumbprint value

After creating the connection, you can update the thumbprint value of a connection using the `Set-Item` PowerShell command. Follow the steps to update the thumbprint value.

1. Get the connection details of a connection. For example:

```
Get-Item -LiteralPath xdhyp:\connections\AmuletCon-101
```

2. Update the thumbprint value. For example:

```
Set-Item -LiteralPath xdhyp:\connections\AmuletCon-101 -Username
Administrator -SslThumbprint xxxxxxxxxxx12AD048480631BB7AB10D69xxxxx
```

3. Check the updated thumbprint value. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-Item -LiteralPath xdhyp:\connections\AmuletCon-101
```

NOTE:

The update fails if you provide an incorrect thumbprint value in the `Set-Item` command.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For Amulet Hotkey CoreStation information, see Create an Amulet Hotkey CoreStation machine catalog

More information

- Create and manage connections and resources
- Amulet Hotkey CoreStation virtualization environments

Connection to AWS EC2

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to AWS cloud environments.

Prerequisites

Do the following before creating a connection to AWS EC2:

- Complete setting up your AWS as a resource location. See AWS virtualization environments.
- Define IAM permissions policy of IAM user or role for Citrix to manage AWS resources on your behalf.

Define IAM permissions

Before creating a host connection, an IAM permissions policy needs to be properly defined for an IAM user or role that gives Citrix proper permissions to provision and manage resources in your AWS account on your behalf. Use the information in this section to define IAM permissions for Citrix DaaS on AWS. Amazon's IAM service permits accounts having multiple users, which can be further organized into groups. These users can possess different permissions to control their ability to perform operations associated with the account. For more information about IAM permissions, see the IAM JSON policy reference.

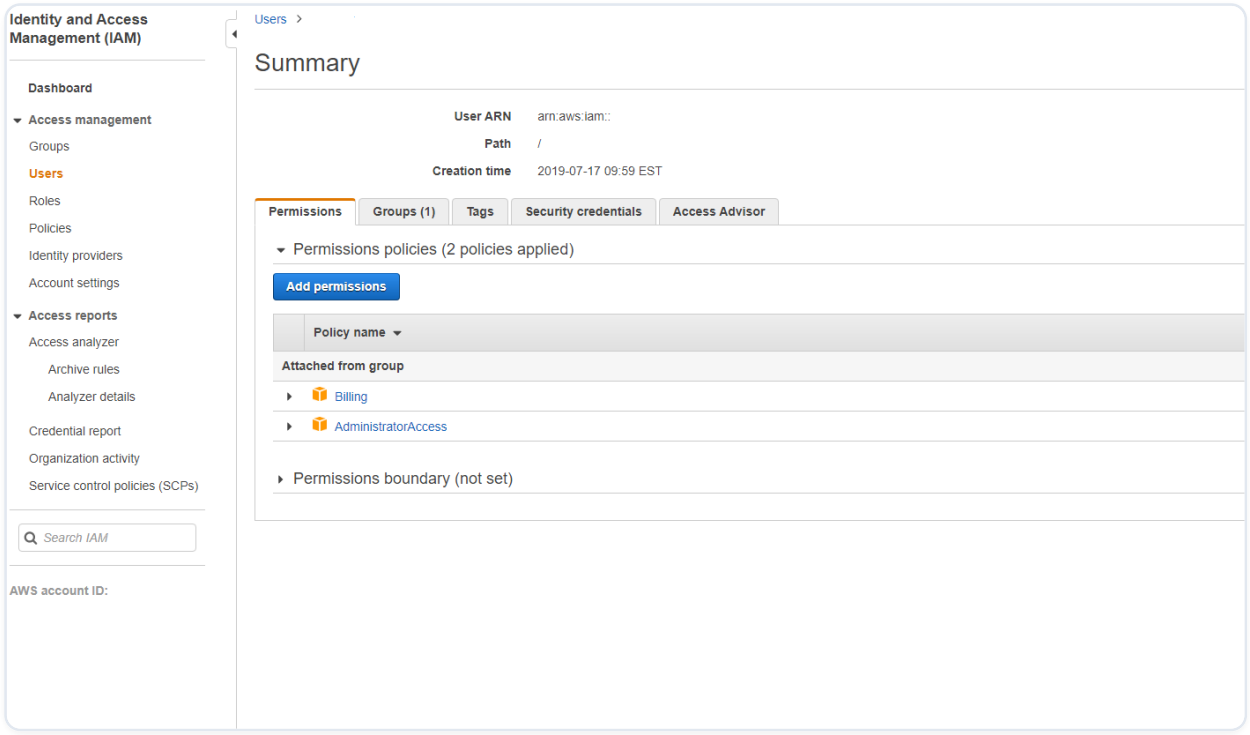
To apply IAM permissions policy to a new group of users:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Log in to the AWS management console and select the **IAM service** from the drop-down list.
2. Select **Create a New Group of Users**.
3. Type a name for the new user group and select **Continue**.
4. On the **Permissions** page, choose **Custom Policy** then **Select**.
5. Type a name for the **Permissions policy**.
6. In the **Policy Document** section, enter the relevant permissions.

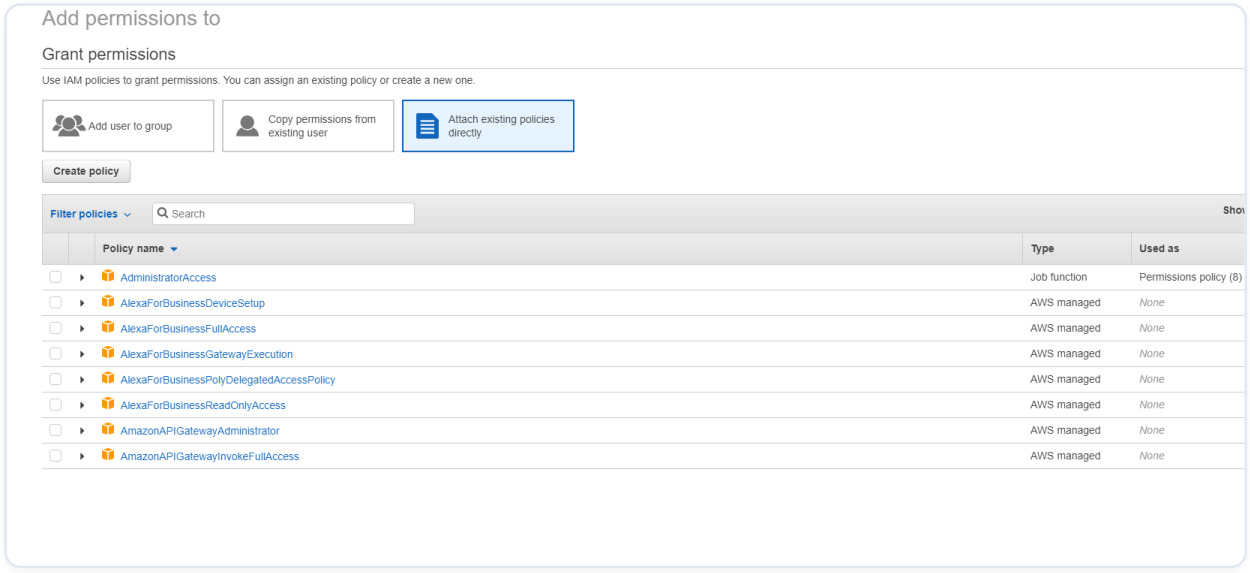
After entering the policy information, select **Continue** to complete the application of the IAM permissions policy to the group of users. Users in the group are granted permissions to do only those actions that are required for Citrix DaaS.

IMPORTANT:



Use the policy text provided in the example provided in this article to list the actions that a Citrix DaaS uses to perform actions within an AWS account without restricting those actions to specific resources. Citrix recommends that you use the example for testing purposes. For production environments, you might choose to add further restrictions on resources.

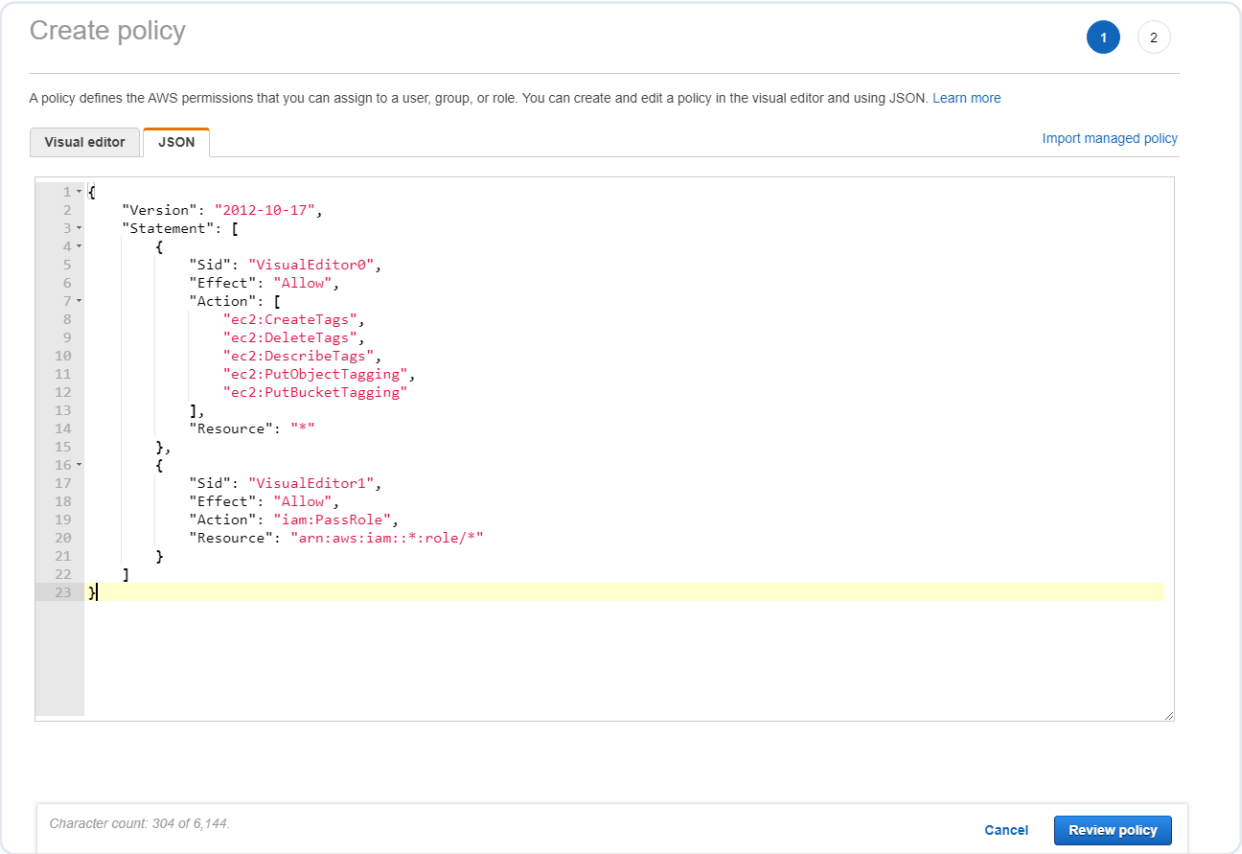
Add IAM permissions



Add the permissions in the **IAM** section of the AWS Management Console:

1. In the **Summary** panel, select the **Permissions** tab.
2. Select **Add permissions.**

© 1997–2026 Citrix Systems, Inc. All rights reserved.



3. In the **Add Permissions to** screen, grant permissions:

4. In the JSON section, include Required AWS permissions for your environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a connection

You can create a connection to Amazon EC2 using:

- Studio
- PowerShell commands

NOTE:

Check your proxy server or firewall restrictions and ensure that the following address is contactable: `https://*.amazonaws.com`. Also, make sure that all the addresses mentioned in Citrix Gateway service connectivity are contactable.

If these are not contactable, it might cause failure while creating or updating the host connection.

Create a connection using Studio

1. Navigate to **Hosting > Add Connection and Resources** page.
2. On the **Connection** page, follow these steps to configure the connection:
   a. Select **Create a new connection**.
   b. In **Zone**, select the resource location you have set up for your AWS environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. Select **Amazon EC2** as the connection type.

d. Select one of the methods to provision the resources:

- If you select **Use this AWS account to provision resources**, then select **Use IAM user access key** or **Use IAM role**. For the IAM user access key, provide your **API key** and **Secret key** for the IAM user that has proper IAM permissions policy for Citrix to manage resources in your AWS account. For the IAM role, make sure that you've assigned an IAM role to the Citrix Cloud Connector instance with proper IAM permissions policy for Citrix to manage resources in your AWS account. See Role-based authentication guide for more information.
- If you select **Use cross-account access to provision resources**, then provide the **ARN** of the IAM role in Account B that the Cloud Connectors (or Delivery Controllers) in Account A must assume and perform provisioning operations in.

e. Enter a connection name and click **Next**.

3. On the **Virtual Machine Location** page, specify the location where the VMs must be provisioned. Select the cloud region, VPC, and availability zone or local zone for creating new VMs.
4. On the **Network** page:

   a. Enter a name for the resources that you selected previously in the availability zone or local zone.

   b. Select one or more subnets in the VPC that you configured in the previous menu.

5. Click through the remaining pages till the **Summary** page.
6. Click **Finish** to create the host connection to Amazon EC2.

IMPORTANT CONSIDERATIONS

When you create a connection using Studio:

- Define proper IAM permissions for Citrix to manage your AWS resources.
- If you use an IAM user access key for Citrix to manage your AWS resources, you must provide the API key and secret key values. You can export the key file containing those values from AWS and then import them. You must also provide the region, availability zone, VPC name, subnet addresses, domain name, security group names, and credentials.
- If you use an IAM role for Citrix to manage your AWS resources, you must make sure to assign a role with proper IAM permissions to all of your Cloud Connector(s). Role-based authentication guide for more information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The credentials file for the root AWS account (retrieved from the AWS console) is not formatted the same as credentials files downloaded for standard AWS users. Therefore, Citrix DaaS cannot use the file to populate the API key and secret key fields. Ensure that you are using AWS Identity Access Management (IAM) credentials files.
- The zone can be an availability zone or local zone.

Create a connection using PowerShell

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run the following commands. Following is an example:

```
$connectionName = "demo-hostingconnection"

$cloudRegion = "us-east-1"

$apiKey = "aaaaaaaaaaaaaaaaaaaa"

$apiSecret = “bbbbb”

$secureKey = ConvertTo-SecureString -String $apiSecret

$zoneUid = "00000000-0000-0000-0000-000000000000"

$connectionPath = "XDHyp:\Connections\" + $connectionName

$connection = New-Item -Path $connectionPath -ConnectionType "<name of
the connection>" -HypervisorAddress " "@("https://ec2.cn-
north-1.amazonaws.com.cn") -Persist -Scope @() -UserName $apiKey
-SecurePassword $secureKey -ZoneUid $zoneUid

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid

$hostingUnitName = "demo-hostingunit"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$availabilityzone = "us-east-1a"

$vpcName = "Default VPC"

$jobGroup = [Guid]::NewGuid()

$hostingUnitPath = "XDHyp:\HostingUnits\" + $HostingUnitName

$rootPath = $connectionPath + "\" + $vpcName + ".virtualprivatecloud\"

$availabilityZonePath = @($rootPath + $availabilityzone +
".availabilityzone")

$networkPaths = (Get-ChildItem $availabilityZonePath[0] | Where
ObjectType -eq "Network") | Select-Object -ExpandProperty FullPath #
will select all the networks in the availability zone

New-Item -Path $hostingUnitPath -AvailabilityZonePath
$availabilityZonePath -HypervisorConnectionName $connectionName
-JobGroup $jobGroup -PersonalvDiskStoragePath @() -RootPath $rootPath
-NetworkPath $networkPaths
```

NOTE:

To create a connection using Role-Based Authentication, specify apiKey and apiSecret as `role_based_auth`.

Limitation

If you change the name of an AWS Virtual Private Cloud (VPC) in the AWS console, then the existing hosting unit in Citrix Cloud™ breaks. When the hosting unit is broken, you cannot create catalogs or add machines to existing catalogs. To resolve the issue, change the name of the AWS VPC back to the original name.

Enhanced proxy configuration for AWS host connection

AWS host connection can read the WinHTTP system proxy value that is configured during Cloud Connector installation if you set the custom property

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`UseSystemProxyForHypervisorTrafficOnConnectors` to `true` when creating or updating a host connection using PowerShell.

Advantages

- Simplifies proxy configuration for AWS host connections.
- Reduces the need for manual PowerShell configuration of server and port values.
- Ensures consistent proxy usage between the Cloud Connector and host connections.
- Improves the success rate of API calls that require proxy access.
- Decreases support requests related to proxy configuration.

Prerequisite

Before setting the custom property while creating the host connection using PowerShell, make sure that you configure the WinHTTP proxy on the Cloud Connector.

Create a new connection with automatic proxy

1. Open PowerShell.
2. Add the Citrix snap-ins:

```
Add-PSSnapin citrix*
```

3. Define the variables for the connection.

```
$hypType = "AWS"

################################################################################
#############

The following items need to be set based on the installed environment

$customProperties is set to enable using the system proxy

$customProperties = '<CustomProperties xmlns="http://
schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance"><Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" /></
CustomProperties>'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$awsEndPoint is set to the desired region for the connection

$awsEndPoint = "https://ec2.us-east-1.amazonaws.com"

$hypConnName is set to the connection name to use

$hypConnName = "ctx-test"

$apiKey is set to the AWS API Key ID or "role_based_auth" if the Cloud
Connector instance has an appropriate role

$apiKey = "role_based_auth"

$secretKey is set to the AWS API Key Secret or "role_based_auth" if the
Cloud Connector instance has an appropriate role

$secretKey = "role_based_auth"

$resourceLocation is set to the connector resource location name

$resourceLocation = "ctx-test"

################################################################################
##############
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$secureSecretKey = ConvertTo-SecureString -String $secretKey
-AsPlainText -Force

$zoneUid = (Get-ConfigZone|Where-Object Name -EQ
"$resourceLocation").Uid
```

NOTE:

Ensure you replace the placeholder values in the `$customProperties`, `$awsEndPoint`, `$hypConnName`, `$apiKey`, `$secretKey`, and `$resourceLocation` variables with the appropriate values for your environment.

4. Create the hypervisor connection.

```
$hypHc = New-Item -Path xdhyp:\Connections `

-Name $hypConnName `

-HypervisorAddress $awsEndPoint `

-UserName $apiKey `

-SecurePassword $secureSecretKey `

-ConnectionType $hypType `

-CustomProperties $customProperties `

-Persist `

-ZoneUid $zoneUid
```

5. Create the Broker hypervisor connection.

```
$bhc = New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$hypHc.HypervisorConnectionUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Also, see Update an existing host connection with automatic proxy

Cross-account provisioning

There are use-cases where the Cloud Connectors would like to be placed in a separate AWS account (shared services account or site components account) with IAM roles that have cross-account access (cross-account IAM role) and MCS-provisioned machine catalogs in separate secondary AWS account (workloads accounts), without the need for additional Cloud Connectors in the separate accounts. To support such scenarios, this feature uses VPC peering and cross-account access using IAM roles to make provisioning across different AWS accounts possible for enterprises managing multiple AWS accounts.

With VPC peering, you can have your Cloud Connector, and provisioned VMs in different regions or accounts be able to communicate among each other.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

To allow Cloud Connector to access the resources of the secondary account, create a host connection after assuming the IAM role from the secondary account.

Prerequisites

Set up the following before creating a host connection for cross-account provisioning:

- Set up VPC peering and configure the security groups in both regions or accounts. See Set up VPC peering.
- Delegate cross-account access using IAM roles. See Delegate cross-account access using IAM role.

Set up VPC peering

Let's assume that VPC A is in the primary account (Account A) and it has the Cloud Connectors and Active Directory. VPC B is in the secondary account (Account B) where you want to provision the VMs.

To set up a VPC peering connection between Account A and Account B, do the following:

1. Create a VPC peering connection. See:
    - Different account same region
    - Different account different region

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Go to your VPC A and to the route table that is associated with the public subnet.
3. Click **Edit Routes > Add route**. Add VPC B's CIDR block in the **Destination** column and add the VPC peering you created in the **Target** column.
4. Repeat Steps 2 and 3, but with the private subnets for VPC A and VPC B (add VPC A's CIDR block). See Update your route tables for a VPC peering connection.
5. Go to the private security group associated with VPC A.
6. Select **Actions**, then **Edit inbound rules**.
7. Select **Add rule**. For type, select **All Traffic**, then in the **Source Column** add:
    - If it is a different region, add VPC B's CIDR Block.
    - If it is a different account but the same region, add the account ID and private security group ID of VPC B separated by a forward slash (Example, 123456789012/sg-1a2b3c4d)
8. Repeat Steps 5 through 7, but with the private security group for VPC B (but add VPC A's CIDR Block or VPC A's account ID and private security group ID of the same region, but different account). See Update your security groups to reference peer security groups.

NOTE:

There is no charge to create a VPC peering connection. However, while VPC peering within an Availability Zone is free, charges apply when data transfer over a VPC peering connection occurs across multiple Availability Zones and regions. See Pricing for a VPC peering connection.

Delegate cross-account access using IAM roles

After setting up VPC peering across accounts, you delegate cross-account access using IAM roles.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

To access cross-account resources, do the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

REMEMBER:

Assumed, VPC A is in the primary account (Account A) and it has the Cloud Connector and Active Directory. VPC B is in the secondary account (Account B) where you want to provision the VMs

1. Set up VPC peering across accounts with the steps mentioned before.
2. Create an IAM role and policy in Account B with minimal Citrix IAM Permissions. See IAM tutorial: Delegate access across AWS accounts using IAM roles. Let's say the arn of this role is "arn:aws:iam::5678:role/citrix-role".
3. Add the Trust policy to the role "arn:aws:iam::5678:role/citrix-role" so that it's allowed to be accessed by Account A role "arn:aws:iam::1234:role/primary-account-citrix-role" as per - Cross account resource access in IAM.
4. Create the IAM role and policy in Account A with the name mentioned before "primary-account-citrix role", which can assume the IAM role and pass the IAM role from the Account B (arn:aws:iam::5678:role/citrix-role).
5. Assign the role "arn:aws:iam::1234:role/primary-account-citrix-role" to all the Cloud Connectors in Account A.

Cloud Connectors can now assume the role from Account B ("arn:aws:iam::5678:role/citrix-role").

Create host connection for cross-account provisioning

Create a host connection in the secondary account (Account B) where you want to provision the VMs. This allows Cloud Connectors of Account A to access the resources in Account B after assuming the role from Account B.

Use PowerShell commands to create the host connection and add the following two custom properties:

- `CrossAccountRoleArn`: If you don't provide `CrossAccountRoleArn` property, then the regular Host Connection is created. In this case, `MaximumAssumeRoleDurationInSeconds` is ignored even if it is provided.
- `MaximumAssumeRoleDurationInSeconds`: `DurationInSeconds` must be between 900 seconds to 3600 seconds. The default is 900 seconds. If you provide a value provided more than 3600, then `DurationInSeconds` is set to 3600.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$connectionName = "cross-account-conn"

$cloudRegion = "us-east-1"

$apiKey = "role_based_auth"

$secretKey = "role_based_auth"

$zoneUid = "xxxxxx"

$secureKey = (ConvertTo-SecureString -String $secretKey -AsPlainText
-Force)

$connectionPath = "XDHyp:\Connections\" + $connectionName

$customProperties = '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="CrossAccountRoleArn"
Value="arn:aws:iam::5678:role/citrix-role" /><Property
xsi:type="StringProperty" Name="MaximumAssumeRoleDurationInSeconds"
Value="3600" />

"</CustomProperties>'

$connection = New-Item -Path $connectionPath -ConnectionType "AWS"
-HypervisorAddress "https://ec2.$($cloudRegion).amazonaws.com" -Persist
-Scope @() -UserName $apiKey -SecurePassword $secureKey -ZoneUid $zoneUid
-CustomProperties $customProperties

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid
```

After the host connection is created, create hosting units using Studio or PowerShell. However, select VPC and Networks.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Edit a connection

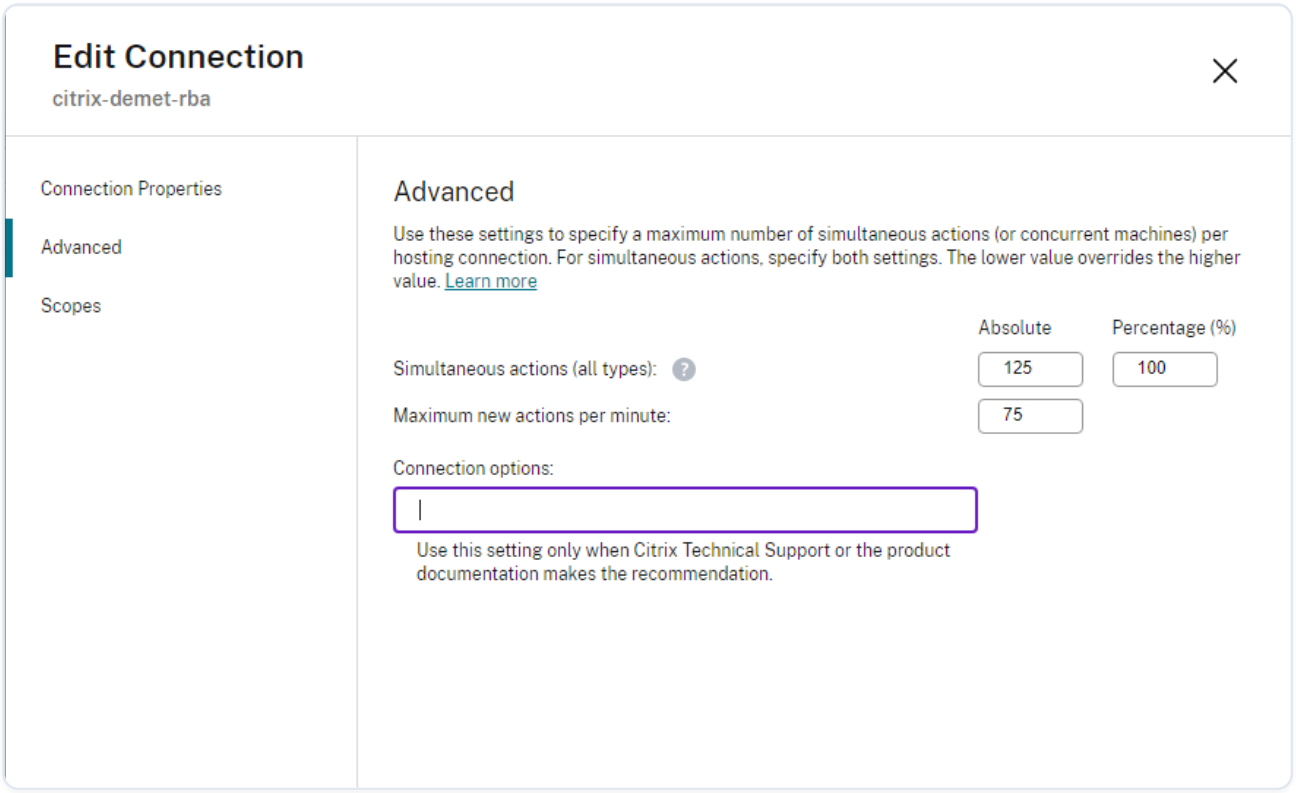
You can edit an existing host connection to:

- Modify the option to provide IAM permissions for Citrix to manage resources
- Modify the maximum number of simultaneous actions (or concurrent machines) per hosting connection
- Modify the scope.
- Configure the maximum number of security groups allowed per elastic network interface (ENI) using PowerShell command
- Update an existing host connection with automatic proxy

Edit options to provide IAM permissions

1. Right-click an existing Amazon EC2 connection.
2. On the **Connection Properties** page, click **Edit settings**.
3. Select one of the options to provide IAM permissions for Citrix to manage resources. Enter the required details and click **Save**.

Modify the maximum number of simultaneous actions



When you create host connections in Studio for Amazon EC2, the following default values display:

OPTION	ABSOLUTE	PERCENTAGE
Simultaneous actions (all types)	125	100
Maximum new actions per minute	150	n/a
Maximum concurrent provisioning operations	100	n/a

MCS supports 100 maximum concurrent provisioning operations by default.

Configure these values by accessing the Citrix Studio **Advanced** section on the **Edit Connection** screen.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Alternatively, you can use the Remote PowerShell SDK to set the maximum number of concurrent operations for optimal settings per your environment.

Use the PowerShell custom property, `MaximumConcurrentProvisioningOperations`, to specify the maximum number of concurrent AWS provisioning operations.

Before configuration:

- Ensure you have installed the PowerShell SDK for Cloud.
- Understand that the default value for `MaximumConcurrentProvisioningOperations` is 100.

Perform the following steps to customize the `MaximumConcurrentProvisioningOperations` value:

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Enter `cd xdhyp:\Connections\`.
4. Enter `dir` to list the connections.
5. Change or Initialize the Custom Properties string:
    - If the Custom Properties string has a value, copy the Custom Properties into Notepad. Next, change the `MaximumConcurrentProvisioningOperations` property to your preferred value. You can enter a value ranging 1–1000. For example, `<Property`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`xsi:type="IntProperty" Name="MaximumConcurrentProvisioningOperations" Value="xyz"/>`.

- If the Custom Properties string is empty or null, you must initialize the string by entering the proper syntax for both the schema and the `MaximumConcurrentProvisioningOperations` property.

6. In the **PowerShell** window, paste the modified Custom Properties from Notepad and assign a variable to the modified Custom Properties. If you initialized the Custom Properties, add the following lines after the syntax:

   `$customProperties = '<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"><Property xsi:type="IntProperty" Name="MaximumConcurrentProvisioningOperations" Value="100"/></CustomProperties>'`.

   This string sets the `MaximumConcurrentProvisioningOperations` property to 100. In the Custom Properties string, you must set the `MaximumConcurrentProvisioningOperations` property to a value that aligns with your needs.

7. Enter `Get-XDAuthentication`, which prompts you for your credentials.
8. Run `$cred = Get-Credential`, which might prompt you for solely a Password (or a Name and Password). You might also be prompted for the application ID and associated secret. For connections using role-based authentication, **role_based_auth** is both the Name and Password. Otherwise, enter the AWS API ID and secret.
9. Run `set-item -PSPath 'XDHyp:\Connections<connection-name>' -CustomProperties $customProperties -username $cred.username -Securepassword $cred.password`. You must set the *<connection-name>* to the name of the connection.
10. Enter `dir` to verify the updated CustomProperties string.

Configure security groups per network interface

When editing a host connection, you can now configure the maximum number of security groups allowed per elastic network interface (ENI) using a PowerShell command. For information on AWS security groups quota values, see Security groups.

To configure security groups per network interface:

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Run `cd xdhyp:\Connections\`.
4. Run `dir` to list the connections.
5. Run the following PowerShell command to configure security groups per network interface:

```
Set-HypHypervisorConnectionMetadata -HypervisorConnectionName aws -Name
"Citrix_MachineManagement_Options" -Value "
AwsMaxENISecurityGroupLimit=<number>"
```

NOTE:

If you do not set a value for `AwsMaxENISecurityGroupLimit`, then it takes the default value of 5.

Update an existing host connection with automatic proxy

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Enter `cd xdhyp:\Connections\`.
4. Enter `dir` to list the connections.
5. Copy the CustomProperties to a notepad and append property setting `<Property xsi:type="StringProperty" Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True"`.
6. In the **PowerShell** window, paste the modified Custom Properties from Notepad and assign a variable to the modified Custom Properties.
7. Enter `Get-XDAuthentication`, which prompts you for your credentials.
8. Run `$cred = Get-Credential`, which might prompt you for solely a Password (or a Name and Password). You might also be prompted for the application ID and associated secret. For connections using role-based authentication, **role_based_auth** is both the Name and Password. Otherwise, enter the AWS API ID and secret.
9. Run `set-item -PSPath 'XDHyp:\Connections<connection-name>' -CustomProperties $customProperties -username $cred.username -Securepassword $cred.password`. You must set the \<*connection-name*\> to the name of the connection.
10. Enter `dir` to verify the updated CustomProperties string.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Service endpoint URL

Standard zone service endpoint URL

When you use MCS, a new AWS connection is added with an API key and an API secret. With this information, along with the authenticated account, MCS queries AWS for the supported zones using the AWS DescribeRegions EC2 API call. The query is made using a generic EC2 Service Endpoint URL `https://ec2.amazonaws.com/`. Use MCS to select the zone for the connection from the list of supported zones. The preferred AWS service endpoint URL is automatically selected for the zone. However, after you create the service endpoint URL, you can no longer set or modify the URL.

Non-standard service endpoint URL

There can be situations where you might not need the automatically chosen AWS Service Endpoint URL for the connection. For such cases, you can use Citrix Cloud SDK and PowerShell to create a connection with a non-standard service endpoint URL. For example, to create a connection using the service endpoint URL `https://ec2.cn-north-1.amazonaws.com.cn`:

1. Set up the AWS hosted Cloud Connector and ensure that it has connectivity.
2. Run the following PowerShell commands to see the list of Cloud Connectors.

```
PS C:\> asnp citrix.*

PS C:\> Get-XDAuthentication

PS C:\> Get-ConfigEdgeServer
```

3. Find the ZoneUid from the newly created Cloud Connector and enter it into the following PowerShell commands. Replace the italicized items with the respective values.

```
PS C:\> $hyp= New-Item -Path xdhyp:\Connections -ZoneUid`*ZoneUid*`-
Name`*"My New Connection”*`-ConnectionType "AWS" -HypervisorAddress
@("https://ec2.cn-north-1.amazonaws.com.cn") -UserName`*"APIkey"* `-
Password`*“API Secret”* `-Persist`

`PS C:\> New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$hyp. HypervisorConnectionUid
```

4. Refresh the **Hosting** tab to verify that the EC2 connection has been created.
5. Add a resource location using the new connection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Required AWS permissions

This section contains the complete list of AWS permissions. Use the complete set of permissions as given in the section for the functionality to work correctly.

NOTE:

The `iam:PassRole` permission is needed only for **role_based_auth**.

Creating a host connection

A new host connection is added using the information obtained from AWS.

                "ec2:GetLaunchTemplateData",
                "ec2:DescribeVolumes",
                "ec2:DescribeVpcs",
                "ec2:DetachVolume",
                "ec2:DisassociateIamInstanceProfile",
                "ec2:RunInstances",
                "ec2:StartInstances",
                "ec2:StopInstances",
                "ec2:TerminateInstances"
            ],
            "Effect": "Allow",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            "Resource": "*"
        },
        {
            "Action": [
                "ec2:CreateSecurityGroup",
                "ec2:DeleteSecurityGroup"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": [
                "ebs:StartSnapshot",
                "ebs:GetSnapshotBlock",
                "ebs:PutSnapshotBlock",
                "ebs:CompleteSnapshot",
                "ebs:ListSnapshotBlocks",
                "ebs:ListChangedBlocks",
                "ec2:CreateSnapshot"
            ],
            "Effect": "Allow",
            "Resource": "*"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        }

    ]

}
```

NOTE:

- The EC2 section related to SecurityGroups is only needed if an Isolation Security Group must be created for the Preparation VM during catalog creation. Once this is done, these permissions are not required.

Importing VMs

A machine catalog is created by importing VMs.

```
{

    "Version": "2012-10-17",

    "Statement": [

        {

            "Action": [

                "ec2:DescribeInstances",

                "ec2:DescribeSecurityGroups",

                "ec2:DescribeAvailabilityZones",

                "ec2:DescribeSubnets",

                "ec2:DescribeVolumes",

                "ec2:DescribeSpotInstanceRequests"

            ],
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

NOTE:

The `ec2:DescribeSpotInstanceRequests` is needed only if there is a spot instance in the AWS region from where VMs are going to be imported.

DIRECT DISK UPLOAD AND DOWNLOAD

Direct disk upload eliminates the volume worker requirement for machine catalog provisioning, and instead uses public APIs provided by AWS. This functionality reduces the cost associated with extra storage accounts and the complexity for maintaining volume worker operations.

NOTE:

The support for volume worker is removed. The direct disk upload and download permissions are required for machine catalog provisioning.

The following permissions must be added to the policy:

- `ebs:StartSnapshot`
- `ebs:GetSnapshotBlock`
- `ebs:PutSnapshotBlock`
- `ebs:CompleteSnapshot`
- `ebs:ListSnapshotBlocks`
- `ebs:ListChangedBlocks`
- `ec2:CreateSnapshot`
- `ec2:DeleteSnapshot`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `ec2:DescribeLaunchTemplates`

IMPORTANT:

- You can add a new VM to existing machine catalogs without any volume worker resources such as volume worker AMI, and volume worker VM.
- If you delete an existing catalog that used any volume worker before, all artifacts that are volume worker related are deleted.

EBS encryption of created volumes

EBS can auto-encrypt newly created volumes if the AMI is encrypted, or EBS is configured to encrypt all new volumes. However, to implement the functionality, the following permissions must be included in the IAM policy.

```
{
     "Version": "2012-10-17",
     "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                 "kms:CreateGrant",
                 "kms:Decrypt",
                 "kms:DescribeKey",
                 "kms:GenerateDataKeyWithoutPlainText",
                 "kms:GenerateDataKey",
                 "kms:ReEncryptTo",
                 "kms:ReEncryptFrom"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            ],
            "Resource": "*"
        }
    ]
}
```

NOTE:

The permissions can be limited to specific keys by including a Resource and Condition block at the discretion of the user. For example, **KMS Permissions with Condition**:

```
{
     "Version": "2012-10-17",
     "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                 "kms:CreateGrant",
                 "kms:Decrypt",
                 "kms:DescribeKey",
                 "kms:GenerateDataKeyWithoutPlainText",
                 "kms:GenerateDataKey",
                 "kms:ReEncryptTo",
                 "kms:ReEncryptFrom"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            ],

            "Resource": [

                "arn:aws:kms:us-east-2:123456789012:key/abcd1234-
a123-456d-a12b-a123b4cd56ef"

            ],

            "Condition": {

                "Bool": {

                    "kms:GrantIsForAWSResource": true

                }

            }

        }

    ]

}
```

The following key policy statement is the entire default key policy for KMS keys that is required to allow the account to use IAM policies to delegate permission for all actions (kms:*) on the KMS key.

```
{

"Sid": "Enable IAM policies",

"Effect": "Allow",

"Principal": {

"AWS": "arn:aws:iam::111122223333:root"

},

"Action": "kms:",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Resource": ""

}
```

For more information, see the AWS Key Management Service official documentation.

IAM role-based authentication

The following permissions are added to support role-based authentication.

```
{

     "Version": "2012-10-17",

     "Statement": [

        {

            "Effect": "Allow",

            "Action": "iam:PassRole",

            "Resource": "arn:aws:iam::*:role/*"

        }

    ]

}
```

Minimal IAM permissions policy

The following JSON can be used for all currently supported features. You can create host connections, create, update, or delete VMs, and do power management using this policy. The policy can be applied to the users as explained in Defining IAM permissions sections or you can also use role-based authentication using **role_based_auth** security key and secret key.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT:

To use **role_based_auth**, first configure the desired IAM role on the cloud connector ec2 instance when setting up the cloud connector. Using Citrix Studio, add the hosting connection and supply the role_based_auth for the authentication key and secret. A hosting connection with these settings then uses role-based authentication.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ec2:AttachVolume",
                "ec2:AssociateIamInstanceProfile",
                "ec2:AuthorizeSecurityGroupEgress",
                "ec2:RevokeSecurityGroupEgress",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateImage",
                "ec2:CreateLaunchTemplate",
                "ec2:CreateNetworkInterface",
                "ec2:CreateTags",
                "ec2:CreateVolume",
                "ec2:DeleteLaunchTemplate",
                "ec2:DeleteNetworkInterface",
                "ec2:DeleteSecurityGroup",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "ec2:DeleteSnapshot",

                "ec2:DeleteTags",

                "ec2:DeleteVolume",

                "ec2:DeregisterImage",

                "ec2:DescribeAccountAttributes",

                "ec2:DescribeAvailabilityZones",

                "ec2:DescribeIamInstanceProfileAssociations",

                "ec2:DescribeImages",

                "ec2:DescribeInstances",

                "ec2:DescribeInstanceTypes",

                "ec2:DescribeInstanceStatus",

                "ec2:DescribeLaunchTemplates",

                "ec2:DescribeLaunchTemplateVersions",

                "ec2:DescribeNetworkInterfaces",

                "ec2:DescribeRegions",

                "ec2:DescribeSecurityGroups",

                "ec2:DescribeSnapshots",

                "ec2:DescribeSubnets",

                "ec2:DescribeTags",

                "ec2:DescribeSpotInstanceRequests",

                "ec2:DescribeInstanceCreditSpecifications",

                "ec2:DescribeInstanceAttribute",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "ec2:GetLaunchTemplateData",
                "ec2:DescribeVolumes",
                "ec2:DescribeVpcs",
                "ec2:DetachVolume",
                "ec2:DisassociateIamInstanceProfile",
                "ec2:RebootInstances",
                "ec2:RunInstances",
                "ec2:StartInstances",
                "ec2:StopInstances",
                "ec2:TerminateInstances"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": [
                "ec2:CreateSecurityGroup",
                "ec2:DeleteSecurityGroup"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        {
            "Action": [
                "ebs:StartSnapshot",
                "ebs:GetSnapshotBlock",
                "ebs:PutSnapshotBlock",
                "ebs:CompleteSnapshot",
                "ebs:ListSnapshotBlocks",
                "ebs:ListChangedBlocks",
                "ec2:CreateSnapshot"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                 "kms:CreateGrant",
                 "kms:Decrypt",
                 "kms:DescribeKey",
                 "kms:GenerateDataKeyWithoutPlainText",
                 "kms:GenerateDataKey",
                 "kms:ReEncryptTo",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "kms:ReEncryptFrom"

            ],

            "Resource": "*"

        },

        {

            "Effect": "Allow",

            "Action": "iam:PassRole",

            "Resource": "arn:aws:iam::*:role/*"

        }

    ]

}
```

NOTE:

- The EC2 section related to SecurityGroups is only needed if an Isolation Security Group must be created for the Preparation VM during catalog creation. Once this is done, these permissions are not required.
- The KMS section is only required when using EBS volume encryption.
- The `iam:PassRole` permission section is needed only for **role_based_auth**.
- Specific resource-level permissions can be added instead of full access based on your requirements and environment. Refer to AWS documents Demystifying EC2 Resource-Level Permissions and Access management for AWS resources for more details.
- Use `ec2:CreateNetworkInterface` and `ec2:DeleteNetworkInterface` permissions only if you are using the volume worker method.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Validate permissions on host connection

You can validate permissions on a host connection to do tasks related to creating and managing MCS machine catalogs. This implementation helps you to find out the missing permissions required for different scenarios such as creating, deleting, and updating VMs, power management of VMs, and EBS encryption, ahead of time so that you can avoid being blocked at critical times.

You can validate the permissions on a host connection using the PowerShell command `Test-HypHypervisorConnection`. The result from the command is captured as a list where each item in the list is broken into three sections.

- Category: The action or task a user can do to create and manage an MCS machine catalog.
- Corrective Action: The step an admin must do to resolve a users' missing permissions discrepancy.
- Missing permission: The list of missing permissions for a category.

To validate the permissions, do the following:

1. Create a host connection to AWS.
2. Open a PowerShell window from the Delivery Controller™ host.
3. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
4. Run the following command to verify if you have the required permissions to look up your permissions.

   ```
   Test-HypHypervisorConnection -LiteralPath "XDHyp:\Connections\AWSCon"
   ```

5. After you add the missing permissions required to look up your permissions, run the following command to verify if you have permissions in the following categories:

   - Create Update delete
   - Power Management
   - EBS encryption

   ```
   Test-HypHypervisorConnection -LiteralPath "XDHyp:
   \Connections\AWSCon" [-SecurePassword -Password] "password" -UserName
   "" -CustomProperties ""
   ```

For more information on adding permissions, see Add IAM permissions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For AWS specific information, see Create an AWS EC2 catalog.

More information

- Create and manage connections and resources
- AWS virtualization environments

Connection to Amazon WorkSpaces Core Managed Instances

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Amazon WorkSpaces Core Managed Instances.

Prerequisites

Do the following before creating a connection to Amazon WorkSpaces Core Managed Instances:

- Complete setting up your AWS as a resource location. See AWS virtualization environments.
- Define IAM permissions policy of IAM user or role for Citrix® to manage AWS resources on your behalf.
- Create a service-linked role.

Define IAM permissions

Before creating a host connection, an IAM permissions policy needs to be properly defined for an IAM user or role that gives Citrix proper permissions to provision and manage resources in your AWS account on your behalf. Use the information in this section to define IAM permissions for Citrix DaaS on Amazon WorkSpaces Core Managed Instances. Amazon's IAM service permits accounts having multiple users, which can be further organized into groups. These users can possess different permissions to control their ability to perform operations associated with the account. For more information about IAM permissions, see the IAM JSON policy reference.

NOTE:

Since Citrix provisions and manages resources and automation in your AWS account on your behalf, configuring IAM permissions policies based on specific tags or resource naming conventions is not supported.

To apply IAM permissions policy to a new group of users:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Log in to the AWS management console and select the **IAM service** from the drop-down list.
2. Select **Create a New Group of Users**.
3. Type a name for the new user group and select **Continue**.
4. On the **Permissions** page, choose **Custom Policy**.
5. Type a name for the **Permissions policy**.
6. In the **Policy Document** section, enter the relevant permissions.

After entering the policy information, select **Continue** to complete the application of the IAM permissions policy to the group of users. Users in the group are granted permissions to do only those actions that are required for Citrix DaaS.

IMPORTANT:

Use the policy text provided in the example provided in this article to list the actions that a Citrix DaaS uses to perform actions within an AWS account without restricting those actions to specific resources. Citrix recommends that you use the example for testing purposes. For production environments, you might choose to add further restrictions on resources.

Add IAM permissions

Add the permissions in the **IAM** section of the AWS Management Console:

1. In the **Summary** panel, select the **Permissions** tab.
2. Select **Add permissions.**
3. In the **Add Permissions to** screen, grant permissions.
4. In the JSON section, include Required AWS permissions for your environment.

Create a service-linked role

For each of your AWS accounts from which Citrix will call Core V2 APIs, create a service-linked role (SLR).

The steps to create the role:

- Open a Command Line Interface (CLI) in the AWS management console.
- Run the following command in the CLI:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
aws iam create-service-linked-role --aws-service-name workspaces-
instances.amazonaws.com
```

You can also configure the service-linked role using the using the Amazon WorkSpaces Core management console. See Creating a service-linked role (console).

Create a connection

You can create a connection to Amazon WorkSpaces Core Managed Instances using:

- Studio
- PowerShell commands

NOTE:

Check your proxy server or firewall restrictions and ensure that the following addresses are contactable: `https://*.amazonaws.com` and `https://*.api.aws`. Also, make sure that all the addresses mentioned in Citrix Gateway service connectivity are contactable.

If these are not contactable, it might cause failure while creating or updating the host connection.

Create a connection using Studio

1. Navigate to **Hosting > Add Connection and Resources** page.
2. On the **Connection** page, follow these steps to configure the connection:
    a. Select **Create a new connection**.
    b. In **Zone**, select the resource location you have set up for your AWS environment.
    c. Select **Amazon WorkSpaces Core** as the connection type.
    d. Select **Use IAM user access key** or **Use IAM role**.

    For the IAM user access key, provide your **API key** and **Secret key** for the IAM user that has proper IAM permissions policy for Citrix to manage resources in your AWS account.

    For the IAM role, make sure that you've assigned an IAM role to the Citrix Cloud Connector instance with proper IAM permissions policy for Citrix to manage resources in your AWS account. See Role-based authentication guide for more information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

e. To route API requests to AWS through Citrix Cloud Connectors, select the **Use the system proxy on Citrix Cloud Connectors** checkbox. This ensures that AWS connectivity works properly when Cloud Connectors have no direct Internet access.

f. Enter a connection name and click **Next**.

3. On the **Virtual Machine Location** page, specify the location where the VMs must be provisioned. Select the cloud region, VPC, and availability zone (or local zone) for creating new VMs.
4. On the **Network** page:

   a. Enter a name for the resources that you selected previously in the availability zone (or local zone).

   b. Select one or more subnets in the VPC that you configured in the previous menu.

5. Click through the remaining pages till the **Summary** page.
6. Click **Finish** to create the host connection to Amazon WorkSpaces Core Managed Instances.

IMPORTANT CONSIDERATIONS

When you create a connection using Studio:

- Define proper IAM permissions for Citrix to manage your AWS resources.
- If you use an IAM user access key for Citrix to manage your AWS resources, you must provide the API key and secret key values. You can export the key file containing those values from AWS and then import them. You must also provide the region, availability zone, VPC name, subnet addresses, domain name, security group names, and credentials.
- If you use an IAM role for Citrix to manage your AWS resources, you must make sure to assign a role with proper IAM permissions to all of your Cloud Connector(s). Role-based authentication guide for more information.
- The credentials file for the root AWS account (retrieved from the AWS console) is not formatted the same as credentials files downloaded for standard AWS users. Therefore, Citrix DaaS cannot use the file to populate the API key and secret key fields. Ensure that you are using AWS Identity Access Management (IAM) credentials files.
- The zone can be an availability zone or local zone.

Create a connection using PowerShell

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Run the following commands. Following is an example:

```
$connectionName = "demo-hostingconnection"

$cloudRegion = "us-east-1"

$apiKey = "aaaaaaaaaaaaaaaaaaaa"

$apiSecret = “bbbbb”

$secureKey = ConvertTo-SecureString -String $apiSecret

$zoneUid = "00000000-0000-0000-0000-000000000000"

$connectionPath = "XDHyp:\Connections\" + $connectionName

$connection = New-Item -Path $connectionPath -ConnectionType
"AmazonWorkSpacesCoreMachineManagerFactory" -HypervisorAddress "
"https://workspaces-instances.$($cloudRegion).api.aws"" -Persist -Scope
@() -UserName $apiKey -SecurePassword $secureKey -ZoneUid $zoneUid

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid

$hostingUnitName = "demo-hostingunit"

$availabilityzone = "us-east-1a"

$vpcName = "Default VPC"

$jobGroup = [Guid]::NewGuid()

$hostingUnitPath = "XDHyp:\HostingUnits\" + $HostingUnitName

$rootPath = $connectionPath + "\" + $vpcName + ".virtualprivatecloud\"

$availabilityZonePath = @($rootPath + $availabilityzone +
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
".availabilityzone")

$networkPaths = (Get-ChildItem $availabilityZonePath[0] | Where
ObjectType -eq "Network") | Select-Object -ExpandProperty FullPath #
will select all the networks in the availability zone

New-Item -Path $hostingUnitPath -AvailabilityZonePath
$availabilityZonePath -HypervisorConnectionName $connectionName
-JobGroup $jobGroup -PersonalvDiskStoragePath @() -RootPath $rootPath
-NetworkPath $networkPaths
```

NOTE:

To create a connection using Role-Based Authentication, specify apiKey and apiSecret as `role_based_auth`.

Limitation

If you change the name of an AWS Virtual Private Cloud (VPC) in the AWS console, then the existing hosting unit in Citrix Cloud™ breaks. When the hosting unit is broken, you cannot create catalogs or add machines to existing catalogs. To resolve the issue, change the name of the AWS VPC back to the original name.

Create a secure environment for AWS-managed traffic

If you have a proxy configured on the Cloud Connectors, then you must create the host connection to use the proxy so that API calls made by MCS are properly routed through the proxy. MCS enables network traffic (API calls from Citrix Cloud to AWS hypervisor) to be routed through Cloud Connectors in your environment.

The host connection can read the WinHTTP system proxy value that is configured during Cloud Connector installation. You can configure the proxy using Studio or by setting the custom property `UseSystemProxyForHypervisorTrafficOnConnectors` to `True` when creating or updating a host connection using PowerShell.

NOTE:

If your environment uses a proxy, ensure that SSL inspection is disabled or SSL connection remains unaltered for `<https://workspaces-instances.*.api.aws/>`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE A HOST CONNECTION CONFIGURED WITH THE PROXY

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run the PowerShell commands to configure the proxy. For example:

```
$connectionName = "demo-hostingconnection"

$cloudRegion = "us-east-1"

$apiKey = "aaaaaaaaaaaaaaaaaaaa"

$zoneUid = "00000000-0000-0000-0000-000000000000"

$securePassword = Read-Host 'Please enter your secret key'
-AsSecureString

$connectionPath = "XDHyp:\Connections\" + $connectionName

$customProperties = @"

<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns="http://schemas.citrix.com/2014/xd/machinecreation">

<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />

</CustomProperties>

"@
```

4. Create a hosting connection. For example:

```
$connection = New-Item -Path $connectionPath `

-ConnectionType "Custom" -PluginId
"AmazonWorkSpacesCoreMachineManagerFactory" `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-HypervisorAddress "https://workspaces-instances.$
($cloudRegion).api.aws" `

-CustomProperties> $customProperties `

-Persist -Scope @()`

-UserName $apiKey -SecurePassword $securePassword `

-ZoneUid $zoneUid

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid
```

To enable the proxy for an existing host connection, see Enable the proxy on an existing connection.

Cross-account provisioning

There are use-cases where the Cloud Connectors would like to be placed in a separate AWS account (shared services account or site components account) with IAM roles that have cross-account access (cross-account IAM role) and MCS-provisioned machine catalogs in separate secondary AWS account (workloads accounts), without the need for additional Cloud Connectors in the separate accounts. To support such scenarios, this feature uses VPC peering and cross-account access using IAM roles to make provisioning across different AWS accounts possible for enterprises managing multiple AWS accounts.

With VPC peering, you can have your Cloud Connector, and provisioned VMs in different regions or accounts be able to communicate among each other.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

To allow Cloud Connector to access the resources of the secondary account, create a host connection after assuming the IAM role from the secondary account.

Prerequisites

Set up the following before creating a host connection for cross-account provisioning:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Set up VPC peering and configure the security groups in both regions or accounts. See Set up VPC peering.
- Delegate cross-account access using IAM roles. See Delegate cross-account access using IAM role.

Set up VPC peering

Let's assume that VPC A is in the primary account (Account A) and it has the Cloud Connectors and Active Directory. VPC B is in the secondary account (Account B) where you want to provision the VMs.

To set up a VPC peering connection between Account A and Account B, do the following:

1. Create a VPC peering connection. See:
    - Different account same region
    - Different account different region
2. Go to your VPC A and to the route table that is associated with the public subnet.
3. Click **Edit Routes > Add route**. Add VPC B's CIDR block in the **Destination** column and add the VPC peering you created in the **Target** column.
4. Repeat Steps 2 and 3, but with the private subnets for VPC A and VPC B (add VPC A's CIDR block). See Update your route tables for a VPC peering connection.
5. Go to the private security group associated with VPC A.
6. Select **Actions**, then **Edit inbound rules**.
7. Select **Add rule**. For type, select **All Traffic**, then in the **Source Column** add:
    - If it is a different region, add VPC B's CIDR Block.
    - If it is a different account but the same region, add the account ID and private security group ID of VPC B separated by a forward slash (Example, 123456789012/sg-1a2b3c4d)
8. Repeat Steps 5 through 7, but with the private security group for VPC B (but add VPC A's CIDR Block or VPC A's account ID and private security group ID of the same region, but different account). See Update your security groups to reference peer security groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

There is no charge to create a VPC peering connection. However, while VPC peering within an availability zone is free, charges apply when data transfer over a VPC peering connection occurs across multiple availability zones and regions. See Pricing for a VPC peering connection.

Delegate cross-account access using IAM roles

After setting up VPC peering across accounts, you delegate cross-account access using IAM roles.

With cross-account access using IAM roles, you allow the primary account (Cloud Connector account) to assume an IAM role to access AWS resources in the secondary account (machine catalog VMs).

To access cross-account resources, do the following:

REMEMBER:

Assumed, VPC A is in the primary account (Account A) and it has the Cloud Connector and Active Directory. VPC B is in the secondary account (Account B) where you want to provision the VMs

1. Set up VPC peering across accounts with the steps mentioned before.
2. Create an IAM role and policy in Account B with minimal Citrix IAM Permissions. See IAM tutorial: Delegate access across AWS accounts using IAM roles. Let's say the arn of this role is "arn:aws:iam::5678:role/citrix-role".
3. Add the Trust policy to the role "arn:aws:iam::5678:role/citrix-role" so that it's allowed to be accessed by Account A role "arn:aws:iam::1234:role/primary-account-citrix-role" as per - Cross account resource access in IAM.
4. Create the IAM role and policy in Account A with the name mentioned before "primary-account-citrix role", which can assume the IAM role and pass the IAM role from the Account B (arn:aws:iam::5678:role/citrix-role).
5. Assign the role "arn:aws:iam::1234:role/primary-account-citrix-role" to all the Cloud Connectors in Account A.

Cloud Connectors can now assume the role from Account B ("arn:aws:iam::5678:role/citrix-role").

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create host connection for cross-account provisioning

Create a host connection in the secondary account (Account B) where you want to provision the VMs. This allows Cloud Connectors of Account A to access the resources in Account B after assuming the role from Account B.

Use PowerShell commands to create the host connection and add the following two custom properties:

- `CrossAccountRoleArn`: If you don't provide `CrossAccountRoleArn` property, then the regular host connection is created. In this case, `MaximumAssumeRoleDurationInSeconds` is ignored even if it is provided.
- `MaximumAssumeRoleDurationInSeconds`: `DurationInSeconds` must be between 900 seconds to 3600 seconds. The default is 900 seconds. If you provide a value provided more than 3600, then `DurationInSeconds` is set to 3600.

Example:

```
$connectionName = "cross-account-conn"

$cloudRegion = "us-east-1"

$apiKey = "role_based_auth"

$secretKey = "role_based_auth"

$zoneUid = "xxxxxx"

$secureKey = (ConvertTo-SecureString -String $secretKey -AsPlainText
-Force)

$connectionPath = "XDHyp:\Connections\" + $connectionName

$customProperties = '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="CrossAccountRoleArn"
Value="arn:aws:iam::5678:role/citrix-role" /><Property
xsi:type="StringProperty" Name="MaximumAssumeRoleDurationInSeconds"
Value="3600" />

"</CustomProperties>'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$connection = New-Item -Path $connectionPath -ConnectionType
"AmazonWorkSpacesCoreMachineManagerFactory" -HypervisorAddress "https://
workspaces-instances.$($cloudRegion).api.aws" -Persist -Scope @()
-UserName $apiKey -SecurePassword $secureKey -ZoneUid $zoneUid
-CustomProperties $customProperties

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid
```

After the host connection is created, create hosting units using Studio or PowerShell. However, select VPC and Networks.

Bypass Cloud Connectors for AWS API requests

In Amazon WorkSpaces Core Managed Instance (MI) environments, the Citrix Machine Creation Services (MCS) plugin typically resides on the Delivery Controller and routes AWS API requests through the Citrix Cloud Connector via a proxy.

You can configure host connections to bypass the Cloud Connector for AWS API requests. When this feature is enabled, the plugin makes API calls—including those for provisioning and power management—directly from the DDC to AWS services (such as Amazon EC2, EBS, and WorkSpaces Instances), removing the dependency on going through Cloud Connector via a proxy.

Benefits

- Reduce AWS API call dependency on Cloud Connectors: Removing the AWS API dependency on the Cloud Connector is a key step for customers aiming to reduce their on-premises or cloud infrastructure footprint.
- Reduced Resource Consumption: Less traffic through the Cloud Connector reduces the compute requirements for the Connector VM, potentially leading to cost savings.
- Operational Flexibility: Provides higher availability by removing a potential point of failure (the Cloud Connector/NGS proxy path) for critical power management and provisioning tasks.

Limitations and considerations

Before enabling this feature, consider the following requirements and limitations:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Authentication: Role-based authentication (IAM roles) is not supported when bypassing the Cloud Connector. You must configure the setup for IAM user access keys only.
- Environment scope: This feature is exclusive to Amazon WorkSpaces Core Managed Instances (MI). It is not supported for standard AWS EC2 host connections.
- Network requirements: The DDC must have a direct network path to the AWS service endpoints.
- Resource location Health: If a Cloud Connector was originally provisioned in the resource location, it must remain powered on. Non-MCS components and health checks still rely on the Cloud Connector if it exists.
- Unsupported features:
  - Cross-account provisioning
  - System proxy usage
- Connector requirements: While this feature removes the API dependency, there are other configurations needed to reduce dependencies on Cloud Connectors (not that requirements for Cloud Connectors may not be limited to the ones listed here):
  - Domain join: Using Non-Domain Joined or Microsoft Entra hybrid joined machines.
  - VDA registration: Enabling Rendezvous V2 (DDC direct to VDA communication via WebSockets) for VDA registration.

Create a host connection with API bypass

When creating a host connection in Full Configuration (Studio), you can now select Amazon WorkSpaces Core resource locations even if no Cloud Connectors are present in that location.

To enable the bypass via PowerShell, use the `BypassConnectorForAwsApiRequests` custom property.

PowerShell Example:

```
$custProp = '<CustomProperties xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns="http://schemas.citrix.com/2014/xd/
machinecreation">

  <Property xsi:type="StringProperty"
Name="BypassConnectorForAwsApiRequests" Value="true" />

</CustomProperties>'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$connectionName = "MyWSCConnection"

$cloudRegion = "us-east-1"

$apiKey = "YOUR_IAM_ACCESS_KEY"

$zoneUid = (Get-ConfigZone | Where-Object {$_.Name -eq
"MyResourceLocation"}).Uid

$securePassword = Read-Host 'Enter your IAM Secret Key' -AsSecureString

$connectionPath = "XDHyp:\Connections\" + $connectionName

$connection = New-Item -Path $connectionPath `

    -ConnectionType "Custom" `

    -PluginId "AmazonWorkSpacesCoreMachineManagerFactory" `

    -HypervisorAddress "https://workspaces-instances.$
($cloudRegion).api.aws" `

    -Persist -Scope @() `

    -CustomProperties $custProp `

    -UserName $apiKey -SecurePassword $securePassword `

    -ZoneUid $zoneUid

New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Manage existing connections

You can enable or disable the bypass feature for existing host connections.

- Enabling on existing connections: You can modify the custom properties of an existing connection to include `BypassConnectorForAwsApiRequests = true.`
- Disabling: If disabled, the DDC resumes routing AWS API calls through the Cloud Connector via the NGS proxy. Note that this requires a functional Cloud Connector and NGS proxy path to be available in the resource location.

Troubleshooting

If you attempt to enable the bypass property under unsupported conditions, the system returns a validation error:

- IAM Roles/Cross-Account/Proxy: If enabled alongside IAM roles, cross-account provisioning, or system proxies, the `New-Item` command fails with:

  ```
  AmazonWorkSpacesCoreException: Bypassing the Cloud Connector For AWS
  API requests is not supported for IAM roles, Cross-Account provisioning
  and System Proxy.
  ```

- Unsupported Connection Type: If applied to a standard Amazon EC2 (AWS) connection, the system fails with:

  ```
  AmazonWorkSpacesCoreException: Bypassing the Cloud Connector For AWS
  API requests is not supported for EC2 host connection.
  ```

Edit a connection

You can edit an existing host connection to:

- Modify the option to provide IAM permissions for Citrix to manage resources
- Modify the maximum number of simultaneous actions (or concurrent machines) per hosting connection
- Modify the scope.
- Configure the maximum number of security groups allowed per elastic network interface (ENI) using PowerShell command
- Enable the proxy to create a secure environment for AWS-managed traffic

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Edit options to provide IAM permissions

1. Right-click an existing Amazon WorkSpaces Core connection.
2. On the **Connection Properties** page, click **Edit settings**.
3. Select one of the options to provide IAM permissions for Citrix to manage resources. Enter the required details and click **Save**.

Modify the maximum number of simultaneous actions

When you create host connections in Studio for Amazon WorkSpaces Core Managed Instances, the following default values display:

OPTION	ABSOLUTE	PERCENTAGE
Simultaneous actions (all types)	125	100
Maximum new actions per minute	150	n/a
Maximum concurrent provisioning operations	150	n/a

MCS supports 150 maximum concurrent provisioning operations by default.

You can configure these values by accessing the Citrix Studio **Advanced** section on the **Edit Connection** screen:

Alternatively, you can use the Remote PowerShell SDK to set the maximum number of concurrent operations for optimal settings per your environment.

Use the PowerShell custom property, `MaximumConcurrentProvisioningOperations`, to specify the maximum number of concurrent AWS provisioning operations.

Before configuration:

- Ensure that you have installed the PowerShell SDK for Cloud.
- Understand that the default value for `MaximumConcurrentProvisioningOperations` is 150.

Perform the following steps to customize the `MaximumConcurrentProvisioningOperations` value:

1. Open a **PowerShell** window.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Enter `cd xdhyp:\Connections\`.
4. Enter `dir` to list the connections.
5. Change or Initialize the Custom Properties string:
   - If the Custom Properties string has a value, copy the Custom Properties into Notepad. Next, change the `MaximumConcurrentProvisioningOperations` property to your preferred value. You can enter a value ranging 1–1000. For example, `<Property xsi:type="IntProperty" Name="MaximumConcurrentProvisioningOperations" Value="xyz"/>`.
   - If the Custom Properties string is empty or null, you must initialize the string by entering the proper syntax for both the schema and the `MaximumConcurrentProvisioningOperations` property.
6. In the **PowerShell** window, paste the modified Custom Properties from Notepad and assign a variable to the modified Custom Properties. If you initialized the Custom Properties, add the following lines after the syntax:

   ```
   $customProperties = '<CustomProperties xmlns="http://
   schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://
   www.w3.org/2001/XMLSchema-instance"><Property xsi:type="IntProperty"
   Name="MaximumConcurrentProvisioningOperations" Value="100"/></
   CustomProperties>'
   ```

   This string sets the `MaximumConcurrentProvisioningOperations` property to 100. In the Custom Properties string, you must set the `MaximumConcurrentProvisioningOperations` property to a value that aligns with your needs.
7. Enter `Get-XDAuthentication`, which prompts you for your credentials.
8. Run `$cred = Get-Credential`, which might prompt you for solely a Password (or a Name and Password). You might also be prompted for the application ID and associated secret. For connections using role-based authentication, **role_based_auth** is both the Name and Password. Otherwise, enter the AWS API ID and secret.
9. Run `set-item -PSPath 'XDHyp:\Connections<connection-name>' -CustomProperties $customProperties -username $cred.username -Securepassword $cred.password`. You must set the *<connection-name>* to the name of the connection.
10. Enter `dir` to verify the updated CustomProperties string.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure security groups per network interface

When editing a host connection, you can now configure the maximum number of security groups allowed per elastic network interface (ENI) using a PowerShell command. For information on AWS security groups quota values, see Security groups.

To configure security groups per network interface:

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run `cd xdhyp:\Connections\`.
4. Run `dir` to list the connections.
5. Run the following PowerShell command to configure security groups per network interface:

```
Set-HypHypervisorConnectionMetadata -HypervisorConnectionName aws -Name
"Citrix_MachineManagement_Options" -Value "
AwsMaxENISecurityGroupLimit=<number>"
```

NOTE:

If you do not set a value for `AwsMaxENISecurityGroupLimit`, then it takes the default value of 5.

Enable the proxy on an existing connection

1. Open a PowerShell window.
2. Run the following commands.

```
Add-PSSnapin citrix*.

cd XDHyp:\Connections\

dir
```

3. Copy the `CustomProperties` from the connection to a notepad and append property setting `<Property xsi:type="StringProperty" Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />` to the `CustomProperties` to enable the proxy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. In the PowerShell window, assign a variable to the modified custom properties. For example:

```
$customProperty = '<CustomProperties xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns="http://schemas.citrix.com/2014/xd/
machinecreation">

<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />

</CustomProperties>'
```

5. Enter `Get-XDAuthentication`, which prompts you for your credentials.
6. Run `$cred = Get-Credential`, which might prompt you for solely a Password (or a Name and Password). You might also be prompted for the application ID and associated secret. For connections using role-based authentication, `role_based_auth` is both the Name and Password. Otherwise, enter the AWS API ID and secret.
7. Run `set-item -PSPath 'XDHyp:\Connections<connection-name>' -CustomProperties $customProperties -username $cred.username -Securepassword $cred.password`. You must set the `<connection-name>` to the name of the connection.
8. Enter `dir` to verify the updated `CustomProperties` string.

Service endpoint URL

Standard zone service endpoint URL

When you use MCS, a new Amazon WorkSpaces Core Managed Instances connection is added with an API key and an API secret. With this information, along with the authenticated account, MCS queries AWS for the supported regions and zones using AWS EC2 and Amazon WokrSpaces Core Managed Instances API calls. The query is made using a Workspace Instances Service Endpoint URL `<https://workspaces-instances.us-east-1.api.aws/>` and EC2 Service Endpoint https:/ec2.us-east-1.api.aws/.

NOTE:

Make sure that `<https://workspaces-instances.us-east-1.api.aws/>` is contactable.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Non-standard service endpoint URL

There can be situations where you might not need the automatically chosen AWS Service Endpoint URL for the connection. For such cases, you can use Citrix Cloud SDK and PowerShell to create a connection with a non-standard service endpoint URL. For example, to create a connection using the service endpoint URL `https://ec2.cn-north-1.amazonaws.com.cn`:

1. Set up the AWS hosted Cloud Connector and ensure that it has connectivity.
2. Run the following PowerShell commands to see the list of Cloud Connectors.

```
PS C:\> asnp citrix.*

PS C:\> Get-XDAuthentication

PS C:\> Get-ConfigEdgeServer
```

3. Find the ZoneUid from the newly created Cloud Connector and enter it into the following PowerShell commands. Replace the italicized items with the respective values.

```
PS C:\> $hyp= New-Item -Path xdhyp:\Connections -ZoneUid ZoneUid -Name
“My New Connection” -ConnectionType "Custom" -HypervisorAddress
@("https://workspaces-instances.$($cloudRegion).api.aws")-PluginId
"AmazonWorkSpacesCoreMachineManagerFactory" -UserName “APIkey”
-Password “API Secret” -Persist

PS C:\> New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$hyp. HypervisorConnectionUid
```

4. Refresh the **Hosting** tab to verify that the connection has been created.
5. Add a resource location using the new connection.

Required AWS permissions

This section contains the complete list of AWS permissions. Use the complete set of permissions as given in the section for the functionality to work correctly.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The `iam:PassRole` permission is needed only for using IAM roles for Citrix to manage resources.

Creating a host connection

A new host connection is added using the information obtained from AWS.

            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": [
                "ec2:CreateSecurityGroup",
                "ec2:DeleteSecurityGroup"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": [
                "ebs:StartSnapshot",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "ebs:GetSnapshotBlock",
                "ebs:PutSnapshotBlock",
                "ebs:CompleteSnapshot",
                "ebs:ListSnapshotBlocks",
                "ebs:ListChangedBlocks",
                "ec2:CreateSnapshot"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": [
                "workspaces-instances:*"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetAccountSummary",
                "ec2:CopyImage"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            ],
            "Resource": "*"
        },

    ]
}
```

NOTE:

- The EC2 section related to SecurityGroups is only needed if an Isolation Security Group must be created for the Preparation VM during catalog creation. Once this is done, these permissions are not required.
- The EC2 `CopyImage` and IAM `GetAccountSummary` permissions are needed only when sharing prepared images across regions. See Share prepared images across availability zones and regions.

Direct disk upload and download

The following permissions must be added to the policy:

- `ebs:StartSnapshot`
- `ebs:GetSnapshotBlock`
- `ebs:PutSnapshotBlock`
- `ebs:CompleteSnapshot`
- `ebs:ListSnapshotBlocks`
- `ebs:ListChangedBlocks`
- `ec2:CreateSnapshot`
- `ec2:DeleteSnapshot`
- `ec2:DescribeLaunchTemplates`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

EBS encryption of created volumes

EBS can auto-encrypt newly created volumes if the AMI is encrypted, or EBS is configured to encrypt all new volumes. However, to implement the functionality, the following permissions must be included in the IAM policy.

```
{
     "Version": "2012-10-17",
     "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                 "kms:CreateGrant",
                 "kms:Decrypt",
                 "kms:DescribeKey",
                 "kms:GenerateDataKeyWithoutPlainText",
                 "kms:GenerateDataKey",
                 "kms:ReEncryptTo",
                 "kms:ReEncryptFrom"
            ],
            "Resource": "*"
        }
    ]
}
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The permissions can be limited to specific keys by including a Resource and Condition block at the discretion of the user. For example, **KMS Permissions with Condition**:

```
{

     "Version": "2012-10-17",

     "Statement": [

        {

            "Effect": "Allow",

            "Action": [

                 "kms:CreateGrant",

                 "kms:Decrypt",

                 "kms:DescribeKey",

                 "kms:GenerateDataKeyWithoutPlainText",

                 "kms:GenerateDataKey",

                 "kms:ReEncryptTo",

                 "kms:ReEncryptFrom"

            ],

            "Resource": [

                "arn:aws:kms:us-east-2:123456789012:key/abcd1234-
a123-456d-a12b-a123b4cd56ef"

            ],

            "Condition": {
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "Bool": {

                    "kms:GrantIsForAWSResource": true

                }

            }

        }

    ]

}
```

The following key policy statement is the entire default key policy for KMS keys that is required to allow the account to use IAM policies to delegate permission for all actions (kms:*) on the KMS key.

```
{

"Sid": "Enable IAM policies",

"Effect": "Allow",

"Principal": {

"AWS": "arn:aws:iam::111122223333:root"

},

"Action": "kms:",

"Resource": ""

}
```

For more information, see the AWS Key Management Service official documentation.

IAM role-based authentication

The following permissions are added to support role-based authentication.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
{

     "Version": "2012-10-17",

     "Statement": [

        {

            "Effect": "Allow",

            "Action": "iam:PassRole",

            "Resource": "arn:aws:iam::*:role/*"

        }

    ]

}
```

Minimal IAM permissions policy

The following JSON can be used for all currently supported features. You can create host connections, create, update, or delete VMs, and do power management using this policy. The policy can be applied to the users as explained in Define IAM permissions sections or you can also use role-based authentication by selecting **Use IAM role** when configuring a host connection.

IMPORTANT:

To use **IAM roles for Citrix to manage resources**, first configure the desired IAM role on the cloud connector ec2 instance when setting up the cloud connector. Using Citrix Studio, add the hosting connection and select the **Use IAM role** option. A hosting connection with these settings then uses role-based authentication.

```
{

    "Version": "2012-10-17",

    "Statement": [

        {
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            "Action": [
                "ec2:AttachVolume",
                "ec2:AssociateIamInstanceProfile",
                "ec2:AuthorizeSecurityGroupEgress",
                "ec2:RevokeSecurityGroupEgress",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateImage",
                "ec2:CreateLaunchTemplate",
                "ec2:CreateNetworkInterface",
                "ec2:CreateTags",
                "ec2:CreateVolume",
                "ec2:DeleteLaunchTemplate",
                "ec2:DeleteNetworkInterface",
                "ec2:DeleteSecurityGroup",
                "ec2:DeleteSnapshot",
                "ec2:DeleteTags",
                "ec2:DeleteVolume",
                "ec2:DeregisterImage",
                "ec2:DescribeAccountAttributes",
                "ec2:DescribeAvailabilityZones",

                "kms:GenerateDataKeyWithoutPlainText",
                "kms:GenerateDataKey",
                "kms:ReEncryptTo",
                "kms:ReEncryptFrom"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::*:role/*"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "workspaces-instances:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetAccountSummary",
                "ec2:CopyImage"
            ],
            "Resource": "*"
        }

    ]
}
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The EC2 section related to SecurityGroups is only needed if an Isolation Security Group must be created for the Preparation VM during catalog creation. Once this is done, these permissions are not required.
- The KMS section is only required when using EBS volume encryption.
- The `iam:PassRole` permission section is needed only for using IAM roles for Citrix to manage resources.
- Specific resource-level permissions can be added instead of full access based on your requirements and environment. Refer to AWS documents Demystifying EC2 Resource-Level Permissions and Access management for AWS resources for more details.
- Use `ec2:CreateNetworkInterface` and `ec2:DeleteNetworkInterface` permissions only if you are using the volume worker method.

Where to go next

- For creating prepared images, see Create a prepared image for Amazon WorkSpaces Core Managed Instances

More information

- Create and manage connections and resources
- AWS virtualization environments
- For Amazon WorkSpaces Core GitHub PowerShell examples, see citrix-mcs-sdk-samples-Amazon WorkSpaces Core.

Connection to Google cloud environments

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Google cloud environments.

NOTE:

Before creating a connection to Google cloud environments, you need to first finish setting up your Google cloud account as a resource location. See Google Cloud virtualization environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add a connection

In Studio, follow the guidance in Create and manage connections and resources. The following description guides you through setting up a hosting connection:

1. From Studio, select **Hosting** in the left pane.
2. Select **Add Connection and Resources** in the action bar.
3. On the **Connection** page, select **Create a new Connection** and **Citrix provisioning™ tools**, and then select **Next**.

    - **Zone name**. Select a zone (equivalent to a resource location) where you want your host resources to reside. Zones are created automatically when you create a resource location and add a Cloud Connector to it. For more information, see Zones.
    - **Connection type**. Select **Google Cloud Platform** from the menu.
    - **Service account key**. Import the key contained in your Google credential file (.json). You can either paste the key from the credential file or browse to the credential file. To paste the key:

        a. Locate your credential file

        b. Open the file with Notepad (or any text editor)

        c. Copy the content.

        d. Return to the **Connection** page, select **Add key**, paste the content, and then select **Done**.

    - **Service account ID**. The field automatically populates with the information from the service account key.
    - **Connection name**. Type a name for the connection.
    - **Route traffic through Citrix Cloud Connectors**. To route the API requests through an available Citrix Cloud Connector™, select this checkbox. When Cloud Connectors have no direct internet access, you can select **Use the proxy configured on Citrix Cloud Connectors** to ensure GCP connectivity works properly through Citrix Cloud Connectors. You can also select **Enable Google Cloud Build to use private pools** checkbox for an additional layer of security.

        Alternatively, you can enable this feature using PowerShell. For more information, see Create a secure environment for GCP-managed traffic.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

This option is available only when there are active Citrix Cloud™ Connectors in your deployment. Currently, this feature is not supported for Connector Appliances.

- **Create virtual machines using**. Select a method to create virtual machines.

4. On the **Region** page, select a project name from the menu, select a region containing the resources you want to use, and then select **Next**.
5. On the **Network** page, type a name for the resources, select a virtual network from the menu, select a subset, and then select **Next**. The resource name helps identify the region and network combination. Virtual networks with the *(Shared)* suffix appended to their name represent shared VPCs. If you configure a subnet-level IAM role for a shared VPC, only specific subnets of the shared VPC appear on the subnet list.

NOTE:

- The resource name can contain 1–64 characters, and cannot contain only blank spaces or the characters `\ / ; : # . * ? = < > | [ ] { } " ' ( ) ' )`.

6. On the **Summary** page, confirm the information and then select **Finish** to exit the **Add Connection and Resources** window.

After you create the connection and resources, the connection and resources you created are listed. To configure the connection, select the connection and then select the applicable option in the action bar.

Similarly, you can delete, rename, or test the resources created under the connection. To do so, select the resource under the connection and then select the applicable option in the action bar.

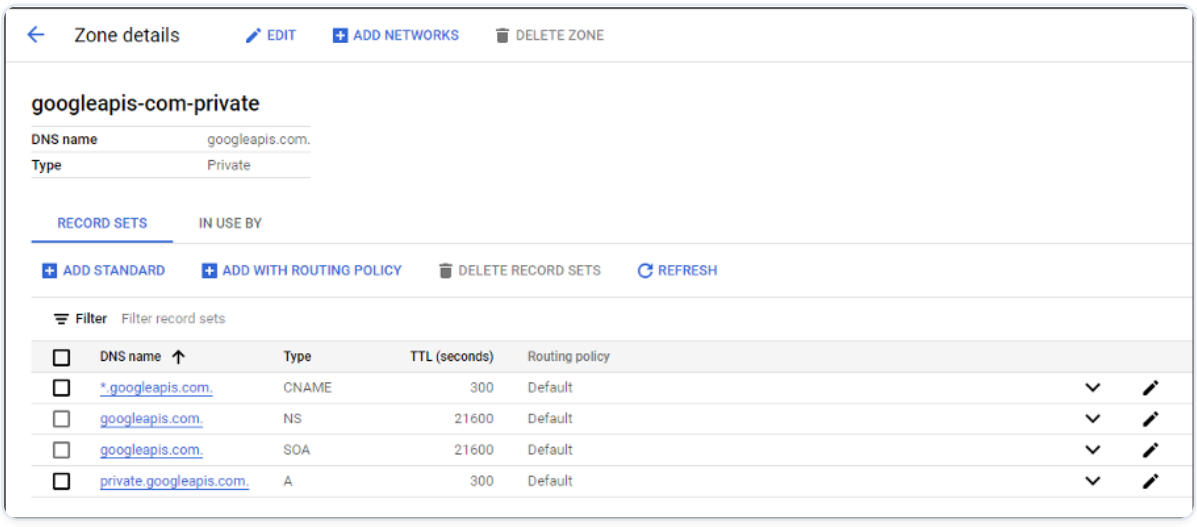
Create a secure environment for GCP managed traffic

You can allow only private Google access to your Google Cloud projects. This implementation enhances security to handle sensitive data. To do this:

1. Install Cloud Connectors in the VPC where you want to enforce VPC service controls. See VPC Service Controls for more information.

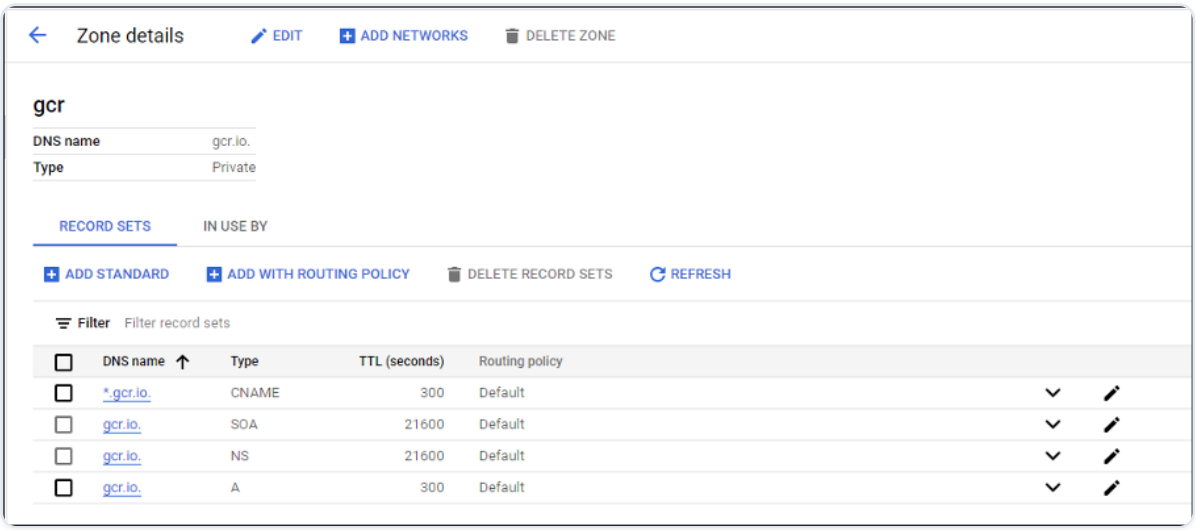
© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Add `ProxyHypervisorTrafficThroughConnector` in `CustomProperties` in case of Citrix Cloud deployment. If you are using a private worker pool, add `UsePrivateWorkerPool` in `CustomProperties`. For information on the private worker pool, see Private pools overview.



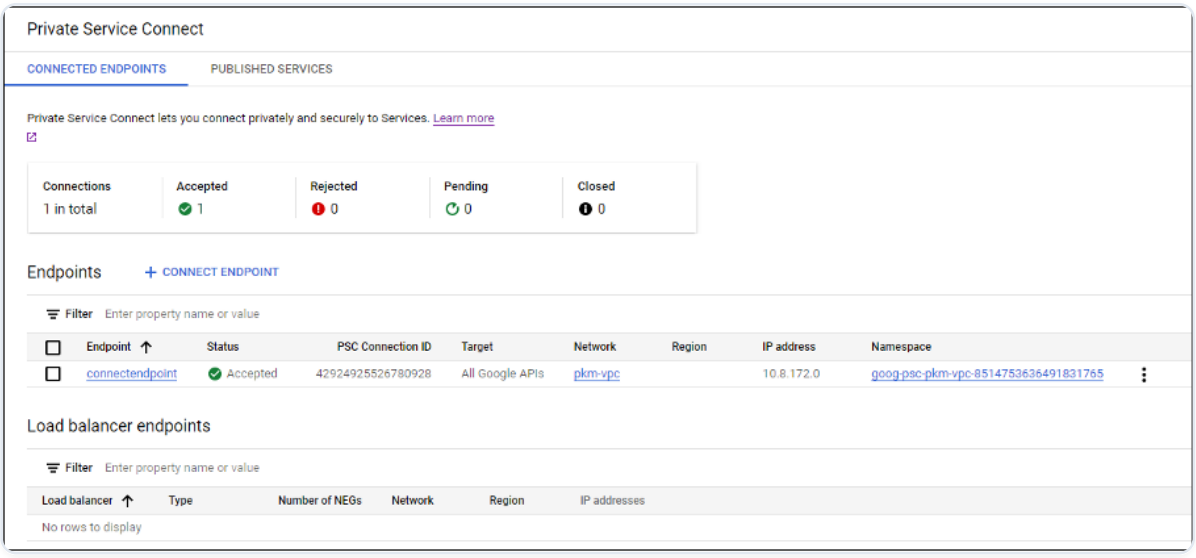
NOTE:

Currently, this feature is not supported for Connector Appliance.

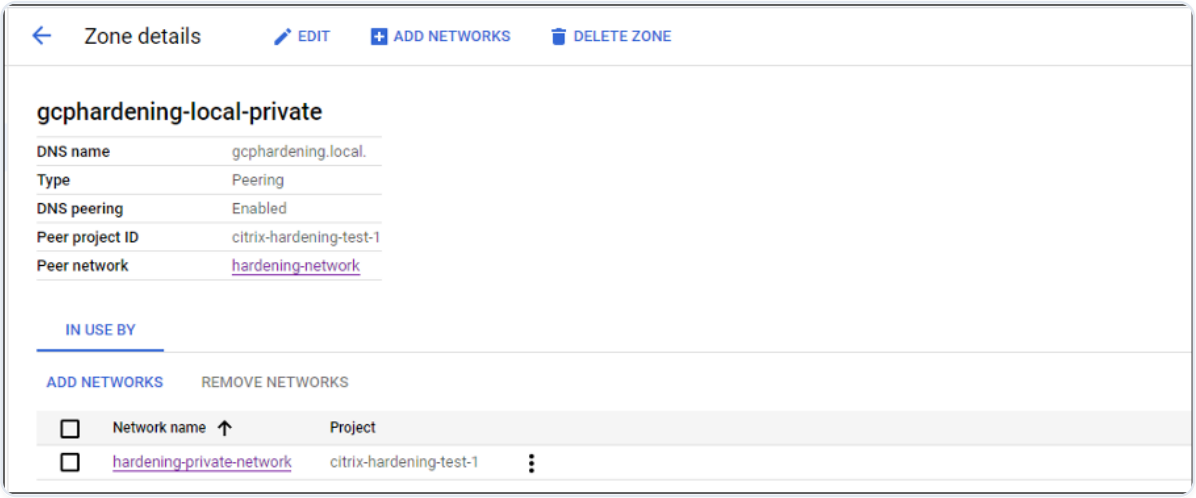


Requirements to create a secure environment for GCP managed traffic

The requirements to create a secure environment for GCP managed traffic are:



- Ensure that the hosting connection is in maintenance mode when updating the custom properties.
- To use private worker pools, the following changes are required:
  - For Citrix Cloud Service Account, add the following IAM roles:
    - Cloud Build Service Account
    - Compute Instance Admin
    - Service Account User
    - Service Account Token Creator
    - Cloud Build WorkerPool Owner
  - Create the Citrix Cloud Service Account in the same project that you use for creating a hosting connection.
  - Set up DNS zones for `private.googleapis.com` and `gcr.io` as described in DNS configuration.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Set up private Network Address Translation (NAT) or use private service connect. For more information, see Access Google APIs through endpoints.

- If using a peered VPC, create a Cloud DNS zone peering to the peered VPC. For more information, see Create a peering zone.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- In VPC service controls, set up Egress rules so that the APIs and VMs can talk to the internet. Ingress rules are optional. For example:

```
Egress Rule 1

From:

Identities:ANY_IDENTITY

To:

Projects =

All projects

Service =

Service name: All services
```

Enable the proxy

To enable the proxy, set the custom properties as follows on the host connection:

1. Open a PowerShell window from the Delivery Controller host or use the Remote PowerShell SDK. For more information on Remote PowerShell SDK, see SDKs and APIs.
2. Run the following commands:
   a. `Add-PSSnapin citrix*`
   b. `cd XDHyp:\Connections\`
   c. `dir`
3. Copy the `CustomProperties` from the connection to a notepad.
4. Append the property setting as follows:
   - In case of cloud deployment (using public pools): Append property setting `<Property xsi:type="StringProperty" Name="ProxyHypervisorTrafficThroughConnector" Value="True"/>` to the `CustomProperties` to enable the proxy. For example:

```
<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xmlns="http://schemas.citrix.com/2014/xd/machinecreation">
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True"/>

</CustomProperties>
```

Allow ingress rule for Cloud Build Service Account in VPC service perimeter. For example:

```
Ingress Rule 1

From:

Identities:

<ProjectID>@cloudbuild.gserviceaccount.com

Source > All sources allowed

To:

Projects =

All projects

Services =

Service name: All services
```

For information on VPC service perimeter, see Service perimeter details and configuration.

- In case of a private worker pool in a cloud deployment, append property setting `<Property xsi:type="StringProperty" Name="ProxyHypervisorTrafficThroughConnector" Value="True"/>` and `<Property xsi:type="StringProperty" Name="UsePrivateWorkerPool" Value="True"/>` to the `CustomProperties` to enable the proxy. For example:

```
<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xmlns="http://schemas.citrix.com/2014/xd/machinecreation">

<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True"/>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="UsePrivateWorkerPool"
Value="True"/>

</CustomProperties>
```

5. In the PowerShell window, assign a variable to the modified custom properties. For example: `$customProperty = '<CustomProperties…</CustomProperties>'`.
6. Run `$gcpServiceAccount = "<ENTER YOUR SERVICE ACCOUNT EMAIL HERE>"`.
7. Run `$gcpPrivateKey = "<ENTER YOUR SERVICE ACCOUNT PRIVATE KEY HERE AFTER REMOVING ALL INSTANCES OF \n >"`.
8. Run `$securePassword = ConvertTo-SecureString $gcpPrivateKey -AsPlainText -Force`.
9. Run the following to update an existing host connection:

```
Set-Item -PassThru -Path @('XDHyp:\\Connections\\<ENTER YOUR CONNECTION
NAME HERE>') -SecurePassword $securePassword -UserName
$gcpServiceAccount -CustomProperties $customProperty
```

Option to use system proxy on Citrix Cloud Connectors for redirected GCP API traffic

To route all external traffic through a non-transparent proxy, configure the host connection with the custom property `UseSystemProxyForHypervisorTrafficOnConnectors`. This redirects GCP API internet traffic on Citrix Cloud Connectors through the system proxy. Do the same steps as outlined in Enable the proxy to configure the host connection with the custom property. However, make sure to append property setting `<Property xsi:type="StringProperty" Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />` to the `CustomProperties` to enable the proxy.

```
<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />
```

Example:

```
<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns="http://schemas.citrix.com/2014/xd/machinecreation">

 <Property xsi:type="StringProperty"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Name="ProxyHypervisorTrafficThroughConnector" Value="True"/>

 <Property xsi:type="StringProperty" Name="UsePrivateWorkerPool"
Value="True"/>

<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />

</CustomProperties>
```

NOTE:

After you set this property, the proxy configured in the `netsh winhttp` settings on the Citrix Cloud Connectors is used for outbound traffic to the cloud service provider.

Specify CMEK global and regional key

NOTE:

Support for CMEK in GCP is currently under Preview.

There are two types of customer-managed encryption keys (CMEK) in GCP:

- Regional: Encryption keys that can only be used by resources in the same region.
- Global: Encryption keys that can be used by resources from multiple regions.

You can browse and use global or regional customer-managed encryption keys (CMEK) from all projects that are accessible to the service account. You can then use the key to create a CMEK enabled MCS machine catalog and update an existing CMEK enabled MCS machine catalog using `Set-ProvScheme` command. For information creating a CMEK enabled catalog using PowerShell, see Create a catalog with CMEK using custom properties.

For this feature, you need additional permissions for the following two service accounts:

- The service account of the current project with which the hosting connection is created.
- The Compute Engine Service Agent of the current project (that has the email: `service-PROJECT_NUMBER@compute-system.iam.gserviceaccount.com`). For more information, see Compute Engine Service Agent.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In Service accounts, you must assign the following roles in the project that has crypto keys that you want to use (for example, shared project):

- Cloud KMS Viewer
- Cloud KMS CryptoKey Encrypter/Decrypter

If you do not assign to the roles, then make sure that you have the following permissions:

- resourcemanager.projects.get
- cloudkms.keyRings.list
- cloudkms.keyRings.get
- cloudkms.cryptoKeys.get
- cloudkms.cryptoKeys.list
- cloudkms.cryptoKeyVersions.useToDecrypt
- cloudkms.cryptoKeyVersions.useToEncrypt

List the encryption keys

You can list the global and regional encryption keys within the same project and all other accessible projects using the PowerShell commands. To do this:

1. Open a PowerShell window from the Delivery Controller™ host or remote PowerShell.
2. Run the command `asnp citrix*` to load Citrix-specific PowerShell modules.
3. Run the following command to list the encryption keys. Example:

    - To list contents of `encryptionKeys` folder:

    ```
    Get-ChildItem XDHyp:\HostingUnits\my-
    hostingunit\encryptionKeys.folder
    ```

    - To get global encryption keys within the same project:

    ```
    Get-Item XDHyp:\HostingUnits\my-
    hostingunit\encryptionKeys.folder\myglobalkeyring.globalkeyring\mygl
    obalkey.cryptokey
    ```

    - To get regional encryption keys within the same project:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-Item XDHyp:\HostingUnits\my-
hostingunit\encryptionKeys.folder\regional-ring.keyring\shared-
key.cryptokey
```

- To get global encryption keys from another accessible project (for example: myanotherproject):

```
Get-Item XDHyp:\HostingUnits\my-
hostingunit\encryptionKeys.folder\myanotherproject.project\shared-
global-ring.globalkeyring\shared-key.cryptokey
```

- To get regional encryption keys from another accessible project (for example: myanotherproject):

```
Get-Item XDHyp:\HostingUnits\my-
hostingunit\encryptionKeys.folder\myanotherproject .project.project\
shared-uscentral.keyring\shared-uscentral-key.cryptokey
```

NOTE:

- The extension of the key ring inventory item for a global key ring is `.globalkeyring`.
- The id of global key rings has the word `global` in it.

Required GCP permissions

This section has the complete list of GCP permissions. Use the complete set of permissions as given in the section for the functionality to work correctly.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

GCP is introducing changes to Cloud Build Services's default behavior and use of service accounts after April 29, 2024. For more information, see Cloud Build Service Account Change. Your existing Google projects with Cloud Build API enabled before April 29, 2024 are not affected by this change. However, if you want to have existing Cloud Build Service behavior after April 29, you can create or apply the organization policy to disable the constraint enforcement before you enable the API. If you set the new organization policy, you can still follow the existing permissions in this section and the items that are marked **Before Cloud Build Service Account Change**. If not, then follow the existing permissions and items that are marked **After Cloud Build Service Account Change**.

Creating a host connection

- Minimum permissions required for Citrix Cloud Service Account in Provisioning project:

  ```
  compute.instanceTemplates.list

  compute.instances.list

  compute.networks.list

  compute.projects.get

  compute.regions.list

  compute.subnetworks.list

  compute.zones.list

  resourcemanager.projects.get
  ```

  The following Google defined roles have the permissions as listed above:

  - Compute Admin
  - Cloud Datastore User

- Additional permissions required for Shared VPC for Citrix Cloud Service Account in Shared VPC project:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.networks.list

compute.subnetworks.list

resourcemanager.projects.get
```

The following Google defined roles have the permissions as listed above:

- Compute Network User

- In Service accounts, you must assign the following roles in the project that has crypto keys that you want to use (for example, shared project):
  - Cloud KMS Viewer
  - Cloud KMS CryptoKey Encrypter/Decrypter

  If you do not assign to the roles, then make sure that you have the following permissions:
  - resourcemanager.projects.get
  - cloudkms.keyRings.list
  - cloudkms.keyRings.get
  - cloudkms.cryptoKeys.get
  - cloudkms.cryptoKeys.list
  - cloudkms.cryptoKeyVersions.useToDecrypt
  - cloudkms.cryptoKeyVersions.useToEncrypt

Power management of VMs

Minimum permissions required for Citrix Cloud Service Account in Provisioning project in case of power managed only catalogs:

```
compute.instanceTemplates.list

compute.instances.list

compute.instances.get

compute.instances.reset

compute.instances.resume
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.instances.start

compute.instances.stop

compute.instances.suspend

compute.networks.list

compute.projects.get

compute.regions.list

compute.subnetworks.list

compute.zones.list

resourcemanager.projects.get

compute.zoneOperations.get
```

The following Google defined roles have the permissions as listed above:

- Compute Admin
- Cloud Datastore User

Creating, updating, or deleting VMs

- Minimum permissions required for Citrix Cloud Service Account in Provisioning project:

```
cloudbuild.builds.create

cloudbuild.builds.get

cloudbuild.builds.list

compute.acceleratorTypes.list

compute.diskTypes.get

compute.diskTypes.list

compute.disks.create
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.disks.createSnapshot

compute.disks.delete

compute.disks.get

compute.disks.list

compute.disks.setLabels

compute.disks.use

compute.disks.useReadOnly

compute.firewalls.create

compute.firewalls.delete

compute.firewalls.list

compute.globalOperations.get

compute.images.create

compute.images.delete

compute.images.get

compute.images.list

compute.images.setLabels

compute.images.useReadOnly

compute.instanceTemplates.create

compute.instanceTemplates.delete

compute.instanceTemplates.get

compute.instanceTemplates.list

compute.instanceTemplates.useReadOnly
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.instances.attachDisk

compute.instances.create

compute.instances.delete

compute.instances.detachDisk

compute.instances.get

compute.instances.getSerialPortOutput

compute.instances.list

compute.instances.reset

compute.instances.resume

compute.instances.setDeletionProtection

compute.instances.setLabels

compute.instances.setMetadata

compute.instances.setServiceAccount

compute.instances.setTags

compute.instances.start

compute.instances.stop

compute.instances.suspend

compute.machineTypes.get

compute.machineTypes.list

compute.networks.list

compute.networks.updatePolicy

compute.nodeGroups.list
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.nodeTemplates.get

compute.projects.get

compute.regions.list

compute.snapshots.create

compute.snapshots.delete

compute.snapshots.list

compute.snapshots.get

compute.snapshots.setLabels

compute.snapshots.useReadOnly

compute.subnetworks.get

compute.subnetworks.list

compute.subnetworks.use

compute.zoneOperations.get

compute.zoneOperations.list

compute.zones.get

compute.zones.list

iam.serviceAccounts.actAs

resourcemanager.projects.get

storage.buckets.create

storage.buckets.delete

storage.buckets.get

storage.buckets.list
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
storage.buckets.update

storage.objects.create

storage.objects.delete

storage.objects.get

storage.objects.list

compute.networks.get

compute.resourcePolicies.use
```

The following Google defined roles have the permissions as listed above:

- Compute Admin
- Storage Admin
- Cloud Build Editor
- Service Account User
- Cloud Datastore User

- Additional permissions required for Shared VPC for Citrix Cloud Service Account in Shared VPC project to create a hosting unit using VPC and subnetwork from Shared VPC project:

```
compute.firewalls.list

compute.networks.list

compute.projects.get

compute.regions.list

compute.subnetworks.get

compute.subnetworks.list

compute.subnetworks.use
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.zones.list

resourcemanager.projects.get
```

The following Google defined roles have the permissions as listed above:

- Compute Network User
- Cloud Datastore User

Minimum permissions required when downloading preparation instruction disk to MCS:

- (Before Cloud Build Service Account Change): Assign these permissions to Cloud Build Service Account in Provisioning project.
- (After Cloud Build Service Account Change): Assign these permissions to Cloud Compute Service Account in Provisioning project.

```
compute.disks.create

compute.disks.delete

compute.disks.get

compute.disks.list

compute.disks.setLabels

compute.disks.use

compute.disks.useReadOnly

compute.images.get

compute.images.list

compute.images.useReadOnly

compute.instances.create

compute.instances.delete

compute.instances.get
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
compute.instances.getSerialPortOutput

compute.instances.list

compute.instances.setLabels

compute.instances.setMetadata

compute.instances.setServiceAccount

compute.machineTypes.list

compute.networks.get

compute.networks.list

compute.projects.get

compute.subnetworks.list

compute.subnetworks.use

compute.subnetworks.useExternalIp

compute.zoneOperations.get

compute.zones.list

iam.serviceAccounts.actAs

logging.logEntries.create

pubsub.topics.publish

resourcemanager.projects.get

source.repos.get

source.repos.list

storage.buckets.create

storage.buckets.get
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
storage.buckets.list

storage.objects.create

storage.objects.delete

storage.objects.get

storage.objects.list
```

The following Google defined roles have the permissions as listed above:

- Cloud Build Service Account (After Cloud Build Service Account Change, it is Cloud Compute Service Account)
- Compute Instance Admin
- Service Account User

- Minimum permissions required for Cloud Compute Service Account in Provisioning project required by Google Cloud Build service when downloading preparation instruction disk to MCS:

```
resourcemanager.projects.get

storage.objects.create

storage.objects.get

storage.objects.list
```

The following Google defined roles have the permissions as listed above:

- Compute Network User
- Storage Account User
- Cloud Datastore User

Additional permissions required for Shared VPC when downloading preparation instruction disk to MCS:

- (Before Cloud Build Service Account Change): Assign these permissions to Cloud Build Service Account in Provisioning project.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - (After Cloud Build Service Account Change): Assign these permissions to Cloud Compute Service Account in Provisioning project.

```
compute.firewalls.list

compute.networks.list

compute.subnetworks.list

compute.subnetworks.use

resourcemanager.projects.get
```

    The following Google defined roles have the permissions as listed above:

    - Compute Network User
    - Storage Account User
    - Cloud Datastore User

- Additional permissions required for Cloud Key Management Service (KMS) for Citrix Cloud Service Account in Provisioning project:

```
cloudkms.cryptoKeys.get

cloudkms.cryptoKeys.list

cloudkms.keyRings.get

cloudkms.keyRings.list
```

    The following Google defined roles have the permissions as listed above:

    - Compute KMS Viewer

General permissions

Following are the permissions for Citrix Cloud Service Account in Provisioning project for all features supported in MCS. These permissions provide the best compatibility going forward:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
resourcemanager.projects.get

cloudbuild.builds.create

cloudbuild.builds.get

cloudbuild.builds.list

compute.acceleratorTypes.list

compute.diskTypes.get

compute.diskTypes.list

```

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For Google Cloud Platform (GCP) specific information, see Create a Google Cloud Platform catalog.

More information

- Create and manage connections and resources
- Google Cloud virtualization environments.

Connection to HPE Moonshot

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to HPE Moonshot.

NOTE:

Before creating a connection to HPE Moonshot, you need to first finish setting up your HPE account. See HPE Moonshot virtualization environments.

Create a connection

You can create a connection to HPE Moonshot using:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Studio
- PowerShell commands

Create a connection using Studio

1. In the **Add Connection and Resources** page, select the **HPE Moonshot** as the connection type.
2. Enter the connection address of your Moonshot iLO Chassis Manager. You can use an IP address, host name, or FQDN for the address.
3. Enter your chassis administrative credentials and a friendly connection name.

Connection setup stops when either of the situations occurs:

- DaaS receives a public CA-signed certificate with errors: An error message appears. Follow the on-screen instructions to fix the issue. Otherwise, you can't proceed with connection creation.
- DaaS receives a private CA-signed certificate. A warning page appears. Compare the received thumbprint with the server's for the certificate validity. If it's valid, select **Trust certificate** and click **OK** to proceed with connection creation. DaaS will then trust the certificate and store the thumbprint for future validation.

Create a connection using PowerShell commands

When you create a connection using PowerShell command, provide the following information:

- IP: HPE Server IP Address
- Username: HPE username
- Password: HPE password

For example:

```
New-Item -ConnectionType "Custom" -HypervisorAddress $IP -Metadata
@{"Citrix_Orchestration_Hypervisor_Secret_Allow_Edit"="false"} -Path
@("XDHyp:\Connections\$connectionName") -Persist -PluginId
"HPMoonshotFactory" -Scope @() -SecurePassword $Password -UserName
$UserName -sslthumbprint $SslThumbprint New-BrokerHypervisorConnection
-HypHypervisorConnectionUid $HypervisorConnectionID
```

NOTE:

The `sslthumbprint` parameter is required for only Private CA-signed certificates.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Certificate and thumbprint validation

For creating a successful connection to **HPE Moonshot**, the certificate must not have errors and the thumbprint must have a correct value. Following are the use cases related to the certificate and thumbprint validation:

- Public CA-signed certificate has errors. The connection is not created successfully. See the error details and resolve the issue.
- Public CA-signed certificate without errors. The connection is created successfully, and the `SslThumbprints` value is **Null**.
- Private CA-signed certificate without errors and a `sslthumbprint` value. The connection is created successfully with a correct `SslThumbprints` value.
- Private CA-signed Certificate with an incorrect thumbprint value. The connection is not created successfully.
- Private CA-signed Certificate without errors. The connection is created successfully. The `SSlThumbprints` is **Null** when creating the connection. The `SSlThumbprints` value is updated to a value by the site service.

Manage connections

This section details how you can manage connections:

- Fix certificate issues using Studio
- Update thumbprint value using PowerShell command

Fix certificate issues

DaaS blocks an HPE Moonshot connection when certificate issues arise, preventing you from delivering and managing workloads on associated HPE Moonshot nodes. You'll see an error icon next to the connection in the **Host connections** list. See the following table for specific issues and solutions.

ISSUE	SOLUTION
A certificate error occurs to the public CA-signed certificate	Click the connection and select the **Troubleshoot** tab. View the error details and resolve the issue.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ISSUE	SOLUTION
The received certificate is private CA-signed or expired.	Edit the host connection to update the certificate thumbprint. Details steps: 1. Select the connection and click **Edit Connection**. 2. On the **Connection Properties** page, click **Edit settings**. 3. Enter the password to connect to the HPE Moonshot chassis, and then click **Save**. 4. On the **Warning** page that appears, compare the received thumbprint with the server's for certificate validity. 5. If they are the same, select **Trust certificate** and then click **OK**.

Update thumbprint values

After creating the connection, you can update the thumbprint value of a connection using the `Set-Item` PowerShell command. For example, run the following commands:

1. Get the connection details of a connection. For example:

```
Get-Item -LiteralPath xdhyp:\connections\SinMoonshot-101
```

2. Update the thumbprint value. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-Item -LiteralPath xdhyp:\connections\SinMoonshot-101 -Username
Administrator -SslThumbprint xxxxxxxxxxx12AD048480631BB7AB10D69xxxxx
```

3. Check the updated thumbprint value. For example:

```
Get-Item -LiteralPath xdhyp:\connections\SinMoonshot-101
```

NOTE:

The update fails if you provide an incorrect thumbprint value in the `Set-Item` command.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For HPE Moonshot specific information, see Create an HPE Moonshot machine catalog.

More information

- Create and manage connections and resources
- HPE Moonshot virtualization environments

Connection to Microsoft Azure Resource Manager

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Azure Resource Manager cloud environments.

NOTE:

Before creating a connection to Microsoft Azure, you must finish setting up your Azure account as a resource location. See Microsoft Azure Resource Manager virtualization environments.

Create service principals and connections

Before creating connections, you must set up service principals that connections use to access Azure resources. You can create a connection in two ways:

- Create a service principal and a connection together using Studio
- Create a connection using a previously created service principal

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This section shows you how to complete these tasks:

- Create a service principal and connection using Studio
- Create a service principal using PowerShell
- Get the application secret in Azure
- Create a connection using an existing service principal

Considerations

Before you start, be aware of these considerations:

- Citrix® recommends using service principals with a *Contributor* role. However, see the Minimum permissions section to get the list of minimum permissions.
- When creating the first connection, Azure prompts you to grant it the necessary permissions. For future connections you must still authenticate, but Azure remembers your previous consent and does not display the prompt again.
- After you authenticate with Azure for the first time, a Citrix owned multi-tenant application (ID: `08b70dc3-76c5-4611-ba7d-3312ba36cb2b`) is invited to your Microsoft Entra ID on behalf of the authenticated account.
- Accounts used for authentication must have permissions to assign roles in the subscription using Azure RBAC. Example, Owner, Role Based Access Control Administrator, or User Access Administrator of the subscription.
- The account used for authentication must be a member of the subscription's directory. There are two types of accounts to be aware of: 'Work or School' and 'personal Microsoft account.' See CTX219211 for details.
- While you can use an existing Microsoft account by adding it as a member of the subscription's directory, there can be complications if the user was previously granted guest access to one of the directory's resources. In this case, they might have a placeholder entry in the directory that does not grant them the necessary permissions, and an error is returned.

  Rectify this by removing the resources from the directory and adding them back explicitly. However, exercise this option carefully, because it has unintended effects on other resources that this account can access.
- There is a known issue where certain accounts are detected as directory guests when they are actually members. Configurations like this typically occur with older established directory accounts. Workaround: add an account to the directory, which takes the proper membership value.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Resource groups are simply containers for resources, and they can contain resources from regions other than their own region. This can potentially be confusing if you expect resources displayed in a resource group's region to be available.
- Ensure that your network and subnet are large enough to host the number of machines you require. This requires some foresight, but Microsoft helps you specify the right values, with guidance about the address space capacity.

Create a service principal and connection using Studio

IMPORTANT:

This feature is not yet available for Azure China subscriptions.

With Studio, you can create both a service principal and a connection in a single workflow. Service principals give connections access to Azure resources. When you authenticate to Azure to create a service principal, an application is registered in Azure. A secret key (called *client secret* or *application secret*) is created for the registered application. The registered application (a *connection* in this case) uses the client secret to authenticate to Microsoft Entra ID.

Before you start, make sure that you've met these prerequisites:

- You have a user account in your subscription's Microsoft Entra tenant.
- Accounts used for authentication must have permissions to assign roles in the subscription using Azure RBAC. Example, Owner, Role Based Access Control Administrator, or User Access Administrator of the subscription.
- You have global administrator, application administrator, or application developer permissions for authentication. The permissions can be revoked after you create a host connection. For more information about roles, see Microsoft Entra built-in roles.

Use the **Add Connection and Resources** wizard to create a service principal and a connection together:

1. On the **Connection** page, select **Create a new connection**, the **Microsoft Azure** connection type, and your Azure environment.
2. Select which tools to use to create the virtual machines and then select **Next**.
3. On the **Connection Details** page, select the **Application client secret** authentication mode, then create a service principal and set the connection name as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Enter your Azure subscription ID and a name for the connection. After you enter the subscription ID, the **Create new** button is enabled.

> **NOTE:**
>
> The connection name can contain 1–64 characters, and cannot contain only blank spaces or the characters `\/;:#.*?=<>|[]{}"'()'`.

a. Select **Create new** and then enter the Microsoft Entra account user name and password.

b. Select **Sign in**.

c. Select **Accept** to give Citrix DaaS™ the listed permissions. Azure creates a service principal that allows Citrix DaaS to manage Azure resources on behalf of the specified user.

> **NOTE:**
>
> Citrix DaaS requires the following permissions to create a new service principal:

- **Access Azure Service Management as you**
- **Read and write applications**
- **Sign you in and read your profile**
- **Maintain access to data you have given it access to**

d. After you select **Accept**, you're taken back to the **Connection Details** page.

> **NOTE:**
>
> After you successfully authenticate to Azure, the **Create new** and **Use existing** buttons disappear. The **Connection successful** text appears with a green check mark, indicating the successful connection to your Azure subscription.

e. To route API requests to Azure through Citrix Cloud™ Connectors, select the **Route traffic through Citrix Cloud Connectors** checkbox. When Cloud Connectors have no direct internet access, you can select **Use the proxy configured on Citrix Cloud Connectors** to ensure Azure connectivity works properly through Citrix Cloud Connectors.

Alternatively, you can enable this feature using PowerShell. For more information, see Create a secure environment for Azure-managed traffic.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

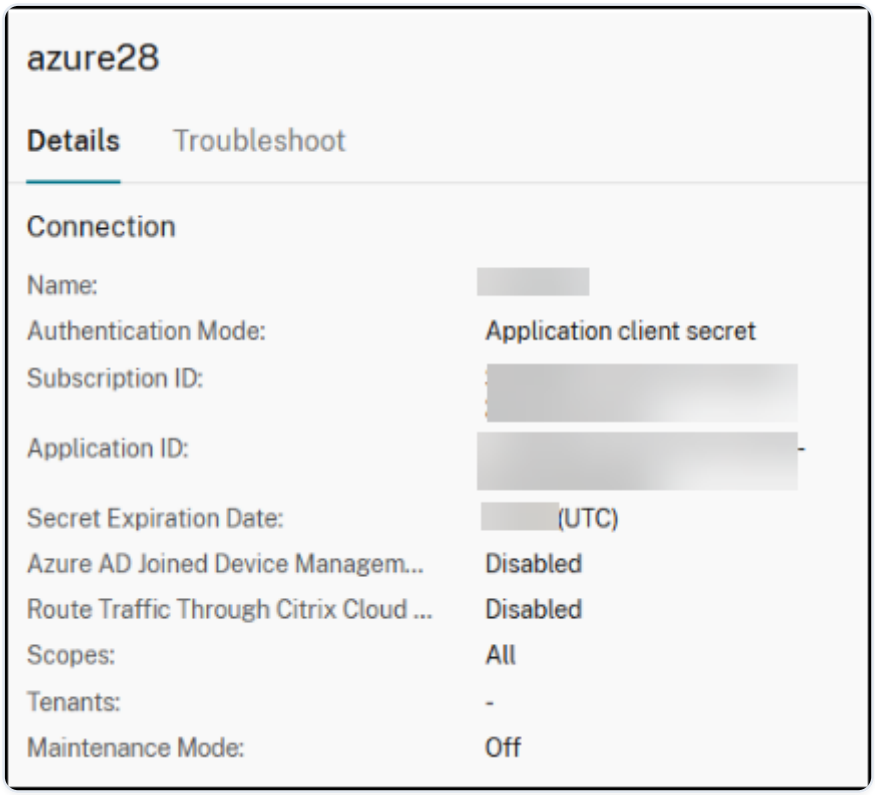
> **NOTE:**
>
> This option is available only when there are active Citrix Cloud Connectors in your deployment. Currently, this feature is not supported for Connector Appliances.

f. Select **Next**.

> **NOTE:**
>
> You cannot proceed to the next page until you successfully authenticate to Azure and consent to giving the required permissions.

4. Configure the resources for the connection as follows:

   - On the **Region** page, select a region.
   - On the **Network** page, do the following:
     - Type a 1–64 character resource name to help identify the region and network combination. A resource name cannot contain only blank spaces or the characters `\/;:#.*?=<>|[]{}"'()'`.
     - Select a virtual network/resource group pair. (If you have more than one virtual network with the same name, pairing the network name with the resource group provides unique combinations.) If the region you selected on the previous page does not have any virtual networks, return to that page and select a region that has virtual networks.



5. On the **Summary** page, view a summary of settings and select **Finish** to complete your setup.

VIEW THE APPLICATION ID

After you create a connection, you can view the application ID that the connection uses to access Azure resources.

In the **Connection and Resources** list, select the connection to view the details. The **Details** tab shows the Application ID.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a service principal using PowerShell

To create a service principal using PowerShell, connect to your Azure Resource Manager subscription and use the PowerShell cmdlets provided in the following sections.

Make sure that you have these items ready:

- **SubscriptionId:** Azure Resource Manager `SubscriptionID` for the subscription where you want to provision VDAs.
- **ActiveDirectoryID**: Tenant ID of the application that you registered with Microsoft Entra ID.
- **ApplicationName:** Name for the application to be created in Microsoft Entra ID.

Detailed steps are as follows:

1. Connect to your Azure Resource Manager subscription.

   ```
   Connect-AzAccount
   ```

2. Select the Azure Resource Manager subscription where you want to create the service principal.

   ```
   Get-AzSubscription -SubscriptionId $subscriptionId | Select-AzSubscription
   ```

3. Create the application in your AD tenant.

   ```
   $AzureADApplication = New-AzADApplication -DisplayName $ApplicationName
   ```

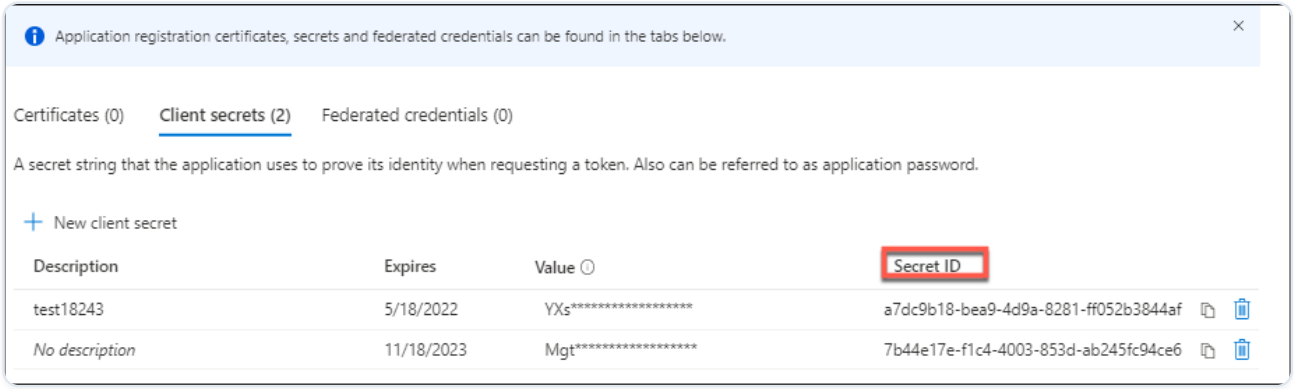
© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Create a service principal.

   ```
   New-AzADServicePrincipal -ApplicationId $AzureADApplication.AppId
   ```

5. Assign a role to the service principal.

   ```
   New-AzRoleAssignment -RoleDefinitionName Contributor -ServicePrincipalName $AzureADApplication.AppId –scope /subscriptions/$SubscriptionId
   ```



6. From the output window of the PowerShell console, note the ApplicationId. You provide that ID when creating the host connection.

Get the application secret in Azure

To create a connection using an existing service principal, you must first get the application ID and secret of the service principal in the Azure portal.

Detailed steps are as follows:

1. Get the **Application ID** from Studio or using PowerShell.
2. Sign in to the Azure portal.
3. In Azure, select **Microsoft Entra ID**.
4. From **App registrations** in Microsoft Entra ID, select your application.
5. Go to **Certificates & secrets**.
6. Click **Client secrets**.

Create a connection using an existing service principal

If you already have a service principal, you can use it to create a connection using Studio.

Make sure that you have these items ready:

- SubscriptionId
- ActiveDirectoryID (tenant ID)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Application ID
- Application secret

  For more information, see Get the application secret.
- Secret expiration date

Detailed steps are as follows:

In the **Add Connection and Resources** wizard:

1. On the **Connection** page, select **Create a new connection**, the **Microsoft Azure** connection type, and your Azure environment.
2. Select which tools to use to create the virtual machines and then select **Next**.
3. On the **Connection Details** page, select the **Application client secret** authentication mode, then enter your Azure subscription ID and a name for the connection.

   NOTE:

   The connection name can contain 1–64 characters, and cannot contain only blank spaces or the characters `\/;:#.*?=<>|[]{}"'()'`.
4. Select **Use existing**. In the **Existing Service Principal Details** window, enter the following settings for the existing service principal. After you enter the details, the **Save** button is enabled. Select **Save**. You cannot progress beyond this page until you provide valid details.

   - **Subscription ID**. Enter your Azure subscription ID. To obtain your subscription ID, sign in to the Azure portal and navigate to **Subscriptions > Overview**.
   - **Active Directory ID** (tenant ID). Enter the Directory (tenant) ID of the application that you registered with Microsoft Entra ID.
   - **Application ID**. Enter the Application (client) ID of the application that you registered with Microsoft Entra ID.
   - **Application secret**. Enter a secret key (client secret). The registered application uses the key to authenticate to Microsoft Entra ID. We recommend that you change keys regularly for security purposes. Be sure to save the key because you cannot retrieve the key later.
   - **Secret expiration date**. Enter the date after which the application secret expires. You receive an alert on the console starting 14 days before the secret key expires. However, if the secret key expires, you receive errors.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> For security purposes, the expiration period cannot be more than two years from now.

- **Authentication URL**. This field is automatically populated and isn't editable.
- **Management URL**. This field is automatically populated and isn't editable.
- **Storage suffix**. This field is automatically populated and isn't editable.
- **Azure blob storage endpoint to upload or download disks or snapshots**. This field is automatically populated and isn't editable.
- **Key Vault Service**. This field is automatically populated and isn't editable.
- **Service bus suffix**. This field is automatically populated and isn't editable.

  Access to the following endpoints is required for creating an MCS catalog in Azure. Access to these endpoints optimizes connectivity between your network and the Azure portal and its services.

  - Authentication URL: `https://login.microsoftonline.com`
  - Management URL: `https://management.azure.com`. This is a request URL for Azure Resource Manager provider APIs. The endpoint for management depends on the environment. For example, for Azure Global, it is `https://management.azure.com`, and for Azure US Government, it is `https://management.usgovcloudapi.net`.
  - Storage suffix: `https://*.core.windows.net`. This (*) is a wildcard character for storage suffix. For example, `https://demo.table.core.windows.net`.
  - Azure blob storage endpoint to upload or download disks or snapshots: `https://*.storage.azure.net`. This (*) is a wildcard character for blob storage import and export operations. For example, `https://md-impexp-xxxxx.z[00-50].blob.storage.azure.net`.
  - Key vault service: `https://*.vault.azure.net`. This (*) is a wildcard character for the key vault name. For example, `https://<your-key-vault-name>.vault.azure.net`.
  - Service bus suffix: `https://*.servicebus.windows.net`. This (*) is a wildcard character for namespaces created in the global Azure cloud. For example, `https://{serviceNamespace}.servicebus.windows.net/{path}`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. After selecting **Save**, you're taken back to the **Connection Details** page. Select **Next** to proceed to the next page.
6. Configure the resources for the connection as follows:
    - On the **Region** page, select a region.
    - On the **Network** page, do the following:
        - Type a 1–64 character resource name to help identify the region and network combination. A resource name cannot contain only blank spaces or the characters `\/;:#.*?=<>|[]{}"'()'`.
        - Select a virtual network/resource group pair. (If you have more than one virtual network with the same name, pairing the network name with the resource group provides unique combinations.) If the region you selected on the previous page does not have any virtual networks, return to that page and select a region that has virtual networks.
7. On the **Summary** page, view a summary of settings and select **Finish** to complete your setup.

Manage service principals and connections

This section details how you can manage service principals and connections:

- Configure Azure throttling settings
- Manage service principal of an existing hosting connection
- Enable image sharing in Azure
- Add shared tenants to a connection using Studio
- Implement image sharing using PowerShell
- Create a secure environment for Azure-managed traffic
- Manage the application secret and secret expiration date

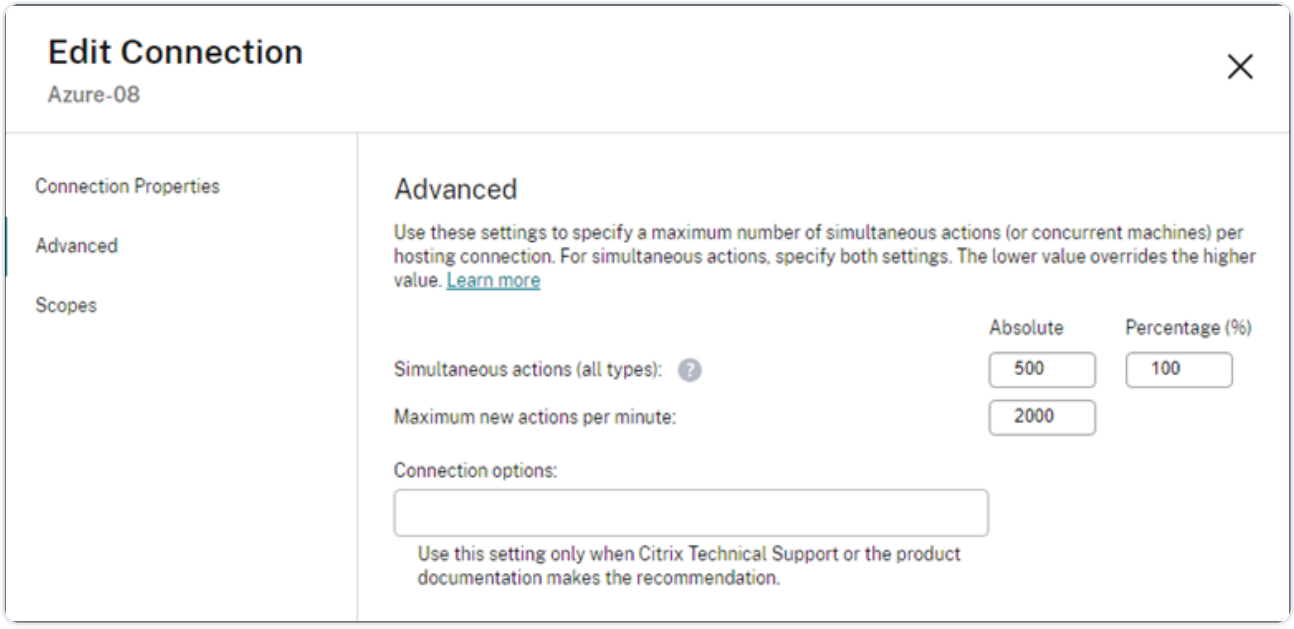
Configure Azure throttling settings

Azure Resource Manager throttles requests for subscriptions and tenants, routing traffic based on defined limits, tailored to the specific needs of the provider. See Throttling Resource Manager requests on the Microsoft site for more information. Limits exist for subscriptions and tenants, where managing many machines can become problematic. For example, a subscription containing many machines might experience performance problems related to power operations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TIP:

For more information, see Improving Azure performance with Machine Creation Services.



To help mitigate these issues, Citrix DaaS allows you to remove MCS internal throttling to use more of the available request quota from Azure.

We recommend the following optimal settings when powering VMs on or off in large subscriptions, for example, those containing 1,000 VMs:

- Absolute simultaneous operations: 500
- Maximum new operations per minute: 2000
- Max concurrency of operations: 500

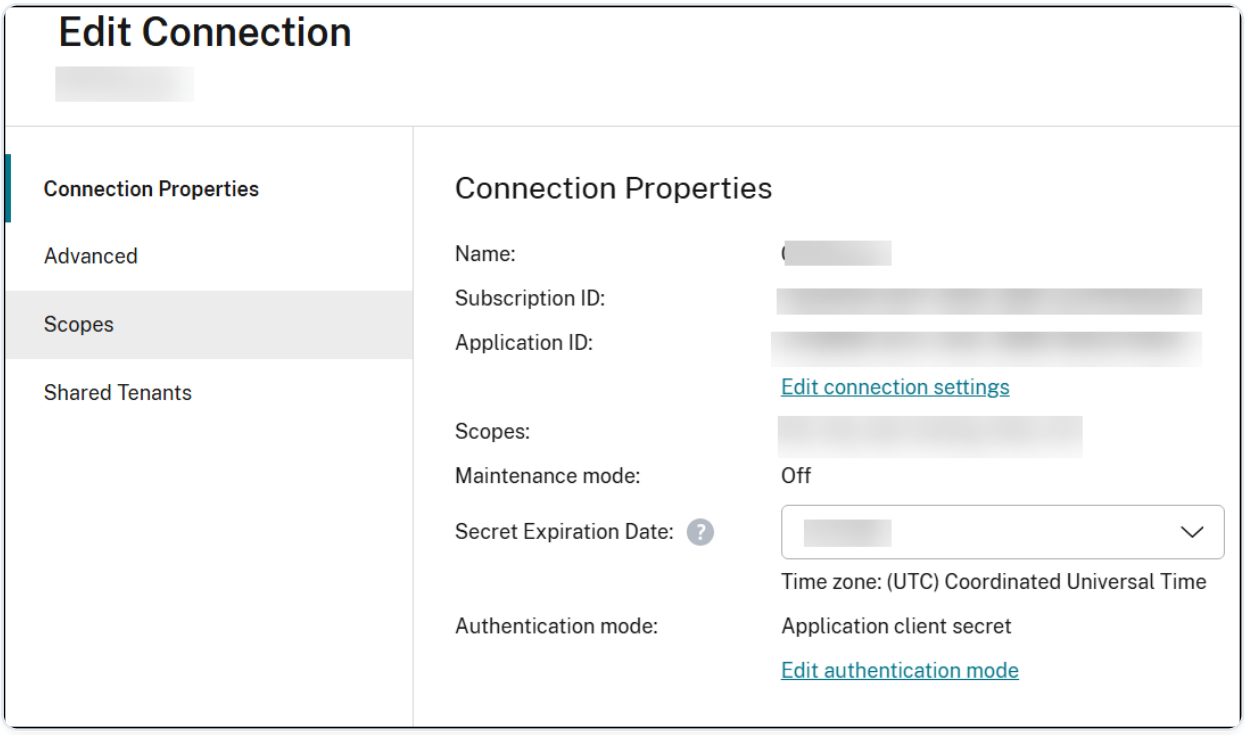
Use Studio to configure Azure operations for a given host connection:

1. From Studio, select **Hosting** in the left pane.
2. Select an Azure-related connection to edit it.
3. In the **Edit Connection** wizard, select **Advanced**.
4. On the **Advanced** page, use the configuration options to specify the number of simultaneous actions and maximum new actions per minute, and any additional connection options.

MCS supports 500 maximum concurrent operations by default. Alternatively, you can use the Remote PowerShell SDK to set the maximum number of concurrent operations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use the **PowerShell** property, `MaximumConcurrentProvisioningOperations`, to specify the maximum number of concurrent Azure provisioning operations. When using this property, consider:



- Default value of `MaximumConcurrentProvisioningOperations` is 500.
- Configure the `MaximumConcurrentProvisioningOperations` parameter using the PowerShell command `Set-item`.

Manage the service principal of an existing hosting connection

After creating a hosting connection using a service principal, you can choose to edit the hosting connection to have:

- New service principal
- Use another existing service principal

1. From Studio, select **Hosting** from the left pane.
2. Select the connection and then select **Edit Connection** in the action bar.
3. Select **Connection Properties** from the left pane.
4. On the **Connection Properties** page that appears, click **Edit conenction settings**. You can now choose to create a new service principal or use another existing service principal.

   - Click **Create service principal** to create a new service principal. Follow the prompt to log in to your Microsoft Entra user account. Citrix uses the multi-tenant application ID

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`08b70dc3-76c5-4611-ba7d-3312ba36cb2b` to create a new service principal for the existing host connection and grant proper permissions.

- Click **Use existing** to use another existing service principal for that hosting connection.

Enable image sharing in Azure

When creating or updating machine catalogs, you can select shared images from different Azure tenants and subscriptions (shared through the Azure Compute Gallery). To enable image sharing within or across tenants, you must make the necessary settings in Azure:

- Share images within a tenant (across subscriptions)
- Share images across tenants

SHARE IMAGES WITHIN A TENANT (ACROSS SUBSCRIPTIONS)

To select an image in Azure Compute Gallery that belongs to a different subscription, the image must be shared with the service principal (SPN) of that subscription.

For example, if there is a service principal (SPN 1), which is configured in Studio as:

Service principal: SPN 1

Subscription: subscription 1

Tenant: tenant 1

The image is in a different subscription, which is configured in Studio as:

Subscription: subscription 2

Tenant: tenant 1

If you want to share the image in subscription 2 with subscription 1 (SPN 1), go to subscription 2, and share the resource group with SPN1.

The image must be shared with another SPN using Azure role-based access control (RBAC). Azure RBAC is the authorization system used to manage access to Azure resources. For more information on Azure RBAC, see the Microsoft document What is Azure role-based access control (Azure RBAC). To grant access, you assign roles to service principals at resource group scope with the Contributor role. To assign Azure roles, you must have `Microsoft.Authorization/roleAssignments/write` permission, such as User Access Administrator or Owner. For more information on sharing images with another SPN, see the Microsoft document Assign Azure roles using the Azure portal.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SHARE IMAGES ACROSS TENANTS

To share images across tenants with Azure Compute Gallery, create or update the application registration and use this application to create hosting connection.

For example, if there are two tenants (Tenant 1 and Tenant 2) and you want to share your image gallery with Tenant 1, then:

1. Create an application registration for Tenant 1. For more information, see Create the app registration.
2. Give Tenant 2 access to the application by requesting a sign-in using a browser. Replace `Tenant2 ID` with the tenant ID of Tenant 1. Replace `Application (client) ID` with the application ID of the application registration that you created. When done making the replacements, paste the URL into a browser and follow the sign-in prompts to sign into Tenant 2. For example:

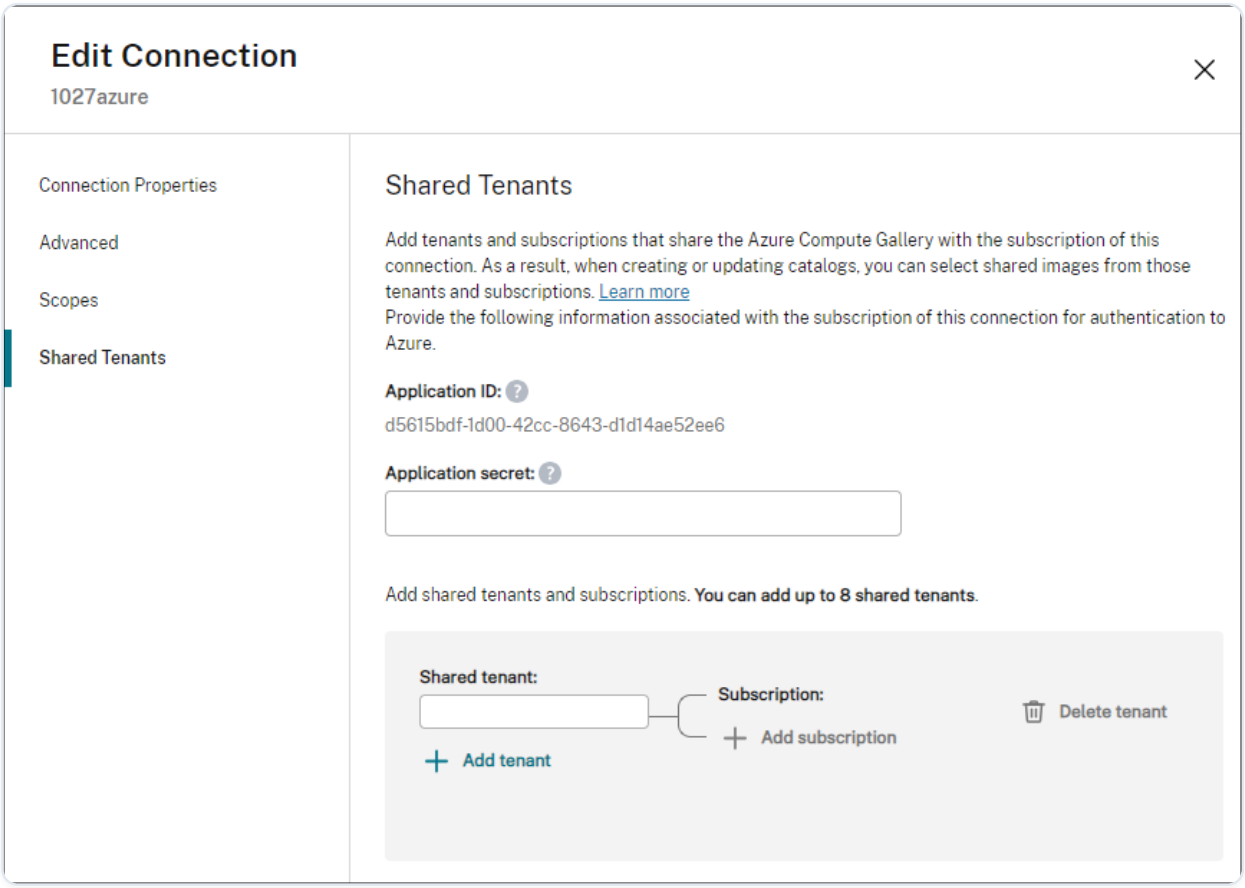
   ```
   https://login.microsoftonline.com/<Tenant 2 ID>/oauth2/authorize?
   client_id=<Application (client)
   ID>&response_type=code&redirect_uri=https%3A%2F%2Fwww.microsoft.com%2F
   ```

   For more information, see Give Tenant 2 access.
3. Give the application access to the Tenant 2 resource group. Sign in as Tenant 2 and give the application registration access to the resource group that has the gallery image. For more information, see Authenticate requests across tenants.

Add shared tenants to a connection using Studio

When creating or updating machine catalogs in Studio, you can select shared images from different Azure tenants and subscriptions (shared through the Azure Compute Gallery). The feature requires that you provide shared tenant and subscription information for associated host connections.

NOTE:



Make sure you've configured the necessary settings in Azure to enable image sharing across tenants. For more information, see Share images across tenants.

Complete the following steps for a connection:

1. From Studio, select **Hosting** in the left pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Select the connection and then select **Edit Connection** in the action bar.

3. In **Shared Tenants**, do the following:

   a. Provide the application ID and application secret associated with the subscription of the connection. DaaS uses this information to authenticate to Microsoft Entra ID.

   b. Add tenants and subscriptions that share the Azure Compute Gallery with the subscription of the connection. You can add up to eight shared tenants and eight subscriptions for each tenant.

4. When you are finished, select **Apply** to apply the changes you made and keep the window open, or select **OK** to apply the changes and close the window.

Implement image sharing using PowerShell

This section guides you through the processes of sharing images using PowerShell:

- Select an image from a different subscription
- Update hosting connection custom properties with shared tenant IDs
- Select an image from a different tenant

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SELECT AN IMAGE FROM A DIFFERENT SUBSCRIPTION

You can select an image in Azure Compute Gallery that belongs to a different shared subscription in the same Azure tenant to create and update MCS catalogs using PowerShell commands.

1. In the hosting unit root folder, Citrix creates a new shared subscription folder called `sharedsubscription`.
2. List all shared subscriptions in a tenant.

```
Get-ChildItem -Path "XDhyp:
\HostingUnits\azres\sharedsubscription.folder"
```

3. Select one shared subscription, and then list all shared resource groups of that shared subscription.

```
Get-ChildItem -Path "XDhyp:
\HostingUnits\azres\image.folder\abc123.sharedsubscription"
```

4. Select a resource group, and then list all galleries of that resource group.

```
Get-ChildItem -Path "XDhyp:
\HostingUnits\azres\image.folder\abc123.sharedsubscription\
xyz.resourcegroup"
```

5. Select a gallery, and then list all image definitions of that gallery.

```
Get-ChildItem -Path "XDhyp:
\HostingUnits\azres\image.folder\abc123.sharedsubscription\xyz.resource
group\testgallery.gallery"
```

6. Select one image definition, and then list all image versions of that image definition.

```
Get-ChildItem -Path "XDhyp:
\HostingUnits\azres\image.folder\abc123.sharedsubscription\xyz.resource
group\sigtestdef.imagedefinition"
```

7. Create and update an MCS catalog using the following elements:
    - Resource group

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Gallery
- Gallery image definition
- Gallery image version

UPDATE HOSTING CONNECTION CUSTOM PROPERTIES WITH SHARED TENANT IDS

Use `Set-Item` to update the hosting connection custom properties with shared tenant IDs and subscription IDs. Add a property `SharedTenants` in `CustomProperties`. The format of `SharedTenants` is:

```
[{"Tenant":"94367291-119e-457c-bc10-25337231f7bd","Subscriptions":
["7bb42f40-8d7f-4230-a920-be2781f6d5d9"]},{"Tenant":"50e83564-c4e5-4209-
b43d-815c45659564","Subscriptions":["06ab8944-6a88-47ee-
a975-43dd491a37d0"]}]
```

For example:

```
Set-Item -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`">

<Property xsi:type=`"StringProperty`" Name=`"SubscriptionId`"
Value=`"123`" />

<Property xsi:type=`"StringProperty`" Name=`"ManagementEndpoint`"
Value=`"https://management.azure.com/`" />

<Property xsi:type=`"StringProperty`" Name=`"AuthenticationAuthority`"
Value=`"https://login.microsoftonline.com/`" />

<Property xsi:type=`"StringProperty`" Name=`"StorageSuffix`"
Value=`"core.windows.net`" />

<Property xsi:type=`"StringProperty`" Name=`"TenantId`" Value=`"123abc`" /
>

<Property xsi:type=`"StringProperty`" Name=`"SharedTenants`"
Value=`"`[ { 'Tenant':'123abc', 'Subscriptions':['345', '567'] } ]`"` />

</CustomProperties>"

-LiteralPath @("XDHyp:\Connections\aazure") -PassThru -UserName "advc345"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-SecurePassword

$psd
```

NOTE:

You can add more than one tenant. Each tenant can have more than one subscription.

SELECT AN IMAGE FROM A DIFFERENT TENANT

You can select an image in the Azure Compute Gallery that belongs to a different Azure tenant to create and update MCS catalogs using PowerShell commands.

1. In the hosting unit root folder, Citrix creates a new shared subscription folder called `sharedsubscription`.
2. List all shared subscriptions.

   ```
   Get-ChildItem XDHyp:\HostingUnits\azres\sharedsubscription.folder
   ```

3. Select one shared subscription, and then list all shared resource groups of that shared subscription.

   ```
   Get-ChildItem XDHyp:
   \HostingUnits\azres\image.folder\abc123.sharedsubscription
   ```

4. Select a resource group, and then list all galleries of that resource group.

   ```
   Get-ChildItem XDHyp:
   \HostingUnits\azres\image.folder\abc123.sharedsubscription\
   xyz.resourcegroup
   ```

5. Select a gallery, and then list all image definitions of that gallery.

   ```
   Get-ChildItem XDHyp:
   \HostingUnits\azres\image.folder\abc123.sharedsubscription\xyz.resource
   group\efg.gallery
   ```

6. Select one image definition, and then list all image versions of that image definition.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-ChildItem XDHyp:
\HostingUnits\azres\image.folder\abc123.sharedsubscription\xyz.resource
group\efg.gallery\hij.imagedefinition
```

7. Create and update an MCS catalog using the following elements:
   - Resource group
   - Gallery
   - Gallery image definition
   - Gallery image version

Create a secure environment for Azure-managed traffic

MCS enables network traffic (API calls from Citrix Cloud to Azure hypervisor) to be routed through Cloud Connectors in your environment. This implementation helps you lock down your Azure subscription to allow network traffic from specific IP addresses. To do this, add `ProxyHypervisorTrafficThroughConnector` in `CustomProperties`. After you set the custom properties, you can configure Azure policies to have private disk access to Azure managed disks.

If you configure the Azure policy to create Disk Accesses automatically for each new disk to use private endpoints, you cannot upload or download more than five disks or snapshots at the same time with the same disk access object as enforced by Azure. This limit is for each machine catalog if you configure Azure policy at resource group level, and for all machine catalogs if you configure Azure policy at subscription level. If you do not configure the Azure policy to create Disk Accesses automatically for each new disk to use private endpoints, the limit of five concurrent operations is not enforced.

NOTE:

Currently, this feature is not supported for Connector Appliance. For Azure limitations related to this feature, see Restrict import/export access for managed disks using Azure Private Link.

ENABLE THE PROXY

To enable the proxy, set the custom properties as follows on the host connection:

1. Open a PowerShell window using the Remote PowerShell SDK. For more information, see `<https://docs.citrix.com/en-us/citrix-daas/sdk-api.html#citrix-virtual-apps-and-desktops-remote-powershell-sdk/>`.
2. Run the following commands:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Add-PSSnapin citrix*.

cd XDHyp:\Connections\

dir
```

3. Copy the `CustomProperties` from the connection to a notepad and append property setting `<Property xsi:type="StringProperty" Name="ProxyHypervisorTrafficThroughConnector" Value="True" />` to the `CustomProperties` to enable the proxy. For example:

```
<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns="http://schemas.citrix.com/2014/xd/machinecreation">

<Property xsi:type="StringProperty" Name="SubscriptionId"
Value="4991xxxx-2xxx-4xxx-8xxx-ff59a830xxxx" />

<Property xsi:type="StringProperty" Name="ManagementEndpoint"
Value="https://management.azure.com/" />

<Property xsi:type="StringProperty" Name="AuthenticationAuthority"
Value="https://login.microsoftonline.com/" />

<Property xsi:type="StringProperty" Name="StorageSuffix"
Value="core.windows.net" />

<Property xsi:type="StringProperty" Name="TenantId"
Value="5cxxxxx-9xxx-4xxx-8xxx-dffe3efdxxxx" />

<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True" />

</CustomProperties>
```

4. In the PowerShell window, assign a variable to the modified custom properties. For example:

```
$customProperty = '<CustomProperties xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns="http://schemas.citrix.com/2014/xd/
machinecreation">

<Property xsi:type="StringProperty" Name="SubscriptionId"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value="4991xxxx-2xxx-4xxx-8xxx-ff59a830xxxx" />

<Property xsi:type="StringProperty" Name="ManagementEndpoint"
Value="https://management.azure.com/" />

<Property xsi:type="StringProperty" Name="AuthenticationAuthority"
Value="https://login.microsoftonline.com/" />

<Property xsi:type="StringProperty" Name="StorageSuffix"
Value="core.windows.net" />

<Property xsi:type="StringProperty" Name="TenantId"
Value="5cxxxxx-9xxx-4xxx-8xxx-dffe3efdxxxx" />

<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True" />

</CustomProperties>'
```

5. Run `$cred = Get-Credential`. If prompted, provide the connection credentials. The credentials are Azure Application ID and secret.
6. Run `Set-Item -PSPath XDHyp:\Connections\<Connection_Name> -CustomProperties $customProperty -username $cred.username -Securepassword $cred.password`.

IMPORTANT:

If you get a message stating `SubscriptionId` is missing, then replace all double quotes (“) with backtick followed by double quotes (`”) in the custom property. For example:

```
<CustomProperties xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`" xmlns=`"http://schemas.citrix.com/2014/xd/machinecreation`">

<Property xsi:type=`"StringProperty`" Name=`"SubscriptionId`"
Value=`"4991xxxx-2xxx-4xxx-8xxx-ff59a830xxxx`" />

<Property xsi:type=`"StringProperty`" Name=`"ManagementEndpoint`"
Value=`"https://management.azure.com/`" />

<Property xsi:type=`"StringProperty`" Name=`"AuthenticationAuthority`"
Value=`"https://login.microsoftonline.com/`" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type=`"StringProperty`" Name=`"StorageSuffix`"
Value=`"core.windows.net`" />

<Property xsi:type=`"StringProperty`" Name=`"TenantId`"
Value=`"5cxxxxx-9xxx-4xxx-8xxx-dffe3efdxxxx`" />

<Property xsi:type=`"StringProperty`"
Name=`"ProxyHypervisorTrafficThroughConnector`" Value=`"True`" />

</CustomProperties>
```

7. Run `dir` to verify the updated `CustomProperties` settings.

Option to use system proxy on Citrix Cloud Connectors for redirected Azure API traffic

To route all external traffic through a non-transparent proxy, configure the host connection with the custom property `UseSystemProxyForHypervisorTrafficOnConnectors`. This redirects Azure API internet traffic on Citrix Cloud Connectors through the system proxy.

Do the same steps as outlined in Enable the proxy to configure the host connection with the custom property. However, make sure to append property setting `<Property xsi:type="StringProperty" Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />` to the `CustomProperties` to enable the proxy.

```
<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />
```

Example:

```
<CustomProperties xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns="http://schemas.citrix.com/2014/xd/machinecreation">

<Property xsi:type="StringProperty" Name="SubscriptionId"
Value="4991xxxx-2xxx-4xxx-8xxx-ff59a830xxxx" />

<Property xsi:type="StringProperty" Name="ManagementEndpoint"
Value="https://management.azure.com/" />

<Property xsi:type="StringProperty" Name="AuthenticationAuthority"
Value="https://login.microsoftonline.com/" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="StorageSuffix"
Value="core.windows.net" />

<Property xsi:type="StringProperty" Name="TenantId"
Value="5cxxxxx-9xxx-4xxx-8xxx-dffe3efdxxxx" />

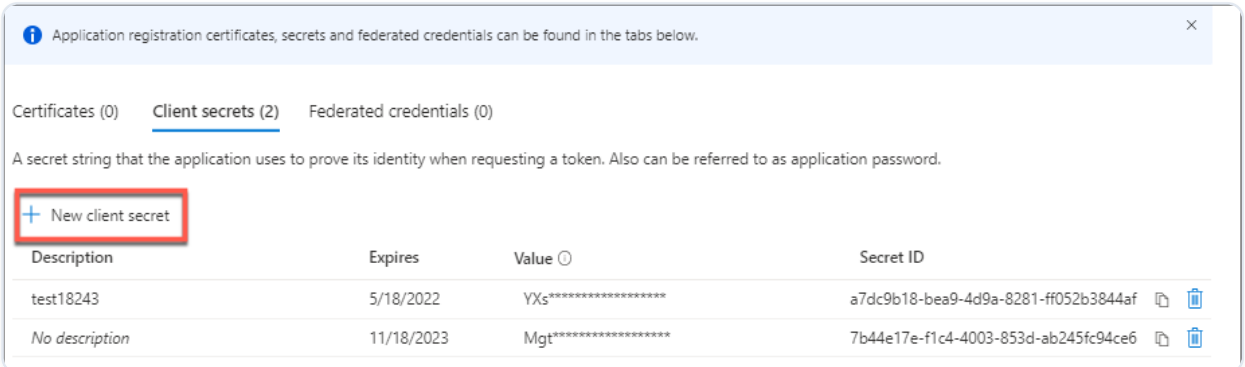
<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True" />

<Property xsi:type="StringProperty"
Name="UseSystemProxyForHypervisorTrafficOnConnectors" Value="True" />

</CustomProperties>
```

NOTE:

After you set this property, the proxy configured in the `netsh winhttp` settings on the Citrix Cloud Connectors is used for outbound traffic to the cloud service provider.



Manage the application secret and secret expiration date

Be sure to change the application secret for a connection before the secret expires. You receive an alert on Studio before the secret key expires.

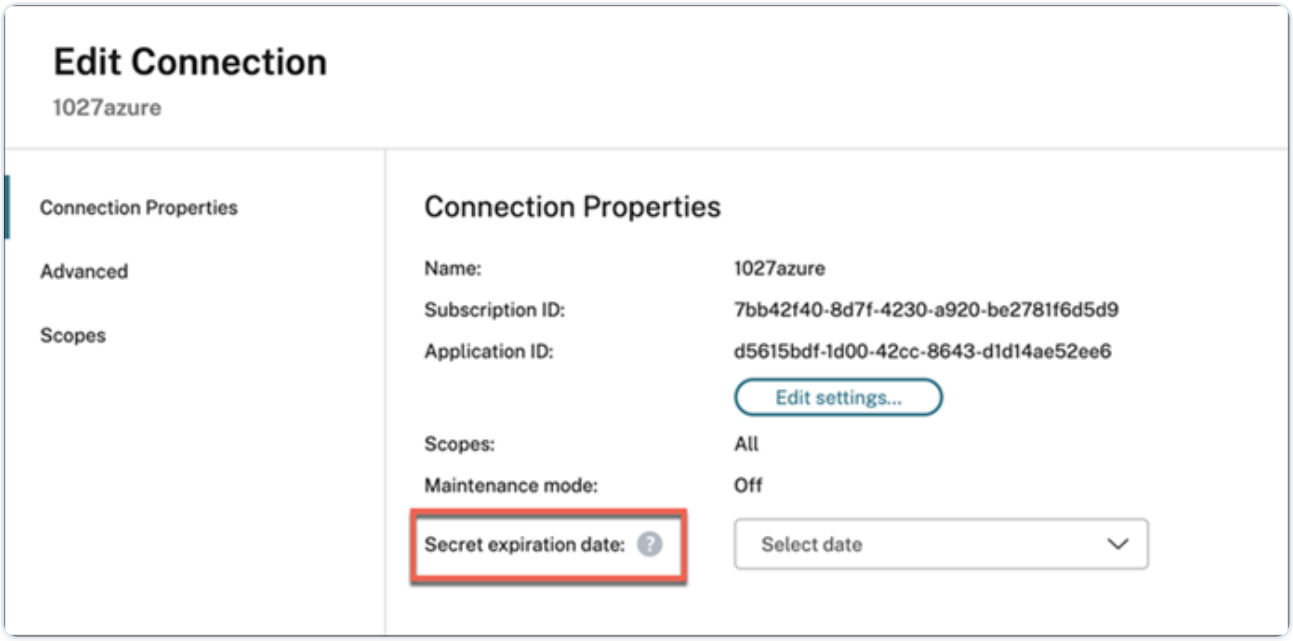
CREATE AN APPLICATION SECRET IN AZURE

You can create an application secret for a connection through the Azure portal.

1. Select **Microsoft Entra ID**.
2. From **App registrations** in Microsoft Entra ID, select your application.
3. Go to **Certificates & secrets**.
4. Click **Client secrets > New client secret**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Provide a description of the secret and specify a duration. When you're done, select **Add**.



> **NOTE:**
>
> Be sure to save the client secret because you cannot retrieve it later.

6. Copy the client secret value and the expiration date.
7. In Studio, edit the corresponding connection and replace the content in the **Application secret** and **Secret expiration date** field with the values you copied.

CHANGE THE SECRET EXPIRATION DATE

You can use Studio to add or modify the expiration date for the application secret in use.

1. In the **Add Connection and Resources** wizard, right-click a connection, and click **Edit Connection**.
2. On the **Connection Properties** page, click **Secret expiration date** to add or modify the expiration date for the application secret in use.

Create a host connection using Azure Managed Identity

You can create a host connection to Microsoft Azure Resource Manager using Azure Managed Identity. The Azure managed identities offer a secure and scalable way to access Azure services without the need to manage credentials. This approach eliminates the risks associated with storing, rotating, and managing secrets.

The **Authentication Mode** has three options:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- AppClientSecret
- SystemAssignedManagedIdentity
- UserAssignedManagedIdentity

Before you begin

Following are the steps you must do before creating the host connection using the Azure Managed Identity:

1. Install a Citrix Cloud Connector™ in an Azure VM.
2. Enable Azure Managed Identity on that Cloud Connector VM.
    - For the user assigned managed identity:
        a. On the Azure portal, create a user assigned managed identity. For information, see Create and assign a User Assigned Managed Identity.
        b. Assign Azure roles to the managed identity. See Required Azure permissions.
        c. Create an Azure VM as a Cloud Connector and add the user assigned identity to it.
    - For the system assigned managed identity:
        a. Open the Azure portal and go to your VM.
        b. Select the Identity blade in the VM's settings.
        c. Under the **System assigned** tab, set the status to **On**.
        d. Click **Save**.
        e. Grant Required Azure permissions.

        NOTE:

        If you enable the system assigned managed identity on a Cloud Connector VM and use it to create a host connection, you can still create host connections with the system assigned managed identity even after disabling it on the Cloud Connector VM. The creation of host connections can succeed even 24 hours after the identity has been disabled. This happens because managed identity tokens are cached by the underlying Azure infrastructure. For more information, see Are managed identities tokens cached?.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create the host connection with Azure Managed Identity using Studio

In the **Add Connection and Resources** wizard:

1. On the **Connection** page:
    a. Select **Create a new connection**, the Microsoft Azure connection type, and your Azure environment.
    b. Select which tools to use to create the virtual machines and then select Next.
2. On the **Connection Details** page, select the **Authentication mode**.
    - For the **User assigned managed identity**, enter the following settings. After you enter the details, select **Next** to proceed to the following pages. You cannot progress beyond this page until you provide valid details.
        - **Subscription ID**: Enter your Azure subscription ID. To obtain your subscription ID, sign in to the Azure portal and navigate to **Subscriptions > Overview**.
        - **Active Directory ID** (tenant ID): Enter the Directory (tenant) ID of the application that you registered with Microsoft Entra ID.
        - **Client ID**: Enter the Client ID of the Managed Identity that you created in the Azure portal.
        - **Authentication URL**: This field is automatically populated and isn't editable.
        - **Management URL**: This field is automatically populated and isn't editable.
        - **Storage suffix**: This field is automatically populated and isn't editable.
    - For the **System assigned managed identity**, enter the following settings. After you enter the details, select **Next** to proceed to the following pages. You cannot progress beyond this page until you provide valid details.
        - **Subscription ID**: Enter your Azure subscription ID. To obtain your subscription ID, sign in to the Azure portal and navigate to **Subscriptions > Overview**.
        - **Active Directory ID** (tenant ID): Enter the Directory (tenant) ID of the application that you registered with Microsoft Entra ID.
        - **Authentication URL**: This field is automatically populated and isn't editable.
        - **Management URL**: This field is automatically populated and isn't editable.
        - **Storage suffix**: This field is automatically populated and isn't editable.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create the host connection with Azure Managed Identity using PowerShell

You can create this host connection using a new CustomProperty `AuthenticationMode`. The `AuthenticationMode` has three options: `AppClientSecret`, `SystemAssignedManagedIdentity`, and `UserAssignedManagedIdentity`. The following is the description of the authentication mode options:

- `AppClientSecret`: This is the default value. This needs an Application ID and secret.
- `UserAssignedManagedIdentity`: This needs a client ID to be provided through a UserName.
- `SystemAssignedManagedIdentity`: This doesn't need any input. Even if you provide a client id, it is ignored.

NOTE:

While using PowerShell, the parameter `ProxyHypervisorTrafficThroughConnector` must be true to use managed identity.

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create host connections. For example:
    - For the user assigned managed identity:

```
$UserName = "should be the Client ID of the user-assigned managed
identity"

$Password = "It can be any string.Not used"

$CustomProperties = '<CustomProperties xmlns="http://
schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance">' `

+ '<Property xsi:type="StringProperty" Name="SubscriptionId"
Value="' + $SubscriptionId + '" />'`

+ '<Property xsi:type="StringProperty" Name="ManagementEndpoint"
Value="https://management.azure.com/" />'`
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
+ '<Property xsi:type="StringProperty"
Name="AuthenticationAuthority" Value="https://
login.microsoftonline.com/" />'`

+ '<Property xsi:type="StringProperty" Name="StorageSuffix"
Value="core.windows.net" />'`

+ '<Property xsi:type="StringProperty" Name="TenantId" Value="' +
$TenantId + '" />'`

+ '<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True" />'`

+ '<Property xsi:type="StringProperty" Name="AuthenticationMode"
Value="UserAssignedManagedIdentity" />'`

+ '</CustomProperties>'

New-Item -ConnectionType "Custom" `

-CustomProperties $CustomProperties `

-HypervisorAddress @($HypervisorAddress) `

-Path @("XDHyp:\Connections\$($ConnectionName)") `

-Metadata $Metadata `

-Persist `

-PluginId "AzureRmFactory" `

-Scope @() `

-Password $Password `

-UserName $UserName `

-ZoneUid $zoneUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For the system assigned managed identity:

```
$UserName = "It can be any string. Not used"

$Password = "It can be any string. Not used"

$CustomProperties = '<CustomProperties xmlns="http://
schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance">' `

+ '<Property xsi:type="StringProperty" Name="SubscriptionId"
Value="' + $SubscriptionId + '" />'`

+ '<Property xsi:type="StringProperty" Name="ManagementEndpoint"
Value="https://management.azure.com/" />'`

+ '<Property xsi:type="StringProperty"
Name="AuthenticationAuthority" Value="https://
login.microsoftonline.com/" />'`

+ '<Property xsi:type="StringProperty" Name="StorageSuffix"
Value="core.windows.net" />'`

+ '<Property xsi:type="StringProperty" Name="TenantId" Value="' +
$TenantId + '" />'`

+ '<Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="True" />'`

+ '<Property xsi:type="StringProperty" Name="AuthenticationMode"
Value="SystemAssignedManagedIdentity" />'`

+ '</CustomProperties>'

New-Item -ConnectionType "Custom" `

-CustomProperties $CustomProperties `

-HypervisorAddress @($HypervisorAddress) `

-Path @("XDHyp:\Connections\$($ConnectionName)") `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-Metadata $Metadata `
-Persist `
-PluginId "AzureRmFactory" `
-Scope @() `
-Password $Password `
-UserName $UserName `
-ZoneUid $zoneUid
```

Manage Azure Managed Identity of an existing hosting connection

Use Studio

After creating a hosting connection, you can choose to update the existing hosting connection to have:

- System assigned managed identity
- User assigned managed identity
- A new user assigned managed identity

1. From Studio, select **Hosting** from the left pane.
2. Select the connection and then select **Edit Connection** in the action bar.
3. On the **Connection Properties** page that appears, click **Edit authentication mode**. You can now choose to update the authentication mode.
    - Click **User assigned managed identity** to use User assigned managed identity for that hosting connection. Follow the Client ID to be filled.
    - Click **System assigned managed identity** to use System assigned managed identity for that hosting connection.

Use PowerShell

You can also update an existing host connection using PowerShell to use a system assigned identity or user assigned managed identity. For example, run the following PowerShell commands:

1. Open a PowerShell window.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run the following commands:

```
$connName = "ConnectionName"

$conn = get-item XDHyp:\Connections\$connName

$conn.CustomProperties
```

4. Change `ProxyHypervisorTrafficThroughConnector` to `True` and add the custom property for `AuthenticationMode` set to `SystemAssignedManagedIdentity` or `UserAssignedManagedIdentity`. For example:

```
$customProps = '<CustomProperties xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns="http://schemas.citrix.com/2014/xd/
machinecreation"><Property xsi:type="StringProperty"
Name="SubscriptionId" Value="subscriptionId" /><Property
xsi:type="StringProperty" Name="ManagementEndpoint" Value="https://
management.azure.com/" /><Property xsi:type="StringProperty"
Name="AuthenticationAuthority" Value="https://
login.microsoftonline.com/" /><Property xsi:type="StringProperty"
Name="StorageSuffix" Value="core.windows.net" /><Property
xsi:type="StringProperty" Name="TenantId" Value="tenantId" /><Property
xsi:type="StringProperty" Name="AzureAdDeviceManagement"
Value="false" /><Property xsi:type="StringProperty"
Name="ProxyHypervisorTrafficThroughConnector" Value="true" /><Property
xsi:type="StringProperty" Name="AuthenticationMode"
Value="SystemAssignedManagedIdentity" /></CustomProperties>'
```

5. Run `$cred = Get-Credential`. Enter anything here.
6. Run `Set-Item -PSPath XDHyp:\Connections\$connName -CustomProperties $CustomProperties -username $cred.username -Securepassword $cred.password`.

Azure Extended Zones

Azure Extended Zones are small-footprint extensions of existing Azure regions, enabling organizations to run workloads closer to their users for improved performance and compliance. MCS on Azure now supports provisioning and power management for VMs in Extended Zones.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To learn more about Azure Extended Zones, see the Microsoft documentation: Azure Extended Zones documentation.

Use cases

This feature is applicable for persistent and non-persistent catalogs:

- Power-managed only VMs: You can import your existing extended zone VMs into a power-managed-only catalog and power-manage them with Citrix MCS.
- MCS Provisioned VMs: You can provision new VMs into an Extended Zone and manage them with MCS. This feature also includes support for image management workflows.

Limitations

There are currently several limitations for using Azure Extended Zones. Many of these limitations are due to current Azure constraints:

- Dedicated hosts are not supported.
- Capacity reservations are not supported.
- Proximity placement groups are not supported.
- Spot VMs are not supported.
- Availability Zones are not supported in Extended Zones.
- Only **StandardSSD_LRS** and **Premium_LRS** storage types are supported.
- You cannot currently use the **UseSharedImageGallery** feature to save a mastered image into an Azure Compute Gallery (or Shared Image Gallery) in an Extended Zone. As a byproduct, Ephemeral OS disks are also not supported.
- If you are using an Azure Compute Gallery image version as your master image, ensure that replication has fully completed in the Extended Zone before attempting to use it. Attempting to use the image version before replication completes might result in deployment failure.

Prerequisites

Before using Extended Zones, ensure you have completed the following prerequisite steps:

1. Register with Azure:
    a. Extended Zones are not enabled by default.
    b. Register the `Microsoft.EdgeZones` resource provider in your Azure subscription: Register your subscription for resource provider Microsoft.EdgeZones.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. Register each required Extended Zone separately (ex: LosAngeles, Perth): Register for an Azure Extended Zone.

2. Prepare Citrix resources:

   a. Create a virtual network in your Extended Zone.

   b. Create master images and snapshots as needed.

Required permissions

To create a catalog in an Extended Zone, your service principal must have the following permission: `Microsoft.EdgeZones/extendedZones/read`.

For more on minimum required permissions, see Minimum permissions.

Configuration steps

1. Create a Hosting Unit in an Extended Zone

   Extended Zones, which use the `.extendedzone` type, are listed alongside regions in the Citrix MCS inventory. To provision into an extended zone, you must create a new hosting unit tied to that extended zone.

   Example: To create a hosting Unit in Los Angeles Extended Zone

```
$RootPath = "XDHyp:\Connections\MyConnectionName\Los
Angeles.extendedzone"

$NetworkPath = "XDHyp:\Connections\MyConnectionName\Los
Angeles.extendedzone\virtualprivatecloud.folder\MyResourceGroup.resourc
egroup\MyExtendedZoneNetwork.virtualprivatecloud\MyExtendedZoneSubnet.n
etwork"

$HostingUnitPath = "XDHyp:\HostingUnits\MyHostingUnitName"

New-Item -HypervisorConnectionName MyConnectionName -NetworkPath
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
@($NetworkPath) -Path @($HostingUnitPath) -RootPath $RootPath
-StoragePath @()
```

2. Create an MCS Catalog in an Extended Zone

   After creating your Hosting Unit, proceed with catalog creation using Studio or PowerShell. Ensure your catalog references the Extended Zone Hosting Unit.

Troubleshooting

If you encounter issues, check the following:

1. Ensure your subscription is registered for extended zones.
   a. Confirm your subscription is registered with the Microsoft.EdgeZones resource provider.
   b. Ensure that each Extended Zone is registered individually.
2. Verify your service principal has the new permission.
   a. Your service principal must have the `Microsoft.EdgeZones/extendedZones/read` permission.

Inventory items in Extended Zones may be shown as "Unknown Extended Zone" if registration or permissions are missing.

NOTE:

If creating a catalog in the parent region using a master image from an Extended Zone, registration and permissions for the Extended Zone are still required.

Use a pre-created network security group

Create a Deny-All network security group for image preparation instead of requesting Citrix to create and modify NSG. Edit the custom properties of the hosting unit using a PowerShell command `Set-Item` to include the parameter `NsgForPreparation` to provide the Deny-All network security group.

Prerequisites

Configure the following permissions required for a service principal:

- `Microsoft.Network/networkSecurityGroups/join/action`: Associate a network security group to a subnet or network interface

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `Microsoft.Network/networkSecurityGroups/read`: Gets network security group
- `Microsoft.Network/networkSecurityGroups/securityRules/read`: Gets rule

Add the pre-created Deny-All network security group

To add the pre-created Deny-All network security group, set the custom properties as follows on the hosting unit:

1. Open a PowerShell window using the Remote PowerShell SDK.
2. Run the following commands:

```
Add-PSSnapin citrix*.

cd XDHyp:\HostingUnits\

Dir
```

3. Select a hosting unit to retrieve the details:

```
Get-Item "XDHyp:\HostingUnits\<hostingunitname>"
```

4. Copy the CustomProperties to a notepad and append property setting `<Property xsi:type="StringProperty` " Name= `"NsgForPreparation` " Value= `"{ResourceGroupName}/{NetworkSecurityGroupName}"/>`. For example:

```
<CustomProperties xmlns=`"http://schemas.citrix.com/2014/xd/
machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`"
Name=`"NsgForPreparation`" Value=`{ResourceGroupName}/
{NetworkSecurityGroupName}`"/></CustomProperties>
```

5. In the PowerShell window, assign a variable to the modified custom properties. For example:

```
$customProperty = "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`"
Name=`"NsgForPreparation`" Value=`"{ResourceGroupName}/
{NetworkSecurityGroupName}`"/></CustomProperties>"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Run `$cred = Get-Credential`. If prompted, provide the connection credentials. The credentials are Azure Application ID and secret.
7. Run the following command.

```
Set-Item -PSPath XDHyp:\HostingUnits\<hostingunitname>
-CustomProperties $customProperty -username $cred.username
-Securepassword $cred.password
```

IMPORTANT:

If you get a message stating SubscriptionId is missing, then replace all double quotes (“) with backtick followed by double quotes (`”) in the custom property.

8. Run `dir` to verify the updated `CustomProperties` settings.

NOTE:

It takes more than a minute for the updates to reflect.

Retrieve network security group details

To retrieve the network security group details, first retrieve the resource groups containing the network security group, and then retrieve the network security group based on the resource group name.

1. Retrieve the resource groups containing network security group. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes":
["networksecuritygroup"]}'
```

2. Retrieve the network security group based on the resource group name. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType securitygroup -MaxRecords
5 -AdditionalDataFilter '{"location": ["eastus", "westus"],
"resourcegroup":["resourcegroupname"]}'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Filter empty resource groups

Use the PowerShell command `Get-HypInventoryItem` to filter empty resource groups while selecting a master image, machine profile, or prepared image during the machine catalog creation.

Examples:

- Retrieve the maximum records in a page:

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5
```

- Retrieve the maximum records in a page, and filter to find resource containers that have specific resources.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["vm",
"manageddisk", "snapshot", "imageversion", "storageaccount"]}'
```

- Retrieve with skip to directly indicate the page, and filter to find resource containers that have specific resources.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -skip 20 -AdditionalDataFilter '{"containedresourcetypes": ["vm",
"manageddisk", "snapshot", "imageversion", "storageaccount"]}'
```

- Use a token to retrieve the next page, and filter to find resource containers that have specific resources.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["vm",
"manageddisk", "snapshot", "imageversion", "storageaccount"]}'
-ContinuationToken
'ew0KICAiJGlkIjogIjEiLA0KICAiTWF4Um93cyI6IDUsDQogICJSb3dzVG9Ta2lwIjogMj
UsDQogICJLdXN0b0NsdXN0ZXJVcmwiOiAiaHR0cHM6Ly9hcmctbmV1LTEzLXNmLmFyZy5jb
3JlLndpbmRvd3MubmV0Ig0KfQ=='
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Retrieve all resource groups with tag Citrix internal tag and limit max records with `MaxRecords`.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5
```

- Filter for machine profile (master image) with tag Citrix internal tag and limit max records with `MaxRecords`.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["vm",
"templatespecversion"]}'
```

- Filter for Prepared image with tag Citrix internal tag and limit max records with `MaxRecords`.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["manageddisk",
"snapshot", "imageversion"]}'
```

- Filter for machine profile (Prepared image) with tag Citrix internal tag and limit max records with `MaxRecords`.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["vm",
"templatespecversion"]}'
```

- Filter for Image with tag Citrix internal tag and limit max records with `MaxRecords` and location.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
5 -AdditionalDataFilter '{"containedresourcetypes": ["manageddisk",
"snapshot", "imageversion", "storageaccount"], "location": ["eastus",
"westus"]}'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Retrieve all resource group without consideration on tags `CitrixResource`.

```
Get-HypInventoryItem -LiteralPath "XDHyp:
\HostingUnits\ctx04con01unit01" -ResourceType resourceGroup -MaxRecords
50 -AdditionalDataFilter '{"containedresourcetypes": ["manageddisk",
"snapshot", "imageversion", "storageaccount"]}' -Force $true
```

Required Azure permissions

This section details the minimum permissions and general permissions required for Azure.

Minimum permissions

Minimum permissions give better security control. However, new features that require additional permissions fail if only minimum permissions are given. This section lists minimum permissions by action.

CREATING A HOST CONNECTION

Add a host connection using the information obtained from Azure.

```
"Microsoft.Network/virtualNetworks/read",

"Microsoft.Compute/virtualMachines/read",

"Microsoft.Compute/disks/read",

"Microsoft.Resources/providers/read",

"Microsoft.Resources/subscriptions/locations/read",

"Microsoft.Resources/tenants/read",

"Microsoft.Network/networkSecurityGroups/join/action",

"Microsoft.Network/networkSecurityGroups/read",

"Microsoft.Network/networkSecurityGroups/securityRules/read",

"Microsoft.EdgeZones/extendedZones/read"
```

POWER MANAGEMENT OF VMS

Power on or off the machine instances.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Compute/virtualMachines/read",

"Microsoft.Resources/subscriptions/resourceGroups/read",

"Microsoft.Compute/virtualMachines/deallocate/action",

"Microsoft.Compute/virtualMachines/start/action",

"Microsoft.Compute/virtualMachines/restart/action",

"Microsoft.Insights/diagnosticsettings/delete",

"Microsoft.Insights/diagnosticsettings/read",

"Microsoft.Insights/diagnosticsettings/write",
```

CREATING, UPDATING, OR DELETING VMS

Create a machine catalog, then add, delete, update machines, and delete the machine catalog.

Following is the list of minimum permissions required when the master images are managed disks or snapshots that are in the same region as the hosting connection.

```
"Microsoft.Resources/subscriptions/resourceGroups/read",

"Microsoft.Resources/deployments/validate/action",

"Microsoft.Resources/tags/read",

"Microsoft.Resources/tags/write",

"Microsoft.Compute/virtualMachines/read",

"Microsoft.Compute/virtualMachines/write",

"Microsoft.Compute/virtualMachines/delete",

"Microsoft.Compute/virtualMachines/deallocate/action",

"Microsoft.Compute/snapshots/read",

"Microsoft.Compute/snapshots/write",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Compute/snapshots/delete",

"Microsoft.Compute/snapshots/beginGetAccess/action",

"Microsoft.Compute/snapshots/endGetAccess/action",

"Microsoft.Compute/disks/read",

"Microsoft.Compute/disks/write",

"Microsoft.Compute/disks/delete",

"Microsoft.Compute/disks/beginGetAccess/action",

"Microsoft.Compute/disks/endGetAccess/action",

"Microsoft.Compute/locations/publishers/artifacttypes/types/versions/
read",

"Microsoft.Compute/skus/read",

"Microsoft.Compute/virtualMachines/extensions/read",

"Microsoft.Compute/virtualMachines/extensions/write",

"Microsoft.Features/providers/features/read",

"Microsoft.Network/virtualNetworks/read",

"Microsoft.Network/virtualNetworks/subnets/join/action",

"Microsoft.Network/virtualNetworks/subnets/read",

"Microsoft.Network/networkSecurityGroups/read",

"Microsoft.Network/networkSecurityGroups/write",

"Microsoft.Network/networkSecurityGroups/delete",

"Microsoft.Network/networkSecurityGroups/join/action",

"Microsoft.Network/networkInterfaces/read",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Network/networkInterfaces/write",

"Microsoft.Network/networkInterfaces/delete",

"Microsoft.Network/networkInterfaces/join/action",

"Microsoft.Network/locations/usages/read",

"Microsoft.Compute/capacityReservationGroups/capacityReservations/read",

"Microsoft.Compute/capacityReservationGroups/deploy/action"
```

You need the following extra permissions based on minimal permissions for the following features:

- If the master image is a VHD in a storage account in the same region as the hosting connection:

  ```
  "Microsoft.Storage/storageAccounts/read",

  "Microsoft.Storage/storageAccounts/listKeys/action",
  ```

- If the master image is an ImageVersion from the Azure Compute Gallery (formerly Shared Image Gallery):

  ```
  "Microsoft.Compute/galleries/read",

  "Microsoft.Compute/galleries/images/read",

  "Microsoft.Compute/galleries/images/versions/read",
  ```

- If the master image is a managed disk, snapshot, or VHD is in a region different from the region of the hosting connection:

  ```
  "Microsoft.Storage/storageAccounts/read",

  "Microsoft.Storage/storageAccounts/listKeys/action",

  "Microsoft.Storage/storageAccounts/write",

  "Microsoft.Storage/storageAccounts/delete",
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Storage/checknameavailability/read",

"Microsoft.Storage/locations/usages/read",

"Microsoft.Storage/skus/read",
```

- If you use the Citrix-managed resource group:

```
"Microsoft.Resources/subscriptions/resourceGroups/write",

"Microsoft.Resources/subscriptions/resourceGroups/delete",
```

- If you put the master image in Azure Compute Gallery (formerly Shared Image Gallery) in a shared tenant or subscription:

```
"Microsoft.Compute/galleries/write",

"Microsoft.Compute/galleries/images/write",

"Microsoft.Compute/galleries/images/versions/write",

"Microsoft.Compute/galleries/read",

"Microsoft.Compute/galleries/images/read",

"Microsoft.Compute/galleries/images/versions/read",

"Microsoft.Compute/galleries/delete",

"Microsoft.Compute/galleries/images/delete",

"Microsoft.Compute/galleries/images/versions/delete",

"Microsoft.Resources/subscriptions/read",
```

- If you use Azure dedicated host support:

```
"Microsoft.Compute/hostGroups/read",

"Microsoft.Compute/hostGroups/write",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Compute/hostGroups/hosts/read",
```

- If you use Server Side Encryption (SSE) with Customer-Managed Keys (CMK):

```
"Microsoft.Compute/diskEncryptionSets/read",
```

- If you deploy VMs using ARM templates (machine profile):

```
"Microsoft.Resources/deployments/write",

"Microsoft.Resources/deployments/operationstatuses/read",

"Microsoft.Resources/deployments/read",

"Microsoft.Resources/deployments/delete",

"Microsoft.Insights/DataCollectionRuleAssociations/Read",

"Microsoft.Insights/dataCollectionRules/read",
```

- If you use Azure template spec as a machine profile:

```
"Microsoft.Resources/templateSpecs/read",

"Microsoft.Resources/templateSpecs/versions/read",
```

CREATING, UPDATING, AND DELETING MACHINES WITH UNMANAGED DISK

Following is the list of minimum permissions required when the master image is VHD and use resource group as provided by admin:

```
"Microsoft.Resources/subscriptions/resourceGroups/read",

"Microsoft.Resources/tags/read",

"Microsoft.Resources/tags/write",

"Microsoft.Storage/storageAccounts/delete",

"Microsoft.Storage/storageAccounts/listKeys/action",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Storage/storageAccounts/read",
"Microsoft.Storage/storageAccounts/write",
"Microsoft.Storage/checknameavailability/read",
"Microsoft.Storage/locations/usages/read",
"Microsoft.Storage/skus/read",
"Microsoft.Compute/virtualMachines/deallocate/action",
"Microsoft.Compute/virtualMachines/delete",
"Microsoft.Compute/virtualMachines/read",
"Microsoft.Compute/virtualMachines/write",
"Microsoft.Resources/deployments/validate/action",
"Microsoft.Network/networkInterfaces/delete",
"Microsoft.Network/networkInterfaces/join/action",
"Microsoft.Network/networkInterfaces/read",
"Microsoft.Network/networkInterfaces/write",
"Microsoft.Network/networkSecurityGroups/delete",
"Microsoft.Network/networkSecurityGroups/join/action",
"Microsoft.Network/networkSecurityGroups/read",
"Microsoft.Network/networkSecurityGroups/write",
"Microsoft.Network/virtualNetworks/subnets/read",
"Microsoft.Network/virtualNetworks/read",
"Microsoft.Network/virtualNetworks/subnets/join/action",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Network/locations/usages/read"
```

COST MANAGEMENT

Following is the minimum permission required to retrieve VM pricing:

```
"Microsoft.Consumption/pricesheets/read"
```

Following is the minimum permission required to retrieve VM cost:

```
"Microsoft.CostManagement/query/read"
```

NOTE:

To view the **Cost Insights** tab for an Azure machine catalog, you must have **Cost Management > Manage > Read cost** permission (default for Cloud Administrators). For information on **Cost Insights** tab, see View catalog details.

General permissions

Contributor role has full access to manage all resources. This set of permissions does not block you from getting new features.

The following set of permissions provides the best compatibility going forward although it does include more permissions than needed with the current feature set:

```
"Microsoft.Compute/diskEncryptionSets/read",

"Microsoft.Compute/disks/beginGetAccess/action",

"Microsoft.Compute/disks/delete",

"Microsoft.Compute/disks/endGetAccess/action",

"Microsoft.Compute/disks/read",

"Microsoft.Compute/disks/write",

"Microsoft.Compute/galleries/delete",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Microsoft.Compute/galleries/images/delete",
"Microsoft.Compute/galleries/images/read",
"Microsoft.Compute/galleries/images/versions/delete",
"Microsoft.Compute/galleries/images/versions/read",
"Microsoft.Compute/galleries/images/versions/write",
"Microsoft.Compute/galleries/images/write",
"Microsoft.Compute/galleries/read",
"Microsoft.Compute/galleries/write",
"Microsoft.Compute/hostGroups/hosts/read",
"Microsoft.Compute/hostGroups/read",
"Microsoft.Compute/hostGroups/write",
"Microsoft.Compute/snapshots/beginGetAccess/action",
"Microsoft.Compute/snapshots/delete",
"Microsoft.Compute/snapshots/endGetAccess/action",
"Microsoft.Compute/snapshots/read",
"Microsoft.Compute/snapshots/write",
"Microsoft.Compute/virtualMachines/deallocate/action",
"Microsoft.Compute/virtualMachines/delete",
"Microsoft.Compute/virtualMachines/read",
"Microsoft.Compute/virtualMachines/restart/action",
"Microsoft.Compute/virtualMachines/start/action",
"Microsoft.Compute/virtualMachines/write",
```

Configure required Azure host connection permissions

You can easily configure all the minimum permissions required for a service principal or user account in Azure tied to a host connection to perform all MCS operations using an ARM template. This ARM template automates the following:

- Creation of an Azure Role with minimal permissions necessary for operations.
- Assignment of this role to an existing Azure Service Principal at the subscription level.

You can deploy this ARM template using the Azure Portal or PowerShell commands. For more information, see ARM Template for Citrix Virtual Apps and Desktops Operations.

Validate permissions on host connection

You can validate permissions on a host connection to do tasks related to creating and managing MCS machine catalogs. This implementation helps you to find out the missing permissions required for different scenarios such as creating, deleting, and updating VMs, power management of VMs, ahead of time so that you can avoid being blocked at critical times.

You can validate the permissions on a host connection using the PowerShell command `Test-HypHypervisorConnection`. The result from the command is captured as a list where each item in the list is broken into three sections.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Category: The action or task a user can do to create and manage an MCS machine catalog.
- Corrective Action: The step an admin must do to resolve a users' missing permissions discrepancy.
- Missing permission: The list of missing permissions for a category.

To validate the permissions, do the following:

1. Create a host connection to Azure.
2. Open a PowerShell window from the Delivery Controller™ host.
3. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
4. Run the following command to verify if you have the required permissions to test a connection.

   ```
   Test-HypHypervisorConnection -LiteralPath "XDHyp:\Connections\AzureCon"
   ```

   Role level permission required for the SPN:

   - Microsoft.Authorization/roleDefinitions/read (at subscription level or the resource group level if resource group is provided)
   - Microsoft.Authorization/roleAssignments/read (at subscription level or the resource group level if resource group is provided)

   API level permissions required for the SPN:

   Microsoft.Graph:

   - Application.Read.All
   - Directory.Read.All
   - ServicePrincipalEndpoint.Read.All

5. After you add the missing permissions required to look up your permissions, run the following command to verify if you have permissions in the various categories.

   Example:

   To test a connection at the subscription level with a higher level of authorization required:

   ```
   Test-HypHypervisorConnection -LiteralPath XDHyp:\Connections\ AzureCon
   -SecurePassword $password -UserName 922e65d5-38ae-4cf5-xxxx-xxxxxxxxx
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example:

To test a connection at the resource group level without a high level of authorization:

```
Test-HypHypervisorConnection -LiteralPath XDHyp:\Connections\testles
-CustomProperties $customProperties | Format-List
```

NOTE:

The `CustomProperties` parameter is used to provide the resource group level because resource group is a connection specific information.

Example:

To test a connection with the higher level of authorization at resource group level:

```
Test-HypHypervisorConnection -LiteralPath XDHyp:\Connections\testles
-SecurePassword $password -UserName
922e65d5-38ae-4cf5-832b-54122196b7dd -CustomProperties
$customProperties
```

For information on permissions, see Required Azure permissions.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For Azure-specific information, see Create a Microsoft Azure catalog.

More information

- Create and manage connections and resources
- Microsoft Azure Resource Manager virtualization environments

Connection to Microsoft SCVMM

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Microsoft System Center Virtual Machine Manager (VMM).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Before creating a connection to VMM, you need to first finish setting up your VMM as a resource location. See Microsoft System Center Virtual Machine Manager virtualization environments.

Create a connection

If you used MCS to provision VMs, do the following in the connection creation wizard:

- Enter the address as a fully qualified domain name of the host server.
- Enter the credentials for the administrator account that you set up earlier. This account must have permission to create new VMs.
- In the Host Details dialog box, select the cluster or standalone host to use when creating VMs.

IMPORTANT

Browse for a cluster or standalone host even if you are using a single Hyper-V host deployment.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For creating machine catalogs with MCS on SMB 3 file share, see Create a Microsoft System Center Virtual Machine Manager catalog.

More information

- Create and manage connections and resources
- Microsoft System Center Virtual Machine Manager virtualization environments.

Connection to Nutanix

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Nutanix.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

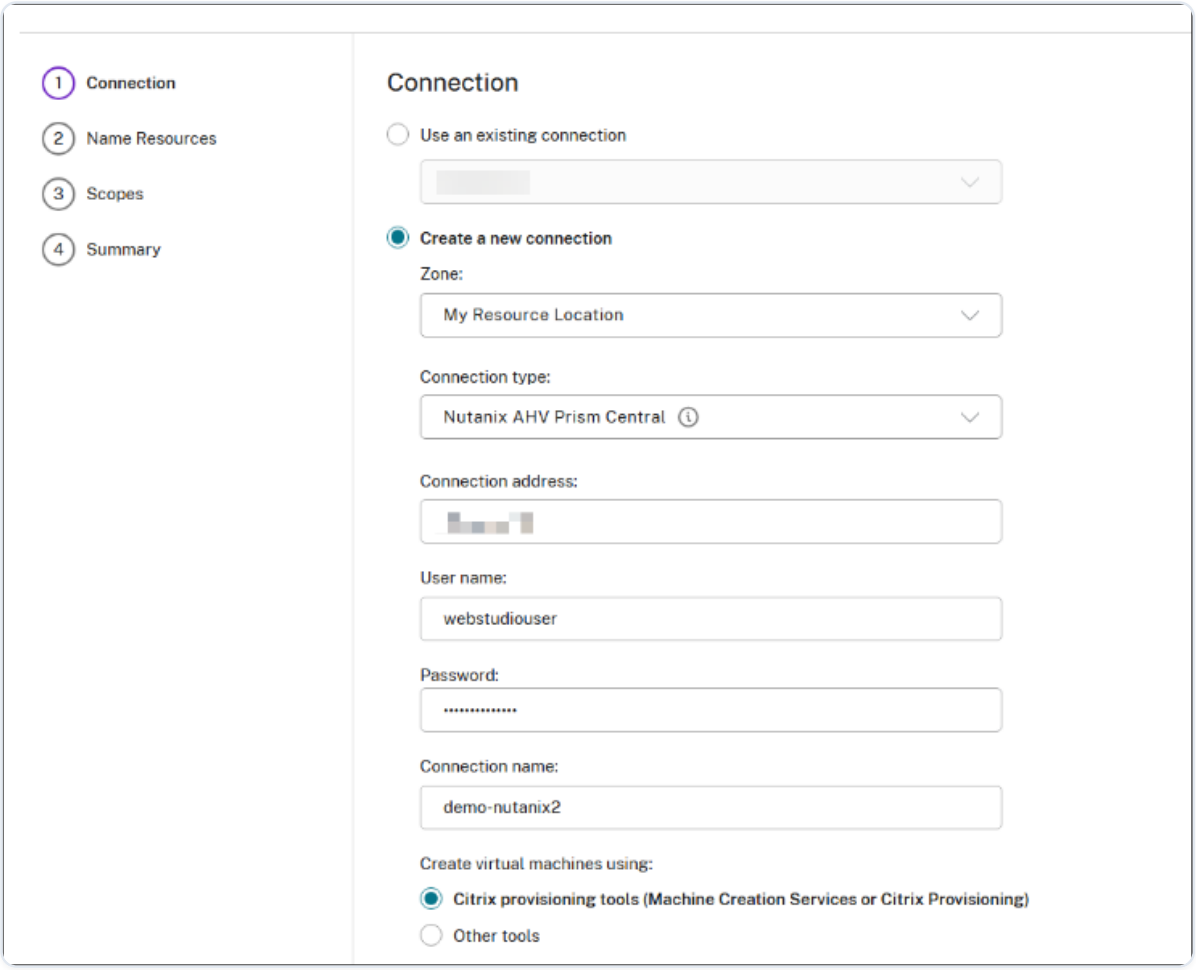
Before creating a connection to Nutanix, you need to first finish setting up your Nutanix account as a resource location. See Nutanix virtualization environments.

Nutanix AHV Prism Central host connection

See the Prerequisites before creating Nutanix AHV Prism Central host connection.

You can create a connection using one of the following:

- Studio
- PowerShell commands



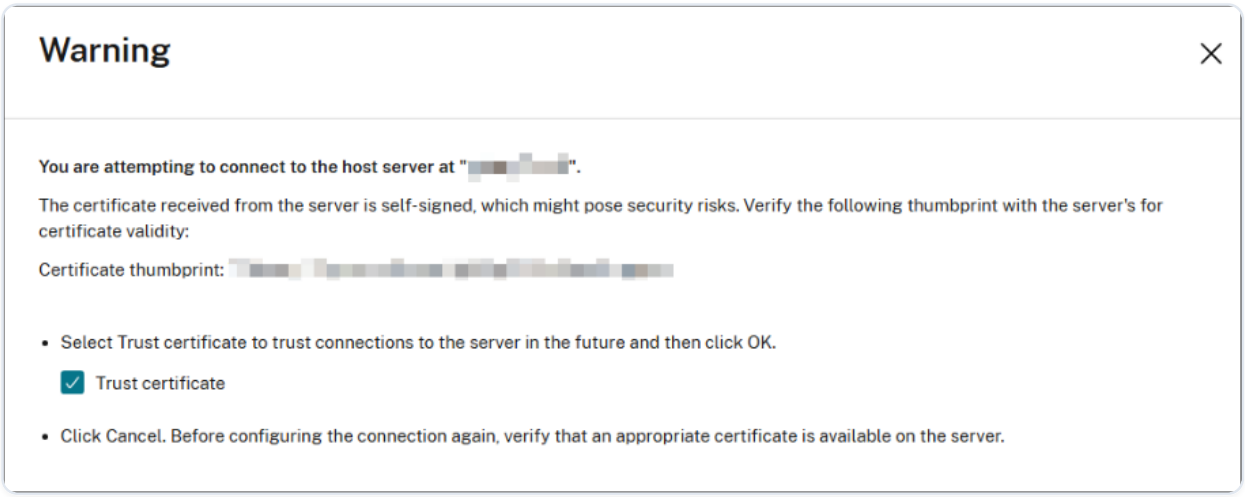
Limitation

- The Nutanix AHV Prism Central host connection doesn't support duplicate object names for items such as templates and networks. Selecting such items for catalog creation might lead to unexpected behavior.

Create a connection using Studio

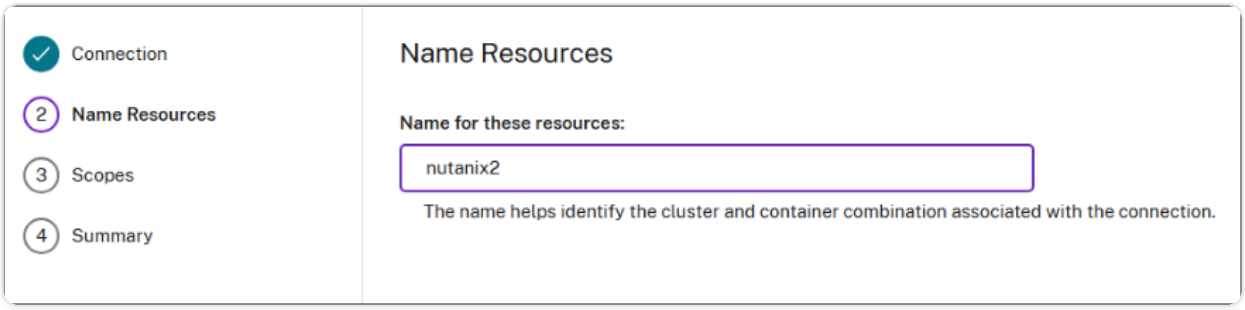
1. Sign in to Citrix Cloud.
2. In the DaaS tile, click **Manage**.
3. Select **Hosting** in the left pane.
4. Click **Add Connections and Resources** in the action bar.
5. On the **Connection** page:
    a. Select **Create a new connection**.
    b. Select **Nutanix AHV Prism Central** as the connection type.
    c. Enter the IP address of your Nutanix AHV Prism Central as the connection address.
    d. Enter your administrative credentials and a friendly connection name.
    e. Select **Citrix provisioning tools (Machine Creation Services™ or Citrix Provisioning)**.
    f. Click **Next**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



NOTE:

While creating the host connection, network or cluster selection is not required. A hosting unit name is only needed. Select the network and cluster while creating the machine catalog.



6. After you click **Next**, Citrix DaaS™ receives a private CA-signed certificate and you see a **Warning** page. For information, see Secure connections to the Nutanix Prism Central.

   Compare the received thumbprint with the server's for the certificate validity. If it's valid, select **Trust certificate** and click **OK** to proceed with connection creation. Citrix DaaS then trusts the certificate and stores the thumbprint for future validation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. On the **Name Resources** page, add a unique name of the resources. Click **Next**.

8. On the **Scopes** page, select one or more scopes for this host.
9. On the **Summary** page, check the configuration and click **Finish**.

NOTE:

The Nutanix AHV Prism Central connection can co-exist with other types of Nutanix connections.

Secure connections to the Nutanix Prism Central

The Nutanix SSL thumbprint feature simplifies certificate trust when establishing a host connection to a Nutanix Prism Central hypervisor. This feature enables the storage of an untrusted certificate's thumbprint in the site database, ensuring that Citrix DaaS consistently recognizes the hypervisor as trusted.

When creating a Nutanix host connection, a **Warning** page is displayed, presenting the certificate of the machine you are connecting to and allowing you to decide whether to trust it.

Create a connection using PowerShell

1. Open the PowerShell window.
2. Run `asnp citrix*`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Set following parameters:

```
$ConnectionName = “Name of the connection”

$UserName = “Username of the account on hypervisor”

$ZoneUid =  “UID of the zone where the hosting connection will be
created”

$HypervisorAddress = “The IP address of the hypervisor”

$SSLThumbprint =  “The Nutanix PC SSL thumbprint can be set using
PowerShell SDK”

$connectionPath = "XDHyp:\Connections\" + $ConnectionName

$SecureUserInput = Read-Host "Enter the password for the user $
($UserName)" -AsSecureString

$EncryptedUserInput = $SecureUserInput | ConvertFrom-SecureString

$SecurePass = ConvertTo-SecureString -String $EncryptedUserInput
```

4. Create an item for the new hosting connection. For example:

```
$connection = New-Item -Path @($connectionPath) -ConnectionType
"Custom" -HypervisorAddress ` @($HypervisorAddress) -Persist -PluginId
"AcropolisHypervisorPCFactory" -Scope @() ` -SecurePassword $SecurePass
-SSLThumbprint @($SSLThumbprint) -UserName $UserName -ZoneUid `
$ZoneUid
```

5. Create a broker hypervisor connection. For example:

```
New-BrokerHypervisorConnection -HypHypervisorConnectionUid
$connection.HypervisorConnectionUid
```

CREATE A HOSTING UNIT

When you create a hosting unit using the PowerShell command, provide the following required parameters:

- `$HostUnitName`: Name of Hosting Unit to create

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `ConnectionName`: Name of the hypervisor connection previously created

1. Open the PowerShell window.
2. Run `add-pssnapin citrix*`.
3. Run PowerShell commands to create the hosting unit. For example:

```
$hostUnitPath = "XDHyp:\HostingUnits\" + $HostUnitName

New-Item -Path @($hostUnitPath) -RootPath $connectionPath
-HypervisorConnectionName $ConnectionName -CustomProperties ""
-NetworkPath @() -StoragePath @()
```

NOTE:

While creating the host connection, network or cluster selection is not required. A hosting unit name is only needed. Select the network and cluster while creating the machine catalog.

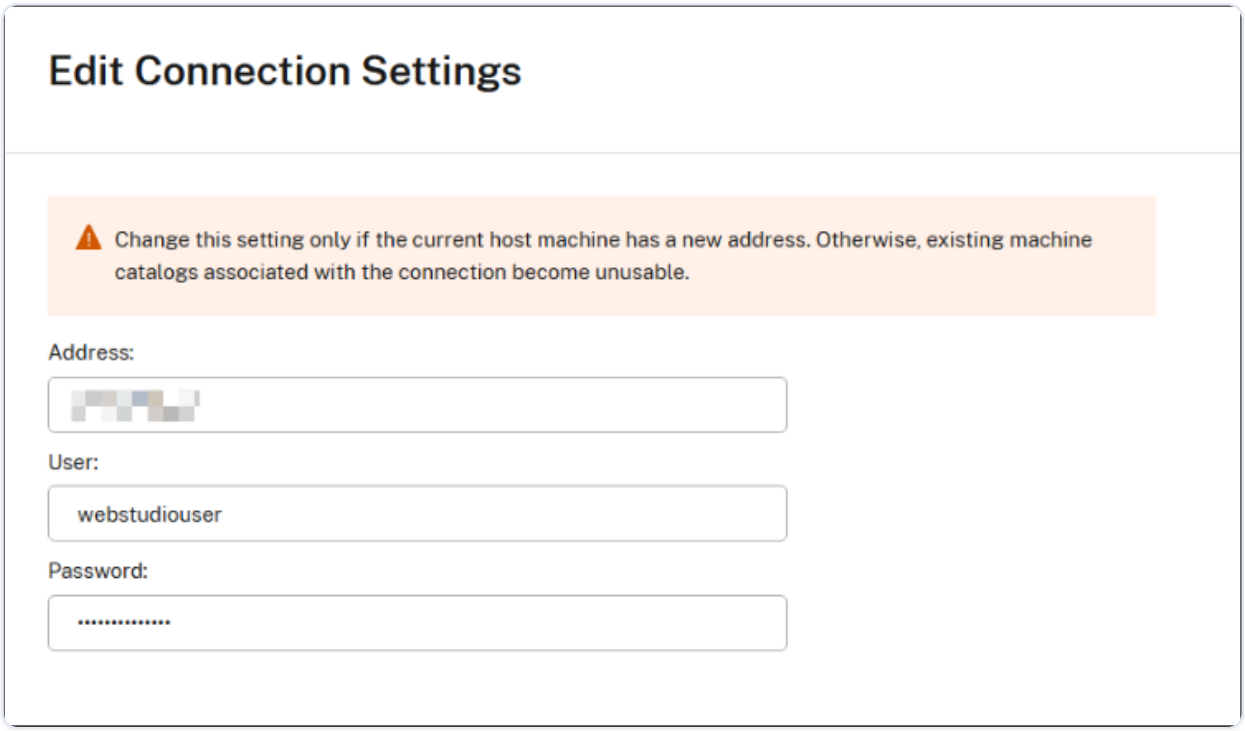
Manage host connections

You can manage an exisiting host connection using:

- Studio
- PowerShell

MANAGE THE HOST CONNECTION USING STUDIO

After creating a host connection, navigate to the **Hosting** node on Studio and right-click a connection to do the following:



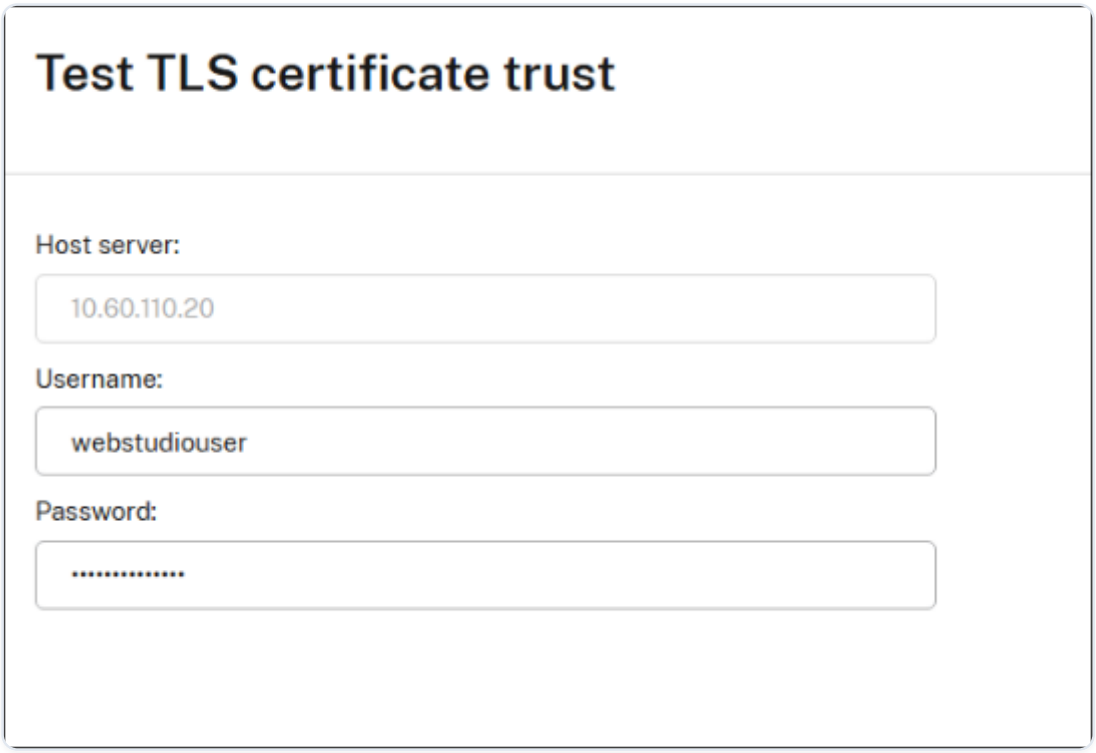
- **Delete Connection**
- **Rename Connection**
- **Edit Connection**
- **Turn on Maintenance Mode**
- **View Machines**
- **Test Connection**
- **Test TLS certificate trust**

EDIT A CONNECTION USING STUDIO

1. Right-click a connection and click **Edit Connection**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Connection Properties** page, click **Edit settings**.
3. On the **Edit Connection settings** page, you can change the certificate information and click **Save**.



4. Select **Trust certificate** on the **Warning** page to trust the new certificate thumbprint.

TEST TLS CERTIFICATE TRUST

1. Right-click a connection and click **Test TLS certificate trust**.
2. On the **Test TLS Certificate Trust** page, you can change the certificate information, then click **Test**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If the test result is not successful, then change the certificate information of the connection using Edit a connection using Studio.

MANAGE THE HOST CONNECTION USING POWERSHELL

You can use PowerShell commands to:

- Change or update the user credential for a host connection. For example:

```
$UserName = "Username of the account on hypervisor"

$SecureUserInput = Read-Host "Enter the password for the user $
($UserName)" -AsSecureString

$EncryptedUserInput = $SecureUserInput | ConvertFrom-SecureString

$SecurePass = ConvertTo-SecureString -String $EncryptedUserInput

Set-Item  -LiteralPath @("XDHyp:\Connections\<Host connection name>")
 -SecurePassword $SecurePass -UserName $UserName
```

- Reset SSLThumbprint. For example:

```
$SSLThumbprint =  "The Nutanix PC SSL thumbprint value"

Set-Item  -LiteralPath @("XDHyp:\Connections\<Host connection name>")
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
 -SecurePassword $SecurePass -UserName $UserName -SSLThumbprint
$SSLThumbprint
```

Nutanix AHV, Nutanix AHV PC, or Nutanix AHV DRaaS host connection

1. Sign in to Citrix Cloud.
2. In the DaaS tile, click **Manage**.
3. Select **Hosting** in the left pane.
4. Click **Add Connections and Resources** in the action bar.
5. On the **Connection** page, the following connection types are available for selection:

    - **Nutanix AHV**: specify the Prism Element (PE) cluster address, and credentials, and a name for the connection. On the **Network** page, select network(s) and give a name for the hosting unit.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> If you deploy machines using Nutanix AHV (Prism Element) as the resource, select the container where the VM's disk resides.

- **Nutanix AHV PC**: specify the Prism Central (PC) address, credentials, and a name for the connection. On the **Network** page, select the network, cluster from the list, and give a name for the hosting unit.

  > **NOTE:**
  >
  > The connection type **Nutanix AHV PC** is only used for creating connection to Nutanix Cloud Cluster (NC2) on Azure. Also, a machine catalog can only be hosted on a single cluster in an NC2 on Azure connection. This type of connection requires a Nutanix plug-in installed on Cloud Connectors

- **Nutanix AHV DRaaS**: specify your address and user name, and then import the public and private keys contained in your Nutanix DRaaS credential files `.pem`. (Public and private keys are generated in Nutanix DRaaS cloud by Nutanix DRaaS administrators.)

  - To import the key, locate your credential file, open it with Notepad (or any text editor), and then copy the content. After that, return to the **Connection** page, select **Import key**, paste the content, and then select **Save**. Do not change the credential content or its format.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For Nutanix specific information, see Create a Nutanix catalog.

More information

- Create and manage connections and resources
- Nutanix virtualization environments
- Nutanix cloud and partner solutions

Connection to Nutanix cloud and partner solutions

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Nutanix cloud and partner solutions.

Nutanix AHV Prism Central

Citrix DaaS™ supports Nutanix Cloud Clusters (NC2) in the following cloud hypervisors for Citrix-managed Nutanix AHV Prism Central plug-in.

- AWS
- Microsoft Azure

NOTE:

- Before creating a connection to NC2 on AWS and Azure, prepare the resources in the cloud platform. See Nutanix cloud and partner solutions.
- For the permissions to create hosting connection, power management of VMs, and provisioning of catalogs, see Required permissions.

Connect to NC2 on Azure and AWS

Connecting to a Nutanix Cloud Cluster (NC2) on Azure or AWS requires access to a deployed Prism Central instance and credentials with the Prism Admin role.

You can create a host connection using:

- Studio
- PowerShell

For the complete information on connection, see Connection to Nutanix AHV Prism Central

Nutanix Prism Element

Citrix DaaS supports Nutanix Cloud Clusters (NC2) in the following cloud hypervisor for the Nutanix Prism Element plug-in.

- AWS

Connect to Nutanix Prism

After you create a Nutanix cluster, connect to Nutanix Prism. To connect to Nutanix Prism:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Create a bastion VM in the 10.0.129.0/24 subnet.
2. RDP into the bastion VM, go to the URL of the **Prism Element** you copied in the previous section.
3. Log in using the default credentials: `admin:nutanix/4u`. Remember to change the password.

Create a VM on the Nutanix Cluster

After connecting to **Nutanix Prism**, create VMs on the Nutanix cluster.

IF THE VM NEEDS INTERNET ACCESS

1. Go to the AWS console.
2. Create a new subnet 10.0.130.0/24 in the same VPC as the one created by Nutanix CFS.
3. Add a route to the route table of this subnet to direct all none local traffic to the NAT gateway above.
4. RDP into the bastion VM, go to the URL of the **Prism Element** you copied in the previous section and login.
5. Add a new network. Go to **Settings>Network Configuration>Create Subnet**. Use the same subnet 10.0.130.0/24 used in AWS.
6. Create all the VMs (AD, CC, VDA, and so on) in that new subnet.

IF THE VM DOES NOT NEED INTERNET ACCESS

1. RDP into the bastion VM, go to the URL of the **Prism Element** you copied in the previous section and login.
2. Add a new network. Go to **Settings>Network Configuration>Create Subnet**. Use the subnet 10.0.129.0/24.
3. Create all the VMs (AD, CC, VDA, and so on) in that subnet.

TIP:

Make sure that the time and timezone information in the VMs are set up correctly. This is especially true for AD.

Create host connection

1. From Studio, select **Hosting** in the left pane.
2. Click **Add Connection and Resources**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Connection** screen, select **Create a new Connection**, and in the **Connection address**, enter `https://xxx.xxx.xxx.xxx:9440`.
4. Follow the UI to complete the wizard.

NOTE:

All connector VMs must have the Nutanix plug-in installed for the Nutanix option to be available in Citrix Studio, even if the plug-ins are not used in the Nutanix zone.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For Nutanix specific information, see Create a Nutanix catalog.

More information

- Create and manage connections and resources
- Nutanix virtualization environments
- Nutanix cloud and partner solutions

Connection to Red Hat OpenShift

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to Red Hat OpenShift.

NOTE:

Before creating a connection to Red Hat OpenShift, you need to first finish setting up your Red Hat OpenShift. See Red Hat OpenShift virtualization environments.

Create a connection

You can create a connection to the Red Hat OpenShift cluster using:

- Studio
- PowerShell

Create a connection using Studio

1. Navigate to **Hosting > Add Connection and Resources**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Connection** page, follow these steps to configure the connection:

    a. Select **Create a new connection**.

    b. Select **Red Hat OpenShift** as the Connection type.

    c. In the **Connection address** field, enter the IP address, hostname, or FQDN of the OpenShift Server.

    d. Enter your service account token and a friendly connection name.

    e. Select a zone in the **Zone name** field. The options are all resource locations you configured.

    f. Select **Other tools** for creating virtual machines.

    > **NOTE:**
    >
    > Selecting **Other tools** creates just the hosting connection without a hosting unit.

3. Click **Next**.
4. If a self-signed certificate is detected, a warning page appears with the certificate thumbprint. To proceed:

    a. Compare the thumbprint with the server's to verify the certificate's validity.

    b. If valid, select **Trust certificate** and click **OK** to complete the connection setup.

    The certificate is marked as trusted, and the thumbprint is saved for future validation.

5. On the **Scopes** page, select one or more scopes for this host.
6. On the **Summary** page, check the configuration and click **Finish**.

Create a connection using PowerShell commands

When you create a connection using PowerShell command, provide the following information:

- Hosting connection name
- Cluster API address
- User name
- Password (Service account token)
- SSLThumbprint: This is a CA Cert thumbprint and not the API server thumbprint. The server provides the CA Cert thumbprint if you try to create a hosting connection without specifying the thumbprint.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- ZoneUid

1. Open the PowerShell window.
2. Run `add-pssnapin citrix*`.
3. Run the following command to create the hosting connection.

   If you try to create a hosting connection without specifying the thumbprint, then the server provides the CA Cert thumbprint. For example:

```
$newItemParameters = @{

ConnectionType= "Custom"

PluginId= "OpenShiftPluginFactory"

HypervisorAddress = "https://
api.myopenshiftclusteraddress.mydomain.local:6443"

Path= "XDHyp:\Connections\OpenShiftConnectionName"

Persist= $true

UserName= "__ServiceAccount__"

Password= "<service account token>"

ErrorVariable= "connectionError"

 }

& New-Item @newItemParameters

$newItemParameters["SSLThumbprint"] =
$connectionError[0].ErrorData.Thumbprint

$connection = & New-Item @newItemParameters
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$brokerConnection = New-BrokerHypervisorConnection
-HypHypervisorConnectionUid $connection.HypervisorConnectionUid
```

Create a hosting unit

A hosting unit represents an environment where VMs are created. To create the hosting unit, you need the following inputs from OpenShift:

- Namespace
- StorageClasses
- Network Attachment Definition

A hosting unit is a namespace-bound. This means that one hosting unit can access only one namespace and manages the VMs under the namespace.

You can create a hosting unit using:

- Studio
- PowerShell

Create hosting units using Studio

1. Navigate to **Hosting > Add Connection and Resources**.
2. On the **Connection** page:
    - To create a new hosting connection along with a hosting unit, select **Create a new connection**, then do the following:
        a. Select **Red Hat OpenShift** as the Connection type.
        b. In the **Connection address** field, enter the IP address, hostname, or FQDN of the OpenShift Server.
        c. Enter your service account token and a friendly connection name.
        d. Select a zone in the **Zone name** field. The options are all resource locations you configured.
        e. Select **Citrix provisioning tools (Machine Creation Services™ or Citrix Provisioning) for creating virtual machines**.
        f. Click **Next**.
        g. On the **Warning** page, verify the certificate's validity, and select **Trust certificate**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To create hosting units from an existing host connection, select **Use an existing Connection** and then choose the relevant connection.

3. On the **Namespace Selection** page, select a namespace for this connection.
4. On the **Storage Selection** page, select at least one storage device for each supported data type before you can proceed to the next page in the wizard. For more information about storage selection, see Host storage.
5. On the **Network** page, enter a name for the resources. This name appears in Studio to identify the storage and network combination associated with the connection. Select one or more networks that the VMs use.
6. On the **Summary** page, check the details and click **Finish**.

Create hosting units using PowerShell

When you create a hosting unit using PowerShell command, provide the following information:

- A hosting connection name
- A hosting unit name
- The target namespace name
- A StorageClasses name
- A NetworkAttachmentDefinition name

1. Open the PowerShell window.
2. Run `add-pssnapin citrix*`.
3. Run PowerShell commands to create the hosting unit. For example:

```
$HostingConnectionName = "OpenShiftConnectionName"

$HostingUnitName = "HostingUnitName"

$TargetNamespace = "TargetNamespaceName"

$StorageClassToUse = "YourStorageClassesName"

$NetworkAttachmentDefinition = "YourNetworkAttachmentDefinitionName"

New-HypStorage `

-StoragePath @("XDHyp:\Connections\$HostingConnectionName\
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$TargetNamespace.namespace\$StorageClassToUse.storage") `

-StorageType "TemporaryStorage"

New-Item `

-CustomProperties "" `

-HypervisorConnectionName $HostingConnectionName `

-NetworkPath @("XDHyp:\Connections\$HostingConnectionName\
$TargetNamespace.namespace\$NetworkAttachmentDefinition.network") `

-Path @("XDHyp:\HostingUnits\$HostingUnitName") -RootPath "XDHyp:
\Connections\$HostingConnectionName\$TargetNamespace.namespace" `

-StoragePath @("XDHyp:\Connections\$HostingConnectionName\
$TargetNamespace.namespace\$StorageClassToUse.storage")
```

Where to go next

- If you're in the initial deployment process, see Create machine catalogs
- For Red Hat OpenShift specific information, see Create a Red Hat OpenShift catalog

More information

- Connections and resources
- Red Hat OpenShift virtualization environments

Connection to VMware

Create and manage connections and resources describes the wizards that create a connection. The following information covers details specific to VMware virtualization environments.

NOTE:

Before creating a connection to VMware, you need to first finish setting up your VMware account as a resource location. See VMware virtualization environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Required permissions

Create a VMware user account and one or more VMware roles with a set or all permissions listed in this article. Base the roles' creation on the specific level of granularity required over the user's permissions to request the various Citrix DaaS™ operations at any time. To grant the user-specific permissions at any point, associate them with the respective role, at the data center level at a minimum, with the **Propagate to children** option selected. However, for `StorageProfile` permissions and a specific `Tags` permission, apply the permissions at the Root vCenter Server level, without **Propagate to Children**. See the notes in each of those tables.

The following tables show the mappings between Citrix DaaS operations and the minimum required VMware permissions.

Add connections and resources

SDK	USER INTERFACE
System. Anonymous, System. Read, and System.View	Added automatically. Can use the built-in read-only role.

Datastore.Browse	**Datastore > Browse datastore**

Provision machines (Machine Creation Services™)

To provision machines using MCS, the following permissions are mandatory:

SDK	USER INTERFACE
Datastore.AllocateSpace	**Datastore > Allocate space**
Datastore.Browse	**Datastore > Browse datastore**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
Datastore.FileManagement	**Datastore > Low level file operations**
Network.Assign	**Network > Assign network**
Resource.AssignVMToPool	**Resource > Assign virtual machine to resource pool**
VirtualMachine.Config.AddExistingDisk	**Virtual machine > Configuration > Add existing disk**
VirtualMachine.Config.AddNewDisk	**Virtual machine > Configuration > Add new disk**
Virtual machine.Config.Add or remove device	**Virtual machine > Configuration > Add or remove device**
VirtualMachine.Config.AdvancedConfig	**Virtual machine > Configuration > Advanced**
VirtualMachine.Config.RemoveDisk	**Virtual machine > Configuration > Remove disk**
VirtualMachine.Config.CPUCount	**Virtual machine > Configuration > Change CPU count**
VirtualMachine.Config.Memory	**Virtual machine > Configuration > Change memory**
VirtualMachine.Config.Settings	**Virtual machine > Configuration > Change settings**
VirtualMachine.Interact.PowerOff	**Virtual machine > Interaction > Power Off**
VirtualMachine.Interact.PowerOn	**Virtual machine > Interaction > Power On**
VirtualMachine.Interact.Reset	**Virtual machine > Interaction > Reset**
VirtualMachine.Interact.Suspend	**Virtual machine > Interaction > Suspend**
VirtualMachine.Inventory.CreateFromExisting	**Virtual machine > Inventory > Create from existing**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
VirtualMachine.Inventory.Create	**Virtual machine > Inventory > Create new**
VirtualMachine.Inventory.Delete	**Virtual machine > Inventory > Remove**
VirtualMachine.Provisioning.Clone	**Virtual machine > Provisioning > Clone virtual machine**
VirtualMachine.State.CreateSnapshot	vSphere 5.0, Update 2, vSphere 5.1, Update 1, and vSphere 6.x, Update 1: **Virtual machine > State > Create snapshot**; vSphere 5.5: **Virtual machine > Snapshot management > Create snapshot**; vSphere 8.0: **Virtual machine > Snapshot management > Create snapshot**
VirtualMachine.Config.Rename	**Virtual machine > Configuration > Rename**

Image update and rollback

SDK	USER INTERFACE
Datastore.AllocateSpace	**Datastore > Allocate space**
Datastore.Browse	**Datastore > Browse datastore**
Datastore.FileManagement	**Datastore > Low level file operations**
Network.Assign	**Network > Assign network**
Resource.AssignVMToPool	**Resource > Assign virtual machine to resource pool**
VirtualMachine.Config.AddExistingDisk	**Virtual machine > Configuration > Add existing disk**
VirtualMachine.Config.AddNewDisk	**Virtual machine > Configuration > Add new disk**
VirtualMachine.Config.AdvancedConfig	**Virtual machine > Configuration > Advanced**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
VirtualMachine.Config.RemoveDisk	**Virtual machine > Configuration > Remove disk**
VirtualMachine.Interact.PowerOff	**Virtual machine > Interaction > Power Off**
VirtualMachine.Interact.PowerOn	**Virtual machine > Interaction > Power On**
VirtualMachine.Interact.Reset	**Virtual machine > Interaction > Reset**
VirtualMachine.Inventory.CreateFromExisting	**Virtual machine > Inventory > Create from existing**
VirtualMachine.Inventory.Create	**Virtual machine > Inventory > Create new**
VirtualMachine.Inventory.Delete	**Virtual machine > Inventory > Remove**
VirtualMachine.Provisioning.Clone	**Virtual machine > Provisioning > Clone virtual machine**

Share prepared images

To share prepared images across different hosting connections, the following permissions are mandatory for target hosting connection:

SDK	USER INTERFACE
Datastore.AllocateSpace	**Datastore > Allocate space**
Network.Assign	**Network > Assign network**
Resource.AssignVMToPool	**Resource > Assign virtual machine to resource pool**
VirtualMachine.Config.Add or remove device	**Virtual machine > Configuration > Add or remove device**
VirtualMachine.Config.RemoveDisk	**Virtual machine > Configuration > Remove disk**
VirtualMachine.Config.Settings	**Virtual machine > Configuration > Change settings**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
VirtualMachine.Inventory.Register	**Virtual machine > Inventory > Register**
VirtualMachine.Inventory.Delete	**Virtual machine > Inventory > Remove**
VirtualMachine.Provisioning.MarkAsTemplate	**Virtual machine > Provisioning > Mark as template**
VirtualMachine.Provisioning.MarkAsVM	**Virtual machine > Provisioning > Mark as virtual machine**
Host.Config.Network	**Host > Configuration > Network configuration**

Delete provisioned machines

SDK	USER INTERFACE
Datastore.Browse	**Datastore > Browse datastore**
Datastore.FileManagement	**Datastore > Low level file operations**
VirtualMachine.Config.RemoveDisk	**Virtual machine > Configuration > Remove disk**
VirtualMachine.Interact.PowerOff	**Virtual machine > Interaction > Power Off**
VirtualMachine.Inventory.Delete	**Virtual machine > Inventory > Remove**

Storage Profile

To view, create, or delete storage policies during catalog creations on a vSAN or vVol datastore, the following permissions are mandatory:

SDK	USER INTERFACE
StorageProfile.Update	**PROFILE-DRIVEN STORAGE > Profile-driven storage update**. For vSphere 8: **VM storage policies > Update VM storage policies**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
StorageProfile.View	**PROFILE-DRIVEN STORAGE > Profile-driven storage view**. For vSphere 8: **VM storage policies > View VM storage policies**

NOTE:

Apply the storage profile permissions at the Root vCenter Server level, without **Propagate to Children**.

Tags and Custom Attributes

Tags and custom attributes allow you to attach metadata to the VMs created in vSphere inventory and make it easier to search and filter these objects. To create, edit, assign, and delete tags or categories, the following permissions are mandatory:

SDK	USER INTERFACE
InventoryService.Tagging.CreateTag	**vSphere Tagging > Create vSphere Tag**
InventoryService.Tagging.CreateCategory	**vSphere Tagging > Create vSphere Tag Category**
InventoryService.Tagging.EditTag	**vSphere Tagging > Edit vSphere Tag**
InventoryService.Tagging.EditCategory	**vSphere Tagging > Edit vSphere Tag Category**
InventoryService.Tagging.DeleteTag	**vSphere Tagging > Delete vSphere Tag**
InventoryService.Tagging.DeleteCategory	**vSphere Tagging > Delete vSphere Tag Category**
InventoryService.Tagging.AttachTag	**vSphere Tagging > Assign or Unassign vSphere Tag**
InventoryService.Tagging.ObjectAttachable	**vSphere Tagging > Assign or Unassign vSphere Tag on Object**
Global.ManageCustomFields	**Global > Manage custom attributes**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
Global.SetCustomField	**Global > Set custom attribute**

NOTE:

- When MCS creates a machine catalog, it tags the target VMs with special name tags. These tags differentiate the master image from MCS created VMs and prevent using MCS created VMs for image preparation. You can identify the difference by the value of `XdProvisioned` attribute in vCenter. The attribute is set to **True** if MCS creates VMs.
- Apply the `InventoryService.Tagging.AttachTag` permission at the Root vCenter Server level, without **Propagate to Children**.

Cryptographic operations

Cryptographic operations privileges control who can perform which type of cryptographic operation on which type of object. vSphere Native Key Provider uses the `Cryptographer.*` privileges. The following minimum permissions are required for cryptographic operations:

NOTE:

These permissions are required for creating MCS machine catalogs with vTPM equipped VM.

SDK	USER INTERFACE
Cryptographer.Access	**Privileges > All Privileges > Cryptographic operations > Direct Access**
Cryptographer.AddDisk	**Privileges > All Privileges > Cryptographic operations > Add disk**
Cryptographer.Clone	**Privileges > All Privileges > Cryptographic operations > Clone**
Cryptographer.Encrypt	**Privileges > All Privileges > Cryptographic operations > Encrypt**
Cryptographer.EncryptNew	**Privileges > All Privileges > Cryptographic operations > Encrypt new**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDK	USER INTERFACE
Cryptographer.Decrypt	**Privileges > All Privileges > Cryptographic operations > Decrypt**
Cryptographer.Migrate	**Privileges > All Privileges > Cryptographic operations > Migrate**
Cryptographer.ReadKeyServersInfo	**Privileges > All Privileges > Cryptographic operations > Read KMS information**

Provision machines (Citrix Provisioning™)

These permissions to clone and deploy a template are required to provision VMs using Citrix Virtual Apps and Desktops™ Setup Wizard and Export Devices Wizard through the Citrix Provisioning console. Set the permissions while creating a hosting connection. You need all the permissions from Provision machines (Machine Creation Services) and the following.

SDK	USER INTERFACE
VirtualMachine.Config.AddRemoveDevice	**Virtual machine > Configuration > Add or remove device**
VirtualMachine.Config.CPUCount	**Virtual machine > Configuration > Change CPU Coun**t
VirtualMachine.Config.Memory	**Virtual machine > Configuration > Memory**
VirtualMachine.Config.Settings	**Virtual machine > Configuration > Settings**
VirtualMachine.Provisioning.CloneTemplate	**Virtual machine > Provisioning > Clone template**
VirtualMachine.Provisioning.DeployTemplate	**Virtual machine > Provisioning > Deploy template**
VApp.Export	**vApp > Export**

NOTE:

The `VApp.Export` is required for creating MCS machine catalogs using machine profile.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Securing connections to the VMware environment

Using `HTTPS/SSL` connections to vCenter requires that the connection is trusted by Citrix DaaS.

There are two options:

- (Recommended) The Citrix DaaS database has the SSL thumbprint installed. This thumbprint is used by Citrix DaaS on each Cloud Connector to trust connections to vCenter.
- (Alternative) Each Cloud Connector trusts the vCenter certificate, and services on the Cloud Connector reuses this trust. This trust can be from:
  - vCenter certificate, issued by the Certificate Authority and trusted by windows, resulting in established trust between Windows and vCenter.
  - vCenter certificate installed on Windows, resulting in established trust between Windows and vCenter.OT

NOTE:

vCenter certificate and VMware SSL thumbprint are not required for VMware Cloud and its partner solutions.

VMware SSL thumbprint

The VMware SSL thumbprint feature addresses a frequently reported error when creating a host connection to a VMware vSphere hypervisor. Previously, administrators had to manually create a trust relationship between the Citrix-managed Delivery Controllers in the Site and the hypervisor's certificate before creating a connection. The VMware SSL thumbprint feature removes that manual requirement: the untrusted certificate's thumbprint is stored on the Site database so that the hypervisor can be continuously identified as trusted by Citrix DaaS, even if not by the Controllers.

When creating a vSphere host connection, a dialog box allows you to view the certificate of the machine you are connecting to. You can then choose whether to trust it.

The VMware SSL thumbprint can be updated later using PowerShell SDK `Set-Item -LiteralPath "<FullPath_to_connection>" -username $cred.username -Securepassword $cred.password -SslThumbprint "<New ThumbPrint>" -hypervisorAddress <vcenter URL>`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TIP:

The certificate thumbprint must be written in capital letters.

Obtain and import a certificate

To protect vSphere communications, Citrix® recommends that you use HTTPS rather than HTTP. HTTPS requires digital certificates. Citrix recommends you use a digital certificate issued from a certificate authority in accordance with your organization's security policy.

If you are unable to use a digital certificate issued from a certificate authority, and your organization's security policy permits it, you can use the VMware-installed self-signed certificate. Add the VMware vCenter certificate to each Cloud Connector.

1. Add the fully qualified domain name (FQDN) of the computer running vCenter Server to the host file on that server, located at %SystemRoot%/WINDOWS/system32/Drivers/etc/. This step is required only if the FQDN of the computer running vCenter Server is not already present in the domain name system.
2. Obtain the vCenter certificate using any of the following three methods:

   From the vCenter server:

   a. Copy the file rui.crt from the vCenter server to a location accessible on your Cloud Connectors.
   b. On the Cloud Connector, navigate to the location of the exported certificate and open the rui.crt file.

   Download the certificate using a web browser: If you are using Internet Explorer, depending on your user account, you must right-click on Internet Explorer and choose **Run as Administrator** to download or install the certificate.

   a. Open your web browser and make a secure web connection to the vCenter server (for example `<https://server1.domain1.com>`).
   b. Accept the security warnings.
   c. Click the address bar displaying the certificate error.
   d. Click **Certificate is not valid**, and then click the **Details** tab.
   e. Click **Export..**
   f. Save the exported certificate.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

g. Navigate to the location of the exported certificate and open the .CER file.

Import directly from Internet Explorer running as an administrator:

a. Open your web browser and make a secure web connection to the vCenter server (for example `<https://server1.domain1.com>`).

b. Accept the security warnings.

c. Click the address bar displaying the certificate error.

d. View the certificate.

3. Import the certificate into the certificate store on each Cloud Connector.

a. Click **Install certificate**, select **Local Machine**, and then click **Next**.

b. Select **Place all certificates in the following store**, and then click **Browse**. On a later supported version: Select **Trusted People** and then click **OK**. Click **Next** and then click **Finish**.

IMPORTANT:

If you change the name of the vSphere server after installation, you must generate a new self-signed certificate on that server before importing the new certificate.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For VMware specific information, see Create a VMware catalog.

More information

- Create and manage connections and resources
- VMware virtualization environments.
- VMware cloud and partner solutions

Connection to VMware cloud and partner solutions

After setting up Azure VMware Solution (AVS) cluster, Google Cloud VMware Engine, and VMware cloud on AWS, create the connections. See Connection to VMware virtualization environments for creating connections.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For VMware specific information, see Create a VMware catalog.

More information

- Create and manage connections and resources
- VMware virtualization environments.
- VMware cloud and partner solutions

Connection to XenServer®

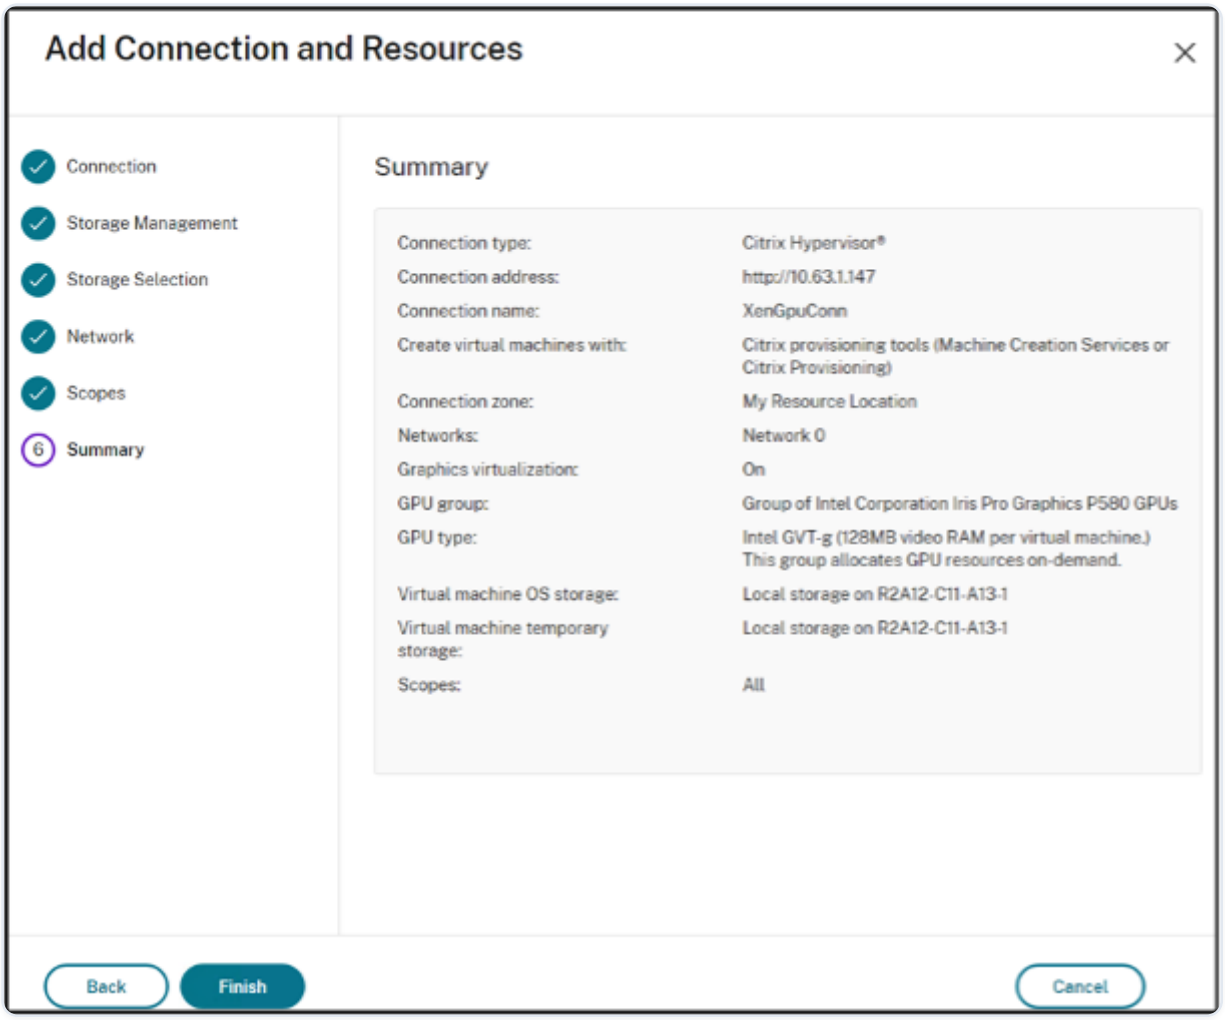
Create and manage connections and resources provides detailed instructions using the wizard to create a connection. Before establishing a connection to XenServer (formerly Citrix Hypervisor), you need to first finish setting up your XenServer as a host. See Add a resource type or activate an unused domain in Citrix Cloud.

Create a connection to XenServer

When you create a connection to XenServer, you must provide the credentials for a Virtual Machine Power Administrator (VM Power Admin) or higher-level user.

Citrix recommends using HTTPS to secure communications with XenServer. To use HTTPS, you must replace the default TLS certificate installed on XenServer. For more information, see Install a TLS certificate on your server.

You can configure high availability if it is enabled on the XenServer server. Citrix® recommends that you select all servers in the pool (from **Edit High Availability**) to allow communication with the XenServer server if the pool master fails.



NOTE:

If you are using HTTPS and want to configure high-availability servers, you can now install a wildcard certificate for all servers in a pool.

When using local storage on one or more XenServer hosts for temporary data storage, make sure that each storage location in the pool has a unique name. (To change a name in XenCenter®, right-click the storage and edit the name property.)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you connect to the XenServer that supports vGPU, you can verify the GPU group and the GPU type in the **Summary** page of the wizard for creating a connection.

Use IntelliCache™ for XenServer connections

Using IntelliCache, hosted VDI deployments are more cost-effective because you can use a combination of shared storage and local storage. This enhances performance and reduces network traffic. The local storage caches the master image from the shared storage, which reduces the amount of reads on the shared storage. For shared desktops, writes to the differencing disks are written to local storage on the host and not to shared storage.

The important considerations are:

- Shared storage must be NFS when using IntelliCache.
- Citrix recommends that you use a high-performance local storage device to ensure the fastest possible data transfer.

To use IntelliCache, enable IntelliCache as detailed:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- When installing XenServer, select **Enable thin provisioning**. See Install the XenServer host for information on installing XenServer host from local media. Citrix does not support mixed pools of servers with some servers that have IntelliCache enabled and some servers that do not IntelliCache enabled.
- In Citrix DaaS™, IntelliCache is disabled by default. You can change the setting only when creating a XenServer connection. You cannot disable IntelliCache later. When you create a XenServer connection:
  - Select **Shared** as the storage type.
  - Select the **Use IntelliCache** checkbox.

See IntelliCache for more information.

Required XenServer permissions

The XenServer permissions are role-based (RBAC). The Role-Based Access Control (RBAC) feature in XenServer allows you to assign users, roles, and permissions to control who has access to your XenServer and what actions they can perform. The XenServer RBAC system maps a user (or a group of users) to defined roles (a named set of permissions). The roles have associated XenServer permissions to perform certain operations.

For more information, see Role-based access control.

The role hierarchy, in order of increasing permissions is: Read-Only → VM Operator → VM Admin → VM Power Admin → Pool Operator → Pool Admin.

The following section summarizes the minimum role required for each provisioning task.

Creating a host connection

TASK	MINIMUM ROLE REQUIRED
Add a host connection using the information obtained from XenServer	Read-Only
View users and their assigned role	Read-Only

Power management of VMs

TASK	MINIMUM ROLE REQUIRED
Power on or off the VMs	VM Operator

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Creating, updating, or deleting VMs

TASK	MINIMUM ROLE REQUIRED
Add or remove VMs to existing snapshots schedules	VM Power Admin
Add, modify, delete snapshot schedules	Pool Operator
Publish master image	Pool Operator (Requires switch-port locking)
Create a machine catalog	Pool Operator: Requires switch-port locking
Add or remove VMs (not GPU enabled VMs)	VM Admin
Add or remove VMs (GPU enabled VMs)	Pool Operator
Add, remove, or configure virtual disk or CD devices	VM Admin
Manage Tags	VM Operator

For more information on RBAC roles and permissions, see RBAC roles and permissions.

For information on switch port locking, see Use switch port locking.

Where to go next

- If you're in the initial deployment process, see Create machine catalogs.
- For XenServer specific information, see Create a XenServer catalog.

More information

- Create and manage connections and resources
- XenServer virtualization environments

Service accounts

A service account is a container for stored credentials, which is configured and used to perform machine identity related operations without user interaction. Create the service account before the operations that require permissions for machine identity management.

You can configure an MCS machine catalog to use a service account to:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- create or delete computer accounts in Active Directory without entering the domain credentials every time.
- manage stale Microsoft Entra joined or Microsoft Intune enrolled devices without manually deleting them through the Microsoft Entra ID or Intune portal.

Supported service account types

Citrix® allows the creation of two types of service accounts based on the type of identity provider.

IDENTITY PROVIDER TYPE	DESCRIPTION	CREDENTIALS
On-premises Active Directory service account	Manages machine catalogs and computer accounts without entering domain credentials every time.	User name and password of an on-premises Active Directory user accounts.
Microsoft Entra service account	Combines a service principal with device management capability to grant permissions for device management.	Application ID and secret of a Microsoft Entra service principal .

Credential protection

Citrix stores the credentials of service accounts in the customer's site database. In DaaS, the site database is a per tenant (customer) database, which is accessible only by the services running for the customer.

The following actions are also enforced to protect the stored credentials:

- The credentials are encrypted using **AES 256** encryption before storing into the database.
- The encryption key is generated per site and stored in the Delivery Controller™ locally, which can only be accessed by the services dedicated to the customer.
- The connection to the database is encrypted using the TLS 1.2 protocol.

On-premises Active Directory service accounts

An on-premises Active Directory service account is a container to store the user name and password of a privileged domain user account. The user account must have sufficient permissions to manage computer accounts in an Active Directory. Machine Creation Service can use this

© 1997–2026 Citrix Systems, Inc. All rights reserved.

service account to do computer accounts related operations without entering the domain credentials every time.

Create an on-premises Active Directory service account

Create an on-premises Active Directory service account using Studio or PowerShell.

Prerequisite

To create an on-premises Active Directory service account, make sure to complete the following task:

- Create a domain user account in your Active Directory with sufficient permissions to create, update, and delete computer objects in your Active Directory or specific OUs.

Use Studio

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. In the **Service Accounts** tab, click **Create Service Account**.
4. On the **Identity Type** page, select **On-premises Active Directory**. Click **Next**.
5. On the **Credentials** page, click **Enter credentials** to provide the username and password of a privileged domain user account which you want to use as the service account.
6. Set the password expiration date or leave it as never expired.
7. Select one or more scopes for this service account.
8. Enter a friendly name and a description (optional) for the service account.
9. Click **Finish** to complete the creation.

Use PowerShell

You can use PowerShell commands to create an on-premises Active Directory service. For example:

```
$credential = ConvertTo-SecureString -String $password -AsPlainText -Force

New-AcctServiceAccount -IdentityProviderType ActiveDirectory
-IdentityProviderIdentifier test.local -AccountId test\svcacct_mcs
-AccountSecret $credential -SecretExpiryTime 2030/08/15 -DisplayName
'scvacct_mcs' -Description 'Service account for test.local'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The `$password` is the matching password for the provided domain user account.

Perform machines identity-related actions

After an Active Directory or a Microsoft Entra hybrid based identity pool is associated with a service account, you can do various machines identity-related actions without requiring to enter the domain credentials.

- To create a new identity account using a service account

```
New-AcctADAccount -IdentityPoolName MyPool -Count 2 -UseServiceAccount
```

- To repair the identity accounts using a service account

```
Repair-AcctADAccount -ADAccountName "Domain\account","Domain\account2"
-UseServiceAccount
```

- To remove identity accounts using service account

```
Remove-AcctADAccount -IdentityPoolName MyPool -RemovalOption Delete
-ADAccountName "Domain\account","domain\account2" -UserServiceAccount
```

Where to go next

- To create on-premises Active Directory joined catalogs, see Identity pool of on-premises Active Directory joined machine identity.
- To manage service accounts, see Manage service accounts.

Microsoft Entra service accounts

A Microsoft Entra service account is a container to store application ID and secret of a Microsoft Entra service principal , which has sufficient permissions to manage Microsoft Entra joined or Microsoft Intune enrolled devices. MCS can use this service account to automatically clean any stale Microsoft Entra or Microsoft Intune devices generated during the lifecycle of the provisioned machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Permissions required for a Microsoft Entra service principal

The permissions required for a Microsoft Entra service principal used by a service account depend on the capabilities enabled for the service account.

- For the service account with Microsoft Entra joined devices management capability, the Microsoft Entra service principal must have `Device.ReadWrite.All` permission in your Microsoft Entra tenant.
- For the service account with Microsoft Intune enrolled devices management capability, the Microsoft Entra service principal must have `DeviceManagementManagedDevices.ReadWrite.All` permission in your Microsoft Entra tenant.
- For the service account with Microsoft Entra security group management capability, the Microsoft Entra service principal must have `Group.ReadWrite.All` and `GroupMember.ReadWrite.All` permissions in your Microsoft Entra tenant.

Limitation

Microsoft Entra role-based access control is currently not supported. Therefore, assign the Microsoft Entra permissions directly to the service principal.

Create a Microsoft Entra service account

Use Studio or PowerShell to create a Microsoft Entra service account.

Prerequisite

To create a Microsoft Entra service account, make sure to complete the following task:

- Create a Microsoft Entra principal in your Microsoft Entra tenant with sufficient permissions based on the capabilities that you want to enable the service account with.

Use Studio

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. In the **Service Accounts** tab, click **Create Service Account**.
4. On the **Identity Type** page, select **Microsoft Entra ID**. A new option to route the traffic is enabled.
    a. Select the **Route traffic through Citrix Cloud Connectors** checkbox.
    b. Select the zones available to route the traffic and click **Next**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. On the **Credentials** page, enter the Microsoft Entra tenant ID, Application ID, and Client secret and set the credential expiration date.
6. Choose the capabilities for the service account.
7. Select one or more scopes for the service account.
8. Enter a friendly name and a description (optional) for the service account.
9. Click **Finish** to complete the creation.

NOTE:

- The capability of Microsoft Entra joined devices management is selected by default and you cannot deselect it.
- To use a multitenant Microsoft Entra application, which is invited to your tenant, the Microsoft Entra tenant ID you entered must be your own tenant ID rather than the home tenant ID of the application.

Use PowerShell

Alternatively, you can use PowerShell commands to create a Microsoft Entra service account. For example:

```
$tenantId = xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

$applicationId = xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

$applicationSecret = xxxxxxxxxxxxxxx

$credential = ConvertTo-SecureString -String $applicationSecret
-AsPlainText -Force

New-AcctServiceAccount -IdentityProviderType AzureAD
-IdentityProviderIdentifier $tenantId -AccountId $applicationId
-AccountSecret $credential -SecretExpiryTime 2030/08/15 -Capabilities
@("AzureADDeviceManagement","IntuneDeviceManagement") -DisplayName
'MyApplication' -Description 'Service account for Microsoft Entra tenant'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Migrate Microsoft Entra joined device management to service account

Previously, Citrix® provided an option to enable Microsoft Entra joined device management when creating or editing a hosting connection to Microsoft Azure Resource Manager. MCS used the permissions of the Microsoft Entra service principal (provisioning SPN) stored along with the hosting connection to manage the stale Microsoft Entra joined device. With service accounts, you can use a dedicated Microsoft Entra service principal (identity management SPN) stored along with a service account to manage Microsoft Entra joined or Microsoft Intune enrolled devices.

Citrix recommends migrating from hosting connection-powered device management to service account-powered device management to separate the responsibility of provisioning SPN and identity management SPN.

For any existing hosting connections that are already enabled with Microsoft Entra joined device management, you can disable it as follows:

1. From Studio, select **Hosting** in the left pane.
2. Select the connection and then select **Edit Connection** in the action bar.
3. On the **Connection Properties** page, clear the **Enable Microsoft Entra joined device management** checkbox.
4. Click **Save** to apply the changes.

NOTE:

Currently, you cannot enable Microsoft Entra joined device management when creating a new hosting connection.

Route Microsoft Entra device management and security group management traffic

Create and modify a Microsoft Entra service account to route Microsoft Entra device management and security group management traffic from Delivery Controller to Microsoft Entra ID through Citrix Cloud Connector.

Include the following custom property while creating or modifying a Microsoft Entra service account:

```
CustomProperties: {"ProxyHypervisorTrafficThroughConnector":true,"ZoneUid":["<zone uid>"]}
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The `$ZoneUid` is the Uid of the zone (resource location) that the network traffic wants to be routed to. Obtain the Uid from `Get-ConfigZone` command.

For example:

- For creating a new Microsoft Entra service account:

```
$tenantId = xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

$applicationId = xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

$applicationSecret = xxxxxxxxxxxxxxx

$SecureString = ConvertTo-SecureString -String "Secretstring"
-AsPlainText -Force

New-AcctServiceAccount -IdentityProviderType AzureAD
-IdentityProviderIdentifier "<Identity provider ID>" -AccountId
"<Account ID>" -AccountSecret $SecureString -SecretExpiryTime <yyyy-mm-
dd>  -Capabilities
@("AzureADDeviceManagement","IntuneDeviceManagement") -DisplayName
"<Display name>" -CustomProperties
'{"ProxyHypervisorTrafficThroughConnector":true,"ZoneUid":["<Zone
UID>"]}'
```

- For modifying an existing Microsoft Entra service account:

```
Set-AcctServiceAccount -ServiceAccountUid $serviceAccountUid
-CustomProperties
'{"ProxyHypervisorTrafficThroughConnector":true,"ZoneUid":[$ZoneUid]}'
```

Where to go next

- To create Microsoft Entra joined catalogs, see Identity pool of Microsoft Entra joined machine identity.
- To manage service accounts, see Manage service accounts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Manage service accounts

Managing service accounts is a critical aspect to ensure that they remain in a healthy state and their credentials are up-to-date. This article describes the steps to view, rename, edit, test, and delete a service account.

View service account details

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. Select the **Service Accounts** tab.
4. Select a service account and view its details in the lower panel. See the properties of each service account along with its associated machine catalogs and troubleshooting tips in the lower panel.

Error or warning icons appear beside a service account if:

- the service account is in an unhealthy state.
- the credential of a service account is nearing expiry.

The **Troubleshooting** tab provides information to diagnose and fix the issues.

NOTE:

After fixing the issues, do a service account test to refresh the status. For more information, see Test a service account.

Rename a service

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. Select the **Service Accounts** tab.
4. Select a service account and click **Rename**.

Edit a service account

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. Select the **Service Accounts** tab.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Select a service account and click **Edit**.

Test a service account

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. Select the **Service Accounts** tab.
4. Select a service account and click **Test Service Account**.

- For an on-premises Active Directory service account, credentials are verified during testing.
- For Microsoft Entra service account, application ID and secret along with the required permissions are verified during testing.

Identity and fix the issues according to the recommendations. The **Troubleshooting** tab provides information to diagnose and fix the issues. After fixing the issues, test the service account.

Delete a service account

Before deleting a service account, make sure that the service account is not used by any MCS machine catalogs.

1. In the **DaaS** tile, click **Manage**.
2. In the left pane, select **Administrators**.
3. Select the **Service Accounts** tab.
4. Select a service account and click **Delete**.

Image management

Introduction

The MCS catalog creation or update process has two phases:

- Mastering: a source image is converted into a published image
- Cloning: new VMs are created from the published image

With the image management functionality, MCS separates the mastering phase from the overall provisioning workflow.

You can prepare various MCS image versions (Prepared Image) from a single source image and use it across multiple different MCS machine catalogs. You can also share prepared image

© 1997–2026 Citrix Systems, Inc. All rights reserved.

versions across hosting units. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process.

The benefits of using this image management functionality are:

- Generate prepared images in advance without creating a catalog.
- Reuse prepared images in multiple scenarios, such as creating and updating a catalog.
- Significantly reduce catalog creation or update time.
- Share prepared image versions across hosting units:
  - For Azure, Nutanix AHV Prism Central, and VMware, image versions can be shared across host connections of the same connection type.
  - For Amazon WorkSpaces Core Managed Instances, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region or in different regions.
  - For AWS EC2, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region.
  - For XenServer, image versions can only be shared across hosting units within the same host connection.

NOTE:

- This feature is currently applicable to Amazon WorkSpaces Core Managed Instances, AWS EC2, Azure, Nutanix AHV Prism Central, Red Hat OpenShift, VMware virtualization, and XenServer environments.
- You can create an MCS machine catalog without using prepared images. In that case, you cannot get the benefits of the feature. However, for Amazon WorkSpaces Core Managed Instances, create the MCS catalog using only a prepared image version. You can’t create the catalog using a master image directly.

Use cases

Some of the use cases of image management functionality are:

- *Version management*: Image versions allow you to:
  - manage different iterations or updates to a particular image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - maintain multiple versions of an image for different purposes.

- *Logical grouping*: You can create multiple image definitions to:
    - logically group image versions based on various criteria such as project, department, or application and desktop type.
    - manage images more efficiently within an organization.
- *Image sharing*: You can share prepared image versions across hosting units within host connections of the same connection type to:
    - ensure consistency and uniformity of images across different hosting units.

What is a prepared image?

With the image management functionality, MCS decouples the mastering phase from the overall catalog creation or update workflow and breaks down the process into two stages:

1. Create prepared images from a single source image.
2. Use the prepared image to create or update an MCS machine catalog.

You can create the prepared images in advance. You can use a single prepared image to create or update multiple MCS provisioned machine catalogs.

Understand how a prepared image is used across multiple MCS machine catalogs when you use Studio:

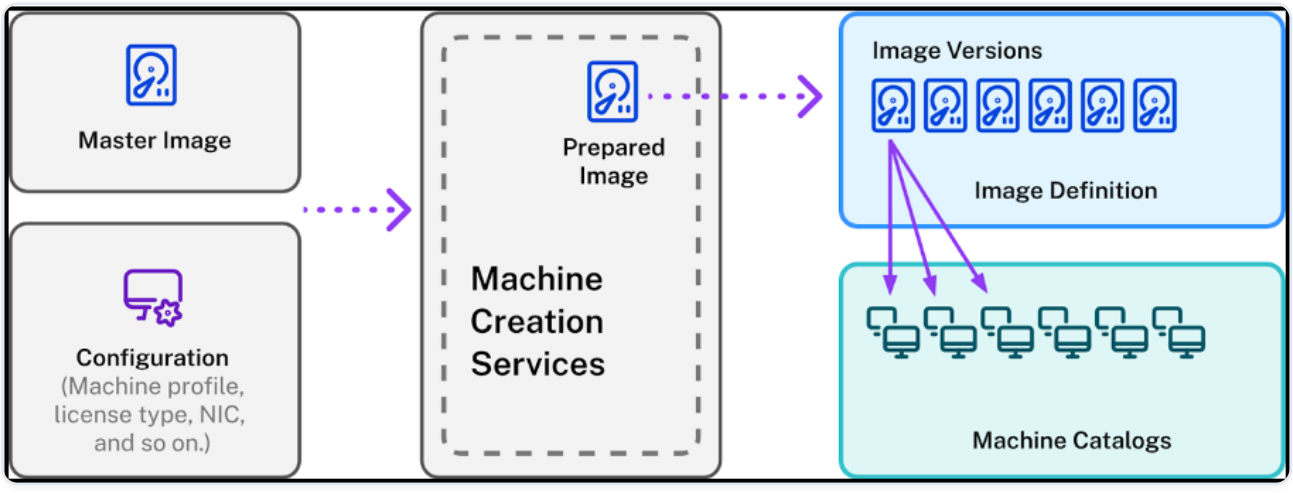


Image definition: Image definitions are a logical grouping of versions of an image. The image definition holds information about:

- why the image was created
- what OS it is for

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- other information about using the image.

A catalog isn't created from an image definition, but from the image versions that are created based on the image definition.

Image version: Image versions manage versionings for the image definition. An image definition can have multiple image versions. Use the image versions as prepared images to create or update a catalog.

- For Azure and VMware, image versions can be shared across host connections of the same connection type.
- For Amazon WorkSpaces Core Managed Instances, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region or in different regions.
- For AWS EC2, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region.
- For XenServer, image versions can only be shared across hosting units within the same host connection.

Alternatively, if you want to use PowerShell commands to create a provisioning scheme to create or update a catalog, then you must create a prepared image version spec based on the master image version spec as needed for your environment.

- For Azure, Nutanix AHV Prism Central, and VMware, image versions can be shared across host connections of the same connection type.
- For Amazon WorkSpaces Core Managed Instances, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region or in different regions.
- For AWS EC2, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region.
- For XenServer, image versions can only be shared across hosting units within the same host connection.

Requirement

- For Windows master images, only VDA images version 2311 or later are supported. The MCS/IO component must be explicitly selected and installed. Enabling or disabling the MCS I/O configuration must be determined during machine catalog creation or updates, as it is not enabled by default.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations

Currently, the feature does not support the following:

- Multiple NIC in Azure
- Persistent data disk feature
- Hibernation for multi-session
- Image type change
- While sharing prepared image version across hosting unit in Azure, the following sharing methods are not allowed:
  - Share Directly
  - Share to public community gallery

Image lifecycle management using Studio

Lifecycle of the image when you use Studio is as follows:

1. Create a prepared image: Create an image definition and its initial image version.
2. Create image versions from the initial image version.
3. If needed, share an image version with a hosting unit in your virtualization environment.
4. Use an image version as a prepared image to create catalogs.
5. Update a machine catalog with a different prepared image.
6. Manage the image definitions and versions: Edit the name and description of image versions, and description of an image definition.
7. Delete an image version.
8. Delete an image definition.

Alternatively, you can also manage images using PowerShell. See Image lifecycle management using PowerShell.

Image lifecycle management using PowerShell

If you want to use PowerShell commands to create a provisioning scheme, then you must create a prepared image version spec based on the master image version spec as needed for your environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Master image version spec: A master image version spec is a specific image added or created under an image version. You can add an existing image in the hypervisor as a master image version spec or create a prepared image version spec based on the master image version spec as needed for your environment. The prepared image version spec can be used for multiple provisioning schemes.

You can share image version specs across hosting units, depending on your virtualization environment:

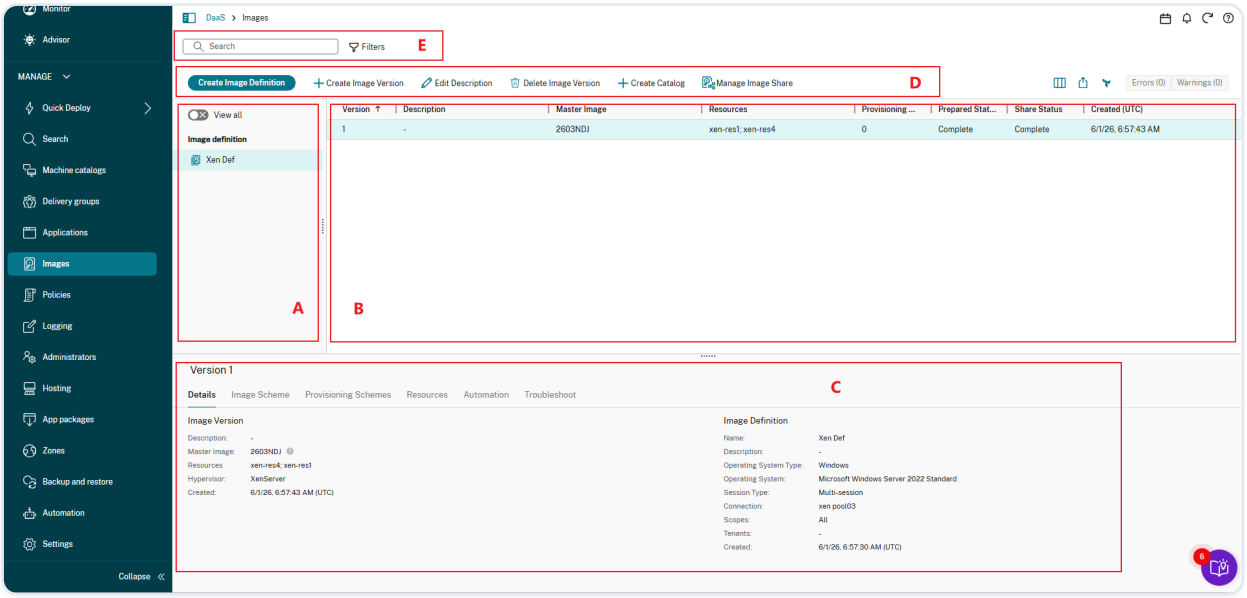
- In Azure, VMware, and Amazon WorkSpaces Core Managed Instances environments, you can share image version specs across hosting units, whether they are in the same or different host connections of the same connection type. In Azure, the sharing is achieved using the disk sharing capability of Azure Compute Gallery (ACG).
- For AWS EC2, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region.
- In Nutanix AHV Prism Central and XenServer, you can share image version specs only across hosting units within the same host connection.

Lifecycle of an image when using PowerShell commands is:

1. Create an image:
    a. Create an image definition.
    b. Add a new configuration for Image Definition in specified hosting connection.
    c. Create an image version.
    d. Add a master image version spec.
    e. Create a prepared image version spec.
2. If needed, share an image version spec with another hosting unit, following the sharing constraints of your virtualization environment:
    - For Azure and VMware, image versions can be shared across host connections of the same connection type.
    - For Amazon WorkSpaces Core Managed Instances, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region or in different regions.
    - For AWS EC2, image versions can be shared across different availability zones, tied to different hosting units, within the same AWS region.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For XenServer, image versions can only be shared across hosting units within the same host connection.



3. Create an MCS machine catalog using a prepared image version spec:
    a. Create a broker catalog.
    b. Create an identity pool.
    c. Create a provisioning scheme with the parameter of prepared image version spec Uid using the `New-ProvScheme` command.
    d. Link the broker catalog with the provisioning scheme.
4. Create VMs in the MCS machine catalog.
5. Change the prepared image version spec of a provisioning scheme using `Set-ProvScheme` command.
6. Manage the image definitions and versions: Edit the image versions and image definitions.
7. Delete an MCS machine catalog: The deletion order is: machine catalog > shared prepared image version spec (if image sharing) > prepared image version spec > master image version spec > image version > configuration for image definition in the specified hosting connection > image definition. Before deleting the image version spec, ensure that the prepared image version spec is not associated with any MCS machine catalog.

Understand Images node

Use the **Images** node to create and manage MCS-prepared images. Its main view is divided into four parts:

- With prepared image being shared across host unit: In Azure and VMware

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LABEL	PART	DESCRIPTION
A	Image definitions	Lists the previously created image definitions.
B	Image versions	Displays image versions for the selected image definition. When **View all** is turned off, only the selected image definition's versions are displayed. When it is turned on, image versions across all definitions are displayed.
C	Details	• The **Details** tab displays detailed information about the selected image definition or

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LABEL	PART	DESCRIPTION
		version such as Master Image, Resource, Hypervisor, name of the image definition, OS type, and session type. • The **Image Scheme** tab displays information about the template used for preparing images such as hard disk, machine size, license type, disk encryption set, machine profile, and so on. • The **Provisioning Schemes** tab displays the provisioning scheme name used for creating the catalog. • The **Troubleshoot**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LABEL	PART	DESCRIPTION
		tab provides the error status of the selected image version. • In case of image sharing: The **Resources** tab provides the status of image version share.
D	Action bar	Lists the actions that you can take on image definitions and versions such as **Create Image Version**, **Edit Description**, **Manage Image Share**(in case of prepared image sharing), **Delete Image Version**, and **Create Catalog**.
E	Search bar	Specifies filter criteria for searching image versions that meet the conditions.

Create prepared image machine catalogs

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Currently, you can create prepared image machine catalogs in Amazon WorkSpaces Core Managed Instances, AWS EC2, Azure, Red Hat OpenShift, VMware, and XenServer® virtualization environments.

NOTE:

You can create an MCS machine catalog without using prepared images. In that case, you cannot get the benefits of the feature. However, for Amazon WorkSpaces Core Managed Instances, create the MCS catalog using only a prepared image version. You can't create the catalog using a master image directly.

Where to go next

- Create catalogs using prepared images in Amazon WorkSpaces Core Managed Instances
- Create catalogs using prepared images in AWS EC2
- Create catalogs using prepared images in Azure
- Create catalogs using prepared images in Red Hat OpenShift
- Create catalogs using prepared images in VMware
- Create catalogs using prepared images in XenServer

Create catalogs using prepared images in Amazon WorkSpaces Core Managed Instances

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell

Key steps

1. Create the image definition and the initial image version.
2. Create image versions from the initial image version.
3. Use the image version as a prepared image to create a catalog.

Create an image definition and initial image version using Studio

To create an image definition and the initial image version, do the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type** for the image definition.
3. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed), a master image to use as a template for creating the image version, and a machine profile for capturing hardware properties from. Select a machine profile to capture hardware properties from a VM instance or launch template version.

   NOTE:

   - Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.
   - The Instance Metadata Service (IMDS) V2 is only supported and not IMDS V1. For information, see How Instance Metadata Service Version 2 works.

4. On the **Machine Specification** page, select a machine size. The machine size of the machine profile (selected on the **Image** page) is selected by default.
5. On the **NICs** page, select or add NICs for the preparation image. For each NIC, select an associated VPC subnet.
6. On the **Version Description** page, enter a description for the initial image version created.
7. On the **Summary** page, verify the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

Create image versions using Studio

Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

NOTE:

The hosting unit of all the image versions must be the same.

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Image definition** page, you can change the hosting unit, and reselect the master image and machine profile for that image version.
3. If you want the configuration of the image version to be different from the initial configured image version, then configure the settings on the **Machine Specification** and **NICs** pages of the **Create Image Version** dialog.
4. Add a description for the image version. Click **Finish**.

NOTE:

If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

Create a prepared image version spec using PowerShell

The detailed PowerShell commands to create a prepared image version spec are as follows:

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

```
Test-ProvImageDefinitionNameAvailable -ImageDefinitionName <string[]>
```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

```
New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
-VdaSessionSupport MultiSession
```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command.

```
Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName test-conn
```

4. Create an image version using the `New-ProvImageVersion` command. For example,

```
New-ProvImageVersion -ImageDefinitionName image1 -Description "version
1"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

```
Add-ProvImageVersionSpec -ImageDefinitionName  image1  -
ImageVersionNumber  1 -HostingUnitName wsc -MasterImagePath "XDHyp:
\HostingUnits\wsc\win10-2411-ami (ami-00123456789abcdef).template”"
```

> **NOTE:**
>
> You can add only one master image version spec to one image version for a hosting unit.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command. The `SourceImageVersionSpecUid` parameter is derived from the `Add-ProvImageVersionSpec` command. For example,

```
New-ProvImageVersionSpec

-SourceImageVersionSpecUid  00000000-0000-0000-0000-00000000000

-MachineProfile 'XDHyp:\HostingUnits\wsc\w2022-2411
(lt-00123456789abcdef).launchtemplate\lt-00123456789abcdef
(1).launchtemplateversion' -RunAsynchronously
```

Example of the complete set of PowerShell commands to create image definition, image version, and prepared image version spec:

```
New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
-VdaSessionSupport MultiSession

Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName wsc -CustomProperties $CustomProperties

$imageVersion = New-ProvImageVersion -ImageDefinitionName image1
-Description "version 1"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid `

    -HostingUnitUid $hostingunit.HostingUnitUid `

    -MasterImagePath "XDHyp:\HostingUnits\wsc\win10-2411-ami
(ami-00123456789abcdef).template”

New-ProvImageVersionSpec -MachineProfile 'XDHyp:
\HostingUnits\wsc\w2022-2411
(lt-00123456789abcdef).launchtemplate\lt-00123456789abcdef
(1).launchtemplateversion' -SourceImageVersionSpecUid
$SourceImageVersionSpec.ImageVersionSpecUid

Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
00000000-0000-0000-0000-00000000000-HostingUnitName wsc

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid | Where SourceImageVersionSpecUid-eq
$SourceImageVersionSpec.ImageVersionSpecUid
```

NOTE:

- All image version specs in an image definition must belong to the same hosting unit.
- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must have a machine profile.

Share prepared images across availability zones and regions

You can now share a single prepared image across different availability zones, tied to different hosting units, within the same AWS region or in different regions for your Amazon WorkSpaces Core Managed Instances. This lets you use one prepared image to create and update MCS machine catalogs in various availability zones and regions. When sharing across different AZs in

© 1997–2026 Citrix Systems, Inc. All rights reserved.

different regions, the prepared image version will be copied from the original region to the destination regions.

You can maintain a single prepared image and use it to create and update machine catalogs across multiple availability zones and regions tied to different hosting units. This significantly reduces your image management overhead, ensures consistency across deployments, and streamlines the provisioning process. You can also seamlessly update existing machine catalogs with prepared images from a different availability zone or region.

Use cases

- **Centralized Image Management:** You create a prepared image in one availability zone (for example, `us-east-1a`). You can then share this image to other availability zones like `us-east-1b` within the same `us-east-1` AWS region or `us-west-1a` in a different `us-west-1 region`. This allows a single image to serve multiple hosting units and simplifies maintenance for you.
- **Efficient Catalog Creation and Updates:** You can use a prepared image created in `AZ 1` (for example, `us-east-1a`) to create new catalogs in `AZ 1`. After sharing this image to `AZ 2` (for example, `us-east-1b`), you can then use the shared image in `AZ 2` to create and update catalogs in `AZ 2`.
- **Cross-hosting unit and hosting connection deployments:** If your environment has multiple hosting units under the same or different AWS regions, you can efficiently share prepared images between these hosting units.

Limitations

- **Sharing within same AWS Account**: You cannot share across different AWS Accounts in the current implementation.

Important considerations

- **Deletion order:** To delete an original prepared image version specification, you must first delete all its shared image version specifications. Alternatively, you must delete the original and shared specifications simultaneously.
- **Image Version dependency:** When you remove an image version, you must first remove any sharing configurations that depend on that specific image version. Catalogs that you created from the original (unshared) image can remain intact.
- **Catalog back-portability:** You can update existing machine catalogs that you deployed before this feature's introduction. Use prepared images that you created in a different availability zone or region from where you originally deployed the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Complete deletion:** When you delete a prepared image, you can no longer use it in any availability zone where you shared or originally created it. Moreover, a prepared image version cannot be deleted until all catalog tied the prepared image version are deleted first.

Prerequisites

Before you configure or use this feature, ensure that you meet the following conditions:

- Your environment must be an Amazon WorkSpaces Core Managed Instances environment.
- You must configure multiple hosting units (each can be tied to different availability zones) and host connections (each can be tied to a different region) under the same AWS account.

Configure using Studio UI

You can share prepared images across availability zones tied to different hosting units using the Studio UI.

TO SHARE A PREPARED IMAGE

1. Navigate to the **Images** node of the Studio and select the prepared image version you wwant to share with other availability zones.
2. Select **Manage Image Share** at the top navigation bar to manage the image sharing for the selected image version.
3. On the **Manage Image Share** page, select one or more resources you want to share the image version with. The resources can be in different availability zones from that of the original image version.
4. Click **Save** to share the image version in the resources across other availability zones. The image version is updated such that it is shared across the different resources that you selected. Once complete, use the image version to create catalogs in the availability zones the image version is shared across.

TO REMOVE SHARING OF A PREPARED IMAGE

1. On the **Images** node of the Studio, select the prepared image version you would like to remove from sharing.
2. Select **Manage Image Share** at the top navigation bar to manage the image sharing for the selected image version.
3. Clear the checkboxes from one or more resources (availability zones) that you want to stop sharing the image version with.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> The resources must no longer have any catalogs associated with and created from the shared image version. Any catalogs created from the shared image version to be removed must be deleted first.

4. Click **Save** to remove sharing of the resources across the cleared availability zones. The image version is updated such that it is no longer shared in those availability zones.

Configure using PowerShell

Alternatively, you can share prepared images across availability zones tied to different hosting units using PowerShell commands.

TO SHARE A PREPARED IMAGE

1. Ensure that you have the `ImageVersionSpecUid` of the prepared image you want to share. You can retrieve this using `Get-ProvImageVersionSpec` or similar `Get-` commands in PowerShell.
2. Determine the `HostingUnitName` of the availability zone (can be the same or a different region) where you want to make the prepared image available. This is the name of the hosting unit you configured for that specific AZ.
3. **Run the `Add-ProvImageVersionSpecHostingUnit` command:** Use the following PowerShell command. Replace `<ImageVersionSpecUid>` with your image's Uid and `<targetHostingUnitName>` with the name of the hosting unit in the target availability zone that you want to share the image version specification to:

   ```
   Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
   <ImageVersionSpecUid> -HostingUnitName <targetHostingUnitName>
   ```

4. After successful execution, you can see the image's status in the Studio UI indicating that you shared it with the specified hosting unit.

TO REMOVE SHARING OF A PREPARED IMAGE

1. Ensure you have the `ImageVersionSpecUid` of the prepared image from which you want to remove sharing.
2. Determine the `HostingUnitName` of the availability zone from which you want to remove the shared image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. **Run the `Remove-ProvImageVersionSpecHostingUnit` command:** Use the following PowerShell command. Replace `<ImageVersionSpecUid>` with your image's Uid and `<targetHostingUnitName>` with the name of the hosting unit in the target Availability Zone that you want to remove the sharing of the image version specification from:

```
Remove-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
<ImageVersionSpecUid> -HostingUnitName <targetHostingUnitName>
```

Network setting during image preparation

During image preparation, a preparation virtual machine (VM) is created based on the original VM. This preparation VM is disconnected from the network. To disconnect the network from the preparation VM, a network security group is created to deny all inbound and outbound traffic. This network security group persists and is reused. The network security group's name is `Citrix.XenDesktop.IsolationGroup-GUID`, where GUID is randomly generated.

A machine profile-based machine catalog

You can use a machine profile to capture the hardware properties from an EC2 instance (VM) or launch template version and apply them to the provisioned machines. Properties that are captured can include, for example, tenancy type, instance type, security groups, network mappings, EBS volume properties, EBS optimization, CPU options, hibernation capability, and other supported AWS configurations.

You can use an AWS EC2 Instance (VM) or AWS Launch Template version as the machine profile input.

NOTE:

- EBS volume properties are derived only from a machine profile.
- The Instance Metadata Service (IMDS) V2 is only supported and not IMDS V1. For information, see How Instance Metadata Service Version 2 works.

AWS tenancy

AWS provides the following tenancy options: shared tenancy (the default type) and dedicated tenancy. Shared tenancy means that multiple Amazon WorkSpaces Core instances from different customers might reside on the same piece of physical hardware. Dedicated tenancy means that

© 1997–2026 Citrix Systems, Inc. All rights reserved.

your Amazon WorkSpaces Core instances run only on hardware with other instances that you have deployed.

NOTE:

The dedicated instances are only supported (dedicated hosts are currently not supported). Other customers do not use the same piece of hardware.

Tenancy type is captured from machine profile

When you use MCS to create a catalog to provision machines in AWS, the tenancy type is captured from the machine profile.

- **Shared hardware**: This setting is suitable for most deployments. Multiple customers share pieces of hardware even though they do not interact with each other. Using shared hardware is the least expensive option for running your Amazon EC2 instances.
- **Dedicated instance**: This setting is more suitable for deployments with specific security or compliance requirements. With a dedicated instance, you still enjoy the benefits of having a host separate from other AWS customers but you do not pay for the entire host. You do not need to worry about the capacity of the host but you are charged at a higher rate for the instances. Additionally, Dedicated Instances provide limited support for Bring Your Own License (BYOL).

Flexible billing

Amazon WorkSpaces Core Managed Instances supports two billing modes:

BILLING MODE	DESCRIPTION
Monthly	Fixed, monthly flat-rate billing. Ideal for persistent desktops and predictable workloads.
Hourly	Pay-as-you-go billing. This is the AWS default configuration if no billing mode is explicitly specified.

These options provide flexibility for managing compute costs based on your workload's persistence and usage patterns.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This feature requires the use of the Amazon WorkSpaces billing service. By default, MCS uses this service to provision and manage instances, letting you benefit from more competitive flat-rate pricing for persistent workloads.

Prerequisites and considerations

- AWS account configuration: Your AWS account must be configured to use the WorkSpaces billing service. While AWS accounts are switched by default, some customers may request AWS to remain on the legacy EC2 billing service for using WorkSpaces Core Managed Instances.

  NOTE:

  If your account is on the legacy EC2 billing service, the **Monthly** billing option is not available.

- Host connection: Flexible billing is only applicable to Amazon WorkSpaces Core host connections. It is not supported for standard AWS EC2 host connections.
- Spot instances: Spot instances are not supported with the WorkSpaces billing service.
- Mixed billing: An AWS account must use either WorkSpaces billing or EC2 billing for core managed instances. A mix of both within a single account is not supported.
- Compatibility: Only specific instance types, platform types (OS), and tenancy types are compatible with certain billing modes. MCS performs a preflight check to ensure your selections (Service Offering, Machine Profile, and Prepared Image) match the chosen billing mode.

See Create a machine catalog with a specific billing mode.

Create a catalog

A prepared image and a machine profile is required for creating catalogs of Amazon WorkSpaces Core Managed Instances. You can use an AWS VM Instance or AWS Launch Template version as the machine profile input.

NOTE:

Currently, creation of catalogs of both persistent and non-persistent VMs (`CleanOnBoot` property is `True` or `False`) is supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Before creating a catalog of Amazon WorkSpaces Core Managed Instances, you need to finish creating:

1. A connection to Amazon WorkSpaces Core Managed Instances. See Connection to Amazon WorkSpaces Core Managed Instances
2. A prepared image.

You can create a catalog using:

- Studio
- PowerShell

Create a catalog using Studio

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node.

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Machine Management** and **Image** pages, the settings are pre-selected based on the selected image version. On the Image page, enter a note for the selected prepared image.
3. Complete the settings on the following pages.
4. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
5. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the Machine Catalogs node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears.
3. On the **Machine Type** page, select a machine type for the catalog, for example, **Multi-session OS**.
4. On the **Machine Management** page, select the following settings:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Select **Machines that are power managed (for example, virtual machines or blade PCs)**.

b. Select **Citrix provisioning technology**. Then, select **Citrix Machine Creation Services™**.

c. In the **Resources** field, select the resources (Availability Zone or Local Zone) that you configured while creating the host connection and click **Next**.

5. On the **Desktop experience** page, select either random or static desktop that you want users to have when they log in. If a static desktop is selected, further specify whether you want to save changes that the user makes on the local disk (persistent or non-persistent).
6. On the **Image** page, click **Select an image** to select a prepared image for the machine catalog. Select the prepared version that you created. Click the image version name. To view more details about the selected image version, click the version number, which is underlined. Click **Done**.

   The machine profile associated with the prepared image appears and its hardware properties (for example, instance type, tenancy type, network mappings, security groups, volume properties) are used to create machines in the catalogs. To change the machine profile source to another VM or launch template version click the edit button.
7. On the **Virtual Machines** page:

   a. Enter the number of VMs for the catalog.

   b. The default machine specification is displayed, which is based on the machine profile. To change it, select the edit icon and select a machine specification.
8. On the **NICs** page, select the NICs (or ENIs) for the VMs.
9. On the **Machine Identities** page, configure the machine identity type for the machines in the catalog:

   a. To configure **domain-joined machines (on-premises Active Directory or Microsoft Entra hybrid joined)**, select the domain and create new AD accounts for the VMs to be created in this machine catalog. The provisioned VMs are joined to the domain selected. To provision **non-domain joined machines**, select the non-domain join option.

   b. Specify the account naming scheme for the new accounts to be created for the VMs.
10. On the **Domain credentials** page, click **Enter credentials** to provide the credentials for the selected domain. Enter admin-level username and password when prompted. You can also use

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a service account if you have domain credentials already saved previously by following our product docs.

11. Click through the remaining pages until the **Summary** page. Enter a name for the machine catalog and select **Finish** to create the machine catalog.

Limitations on creating a machine catalog in an AWS local zone

- Certain local zones only support certain hardware configurations (for example, Perth local zone does not support GP3 volumes, only GP2).
- Since only gp2 is universally supported across all local zones, and not all support gp3, ID disk creation defaults to using gp2 volume type.
- You must select a machine profile with hardware specifications that are supported in the desired local zone.
- Prepared image AMIs snapshots and ID disk snapshots defaults to being placed in the region, rather than the local zone (due to AWS limitations regarding visibility into EBS snapshot support in local zones).
- Only local zones supporting full EC2 and EBS services are supported zones.

Create a catalog using PowerShell

Create a catalog using a prepared image version spec and machine profile

- Create an MCS non-persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$true] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

- Create an MCS persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$false] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

Example of the complete set of Powershell commands to create a catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" -Name "wsccatalog" -PersistUserChanges
"Discard" -ProvisioningType "MCS" -Scope @() -SessionSupport
"MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain "domainname"
-IdentityPoolName "wsccatalog" -IdentityType "ActiveDirectory"  -
NamingScheme "aws##" -NamingSchemeType "Numeric" -Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

$Task = New-ProvScheme -ProvisioningSchemeName wsccatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
-HostingUnitName wsc -IdentityPoolName wsccatalog -CleanOnBoot -Scope @()
-SecurityGroup @() -MachineProfile 'XdHyp:\HostingUnits\cvad-test-
scalestress\us-east-1a.availabilityzone\machine-profile-instance i
(i-0xxxxxxx).vm' -RunAsynchronously

Get-ProvTask -TaskId $Task.TaskId

$ProvScheme = Get-ProvScheme -ProvisioningSchemeName wsccatalog

Set-BrokerCatalog -Name $Catalog.Name -ProvisioningSchemeId
$ProvScheme.ProvisioningSchemeUid
```

Update the machine profile

To update the machine profile on a catalog that was initially provisioned with a machine profile, do the following. You can also change the tenancy type and hibernation capability of the machine profile source while editing an MCS machine catalog.

1. Run `Set-ProvScheme` command. For example,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-ProvScheme `

-ProvisioningSchemeUid "<ID" `

-MachineProfile "XDHyp:\HostingUnits\abc\us-
east-1a.availabilityzone\citrix-cvad-machineprofile-instance
(i-0xxxxxxxx).vm"
```

Create a machine catalog with a specific billing mode

You can specify the billing mode while creating a machine catalog using only PowerShell currently.

To specify the billing mode through PowerShell, use the `CustomProperties` parameter in the `New-ProvScheme` command.

```
$custprop = "BillingMode,Monthly"

New-ProvScheme -ProvisioningSchemeName "MyCatalog" `

-ImageVersionSpecUid $ImageVersionSpecUid `

-HostingUnitName "wsc-unit" `

-IdentityPoolName "MyIdentityPool" `

-MachineProfile "XdHyp:\HostingUnits\wsc-unit\machine-profile
lt-123.launchtemplate\lt-123 (1).launchtemplateversion" `

-CustomProperties $custprop `

-CleanOnBoot
```

NOTE:

If the `BillingMode` property is omitted, the catalog defaults to `Hourly`.

CHANGE THE BILLING MODE OF AN EXISTING CATALOG

You can convert an existing catalog from `Monthly` to `Hourly`, or vice versa. This change can apply to both new and existing VMs in the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT CONSIDERATIONS FOR UPDATES

- Service window: Existing VMs must undergo a service window or power cycle to apply the billing change.
- Validation: MCS validates that the existing instance types and platforms are compatible with the new billing mode before applying the change.

UPDATE USING POWERSHELL

- To update the billing mode of only new VMs added to a catalog, update the billing mode custom property of the provisioning scheme:

```
$custprop = "BillingMode,Hourly"

Set-ProvScheme -ProvisioningSchemeName "MyCatalog" -CustomProperties
$custprop
```

- To update the billing mode of new and existing VMs in a catalog, create a new provisioning scheme version with the updated custom property, and apply the new version to all VMs:

```
$custprop = "BillingMode,Hourly"

New-ProvSchemeVersion -ProvisioningSchemeName "MyCatalog"
-CustomProperties $custprop

New-ProvSchemeHardwareUpdate -ProvisioningSchemeVersion 2 `

-StartsNow -AllVMs `

-MaxDurationInMinutes 100 `

-ProvisioningSchemeName "MyCatalog"
```

MONITOR BILLING INFORMATION

You can verify the billing mode for catalogs and individual virtual machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Run the following PowerShell commands to check your account's billing eligibility:

- Returns `BillingMode` as part of CustomProperties

```
Get-ProvScheme –ProvisioningSchemeName “"MyCatalog" "  | Select
 ProvisioningSchemeName,  CustomProperties
```

- Returns `BillingMode` as part of VMInfo

```
Get-ProvVMDetails –ProvisioningSchemeName “"MyCatalog" "  | Select-
Object  -ExpandProperty VMInfo
```

TROUBLESHOOTING AND VALIDATION

MCS includes preflight checks to prevent incompatible configurations. You may encounter the following errors during catalog creation or editing:

- **NoInstanceConfigFoundForBillingMode**: Occurs if the selected Service Offering (instance type), Tenancy, and Platform Type are not supported for the chosen billing mode.
- **Spot Instance Not Supported**: If you attempt to use Spot instances with a WorkSpaces host connection, validation fails.
- **EC2 billing restriction**: If your AWS account is on the legacy EC2 billing model, attempting to set a Monthly billing mode results in a validation error.

Create a catalog with launch template version using PowerShell

You can create an MCS machine catalog with a launch template version as a machine profile input. You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM.

On the AWS EC2 console, you can provide the instance configuration information of a launch template along with version number. When you specify the launch template version as a machine profile input while creating or updating a machine catalog, the properties from that version of the launch template are copied to the provisioned VDA VMs.

The following properties can be provided using machine profile input or explicitly as parameters in `New-ProvScheme` or `Set-ProvScheme`commands. If they are provided in `New-ProvScheme` or `Set-ProvScheme` commands, they take precedence over the machine profile values of these properties.

- Service Offering

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Networks

NOTE:

If service offering is not provided in the machine profile launch template or as a parameter in the `New-ProvScheme` command, you get an appropriate error.

To create a catalog using launch template version as a machine profile input:

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Get the list of launch template versions of a launch template. For example:

```
XDHyp:\HostingUnits\test\test-mp-sard (lt-01xxxxx).launchtemplate> ls |
Select FullPath
```

4. Create an identity pool if not created. For example:

```
New-AcctIdentityPool `

-IdentityPoolName "abc11" `

-NamingScheme "abc1-##" `

-NamingSchemeType Numeric `

-Domain "citrix-xxxxxx.local" `

-ZoneUid "xxxxxxxx" `
```

5. Create a provisioning scheme with a launch template version as a machine profile input. For example:

```
New-ProvScheme `

-ProvisioningSchemeName "MPLT1" `

-HostingUnitUid "c7f71f6a-3f45-4xxx-xxxx-xxxxxxxxxx" `

-IdentityPoolUid "bf3a6ba2-1f80-4xxx-xxxx-xxxxxxxxx" `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-ImageVersionSpecUid ‘24dfb047-e867-527g-896c-25664xxxxx1t’ `

-CleanOnBoot `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-01xxxxx).launchtemplate\lt-01xxxxx (1).launchtemplateversion"
```

6. Register a provisioning scheme as a broker catalog. For example:

```
New-BrokerCatalog -Name "MPLT1" `

-AllocationType Random `

-Description "Machine profile catalog" `

-ProvisioningSchemeId fe7df345-244e-4xxxx-xxxxxxxxx `

-ProvisioningType Mcs `

-SessionSupport MultiSession `

-PersistUserChanges Discard
```

7. Complete creating the catalog.

Update the machine profile source

You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM. For example:

- To update the input of a machine profile catalog from a VM to a launch template version:

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-0bxxxxxxxxxxx).launchtemplate\lt-0bxxxxxxxxxxx
(1).launchtemplateversion"
```

- To update the input of a machine profile catalog from a launch template version to a VM:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\sard-ue1a\us-
east-1a.availabilityzone\apollo-non-persistent-vda-win2022-2
(i-08xxxxxxxx).vm"
```

MCSIO enabled catalog

MCS Storage Optimization (MCSIO) improves virtual machine I/O performance by caching disk write operations through a two-tier mechanism:

- in memory, or
- on a dedicated high-speed disk (overflows to disk when memory is full).

For Amazon WorkSpaces Core Managed Instances, enabling MCSIO attaches a Write-Back Cache (WBC) disk to each provisioned VM in addition to the standard OS and Identity disks.

Enable and configure MCSIO using:

- Studio
- PowerShell

Use Studio to enable MCSIO

PREREQUISITES

Before configuring MCSIO in Studio, ensure the following:

- The MCSIO driver is installed on the master image (AMI). When installing or upgrading the VDA, select the option to install the MCSIO driver. By default, the driver is not installed.
- A prepared image version is created from a master image that includes the MCSIO driver.
- The machine catalog uses a non-persistent (CleanOnBoot) desktop experience. MCSIO applies to non-persistent VDI catalogs.

CREATE AN MCSIO-ENABLED MACHINE CATALOG USING STUDIO

Complete the preceding catalog creation steps (Machine Type, Machine Management, Desktop Experience, Image, Virtual Machines, NICs, Machine Identities, Domain Credentials) as described in Create a catalog. When you reach the Disk Settings page, do the following:

1. On the **Disk Settings** page, select the **Enable and configure write-back cache for optimum I/O performance** checkbox.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Configure the write-back cache disk settings:

   - **Disk cache size (GB)**: Enter the size in gigabytes of the disk used for caching. The value must be at least 1 GB and must not exceed the OS disk size.
   - **Disk drive letter**: Select Auto-assigned to let the system assign a drive letter, or specify a drive letter manually.
   - **Memory allocated to cache (MB)**: Enter the amount of memory in megabytes to allocate for caching. The value must be greater than zero and less than the total machine memory.

   NOTE:

   Write-back cache requires that the MCSIO driver is installed on the master image.

3. Under **Select the storage type for the write-back cache disk**, select an EBS SSD volume type:

   Storage Type:

   - General Purpose SSD (gp2)
   - General Purpose SSD (gp3)
   - Provisioned IOPS SSD (io1)
   - Provisioned IOPS SSD (io2)

   NOTE:

   Write-back caching supports EBS SSD volume types only. HDD volume types and local instance storage (ephemeral storage) are not supported.

4. Under **Select the persistence type for the write-back cache disk**, select one of the following:

   - **Use non-persistent write-back cache disk**: The cache disk is created when the machine powers on and deleted when it powers off. This is the default.
   - **Use persistent write-back cache disk**: The cache disk is retained across power cycles.

5. Under **System disk**, optionally select **Retain system disk during power cycles** to keep the OS disk when the machine powers off. When enabled, machines skip recreating the root disk from the template on each boot, which reduces boot time.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

For optimal boot performance, enable both **Use persistent write-back cache disk** and **Retain system disk during power cycles**. With both options enabled, machines reuse the existing cache disk and OS disk on startup rather than initializing new ones.

6. Click **Next** to proceed through the remaining wizard pages.
7. On the **Summary** page, verify the MCSIO-related settings before finishing. The summary displays the following write-back cache fields:
   - Enable temporary disk cache
   - Memory cache size (MB)
   - Disk cache size (GB)
   - Persistent with write-back cache disk
   - Write-back cache disk type
   - Write-back cache disk drive letter
   - Retain system disk
8. Enter a name and optional description for the machine catalog, then click **Finish**.

UPDATE MCSIO SETTINGS ON AN EXISTING CATALOG USING STUDIO

You can update write-back cache settings on an existing catalog from **Edit Machine Catalog**.

NOTE:

Changes you make on the **Disk Settings** page apply only to new machines you add to the catalog later. Existing machines remain unchanged.

1. From **Machine Catalogs**, select the catalog to update and click **Edit Machine Catalog**.
2. Navigate to the **Disk Settings** page. Update any of the following settings:
   - **Disk cache size (GB)**: Change the size of the write-back cache disk.
   - **Memory allocated to cache (MB)**: Change the memory allocated for caching.
   - **Storage type**: Change the EBS volume type for the write-back cache disk.
   - **Persistence type**: Toggle between persistent and non-persistent write-back cache disk.
   - **Retain system disk during power cycles**: Enable or disable OS disk retention.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Click **Apply** to save without closing, or **Save** to save and close.

EBS DISK LAYOUT FOR MCSIO-ENABLED MACHINES

When MCSIO is enabled, each provisioned Amazon WorkSpaces Core VM has three EBS volumes attached. You can verify the disk layout from the AWS Management Console under the Elastic Block Store section of the EC2 instance details.

DISK	DEVICE INDEX	DESCRIPTION
OS disk	/dev/sda1	Root volume cloned from the prepared image. If Retain system disk during power cycles is enabled, this disk persists when the machine powers off.
Identity disk	xvdf	Stores machine identity information for the provisioned VM. Always persists.
Write-back cache disk	xvdg	High-speed cache disk for MCSIO write operations. Persists across power cycles only if Use persistent write-back cache disk is selected.

WRITE-BACK CACHE AND OS DISK BEHAVIOR REFERENCE

The following table summarizes how write-back cache and OS disk behave based on the persistence settings selected.

WBC PERSISTENCE	OS DISK RETENTION	ON POWER-OFF	BOOT PERFORMANCE	STORAGE COSTS WHEN VM POWERED-OFF
Non-persistent (default)	Disabled (default)	Both WBC disk and OS disk are deleted. New disks are created on next power-on.	Standard	No OS disk or WBC disk costs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

WBC PERSISTENCE	OS DISK RETENTION	ON POWER-OFF	BOOT PERFORMANCE	STORAGE COSTS WHEN VM POWERED-OFF
Non-persistent (default)	Enabled	WBC disk is deleted. OS disk is retained.	Faster — skips OS disk initialization	OS disk costs, no WBC disk costs.
Persistent	Disabled (default)	WBC disk is retained. OS disk is deleted and recreated from template on next power-on.	Faster — skips WBC initialization	WBC disk costs, no OS disk costs.
Persistent	Enabled	Both WBC disk and OS disk are retained.	Fastest — no disk initialization required	OS disk and WBC disk costs.

NOTE:

Enabling OS disk retention on a non-persistent catalog means the OS disk is not reset on reboot. This trades faster boot times for storage costs of the OS disk. All writes, though, still only go to the Write-back memory cache or Write-back cache disk. User changes are not accumulated on the OS disk even when enabling OS disk retention. Evaluate based on your environment requirements.

USE POWERSHELL TO ENABLE MCSIO

CREATE AN MCSIO ENABLED CATALOG USING POWERSHELL

The four parameters added to the New-ProvScheme PowerShell command are:

- `UseWriteBackCache`: Turns on caching (write-back cache) for the given provisioning scheme
- `WriteBackCacheDiskSize`: Specifies the size in GB of the temporary disk used for caching
- `WriteBackCacheMemorySize`: Specifies how much memory in MB to use for caching. This is an optional parameter.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The value of `WriteBackCacheDiskSize` must be more than zero because at least 1 GB of cache disk storage is required. The cache disk size must not be bigger than the OS disk size.
- The value of `WriteBackCacheMemorySize` must be non-zero and less than the machine catalog memory size.

The custom properties that affect MCSIO are:

- `WBCDiskStorageType`: Defines the volume type, which is used for the temporary disk in Amazon WorkSpaces Core Managed Instances. This parameter takes a string argument in the format `volume-type[:iops][:throughput]`. The following are the volume types:
  - gp2: Do not use iops and throughput parameters for this volume type
  - gp3: Use iops and throughput parameters for this volume type
  - io1: Use only iops parameter for this volume type
  - io2: Use only iops parameter for this volume type

  The default volume type is **gp2**.
- `PersistWBC`: Controls whether to keep or discard the cache disk whenever the Amazon WorkSpaces Core Managed Instances is powered off. If set to `true`, the cache disk is kept. If set to `false` (the default), the cache disk is only created and kept while the AMI instance is powered on.
- `PersistOSDisk`: Controls whether to keep or discard the OS disk whenever the Amazon WorkSpaces Core Managed Instances is powered off. If set to `true`, the OS disk is kept. If set to `false` (the default), the OS disk is only created and kept while the AMI instance is powered on.

Perform the following steps in the PowerShell window to create an MCSIO enabled non-persistent catalog:

1. Open the PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a broker catalog and an identity pool.
4. Create the provisioning scheme. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$HostingUnitUid = '0xxxx1d9-bbfc-xxxf-bxxb-exxxxxe008b2'

$MasterImageVM = 'XDHyp:\HostingUnits\ctx-test\aws-apollo-non-
persistent-multi-mcsio-vda-win2022 (ami-0bf1810488acbxxxb).template'

$NetworkMap = @{ 'NetworkPath' = 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\10.0.128.0`/17
(vpc-0fa6e41d72507fxxx).network' }

$SecurityGroup = $( 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\private.securitygroup' )

$ServiceOffering = 'XDHyp:\HostingUnits\ctx-test\T3 Medium
Instance.serviceoffering'

$CustomProperties = 'WBCDiskStorageType,gp3:6000:250;PersistWBC,false'

$provScheme = New-ProvScheme -ProvisioningSchemeName $CatalogName
-HostingUnitUid $HostingUnitUid `

-IdentityPoolUid $acctPool.IdentityPoolUid -CleanOnBoot `

- MasterImageVM $MasterImageVM `

-NetworkMap $NetworkMap `

-ServiceOffering $ServiceOffering `

-SecurityGroup $SecurityGroup `

-CustomProperties $CustomProperties `

-UseWriteBackCache -WriteBackCacheDiskSize 16 -WriteBackCacheMemorySize
256
```

5. Add VMs to the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Improve boot performance with MCSIO

You can improve the boot performance of VMs if you enable MCSIO and set `PersistWBC` and `PersistOSDisk` custom properties as `true`. With such a setting, VMs can boot faster because they do not need to initialize a new cache disk or to recreate a root disk from their template.

Encrypt OS and ID disks

You can create a catalog of VMs with AWS KMS keys (Customer managed key and AWS managed key) that can be used to encrypt OS disk and Identity Disk (ID).

- AWS managed keys are automatically rotated every year.
- Customer managed keys are optional for automatic rotation and can be managed manually.

You can see the following AWS documents for more information on KMS keys:

- AWS KMS concepts
- How automatic key rotation works

For encryption of OS and ID disks, configure one of the following:

- Use a prepared image that is encrypted (for example, an AMI created from an instance or snapshot that contains an EBS root volume encrypted with KMS key)
- Use a machine profile source (VM or launch template) that contains an encrypted EBS root volume.

Limitations

Consider the following limitations:

- MCS currently supports only one disk on prepared image AMI.
- You cannot directly encrypt existing unencrypted EBS volumes or snapshots, or modify the KMS key of an existing encrypted volume. To do that, you must:

  a. Create a new snapshot of that volume.

  b. Create a new volume from that snapshot

  c. Encrypt the new volume.

See the following AWS documents:

- Encrypt unencrypted resources
- Limitations of automatic or default encryption of EBS volumes: Automatically encrypt existing and new Amazon EBS volumes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog with disk encryption

You can create an MCS machine catalog with disk encryption using:

- Prepared image (created using image management from master image that has encrypted disk)
- Machine profile

Considerations while using machine profile input are:

- The KMS key of the machine profile input takes precedence over the prepared image's KMS key.
- If no machine profile input is provided, then the KMS key of the prepared image AMI is used to encrypt the disks of catalog VMs.
- If the machine profile has Block Device Mappings present, then the block devices present in the prepared image template (AMI) and the machine profile must match. For example, if AMI has a device defined on `/dev/sda1`, then the Machine Profile must also have a device defined on `/dev/sda1`.
- If there is no key in the machine profile source and the prepared image is unencrypted, then disks of catalog VMs are not encrypted.
- When the prepared image is encrypted, a machine profile source VM or launch template must have an encrypted root volume to be considered a valid input.

Modify an existing catalog

You can modify an existing catalog using the `Set-ProvScheme` PowerShell command to have:

- A machine profile input with a volume containing a new KMS key.
- A prepared image created from the master image with encrypted AMI using image management.

Important considerations:

- The volumes of new VMs added to the catalog are encrypted with the new KMS key.
- To update the encryption settings when there is an existing machine profile, run `Set-ProvScheme` with a new machine profile.
- You cannot modify an existing catalog from having encrypted volumes to unencrypted volumes. You cannot do an image update from an encrypted prepared image AMI to an unencrypted prepared image AMI.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable NitroTPM and UEFI secure boot for VM instances

When creating a catalog, you can now select a prepared image (AMI) with NitroTPM and/or UEFI secure boot enabled. Accordingly, the provisioned VMs in the catalog are also enabled with NitroTPM and/or UEFI secure boot. This implementation ensures that the VMs are secured and trusted. For more information on NitroTPM and UEFI Secure Boot, see the Amazon documentation.

Limitations

- You can use both NitroTPM and Secure Boot currently in all AWS Regions (including the AWS GovCloud (US) Regions) except China.
- You cannot enable NitroTPM and UEFI secure boot on existing catalogs. If you want a catalog with NitroTPM and UEFI secure boot enabled, create a new catalog.

Key steps

1. Set up your AWS environment.
2. Create a connection to AWS.
3. Create a master image (AMI) enabled with NitroTPM and/or UEFI secure boot.
4. Create a prepared image from the master image. See Create a prepared image for Amazon WorkSpaces Core Managed Instances.
5. Create a machine catalog by selecting the prepared image with NitroTPM and UEFI secure boot enabled in Citrix Studio catalog creation menu or when creating a Provisioning Scheme using PowerShell commands.

VMs added to the created catalog have NitoTPM and UEFI secure boot enabled.

Create an AMI that supports NitroTPM and UEFI secure boot

1. You can create an AMI from a VM that has NitroTPM and/or UEFI secure boot enabled.
    a. Create the instance from using the AWS marketplace images. Example, search for `TPM-Windows_Server-2022-English-Full-Base on the aws-marketplace`.
    b. Download single or multi session VDA.
    c. Create an AMI from that VM.
2. Use the register-image command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
--boot-mode (string)

--tpm-support (string)
```

For more information, see register-image.

See the following AWS documents:

- Determine the supported boot modes of an EC2 instance type
- Requirements for using NitroTPM with Amazon EC2 instances/.

You can open a PowerShell window from the Delivery controller™ host to check if a specific:

- service offering supports NitroTPM or UEFI secure boot

```
(Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
Instance.serviceoffering”).AdditionalData.BootMode

(Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
Instance.serviceoffering”).AdditionalData.NitroTpmSupportVersions
```

- template supports NitroTPM or UEFI secure boot

```
(Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
-ResourceType “template -Id “ID”).AdditionalData.BootMode

(Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
-ResourceType “template -Id “ID”).AdditionalData.TpmSupport
```

Update the service offering of existing catalog

You can change the service offering of an existing catalog using `Set-ProvScheme`. The change applies to the newly added VMs. However, you get errors in the following scenarios:

AMIS BOOT MODE	AMI SUPPORTS NITRO TPM?	SERVICE OFFERING SUPPORTS NITROTPM AND UEFI SECURE BOOT?
UEFI	No	No

© 1997–2026 Citrix Systems, Inc. All rights reserved.

AMIS BOOT MODE	AMI SUPPORTS NITRO TPM?	SERVICE OFFERING SUPPORTS NITROTPM AND UEFI SECURE BOOT?
Legacy BIOS	Yes	No
UEFI	Yes	No
UEFI Preferred	Yes	No

Copy tags on VMs

You can copy tags on NICs, and disks (Identity disk, write back cache disk, and OS disk) that are specified in the machine profile to newly created VMs in an MCS machine catalog. You can specify these tags in any of the machine profile sources (AWS VM instance or AWS launch template version). This feature is applicable to persistent and non-persistent machine catalogs and VMs.

NOTE:

- On the AWS EC2 console, you cannot see the **Tag Network Interfaces** values under the **Launch Template Version Resource Tags**. However, you can run the PowerShell command `aws ec2 describe-launch-template-versions --launch-template-id lt-0bb652503d45dcbcd --versions 12` to see the tag specifications.
- If a machine profile source (VM or launch template version) has two network interfaces (eni-1 and eni-2), and eni-1 has tag t1 and eni-2 has tag t2, then the VM gets both the two network interfaces' tags.

Filter VM instances using PowerShell

An AWS VM instance that you use as a machine profile VM must be compatible for the machine catalog to create and function correctly. To list the AWS VM instances that can be used as machine profile input VMs, you can use the `Get-HypInventoryItem` command. The command can page and filter the inventory of VMs available on a hosting unit.

Pagination:

Get-HypInventoryItem supports two modes of pagination:

- Paging mode uses the `-MaxRecords` and `-Skip` parameters to return sets of items:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - `-MaxRecords`: The default is **1**. This controls how many items to return.
  - `-Skip`: The default is **0**. This controls how many items to skip from the absolute beginning (or absolute end) of the list in the hypervisor.

- Scrolling mode uses `-MaxRecords`, `-ForwardDirection`, and `-ContinuationToken` parameters to allow scrolling of the records:
  - `-ForwardDirection`: The default is **True**. This is used along with `-MaxRecords` to return either the next set of matching records or the previous set of matching records.
  - `-ContinuationToken`: The returns the items immediately after (or before if `ForwardDirection` is **false**) but not including the item given in the `ContinuationToken`.

Examples of pagination:

- To return a single record of the machine template with the lowest name. The `AdditionalData` field has the `TotalItemsCount` and the `TotalFilteredItemsCount`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template
```

- To return 10 records of the machine template with the lowest name:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 10 | select Name
```

- To return an array of records ending with the highest name:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ForwardDirection $False -MaxRecords 10 | select
Name
```

- To return an array of records starting at the machine template associated with the given `ContinuationToken`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ContinuationToken "ami-07xxxxxxxxx"
-MaxRecords 10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Filtering:

The following additional optional parameters are supported for filtering. You can combine these parameters with the pagination options.

- `-ContainsName "my_name"`: If the given string matches part of an AMI name, then the AMI is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -ContainName ‘apollo’ | select
Name
```

- `-Tags '{ "Key0": "Value0", "Key1": "Value1", "Key2": "Value2" }'`: If an AMI has at least one of these tags, it is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -Tags '{"opex owner": "Not
tagged"}' | select Name
```

NOTE:

Two tag values are supported. **Not Tagged** tag value matches items which do not have the given tag in their list of tags. **All values** tag value matches items which have the tag regardless of the value of the tag. Otherwise, the match happens only if the item has the tag and the value equals to what is given in the filter.

- `-Id "ami-0a2d913927e0352f3"`: If the AMI matches the given ID, it is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -Id ami-xxxxxxxxxxxxx
```

Filtering on AdditionalData parameter:

The `AdditionalData` filter parameter lists templates or VMs based on their capability, service offering, or any property which is in AdditionalData. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200).AdditionalData
```

You can also add a `-Warn` parameter to indicate the incompatible VMs. The VMs are included with an `AdditionalData` field named **Warning**. For example:

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200 -Template "ami-015xxxxxxxx"
-Warn $true).AdditionalData
```

Where to go next

- Manage catalogs created using prepared images

More information

- Image management
- For Amazon WorkSpaces Core GitHub PowerShell examples, see citrix-mcs-sdk-samples-Amazon WorkSpaces Core

Create catalogs using prepared images in AWS EC2

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

The key steps to create an MCS machine catalog using the prepared image are:

1. Create the image definition and the initial image versions.
2. Use the image version as a prepared image to create a catalog

Create an image definition and initial image version

Use Studio

To create an image definition and the initial image version, do the following:

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type** for the image definition.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed), a master image to use as a template for creating the image version, and a machine profile for capturing hardware properties from. Select a machine profile to capture hardware properties from a VM instance or launch template version.

   NOTE:

   - Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.
   - The Instance Metadata Service (IMDS) V1 and V2 are both supported.

4. On the **Machine Specification** page, select a machine size. The machine size of the machine profile (selected on the **Image** page) is selected by default.
5. On the **NICs** page, select or add NICs for the preparation image. For each NIC, select an associated VPC subnet.
6. On the **Version Description** page, enter a description for the initial image version created.
7. On the **Summary** page, check the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

CREATE IMAGE VERSIONS

Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

NOTE:

The hosting unit of all the image versions must be the same.

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.
2. On the **Image definition** page, you can change the hosting unit, and reselect the master image and machine profile for that image version.
3. If you want the configuration of the image version to be different from the initial configured image version, then configure the settings on the **Machine Specification** and **NICs** pages of the **Create Image Version** dialog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Add a description for the image version. Click **Finish**.

> **NOTE:**
>
> If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

Use PowerShell

The detailed PowerShell commands to create a prepared image version spec are as follows:

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

```
Test-ProvImageDefinitionNameAvailable -ImageDefinitionName <string[]>
```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

```
New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
-VdaSessionSupport MultiSession
```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command.

```
Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName test-conn
```

4. Create an image version using the `New-ProvImageVersion` command. For example,

```
New-ProvImageVersion -ImageDefinitionName image1 -Description "version
1"
```

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

```
Add-ProvImageVersionSpec -ImageDefinitionName  image1  -
ImageVersionNumber  1 -HostingUnitName aws -MasterImagePath "XDHyp:
\HostingUnits\aws\win10-2411-ami (ami-00123456789abcdef).template”"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

You can add only one master image version spec to one image version for a hosting unit.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command. The `SourceImageVersionSpecUid` parameter is derived from the `Add-ProvImageVersionSpec` command. For example,

```
New-ProvImageVersionSpec

-SourceImageVersionSpecUid  00000000-0000-0000-0000-00000000000

-MachineProfile 'XDHyp:\HostingUnits\aws\w2022-2411
(lt-00123456789abcdef).launchtemplate\lt-00123456789abcdef
(1).launchtemplateversion' -RunAsynchronously
```

Example of the complete set of Powershell commands to create image definition, image version, and prepared image version spec:

```
New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
-VdaSessionSupport MultiSession

Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName aws-CustomProperties $CustomProperties

$imageVersion = New-ProvImageVersion -ImageDefinitionName image1
-Description "version 1"

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid `

    -HostingUnitUid $hostingunit.HostingUnitUid `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    -MasterImagePath "XDHyp:\HostingUnits\aws\win10-2411-ami
(ami-00123456789abcdef).template”

New-ProvImageVersionSpec -MachineProfile 'XDHyp:
\HostingUnits\aws\w2022-2411
(lt-00123456789abcdef).launchtemplate\lt-00123456789abcdef
(1).launchtemplateversion' -SourceImageVersionSpecUid
$SourceImageVersionSpec.ImageVersionSpecUid

Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
00000000-0000-0000-0000-00000000000-HostingUnitName aws

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid | Where SourceImageVersionSpecUid-eq
$SourceImageVersionSpec.ImageVersionSpecUid
```

NOTE:

- All image version specs in an image definition must belong to the same hosting unit.
- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must have a machine profile.

Share prepared images across availability zones and regions

You can now share a single prepared image across different availability zones, tied to different hosting units, within the same AWS region or in different regions for your AWS EC2 environments. This lets you use one prepared image to create and update MCS machine catalogs in various availability zones and regions. When sharing across different AZs in different regions, the prepared image version will be copied from the original region to the destination regions.

You can maintain a single prepared image and use it to create and update machine catalogs across multiple availability zones and regions tied to different hosting units. This significantly reduces your image management overhead, ensures consistency across deployments, and streamlines the provisioning process. You can also seamlessly update existing machine catalogs with prepared images from a different availability zone or region.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use cases

- **Centralized Image Management:** You create a prepared image in one availability zone (for example, `us-east-1a`). You can then share this image to other availability zones like `us-east-1b` within the same `us-east-1` AWS region or `us-west-1a` in a different `us-west-1` region. This allows a single image to serve multiple hosting units and simplifies maintenance for you.
- **Efficient Catalog Creation and Updates:** You can use a prepared image created in `AZ 1` (for example, `us-east-1a`) to create new catalogs in `AZ 1`. After sharing this image to `AZ 2` (for example, `us-east-1b`), you can then use the shared image in `AZ 2` to create and update catalogs in `AZ 2`.
- **Cross-hosting unit and hosting connection deployments:** If your environment has multiple hosting units under the same or different AWS regions, you can efficiently share prepared images between these hosting units.

Limitations

Sharing within same AWS account: In the current implementation, you can share only within the same AWS account.

Important considerations

- **Deletion order:** To delete an original prepared image version specification, you must first delete all its shared image version specifications. Alternatively, you must delete the original and shared specifications simultaneously.
- **Image Version dependency:** When you remove an image version, you must first remove any sharing configurations that depend on that specific image version. Catalogs that you created from the original (unshared) image can remain intact.
- **Catalog back-portability:** You can update existing machine catalogs that you deployed before this feature's introduction. Use prepared images that you created in a different availability zone or region from where you originally deployed the catalog.
- **Complete deletion:** When you delete a prepared image, you can no longer use it in any availability zone where you shared or originally created it. Moreover, a prepared image version cannot be deleted until all catalog tied the prepared image version are deleted first.

Prerequisites

Before you configure or use this feature, ensure that you meet the following conditions:

- Your environment must be an AWS EC2 environment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You must configure multiple hosting units (each can be tied to different availability zones) and host connections (each can be tied to a different region) under the same AWS account.

Configure using PowerShell

You can share prepared images across availability zones tied to different hosting units using only PowerShell commands currently.

TO SHARE A PREPARED IMAGE

1. Ensure that you have the `ImageVersionSpecUid` of the prepared image you want to share. You can retrieve this using `Get-ProvImageVersionSpec` or similar `Get-` commands in PowerShell.
2. Determine the `HostingUnitName` of the availability zone (can be the same or a different region) where you want to make the prepared image available. This is the name of the hosting unit you configured for that specific availability zone.
3. **Run the `Add-ProvImageVersionSpecHostingUnit` command:** Use the following PowerShell command. Replace `<ImageVersionSpecUid>` with your image's Uid and `<targetHostingUnitName>` with the name of the hosting unit in the target availability zone that you want to share the image version specification to:

   ```
   Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
   <ImageVersionSpecUid> -HostingUnitName <targetHostingUnitName>
   ```

4. After successful execution, you can see the image's status in the Studio UI indicating that you shared it with the specified hosting unit.

TO REMOVE SHARING OF A PREPARED IMAGE

1. Ensure you have the `ImageVersionSpecUid` of the prepared image from which you want to remove sharing.
2. Determine the `HostingUnitName` of the availability zone from which you want to remove the shared image.
3. **Run the `Remove-ProvImageVersionSpecHostingUnit` command:** Use the following PowerShell command. Replace `<ImageVersionSpecUid>` with your image's Uid and `<targetHostingUnitName>` with the name of the hosting unit in the target availability zone that you want to remove the sharing of the image version specification from:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Remove-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid
<ImageVersionSpecUid> -HostingUnitName <targetHostingUnitName>
```

Create a machine catalog

Use Studio

CREATE A MACHINE CATALOG FROM THE IMAGES NODE

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node.

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Machine Management** and **Image** pages, the settings are pre-selected based on the selected image version. On the Image page, enter a note for the selected prepared image.
3. Complete the settings on the following pages.
4. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
5. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the Machine Catalogs node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears.
3. On the **Machine Type** page, select a machine type for the catalog, for example, **Multi-session OS**.
4. On the **Machine Management** page, select the following settings:
    a. Select **Machines that are power managed (for example, virtual machines or blade PCs)**.
    b. Select **Citrix provisioning technology**. Then, select **Citrix Machine Creation Services™**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. In the **Resources** field, select the resources (Availability Zone) that you configured while creating the host connection and click **Next**.

5. On the **Desktop experience** page, select either random or static desktop that you want users to have when they log in. If a static desktop is selected, further specify whether you want to save changes that the user makes on the local disk (persistent or non-persistent).
6. On the **Image** page, click **Select an image** to select a prepared image for the machine catalog. Select the prepared version that you created. Click the image version name. To view more details about the selected image version, click the version number, which is underlined. Click **Done**.

   The machine profile associated with the prepared image appears and its hardware properties (for example, instance type, tenancy type, network mappings, security groups, volume properties) are used to create machines in the catalogs. To change the machine profile source to another VM or launch template version click the edit button.
7. On the **Virtual Machines** page:

   a. Enter the number of VMs for the catalog.

   b. The default machine specification is displayed, which is based on the machine profile. To change it, select the edit icon and select a machine specification.
8. On the **NICs** page, select the NICs (or ENIs) for the VMs.
9. On the **Machine Identities** page, configure on-premises Active Directory or Microsoft Entra hybrid joined for the machines in the catalog by selecting the domain and creating new AD accounts for the VMs to be created in this machine catalog. The provisioned VMs are joined to the domain selected. Specify the account naming scheme for the new AD accounts to be created for the VMs. Click **Next**.
10. On the **Domain credentials** page, click **Enter credentials** to provide the credentials for the selected domain. Enter admin-level username and password when prompted. You can also use a service account if you have domain credentials already saved previously by following our product docs.
11. Click through the remaining pages until the **Summary** page. Enter a name for the machine catalog and select **Finish** to create the machine catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use PowerShell

CREATE A CATALOG USING A PREPARED IMAGE VERSION SPEC AND MACHINE PROFILE

- Create an MCS non-persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$true] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

- Create an MCS persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$false] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

Example of the complete set of Powershell commands to create a catalog:

```
$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" -Name "awscatalog" -PersistUserChanges
"Discard" -ProvisioningType "MCS" -Scope @() -SessionSupport
"MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain "domainname"
-IdentityPoolName "awscatalog" -IdentityType "ActiveDirectory"  -
NamingScheme "aws##" -NamingSchemeType "Numeric" -Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

$Task = New-ProvScheme -ProvisioningSchemeName awscatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
-HostingUnitName aws -IdentityPoolName awscatalog -CleanOnBoot -Scope @()
-SecurityGroup @() -MachineProfile 'XdHyp:\HostingUnits\cvad-test-
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
scalestress\us-east-1a.availabilityzone\machine-profile-instance i
(i-0xxxxxxxx).vm' -RunAsynchronously

Get-ProvTask -TaskId $Task.TaskId

$ProvScheme = Get-ProvScheme -ProvisioningSchemeName awscatalog

Set-BrokerCatalog -Name $Catalog.Name -ProvisioningSchemeId
$ProvScheme.ProvisioningSchemeUid
```

Where to go next

- Manage catalogs created using prepared images

More information

- Image management

Create catalogs using prepared images in Azure

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

The key steps to create an MCS machine catalog using the prepared image are:

1. Create the image definition and the initial image versions.
2. Use the image version as a prepared image to create a catalog

Use Studio

Create an image definition and initial image version

To create an image definition and the initial image version, do the following:

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type** for the image definition.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Select an existing resource group or create a new one for holding the image resources. To enable image sharing, select **Store image versions in Azure Compute Gallery** and then choose to create a new gallery or use an existing one to hold its image versions.
4. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed) and a master image to use as a template for creating the image version. You can select the **Use a machine profile** checkbox and select a machine profile.

   NOTE:

   - Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.
   - If you want to use a confidential VM type prepared image to create an MCS catalog, then create a prepared image using the confidential VM type master image and a confidential VM type machine profile. See Azure confidential VMs for information on preparing confidential VM type master images and machine profiles.

5. On the **Storage and Licenses Types** page, select the storage and license type to be used as part of the image preparation process.

   NOTE:

   If you select a machine profile on the **Image** page, the license type of the machine profile is pre-selected based on the profile setting.

6. On the **Machine Specification** page, select a machine size. If you select a machine profile on the **Image** page, the machine size of the machine profile is selected by default.
7. On the **NICs** page, select or add NICs for the preparation image. For each NIC, select an associated virtual network.
8. On the **Disk Settings** page, select the customer-managed encryption key (CMEK). If the machine profile doesn't have a CMEK but the master image has, it pre-selects the CMEK from the master image.
9. On the **Image Definition** page, if you enable **Store image versions in Azure Compute Gallery**, the **Image Share** page appears, where you can select the resources with which to share the image version.
10. On the **Version Description** page, enter a description for the initial image version created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

11. On the **Summary** page, check the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

Create image versions

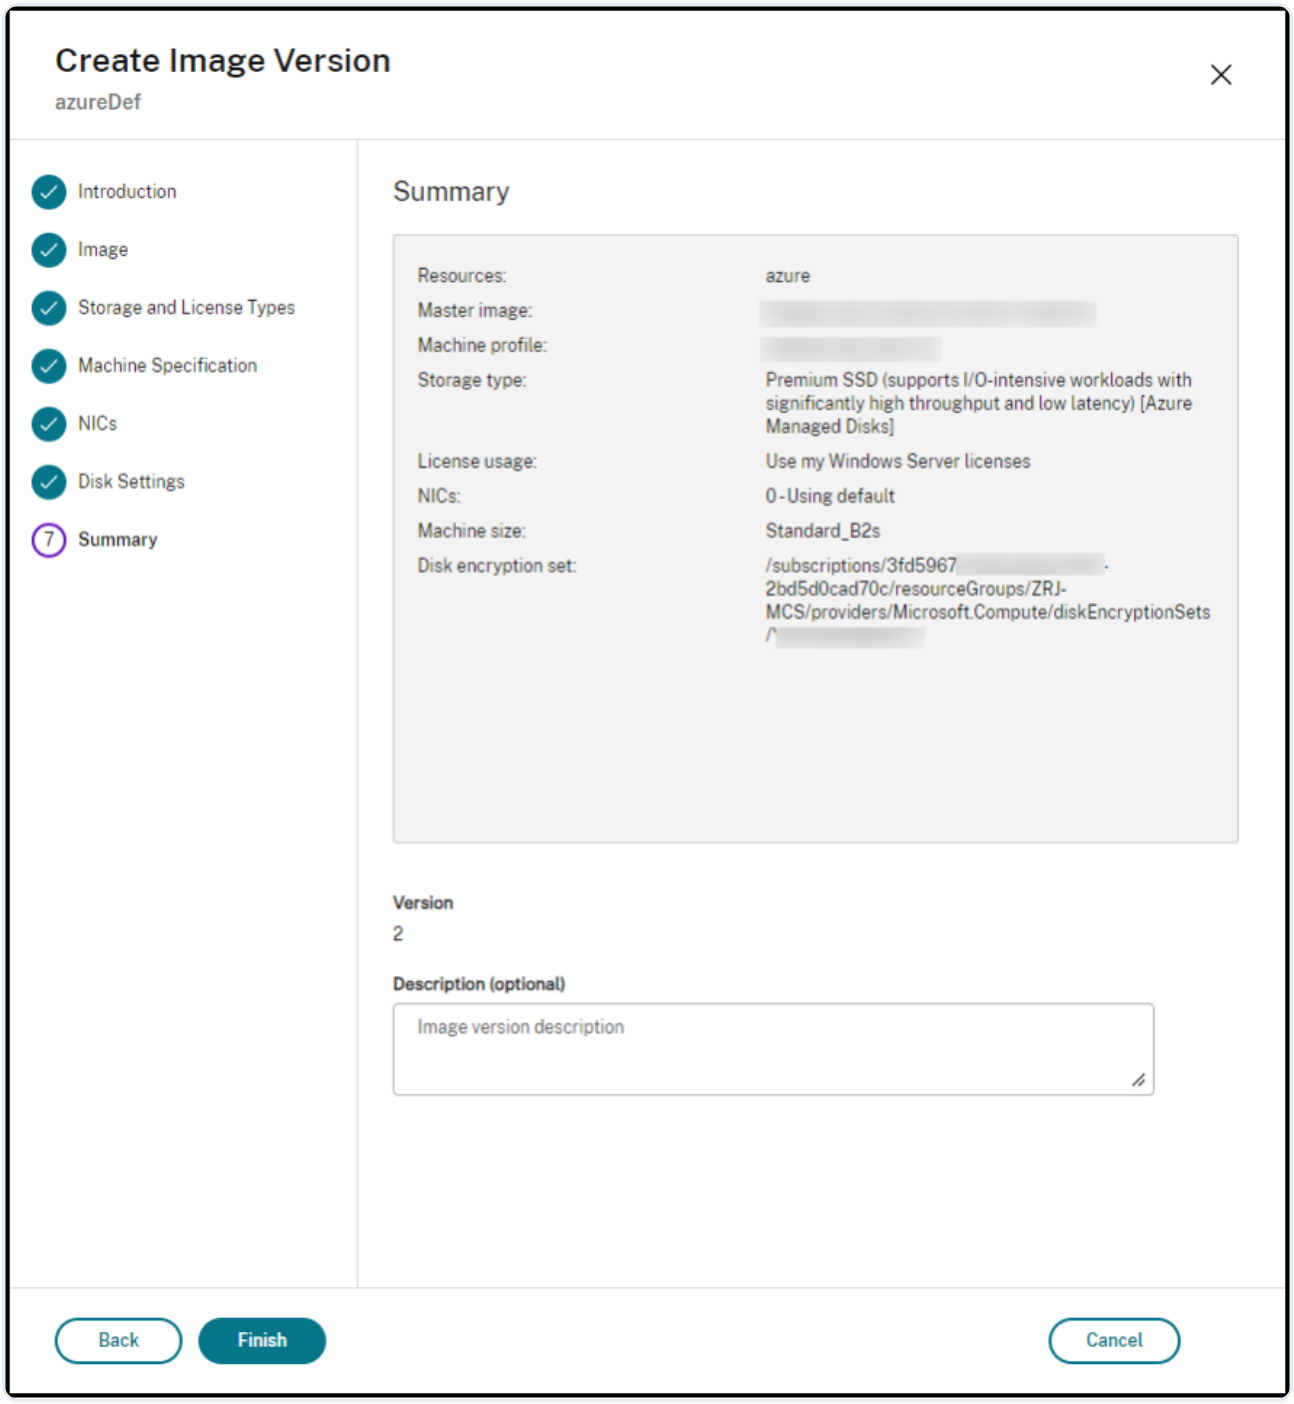


Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

> **NOTE:**
>
> The hosting unit of all the image versions must be the same.

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.
2. On the Image definition page, you can change the hosting unit, and reselect the master image and machine profile for that image version.
3. If you want the configuration of the image version to be different from the initial configured image version, then configure the settings on the **Storage and License Types**, **Machine Specification**, **NICs**, and **Disk Settings** pages of the **Create Image Version** dialog.
4. If the image definition enables **Store image versions in Azure Compute Gallery**, you can select the resources you want to share the image version with in the **Image Share** page.
5. Add a description for the image version. Click **Finish**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

Share prepared image

To share prepared images across different hosting units for Azure, follow these steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Right-click an image version and select **Manage Image Share**. All hosting units in your Azure environment appear. The resources where the image version is created from is disabled for any actions.
2. Select the hosting units with which you want to share the image and click **Save**. The **Share Status** column shows **In progress**.
3. Click the **Resources** tab for more details about the sharing status.

NOTE:

When the status of the image version sharing is in progress, the option to **Delete Image Version** or **Manage Image Share** is disabled.

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Desktop Experience** page, select the required desktop experience.
3. From the **Image** page to **Disk Settings** page, the settings are pre-selected based on the selected image version.
4. On the **Resource Group** page, you can choose to create a new resource group or use an existing resource group to place the resources of this catalog.
5. Complete the settings on the following pages.
6. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
7. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Machine Catalogs** node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears. Click **Next** through the **Introduction** and **Machine Type** pages.
3. On the **Machine Management** page, select the following settings:
    a. Select **Machines that are power managed (for example, virtual machines or blade PCs).**
    b. Select **Citrix provisioning technology**. Then, select **Citrix Machine Creation Services™**.
    c. In the **Resources** field, the resources belonging to different zones are listed. Select any Azure network resource and click **Next**.
4. On the **Image** page: For Prepared image type, follow the steps:
    a. Select **Prepared image**.
    b. Under the **Prepared image**, select an image version of an image definition. If needed, add a note for the selected prepared image version.
    c. Click the image version name. To view more details about the selected image version, click the version number, which is underlined.
    d. If the selected image version is configured with a machine profile, select a machine profile. If the selected image version is not configured with a machine profile, you cannot choose to use a machine profile.
5. Configure the settings on the following pages.
6. On the **Disk Settings** page, if the selected prepared image uses a disk encryption set, then you cannot remove the encryption set, but you can change the key to another encryption key.
7. On the **Resource Group** page, you can choose to create a new resource group or use an existing resource group to place the resources of this catalog.
8. Complete the settings on the following pages.
9. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.

Use PowerShell

Create a prepared image

The detailed PowerShell commands to create a prepared image version spec are as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

   ```
   Test-ProvImageDefinitionNameAvailable -ImageDefinitionName <string[]>
   ```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

   ```
   New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
   -VdaSessionSupport MultiSession
   ```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command.

   The `CustomProperties` for `Add-ProvImageDefinitionConnection` can include the following. If you do not use the parameters, then default values are used.

   - `ResourceGroups`: The resource group that has the base disks.
   - `UseSharedImageGallery`: Indicator for the type of base disks. Use `true` for ACG (image sharing) and `false` for snapshot.
   - `ImageGallery`: The gallery name when the base disk is an ACG image version.

   For example,

   - In case of snapshot and customer provided resource group:

     ```
     $CustomerOwnRsourceGroupProperties = @"

     <CustomProperties xmlns="http:// schemas.citrix.com/2014/xd/
     machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
     instance">

     <Property xsi:type="StringProperty" Name="ResourceGroups"
     Value="yangj_image" />

     </CustomProperties>

     "@
     ```

   - In case of ACG and customer provided resource group and image gallery:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$CustomerOwnAllProperties = @"

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseSharedImageGallery"
Value="true" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="rg" />

<Property xsi:type="StringProperty" Name="ImageGallery"
Value="gallery" />

</CustomProperties>

"@
```

- In case of ACG and customer provided resource group only:

```
$CustomerOwnResourceGroupProperties = @"

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseSharedImageGallery"
Value="true" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="rg" />

</CustomProperties>

"@
```

- In case of ACG and resource group and image gallery managed by Citrix:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$CustomerOwnResourceGroupNothingProperties = @"

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseSharedImageGallery"
Value="true" />

</CustomProperties>

"@
```

```
Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName Azure28 [-CustomProperties $CustomProperties]
```

4. Create an image version using the `New-ProvImageVersion` command. For example,

```
New-ProvImageVersion -ImageDefinitionName image1 -Description "version
1"
```

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

```
Add-ProvImageVersionSpec -ImageDefinitionName  image1  -
ImageVersionNumber  1 -HostingUnitName azure -MasterImagePath "XDHyp:
\HostingUnits\azure\image.folder\azureresourcegroup.resourcegroup\win20
22-snapshot.snapshot"
```

NOTE:

You can add only one master image version spec to one image version for a hosting unit.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command.

   The CustomProperties for `New-ProvImageVersionSpec` can include the following. If you do not use the parameters, then default values are used:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `PreparedImageStorageType`: The storage type to use for the prepared image. Defaults to `Standard_LRS`, can also be `Premium_LRS` or `Standard_ZRS`. `Standard_ZRS` provides zone redundancy for the image.

```
New-ProvImageVersionSpec

-SourceImageVersionSpecUid  c6e7384c-b2f8-46d6-9519-29a2c57ed3cb

-NetworkMapping @{"0"="XDHyp:
\HostingUnits\azure\virtualprivatecloud.folder\azureresourcegroup.resou
rcegroup\azure-vnet-eastus.virtualprivatecloud\dev.network"}

-ServiceOffering"XDHyp:
\HostingUnits\azure\serviceoffering.folder\Standard_B2ms.serviceofferin
g" -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"></CustomProperties>"
-RunAsynchronously
```

7. You can also share a prepared image version spec with another hosting unit in all hosting connections by using the `Add-ProvImageVersionSpecHostingUnit` command.

   The CustomProperties for `Add-ProvImageVersionSpecHostingUnit` can include the following. If you do not use the parameters, then values from the source prepared image spec are used:

   - `PreparedImageStorageType`: The storage type to use for the prepared image.

```
Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx
-HostingUnitName AzureWest
```

NOTE:

One hosting unit and preparation type can have only one prepared instance.

Example of the complete set of Powershell commands to create image definition, image version, and prepared image version spec:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-ProvImageDefinition -ImageDefinitionName image1 -OsType Windows
-VdaSessionSupport MultiSession

$ImageDefinitionCustomProperties = @" <CustomProperties xmlns="http://
schemas.citrix.com/2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/
2001/XMLSchema-instance"> <Property xsi:type="StringProperty"
Name="UseSharedImageGallery" Value="true" /> <Property
xsi:type="StringProperty" Name="ResourceGroups" Value="rg" /> <Property
xsi:type="StringProperty" Name="ImageGallery" Value="gallery" /> </
CustomProperties> "@

Add-ProvImageDefinitionConnection -ImageDefinitionName image1
-HypervisorConnectionName Azure28 -CustomProperties
$ImageDefinitionCustomProperties

$imageVersion = New-ProvImageVersion -ImageDefinitionName image1
-Description "version 1"

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid ` -HostingUnitUid
$hostingunit.HostingUnitUid ` -MasterImagePath "XDHyp:
\HostingUnits\azure28\image.folder\abc.resourcegroup\def-
snapshot.snapshot"

$ImageVersionSpecCustomProperties = @'

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="PreparedImageStorageType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client" />

</CustomProperties>

'@

New-ProvImageVersionSpec -NetworkMapping @{"0" = "XDHyp:
\HostingUnits\azure28\virtualprivatecloud.folder\East
US.region\virtualprivatecloud.folder\studio-mcs-
infrastructure.resourcegroup\studio-mcs-vnet-
eastus.virtualprivatecloud\mcs-dev.network" } -CustomProperties
$ImageVersionSpecCustomProperties -ServiceOffering "XDHyp:
\HostingUnits\azure28\serviceoffering.folder\Standard_B2s.serviceoffering"
-SourceImageVersionSpecUid $SourceImageVersionSpec.ImageVersionSpecUid

$TargetCustomProperties = @'

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="PreparedImageStorageType"
Value="Standard_ZRS" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>

'@

Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx
-HostingUnitName AzureWest –TargetCustomProperties
$TargetCustomProperties

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid | Where SourceImageVersionSpecUid-eq
$SourceImageVersionSpec.ImageVersionSpecUid
```

NOTE:

- All image version specs in an image definition must belong to the same hosting unit.
- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must either have a machine profile or none of the image version specs must have a machine profile.

Create a catalog using a prepared image version spec

Create an MCS machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-VMCpuCount <int>]
[-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping <Hashtable>] [-
CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-ServiceOffering
<string>] [-SecurityGroup <string[]>] [-TenancyType <string>] [-
MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<ProvisioningSchemeType>]

[-ImageAssignmentNote <string>]
```

Or,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitName <string> -IdentityPoolName <string> [-VMCpuCount
<int>] [-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping
<Hashtable>] [-CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-
ServiceOffering <string>] [-SecurityGroup <string[]>] [-TenancyType
<string>] [-MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
<ProvisioningSchemeType>]

[-ImageAssignmentNote <string>]
```

If you want to use an ACG image version spec, then set `UseSharedImageGallery` as `true`. For example,

```
$provSchemeCustomProperties= @"

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

    <Property xsi:type="StringProperty" Name="UseSharedImageGallery"
Value="true" />

    <Property xsi:type="StringProperty" Name="StorageAccountType"
Value="StandardSSD_LRS" />

</CustomProperties>

"@

New-ProvScheme -ProvisioningSchemeName assignimage -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid `

    -HostingUnitUid $hostingunit.HostingUnitUid `

    -IdentityPoolUid $IdentityPool.IdentityPoolUid `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    -CleanOnBoot -Scope @() -SecurityGroup @() `

    -ServiceOffering "XDHyp:
\HostingUnits\azure28\serviceoffering.folder\Standard_B2s.serviceoffering"
`

    -NetworkMapping @{"0"="XDHyp:
\HostingUnits\azure28\virtualprivatecloud.folder\East
US.region\virtualprivatecloud.folder\studio-mcs-
infrastructure.resourcegroup\studio-mcs-vnet-
eastus.virtualprivatecloud\mcs-dev.network"} `

    -CustomProperties $provSchemeCustomProperties
```

Example of the complete set of Powershell commands to create a catalog:

```
$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" -Name "azurecatalog" -PersistUserChanges
"Discard" -ProvisioningType "MCS" -Scope @() -SessionSupport
"MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain "azure.local"
-IdentityPoolName "azurecatalog" -IdentityType "ActiveDirectory"  -
NamingScheme "azure##" -NamingSchemeType "Numeric" -Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

$Task = New-ProvScheme -ProvisioningSchemeName azurecatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
-HostingUnitName azure -IdentityPoolName azurecatalog -CleanOnBoot -Scope
@() -SecurityGroup @() -ServiceOffering "XDHyp:
\HostingUnits\azure\serviceoffering.folder\Standard_B2s.serviceoffering"
-NetworkMapping @{"0"="XDHyp:
\HostingUnits\azure\virtualprivatecloud.folder\azureresourcegroup.resource
group\azure-vnet-eastus.virtualprivatecloud\dev.network"}
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`">    <Property xsi:type="StringProperty"
Name="UseSharedImageGallery" Value="true" /><Property
xsi:type=`"StringProperty`" Name=`"StorageAccountType`"
Value=`"StandardSSD_LRS`" /></CustomProperties>" -RunAsynchronously

Get-ProvTask -TaskId $Task.TaskId

$ProvScheme = Get-ProvScheme -ProvisioningSchemeName azurecatalog

Set-BrokerCatalog -Name $Catalog.Name -ProvisioningSchemeId
$ProvScheme.ProvisioningSchemeUid
```

Create Microsoft Entra joined and Microsoft Intune enrolled catalogs with prepared images

You can now use prepared images to create Microsoft Entra joined and Microsoft Intune enrolled catalogs. This feature is applicable to single and multi-session persistent and non-persistent type MCS catalogs. This implementation significantly reduces the storage and time costs, and simplifies the VM deployment and image update process.

EXAMPLES

- To create a Microsoft Entra catalog using a prepared image.

  ```
  New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
  <preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid>
  -IdentityPoolUid <IdentityPoolUid> [-CleanOnBoot] -NetworkMapping
  @{"0"="XDHyp:
  \HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.fol
  der\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<s
  unNetName>.network"} -ServiceOffering <serviceofferingPath> [-
  MachineProfile <machineProfilePath>] [-CustomProperties <>]
  ```

- To create a Microsoft Entra catalog enrolled in Microsoft Intune using a prepared image:

  ```
  New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
  <preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid>
  -IdentityPoolUid <IdentityPoolUid> [-CleanOnBoot] -NetworkMapping
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
@{"0"="XDHyp:
\HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.fol
der\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<s
unNetName>.network"} -ServiceOffering <serviceofferingPath> [-
MachineProfile <machineProfilePath>] [-CustomProperties <>]
```

Share prepared images across Azure subscriptions or tenants

To share a prepared image across subscriptions or tenants on the Azure platform, follow this example:

- **Service principal**: SPN 1
- **Subscription**: Subscription 1
- **Tenant**: Tenant 1

You want to share this image with:

- **Service principal**: SPN 2
- **Subscription**: Subscription 2
- **Tenant**: Tenant 2 (can be the same as Tenant 1)

To successfully share and use the image, you must grant SPN 2 the following permissions in **Subscription 1**—at the gallery, resource group, or subscription scope:

- `Microsoft.Resources/subscriptions/read`
- `Microsoft.Compute/galleries/images/read`
- `Microsoft.Compute/galleries/images/versions/read`

> **NOTE:**
>
> Any service principal that has any permission on a subscription or resource automatically inherits the `Microsoft.Resources/subscriptions/read` permission.

Alternatively, assign the **Compute Gallery Image Reader** built-in role to **SPN 2**.

For step-by-step guidance, see this Microsoft article.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Share encrypted prepared image across regions, subscriptions, and tenants

Azure Compute Gallery (ACG) images can be encrypted with a Disk Encryption Set (DES). With ACG sharing feature, you can share an encrypted prepared image across regions, subscriptions and tenants for Azure. The target resource needs to pick a DES in its region from the subscription where the prepared image belongs. You can thereafter create a machine catalog in the resource where the encrypted prepared image is shared.

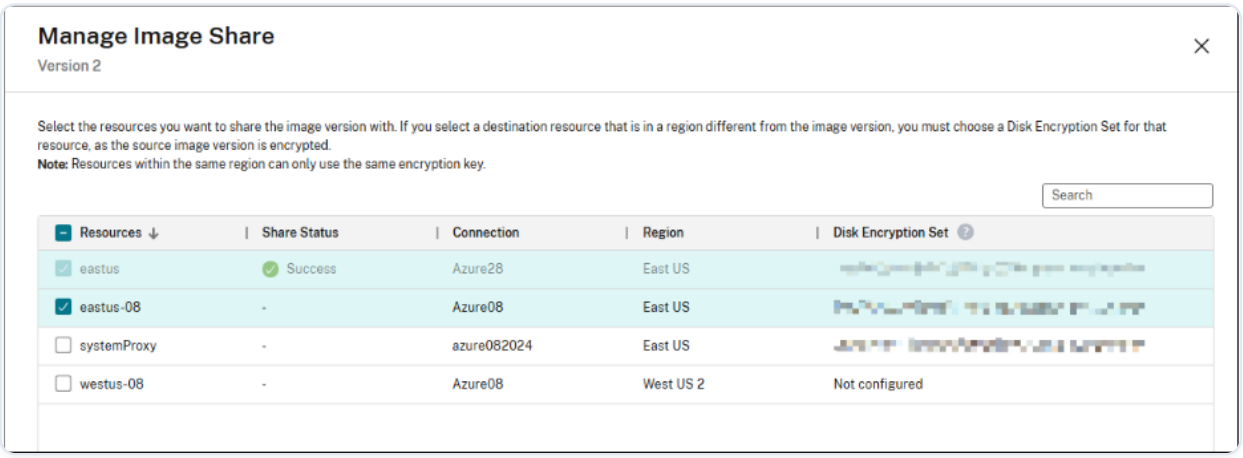
The key steps to share an encrypted prepared image are:

1. Create Disk Encryption Set (DES) in each region: See the microsoft documentation Use the Azure portal to enable server-side encryption with customer-managed keys for managed disks.
2. Create an image definition for the Azure host connection and image versions in Azure Compute Gallery (ACG) and specify the DES to encrypt the prepared image : See Create an image definition and initial image version.
3. Share the encrypted prepared image across regions, subscriptions, and tenants: You can use Studio or PowerShell commands.

You can now create a machine catalog in the resource where the encrypted prepared image is shared. For more information on creating the catalog, see Create a prepared image machine catalog in Azure.

NOTE:

- If the primary region is not encrypted, the shared regions also cannot have DES.
- If two host units target the same region, they have the same DES.



Share the encrypted image across regions, subscriptions, and tenants using Studio

1. Right-click an image version and select **Manage Image Share**. The resources with region and disk encryption set are listed.
2. Select the resources that you want to share with the image version. The resources where the image version is created from is disabled for any actions. Select a DES from the drop-down menu if DES is not configured for a resource.

   NOTE:

   Resources within the same region must use the same encryption key.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Click **Save**.
4. Click the **Resources** tab for more details about the sharing status.

NOTE:

- When the status of the image version sharing is in progress, the option to **Delete Image Version** or **Manage Image Share** is disabled.
- When a resource is successfully shared, the DES is not editable.

Share the encrypted image across regions, subscriptions, and tenants using PowerShell

Use the command `Add-ProvImageVersionSpecHostingUnit` and add the parameter `CustomProperties`. In `CustomProperties`, configure the DES for the target resource. When sharing the prepared encrypted image, each resource picks a DES in its region from the subscription which the prepared image belongs to. For example,

```
$CustomProperties = "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`">"

 "<Property xsi:type=`"StringProperty`" Name=`"DiskEncryptionSetId`"
Value=`"/subscriptions/xxxxxx-7152-46c4-b061-xxxxxx70c/resourceGroups/
resourcegroup1/providers/Microsoft.Compute/diskEncryptionSets/desid1`" /
>"+

 "</CustomProperties>"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid <Guid>
-HostingUnitUid <Guid> -CustomProperties $CustomProperties
```

-IdentityPoolName $IdentityPoolName -CleanOnBoot -Scope @() -SecurityGroup
@() -NetworkMapping $NetworkMapping -CustomProperties $CustomProperties
-RunAsynchronously
```

More information

- Image management

Where to go next

- Manage catalogs created using prepared images

Create catalogs using prepared images in Red Hat OpenShift

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

The key steps to create an MCS machine catalog using the prepared image are:

1. Create the image definition and the initial image versions.
2. Use the image version as a prepared image to create a catalog

Use Studio

Create an image definition and initial image version

To create an image definition and the initial image version, do the following:

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type** for the image definition.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed) and a master image to use as a template for creating the image version. You can select the **Use a machine profile** checkbox and select a machine profile.

   NOTE:

   Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.

4. On the **Machine Specification** page, select a machine size. If you select a machine profile, then you can see the Virtual CPU count derived from the machine profile and it is unchangeable. If you do not select a machine profile, then you can see only the memory size that is derived from the master image.
5. On the **NICs** page, select NICs for the preparation image. For each NIC, select an associated virtual network. The NIC associated with the hosting unit is selected by default.
6. On the **Version Description** page, enter a description for the initial image version created.
7. On the **Summary** page, check the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

Create image versions

Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.
2. On the **Image** page, you can reselect the master image for this image version.
3. If you want the configuration of the image version to be different from the initial configured image version, then configure the settings on the **Machine Specification** and **NICs** pages of the **Create Image Version** dialog.
4. Add a description for the image version. Click **Finish**.

NOTE:

If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. Click **Next** on the **Machine Management** page.
3. On the **Desktop Experience** page, select the required desktop experience.
4. From the **Image** page to **Virtual Machines** page, the settings are pre-selected based on the selected image version.
5. Complete the settings on the following pages.
6. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
7. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Machine Catalogs** node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears. Click **Next** through the **Introduction**, **Machine Type**, and **Machine Management** pages.
3. On the **Image** page:
    a. Select **Prepared image**.
    b. Under the **Prepared image**, select an image version of an image definition.
    c. Click the image version name. To view more details about the selected image version, click the version number, which is underlined.
4. Configure the settings on the following pages.
5. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use PowerShell

Create a prepared image

The detailed PowerShell commands to create a prepared image version spec are as follows:

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

   ```
   Test-ProvImageDefinitionNameAvailable -ImageDefinitionName <string[]>
   ```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

   ```
   New-ProvImageDefinition -ImageDefinitionName image2 -OsType Windows
   -VdaSessionSupport SingleSession
   ```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command. For example,

   ```
   Add-ProvImageDefinitionConnection -ImageDefinitionUid
   $imageDef.ImageDefinitionUid -HypervisorConnectionUid
   "00000000-0000-0000-0000-000000000000"
   ```

4. Create an image version using the `New-ProvImageVersion` command. For example,

   ```
   New-ProvImageVersion -ImageDefinitionName
   $ImageDefintion.ImageDefinitionName -Description "version 1"
   ```

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

   ```
   Add-ProvImageVersionSpec -MasterImagePath "XDHyp:
   \HostingUnits\YourHostingUnitName\YourMasterImage.vm" -HostingUnitUid
   "11111111-1111-1111-1111-111111111111" -ImageVersionUid
   $imageVersion.ImageVersionUid
   ```

   NOTE:

   You can add only one master image version spec to one image version for a hosting unit.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command. For example,

```
New-ProvImageVersionSpec -SourceImageVersionSpecUid
$masterImageVersionSpec.ImageVersionSpecUid -NetworkMapping @{"1" =
"XDHyp:
\HostingUnits\YourHostingUnitName\YourNamespaceName.namespace\YourNetwo
rkAttachmentDefinition.network" }
```

Example of the complete set of Powershell commands to create image definition, image version, and prepared image version spec:

```
$imageDef = New-ProvImageDefinition -ImageDefinitionName "ImageDefinition"
-OsType "Windows" -VDASessionSupport "MultiSession"

$task = Add-ProvImageDefinitionConnection -ImageDefinitionUid
$imageDef.ImageDefinitionUid -HypervisorConnectionUid
"00000000-0000-0000-0000-000000000000"

$imageVersion = New-ProvImageVersion -ImageDefinitionName
"ImageDefinition"

$masterImageVersionSpec = Add-ProvImageVersionSpec -MasterImagePath
"XDHyp:\HostingUnits\YourHostingUnitName\YourMasterImage.vm"
-HostingUnitUid "11111111-1111-1111-1111-111111111111" -ImageVersionUid
$imageVersion.ImageVersionUid

$newProvImageVersionSpecResult = New-ProvImageVersionSpec
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-SourceImageVersionSpecUid $masterImageVersionSpec.ImageVersionSpecUid
-NetworkMapping @{"1" = "XDHyp:
\HostingUnits\YourHostingUnitName\YourNamespaceName.namespace\YourNetworkA
ttachmentDefinition.network" }
```

NOTE:

- All image version specs in an image definition must belong to the same hosting unit.
- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must either have a machine profile or none of the image version specs must have a machine profile.

Create a catalog using a prepared image version spec

Create an MCS machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
$getProvImageVersionSpecResult = Get-ProvImageVersionSpec
-ImageVersionSpecUid $newProvImageVersionSpecResult.ImageVersionSpecUid

New-ProvScheme -ImageVersionSpecUid
$newProvImageVersionSpecResult.ImageVersionSpecUid -ProvisioningSchemeName
"ProvSchemeImageDecoupling" -HostingUnitName "YourHostingUnitName"
-IdentityPoolName "YourIdentityPoolName" -NetworkMapping @{"1" = "XDHyp:
\HostingUnits\YourHostingUnitName\YourNamespaceName.namespace\YourNetworkA
ttachmentDefinition.network"}
```

Create catalogs using prepared images in VMware

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

The key steps to create an MCS machine catalog using the prepared image are:

1. Create the image definition and the initial image versions.
2. Use the image version as a prepared image to create a catalog

Use Studio

Create an image definition and initial image version

To create an image definition and the initial image version, do the following:

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type** for the image definition and **Connection** for the image definition.
3. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed) and a master image to use as a template for creating the image version. You can select the **Use a machine profile** checkbox and select a machine profile.

   NOTE:

   Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.

4. On the **Machine Specification** page, select a machine size. If you select a machine profile, then you can see the Virtual CPU count derived from the machine profile and it is unchangeable. If you do not select a machine profile, then you can see only the memory size that is derived from the master image.
5. On the **NICs** page, select or add NICs for the preparation image. For each NIC, select an associated virtual network. If you do not select a machine profile, then the NIC associated with the master image is selected by default. If you select a machine profile, then the NICs are derived from the machine profile and the count is unchangeable.
6. On the **Version Description** page, enter a description for the initial image version created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. On the **Summary** page, check the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

Create image versions

Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.
2. On the **Image** page, you can change the hosting unit within the same hosting connection, and reselect the master image and machine profile for that image version.
3. If you want the configuration of the image version to be different from the initial configured image version, then configure the settings on the **Machine Specification** and **NICs** pages of the **Create Image Version** dialog.
4. Add a description for the image version. Click **Finish**.

NOTE:

If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

Share prepared images

PREREQUISITES

Share prepared images replicates images across vCenter Server instances using cold migration. The following prerequisites apply to the hosting units belonging to different hosting connections:

- Cloud Connector to target vCenter Connectivity: The source Resource Location Cloud Connector must have HTTPS access (port 443) to the target vCenter. Replication fails if the source connector can't establish a vSphere SDK connection to coordinate the operation.

SOURCE	DESTINATION	PORT	PROTOCOL	PURPOSE
Source Cloud Connector	Target vCenter Server	443	TCP	vSphere SDK management connection

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Cold migration between vCenter Servers: Cold migration requires cross-vCenter migration support in both environments.
  - Both vCenter Servers must run vSphere 7.0 or later (vSphere 8.0+ recommended).
  - Enhanced linked mode is not required.

  Port requirement: Ensure the following ports are open for migration:

SOURCE	DESTINATION	PORT	PROTOCOL	PURPOSE
Source vCenter Server	Target vCenter Server	443	TCP	API communication between vCenters
Source ESXi Host	Target ESXi Host	902	TCP	NFC (Network File Copy) data transfer
Source ESXi Host	Target ESXi Host	8000	TCP	vMotion traffic

NOTE:

Ports must be open bidirectionally. Migration primarily uses NFC (port 902) for data and port 443 for management. Port 8000 may be used depending on the path. The source vCenter must validate the target's SSL certificate thumbprint during the clone operation.

VMkernel adapter configuration:

ESXI HOST	REQUIRED SERVICE
Source ESXi Host	Provisioning or Management
Target ESXi Host	Same service as source (Provisioning or Management)

Both sides must enable the same traffic service (Provisioning or Management) on VMkernel adapters. Mismatches cause migration failure.

Verify in the vSphere Client under **Host > Configure > Networking > VMkernel adapters**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Known limitation: Custom storage policies are not preserved during cross-vCenter replication. The default storage policy of the target datastore is applied.

- vTPM-enabled machine profile: Key provider compatibility. For profiles with vTPM, both vCenter Servers must access a compatible Key Provider.

REQUIREMENT	DETAIL
Same Key Provider access	The destination vCenter must have access to the same key provider as the source, or use the Native Key Provider as a bridge
Key material	For external KMS: both vCenters must be enrolled to the same KMS cluster (or a KMS cluster that shares key material)
Native Key Provider	Configure a Native Key Provider on both vCenter Servers. Each vCenter's Native Key Provider is independent, but vSphere accepts this combination for cross-vCenter operations. The Native Key Provider can also act as a bridge if the source and destination do not share an external KMS. The Native Key Provider must be backed up on both vCenters before use.

NOTE:

The Native Key Provider is the simplest option. Configure and back it up on both servers. If using external KMS, ensure both vCenters share the same cluster or key material. Verify Key Provider configuration in the **vSphere Client under vCenter > Configure > Security > Key Providers before enabling image sharing for vTPM-enabled catalogs**.

SHARE PREPARED IMAGES ACROSS DIFFERENT HOST UNITS

To share prepared images across different host units, follow these steps:

1. Right-click an image version and select **Manage Image Share**. All hosting units in your VMware environment appear. The resources where the image version is created from is disabled for any actions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Select the hosting units with which you want to share the image and click **Save**. The **Share Status** column shows **In progress**.
3. Click the **Resources** tab at the bottom for more details about the sharing status.

NOTE:

When the status of the image version sharing is in progress, the option to **Delete Image Version** or **Manage Image Share** is disabled. To share an image with a hosting unit in a different VMware connection, ensure the following requirements are met:

- The two connections can communicate with each other. The hypervisor versions are consistent.
- The Provisioning services are enabled on management VMkernel adapters of both the source and target hosts. The **Host > Configure > Networking > VMkernel adapters** is the navigation path in the VMware vSphere Client.

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Desktop Experience** page, select the required desktop experience.
3. From the **Image** page to **Virtual Machines** page, the settings are pre-selected based on the selected image version.
4. Complete the settings on the following pages.
5. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
6. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Machine Catalogs** node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears. Click **Next** through the **Introduction**, **Machine Type**, and **Machine Management** pages.
3. On the **Image** page:
   a. Select **Prepared image**.
   b. Under the **Prepared image**, select an image version of an image definition. If needed, add a note for the selected prepared image version.
   c. Click the image version name. To view more details about the selected image version, click the version number, which is underlined.
   d. If the selected image version is configured with a machine profile, select a machine profile. If the selected image version is not configured with a machine profile, you cannot choose to use a machine profile.
4. Configure the settings on the following pages.
5. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.

Use PowerShell

Create a prepared image

The detailed PowerShell commands to create a prepared image version spec are as follows:

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

```
Test-ProvImageDefinitionNameAvailable -ImageDefinitionName <string[]>
```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

```
New-ProvImageDefinition -ImageDefinitionName image2 -OsType Windows
-VdaSessionSupport SingleSession
```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command. For example,

```
Add-ProvImageDefinitionConnection -ImageDefinitionName image2
-HypervisorConnectionName VMware
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Create an image version using the `New-ProvImageVersion` command. For example,

```
New-ProvImageVersion -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -Description "version 1"
```

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

```
$MasterImagePath = "XDHyp:\HostingUnits\vmware\win10-master.vm\win10-
master-snap.snapshot"

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageDefinitionName
$ImageVersion.ImageDefinitionName -ImageVersionNumber
$ImageVersion.ImageVersionNumber -HostingUnitName vmware
-MasterImagePath $MasterImagePath
```

> **NOTE:**
>
> You can add only one master image version spec to one image version for a hosting unit.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command. For example,

```
New-ProvImageVersionSpec -SourceImageVersionSpecUid
 $SourceImageVersionSpec.ImageVersionSpecUid -NetworkMapping
@{"0"="XDHyp:\HostingUnits\vmware\\DSwitch-VM Network.network"}
-VMCpuCount 2 -VMMemoryMB 4096 -RunAsynchronously
```

7. You can also share a prepared image version spec with another hosting unit within the same hosting connection using the `Add-ProvImageVersionSpecHostingUnit` command. For example,

```
Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx
-HostingUnitName VMwareabc
```

Example of the complete set of Powershell commands to create image definition, image version, and prepared image version spec:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-ProvImageDefinition -ImageDefinitionName image2 -OsType Windows
-VdaSessionSupport Single

Add-ProvImageDefinitionConnection -ImageDefinitionName image2
-HypervisorConnectionName VMware

$imageVersion = New-ProvImageVersion -ImageDefinitionName image2

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid `

    -HostingUnitUid $hostingunit.HostingUnitUid `

    -MasterImagePath "XDHyp:\HostingUnits\vmware\shuaiz-win10-
master.vm\shuaiz-win10-master-snap.snapshot"

New-ProvImageVersionSpec -SourceImageVersionSpecUid
$SourceImageVersionSpec.ImageVersionSpecUid `

    -NetworkMapping @{"0"="XDHyp:\HostingUnits\vmware\\DSwitch-
VMNetwork.network"} `

    -VMCpuCount 2 -VMMemoryMB 4096

Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx
-HostingUnitName VMwareabc

 $PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageVersionUid
$imageVersion.ImageVersionUid | Where SourceImageVersionSpecUid-eq
$SourceImageVersionSpec.ImageVersionSpecUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- All image version specs in an image definition must belong to the same hosting unit.
- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must either have a machine profile or none of the image version specs must have a machine profile.

Create a catalog using a prepared image version spec

Create an MCS machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-VMCpuCount <int>]
[-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping <Hashtable>] [-
CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-ServiceOffering
<string>] [-SecurityGroup <string[]>] [-TenancyType <string>] [-
MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
<ProvisioningSchemeType>]

[-ImageAssignmentNote <string>]
```

Or,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitName <string> -IdentityPoolName <string> [-VMCpuCount
<int>] [-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping
<Hashtable>] [-CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-
ServiceOffering <string>] [-SecurityGroup <string[]>] [-TenancyType
<string>] [-MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
<ProvisioningSchemeType>]

[-ImageAssignmentNote <string>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example of creating a catalog using a prepared image version spec in VMware:

```
New-ProvScheme -ProvisioningSchemeName assignimage -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid `

    -HostingUnitName $hostingunit.c-IdentityPoolName
$IdentityPool.IdentityPoolName `

    -CleanOnBoot -Scope @() -SecurityGroup @() -VMCpuCount 2 -VMMemoryMB
8192 `

    -NetworkMapping @{"0"="XDHyp:\HostingUnits\vmware\\DSwitch-VM
Network.network"}
```

Example of the complete set of Powershell commands to create a catalog:

```
$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" -Name "vmwarecatalog" -PersistUserChanges
"Discard" -ProvisioningType "MCS" -Scope @() -SessionSupport
"MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain
"vmware.local" -IdentityPoolName "vmwarecatalog" -IdentityType
"ActiveDirectory"  -NamingScheme "vmware##" -NamingSchemeType "Numeric"
-Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image2 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

$Task = New-ProvScheme -ProvisioningSchemeName vmwarecatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
-HostingUnitName vmware -IdentityPoolName vmwarecatalog -CleanOnBoot
-Scope @() -SecurityGroup @() -NetworkMapping @{"0"="XDHyp:
\HostingUnits\vmware\\DSwitch-VM Network.network"} -VMCpuCount 2
-VMMemoryMB 4096 -RunAsynchronously

Get-ProvTask -TaskId $Task.TaskId

$ProvScheme = Get-ProvScheme -ProvisioningSchemeName vmwarecatalog
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-BrokerCatalog -Name $Catalog.Name -ProvisioningSchemeId
$ProvScheme.ProvisioningSchemeUid
```

More information

- Image management

Where to go next

- Manage catalogs created using prepared images

Create catalogs using prepared images in XenServer®

Create prepared images and use the prepared images to create an MCS machine catalog using:

- Studio
- PowerShell commands

The key steps to create an MCS machine catalog using the prepared image are:

1. Create the image definition and the initial image versions.
2. Use the image version as a prepared image to create a catalog

Use Studio

Create an image definition and initial image version

To create an image definition and the initial image version, do the following:

1. From Studio, go to the **Images** node, and click **Create Image Definition**. Click **Next** on the **Introduction** page.
2. On the **Image Definition** page, specify the **OS type** and **Session type**, and **Connection** for the image definition.
3. On the **Image** page, select **Resources** (only the resources applicable for the set connection are listed) and a master image to use as a template for creating the image version.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Before selecting an image, verify that the master image has VDA 2311 or later installed and the MCSIO driver is installed on the VDA.

4. On the **Machine Specification** page, you can see only the memory size that is derived from the master image, and you can change it if needed.
5. On the **NICs** page, select NICs for the preparation image. For each NIC, select an associated virtual network. The NIC associated with the master image is selected by default.
6. On the **Version Description** page, enter a description for the initial image version created.
7. On the **Summary** page, check the details of the image definition and the initial image version created. Enter a name and description for the image definition. Click **Finish**.

Create image versions

Image versions allow for the management of different iterations or updates to a particular image. This functionality enables you to maintain multiple versions of an image for different purposes.

To create image versions from the initial image version, do the following:

1. Go to the **Images** node, select an image version or an image definition, and click **Create Image Version**.
2. On the **Image** page, change the hosting unit, and reselect the master image if needed.
3. To use different settings from the initial image version, configure the settings on the **Machine Specification** and **NICs** pages in the **Create Image Version** dialog.
4. Add a description for the image version. Click **Finish**.

NOTE:

If the creation of the image version fails for any reason, the **Troubleshoot** tab at the bottom provides a **Retry** option.

Shared prepared image

To share prepared images across different host units for Xenserver, follow these steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Right-click an image version and select **Manage Image Share**. All the host units under the selected connection are listed. The resources where the image version is created from is disabled for any actions.
2. Select the host units with which you want to share the image and click **Save**. The **Share Status** column shows **In progress**.
3. Click the **Resources** tab for more details about the sharing status.

NOTE:

When the status of the image version sharing is in progress, the option to delete image version or manage image share is disabled.

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Machine Management** page, select the hosting unit and click **Next**.
3. On the **Desktop Experience** page, select the required desktop experience.
4. From the **Image** page to the **Virtual Machines** page, settings are pre-selected based on the selected image version.
5. Complete the settings on the following pages.
6. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
7. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the **Machine Catalogs** node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears. Click **Next** through the **Introduction**, **Machine Type**, and **Machine Management** pages.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Image** page:
    a. Select **Prepared image**.
    b. Under the **Prepared image**, select an image version of an image definition.
    c. Select the image version. To view more details about the selected image version, click the version number, which is underlined.
4. Complete the settings on the following pages.
5. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.

Use PowerShell

Create a prepared image

The detailed PowerShell commands to create a prepared image version spec are as follows:

1. Check the available image definition names using the `Test-ProvImageDefinitionNameAvailable command`. For example,

```
Test-ProvImageDefinitionNameAvailable -ImageDefinitionName xenimage1
```

2. Create an image definition using the `New-ProvImageDefinition` command. For example,

```
$ImageDefintion = New-ProvImageDefinition -ImageDefinitionName
xenimage1 -OsType Windows -VdaSessionSupport SingleSession
```

3. Create a new configuration for image definition in the specified Hosting connection using the `Add-ProvImageDefinitionConnection` command.

```
Add-ProvImageDefinitionConnection -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -HypervisorConnectionName
XenServer1
```

4. Create an image version using the `New-ProvImageVersion` command. For example,

```
$ImageVersion = New-ProvImageVersion -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -Description "version 1"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Add a master image version spec to the image version using the `Add-ProvImageVersionSpec` command. For example,

```
$MasterImagePath = "XDHyp:\HostingUnits\xenhu \win10-master.vm\win10-master-snap.snapshot"

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageDefinitionName $ImageDefintion.ImageDefinitionName -ImageVersionNumber $ImageVersion.ImageVersionNumber -HostingUnitName xenhu -MasterImagePath $MasterImagePath
```

> **NOTE:**
>
> You can add only one master image version spec to one image version for a hosting unit.

6. Create a prepared image version spec from the master image version spec using the `New-ProvImageVersionSpec` command. For example,

```
New-ProvImageVersionSpec -SourceImageVersionSpecUid
 $SourceImageVersionSpec.ImageVersionSpecUid -NetworkMapping
@{"0"="XDHyp:\HostingUnits\xenhu\VM Network.network"}

-VMCpuCount 2 -VMMemoryMB 4096 -RunAsynchronously
```

7. You can also share prepared image version spec with another hosting unit within the same hosting connection using the `Add-ProvImageVersionSpecHostingUnit` command. For example,

```
Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx -HostingUnitName xenhu2
```

Example of the complete set of Powershell commands to create image definition, image version, and prepared image version spec:

```
$ImageDefintion = New-ProvImageDefinition -ImageDefinitionName xenimage1 -OsType Windows -VdaSessionSupport SingleSession
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Add-ProvImageDefinitionConnection -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -HypervisorConnectionName XenServer1

$ImageVersion = New-ProvImageVersion -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -Description "version 1"

$MasterImagePath = "XDHyp:\HostingUnits\xenhu \win10-master.vm\win10-
master-snap.snapshot"

$SourceImageVersionSpec = Add-ProvImageVersionSpec -ImageDefinitionName
$ImageDefintion.ImageDefinitionName -ImageVersionNumber
$ImageVersion.ImageVersionNumber -HostingUnitName xenhu -MasterImagePath
$MasterImagePath

New-ProvImageVersionSpec -SourceImageVersionSpecUid
 $SourceImageVersionSpec.ImageVersionSpecUid -NetworkMapping @{"0"="XDHyp:
\HostingUnits\xenhu\VM Network.network"}

 -VMCpuCount 2 -VMMemoryMB 4096 -RunAsynchronously

Add-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid xxxxxxx
-HostingUnitName xenhu2
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- An image version can have only one master image version spec and one prepared image version spec.
- All image version specs must either have a machine profile or none of the image version specs must have a machine profile.

Create a catalog using a prepared image version spec

Create an MCS machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-VMCpuCount <int>]
[-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping <Hashtable>] [-
CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-ServiceOffering
<string>] [-SecurityGroup <string[]>] [-TenancyType <string>] [-
MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
<ProvisioningSchemeType>]
```

Or,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitName <string> -IdentityPoolName <string> [-VMCpuCount
<int>] [-VMMemoryMB <int>] [-UseWriteBackCache] [-NetworkMapping
<Hashtable>] [-CleanOnBoot] [-Scope <string[]>] [-Metadata <Hashtable>] [-
ServiceOffering <string>] [-SecurityGroup <string[]>] [-TenancyType
<string>] [-MachineProfile <string>] [-CustomProperties <string>] [-
ResetAdministratorPasswords] [-UseFullDiskCloneProvisioning] [-
RunAsynchronously] [-PurgeJobOnSuccess] [-ProvisioningSchemeType
<ProvisioningSchemeType>]
```

Example of creating a catalog using a prepared image version spec in XenServer:

```
New-ProvScheme -ProvisioningSchemeName assignimage -imageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid 1 `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
  -HostingUnitName xenhu -IdentityPoolName poo1 `

  -CleanOnBoot -Scope @() -SecurityGroup @() -VMCpuCount 2 -VMMemoryMB
8192 `

  -NetworkMapping @{"0"="XDHyp:\HostingUnits\xenhu\VM Network.network"}
```

Example of the complete set of Powershell commands to create a catalog:

```
$CatalogName = "XenCatalog"

$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" `

  -Name $CatalogName -PersistUserChanges "Discard" -ProvisioningType "MCS"
-Scope @() -SessionSupport "MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain "xen.local"
-IdentityPoolName $CatalogName `

  -IdentityType "ActiveDirectory"  -NamingScheme "xen##" -NamingSchemeType
"Numeric" -Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName

More information

- Image management

Where to go next

- Manage catalogs created using prepared images

Manage catalogs created using prepared images

You can update an existing MCS machine catalog with a different prepared image and manage the image definitions and versions using:

- Studio
- PowerShell

Use Studio

Update a machine catalog with a different prepared image

To update an existing MCS machine catalog with a different prepared image, do the following:

1. Click **Machine Catalogs** in the left pane and select a machine catalog that you want to update. Right-click and select **Change Prepared Image**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Image** page, select a prepared image. If needed, add a note for the selected prepared image.

   NOTE:

   (Azure only) You can also choose an image with ACG not enabled and later select **Place prepared image in Azure Compute Gallery** check box to place the images in the gallery.

3. To roll back to a previously assigned prepared image, click **Use previous image assignment for quick rollback** at the bottom of the wizard.

   A new window opens and displays a list of all available historical image assignments. When you select an image from the list, the corresponding version is automatically selected in the prepared image tree on the image page.

4. On the **Rollout strategy** page, select when you want to update this catalog with the selected prepared image.
5. On the **Summary** page, check the details. Click **Finish**.

To view the history of image changes made to a catalog, follow these steps:

1. Select a machine catalog.
2. Under the **Template Properties** tab in the **Prepared image** field, click **View Image history**.

Manage the image definitions and versions

You can edit and delete the image definitions and versions to manage the use of various created image versions and definitions.

EDIT AN IMAGE DEFINITION

You can edit the name and description of an image definition.

To edit an image definition, do the following:

1. Go to the **Images** node, select an image definition, and select **Edit Image Definition**.

EDIT IMAGE VERSION

You can edit the description of an image version to specify the purpose of that image version.

To edit an image version, do the following:

1. Go to the **Images** node, select an image version, and select **Edit Description**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

DELETE AN IMAGE VERSION

To delete an image version, do the following:

1. Go to the **Images** node, select an image version, and select **Delete Image Version**.

> **NOTE:**
>
> You cannot delete an image version if it is used by a machine catalog.

DELETE AN IMAGE DEFINITION

To delete an image definition, do the following:

1. Go to the **Images** node, select an image definition, and select **Delete Image Definition**.

> **NOTE:**
>
> You cannot delete an image definition if it contains an image version.

Use PowerShell

Update a catalog using a prepared image version spec

You can update a catalog using the `Set-ProvSchemeImage` command. For example,

```
Set-ProvSchemeImage -ProvisioningSchemeUid <Guid> -ImageVersionSpecUid
<Guid> [-DoNotStoreOldImage] [-RunAsynchronously] [-PurgeJobOnSuccess]

[-ImageAssignmentNote <string>]
```

Or,

```
Set-ProvSchemeImage -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> [-DoNotStoreOldImage] [-RunAsynchronously] [-PurgeJobOnSuccess]

[-ImageAssignmentNote <string>]
```

Example of the complete set of Powershell commands to update a catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 2 -Filter "PreparationType -eq 'Mcs'"

Set-ProvSchemeImage -ProvisioningSchemeName azurecatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
-RunAsynchronously -ImageAssignmentNote "Update from VST team"
```

Get the image change history for the provisioning scheme

```
Get-ProvSchemeImageVersionSpecHistory -ProvisioningSchemeName azurecatalog
```

Delete image definition, image version, and prepared image version spec

Consider the following before deleting an image definition, image version, and prepared image version spec:

- An image definition can't be deleted if it contains any image version.
- An image version can't be deleted if it contains any image version specification.
- A master image version spec can't be deleted if it is used by any other prepared image version spec.
- A prepared image version spec can't be deleted if it is used by any MCS machine catalog.
- A hosting unit can’t be deleted if it is used by any other prepared image version spec.

The detailed steps are as follows:

1. Remove the machine catalog. For example,

   ```
   Remove-ProvScheme -ProvisioningScheneName decouplingCatalog
   ```

2. Remove the shared prepared image version spec. For example,

   ```
   Remove-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid <uid>
   -HostingUnitName AzureWest
   ```

3. Remove a prepared image version spec. For example,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$PreparedImageVersionSpec = Get-ProvImageVersionSpec
-ImageDefinitionName image1 -ImageVersionNumber 1 -Filter
"PreparationType -eq 'Mcs'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid -RunAsynchronously
```

4. Remove master image version specification. For example,

```
$MasterImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'None'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid -RunAsynchronousl
```

NOTE:

Master image version spec can only be deleted when there is no associated prepared image version spec.

5. Remove an image version. For example,

```
Remove-ProvImageVersion -ImageDefinitionName image1 -ImageVersionNumber
1
```

6. Remove the configuration for image definition in the specified hosting connection. For example,

```
Remove-ProvImageDefinitionConnection -ImageDefinitionName xx
-HypervisorConnectionName xxx
```

7. Remove an image definition. For example,

```
Remove-ProvImageDefinition -ImageDefinitionName image1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example of the complete set of PowerShell commands when prepared image is not shared across host unit:

```
Remove-ProvScheme -ProvisioningSchemeName decouplingCatalog

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid -RunAsynchronously

$MasterImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'None'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$MasterImageVersionSpec.ImageVersionSpecUid -RunAsynchronously

Remove-ProvImageVersion -ImageDefinitionName image1 -ImageVersionNumber 1

Remove-ProvImageDefinition -ImageDefinitionName image1
```

Example of the complete set of PowerShell commands when prepared image is shared across host unit:

```
Remove-ProvScheme -ProvisioningSchemeName decouplingCatalog

Remove-ProvImageVersionSpecHostingUnit -ImageVersionSpecUid <uid>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-HostingUnitName AzureWest

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$PreparedImageVersionSpec.ImageVersionSpecUid -RunAsynchronously

$MasterImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'None'"

Remove-ProvImageVersionSpec -ImageVersionSpecUid
$MasterImageVersionSpec.ImageVersionSpecUid -RunAsynchronously

Remove-ProvImageVersion -ImageDefinitionName image1 -ImageVersionNumber 1

Remove-ProvImageDefinitionConnection -ImageDefinitionName xx
-HypervisorConnectionName xxx

Remove-ProvImageDefinition -ImageDefinitionName image1
```

Manage image definition and image version

You can rename and edit an image definition, and edit an image version.

- Rename an image definition using the `Rename-ProvImageDefinition` command. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Rename-ProvImageDefinition -ImageDefinitionUid <Guid>
-NewImageDefinitionName <string>
```

Or,

```
Rename-ProvImageDefinition -ImageDefinitionName <string>
-NewImageDefinitionName <string>
```

- Edit an image definition using the `Set-ProvImageDefinition` command. For example:

```
Set-ProvImageDefinition -ImageDefinitionUid <Guid> [-Description
<string>]
```

Or,

```
Set-ProvImageDefinition -ImageDefinitionName <string> [-Description
<string>]
```

- Edit an image version using the `Set-ProvImageVersion` command. For example:

```
Set-ProvImageVersion -ImageVersionUid <Guid> [-Description <string>]
```

Or,

```
Set-ProvImageVersion -ImageDefinitionName <string> -ImageVersionNumber
<int> [-Description <string>]
```

Get image definition, image version, prepared image version spec, and provisioning scheme details

- Get image definition details using the `Get-ProvImageDefinition` command. For example:

```
Get-ProvImageDefinition [-ImageDefinitionName <string>] [-
ImageDefinitionUid <Guid>] [-ReturnTotalRecordCount] [-MaxRecordCount
<int>] [-Skip <int>] [-SortBy <string>] [-Filter <string>]
```

- Get image version details using the `Get-ProvImageVersion` command. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - To list image versions in an image definition,

    ```
    Get-ProvImageVersion -ImageDefinitionUid <Guid>
    ```

    Or,

    ```
    Get-ProvImageVersion -ImageDefinitionName <string>
    ```

  - To get an image version detail,

    ```
    Get-ProvImageVersion -ImageVersionUid <Guid>
    ```

    Or,

    ```
    Get-ProvImageVersion -ImageDefinitionName <string>
    -ImageVersionNumber <int>
    ```

- Get prepared image version spec using the `Get-ProvImageVersionSpec` command. For example:

  - To list all prepared image version specs in an image version,

    ```
    Get-ProvImageVersionSpec -ImageVersionUid <Guid>
    ```

  - To list master image version specs in a prepared image version spec,

    ```
    Get-ProvImageVersionSpec -ImageVersionUid <Guid> -Filter
    'PreparationType -eq "None"'
    ```

  - To list prepared image version specs in an image version, which is associated with a master image,

    ```
    Get-ProvImageVersionSpec -ImageVersionUid <Guid> -Filter
    'PreparationType -eq "MCS" -and SourceImageVersionSpecUid -eq
    "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"'
    ```

  - To get successful prepared image version specs in an image version,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-ProvImageVersionSpec -ImageVersionUid <Guid> -Filter
'PreparationType -eq "MCS" -and SourceImageVersionSpecUid -eq
"xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" -and ImageVersionSpecStatus
-eq "Complete"'
```

- To get a prepared image version spec detail,

```
Get-ProvImageVersionSpec -ImageVersionSpecUid <Guid>
```

- Get provisioning scheme details using the `Get-ProvScheme` command. For example:

```
Get-ProvScheme [[-ProvisioningSchemeName] <String>] [-
ProvisioningSchemeUid <Guid>] [-ScopeId <Guid>] [-ScopeName <String>]
[-ReturnTotalRecordCount] [-MaxRecordCount <Int32>] [-Skip <Int32>] [-
SortBy <String>] [-Filter <String>] [-FilterScope <Guid>]
```

- Get prepared image version spec history of a provisioning scheme using the `Get-ProvSchemeImageVersionSpecHistory` command. For example:

```
Get-ProvSchemeImageVersionSpecHistory [-ProvisioningSchemeName
<String>] [-ProvisioningSchemeUid <Guid>] [-ImageVersionSpecUid <Guid>]
[-ImageVersionSpecHistoryUid <Guid>] [-ReturnTotalRecordCount] [-
MaxRecordCount <Int32>] [-Skip <Int32>] [-SortBy <String>] [-Filter
<String>] [-FilterScope <Guid>]
```

More information

Create machine catalogs

NOTE:

This article describes how to create catalogs using Studio. If you're using Quick Deploy to create Azure resources, follow the guidance in Create catalogs using Quick Deploy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Collections of physical or virtual machines are managed as a single entity called a machine catalog. Within a machine catalog, all machines share a common operating system type, which can be either multi-session OS or single-session OS, such as Windows or Linux-based systems.

NOTE:

For more information about provisioning macOS machines using machine catalogs, see this article in the macOS VDA documentation.

Studio guides you to create the first machine catalog. After you create the first catalog, you create the first delivery group. Later, you can change the catalog you created, and create more catalogs.

Overview

When you create a catalog of VMs, you specify how to provision those VMs. You can use Machine Creation Services™ (MCS). Or, you can use your own tools to provide machines.

- If you use MCS to provision VMs, you provide an image (or snapshot) to create identical VMs in the catalog. Before you create the catalog, you must set up a hosting connection for the first time to the hypervisor or cloud service of choice and then you must create and configure the master image on the same. Configuring the master image requires tasks such as domain joining when necessary, installing required drivers, applications to be published, and deploying the Virtual Delivery Agent (VDA) on the image.
- After you create the master image, you then create the machine catalog in Studio. You select that image (or a snapshot of an image), specify the number of VMs to create in the catalog, and configure additional information.
- If your machines are already available, you must still create one or more machine catalogs to import these VMs into the catalog.

When using MCS to create the first catalog, you specify a hosting unit that you created previously. Hosting unit provide resource configuration for you to create a virtual machine. Later (after you create your first catalog and delivery group), you can change information about that hosting unit or its parent host connection or create more connections and hosting units.

If a Cloud Connector is not operating properly, MCS provisioning operations (such as catalog updates) take longer than usual, and the management interface's performance degrades significantly.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

RDS license check

Creation of a machine catalog containing Windows multi-session OS machines includes an automatic check for valid Microsoft RDS licenses. The catalog is searched for a powered-on and registered machine to do the check on.

- If a powered-on and registered machine cannot be found, a warning is displayed, explaining that the RDS licensing check cannot be performed.
- If a machine is found and an error is detected, Studio displays a warning message for the catalog containing the detected issue. To remove an RDS license warning from a catalog (so that it no longer appears in the display), select the catalog. Select **Remove RDS license warning**. When prompted, confirm the action.

VDA registration

A VDA must be registered with a Cloud Connector to be considered when launching brokered sessions. Unregistered VDAs can result in underutilization of otherwise available resources. There are various reasons that a VDA might not be registered, many of which you can troubleshoot. Troubleshooting information is provided in the catalog creation wizard, and after you add a catalog to a delivery group.

In the catalog creation wizard, after you add existing machines, the list of computer account names indicates whether each machine is suitable for adding to the catalog. Hover over the icon next to each machine to display an informative message about that machine.

If the message identifies a problematic machine, you can either remove that machine (using the **Remove** button), or add the machine. For example, if a message indicates that information cannot be obtained about a machine (perhaps because it was never registered), you might choose to add the machine anyway.

For more information about VDA registration troubleshooting, see CTX136668.

MCS catalog creation summary

Here's a brief overview of default MCS actions after you provide information in the catalog creation wizard.

- If you select an image (rather than a snapshot), MCS creates a snapshot.
- MCS creates a full copy of the snapshot and places the copy on each storage location defined in the host connection.
- MCS adds the machines to Active Directory, which creates unique identities.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- MCS creates the number of VMs specified in the wizard, with two disks defined for each VM. In addition to the two disks per VM, full copy of the snapshot or master image is also stored in the same storage location. If you have multiple storage locations defined, each gets the following disk types:
  - The full copy of the snapshot (noted before), which is read-only and shared across the just-created VMs.
  - A unique 16 MB identity disk that gives each VM a unique identity. Each VM gets an identity disk.
  - A unique difference disk to store writes made to the VM. This disk is thin provisioned (if supported by the host storage) and increases to the maximum size of the master image, if necessary. Each VM gets a differencing disk. The difference disk holds changes made during sessions. It is permanent for dedicated desktops. For pooled desktops, it is deleted and a new one created after each restart.
- For Windows VMs on VDA version 2511 (Update 1) or later, MCS can assign a unique `MachineGuid` to each machine. This `MachineGuid` is used for licensing purposes by some software installed on the VDA. This behavior is disabled by default but can be enabled by setting registry key value `HKLM:\Software\Citrix\MachineIdentityServiceAgent\EnableUniqueMachineGuid` to `1` on the master image or individual machines.

Alternatively, when creating VMs to deliver static desktops, you can specify (on the **Machines** page of the catalog creation wizard) thick (full copy) VM clones. Full clones do not require retention of the master image on every data store. Each VM has its own file.

MCS storage considerations

There are many factors when deciding on storage solutions, configurations, and capacities for MCS. The following information provides proper considerations for storage capacity:

Capacity considerations:

- Disks

  The Delta or Differencing (Diff) Disks consume the largest amount of space in most MCS deployments for each VM. Each VM created by MCS is given at minimum 2 disks upon creation.

  - Disk0 = Diff Disk: contains the OS when copied from the base master image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Disk1 = Identity Disk: 16 MB - contains Active Directory data for each VM.

As the product evolves, you might have to add more disks to satisfy certain use cases and feature consumption. For example:

- MCS Storage Optimization creates a write cache style disk for each VM. In XenServer, VMware, and SCVMM virtualization environments, MCS places Write-back cache (WBC) disk on the same storage location as OS disk if you configure the available OS storage list the same as the available temporary storage list while creating a host connection.
- MCS added the ability to use full clones as opposed to the Delta disk scenario described in the previous section.

Hypervisor features might also enter into the equation. For example:

- XenServer IntelliCache creates a Read Disk on local storage for each XenServer. This option saves on IOPS against the image which might be held on the shared storage location.

- Hypervisor overhead

  Different hypervisors use specific files that create overhead for VMs. Hypervisors also use storage for management and general logging operations. Calculate the space to include overhead for:

  - Log files
  - Hypervisor-specific files. For example:
    - VMware adds more files to the **VM storage** folder. See VMware Best Practices.
    - Calculate your total virtual machine size requirements. Consider a virtual machine containing 20 GB for the virtual disk, 16 GB for the swap file, and 100 MB for log files consuming 36.1 GB total.
  - Snapshots for XenServer; Snapshots for VMware.

- Process overhead

  Creating a catalog, adding a machine, and updating a catalog have unique storage implications. For example:

  - Initial catalog creation requires a copy of the base disk to be copied to each storage location.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Adding a machine to a catalog does not require copying of the base disk to each storage location. Catalog creation varies based on the features selected.
- Updating the catalog to create an extra base disk on each storage location. Catalog updates also experience a temporary storage peak where each VM in the catalog has 2 Diff disks for a certain amount of time.

More considerations:

- **RAM sizing:** Affects the size of certain hypervisor files and disks, including I/O optimization disks, write cache, and snapshot files.
- **Thin / Thick provisioning:** NFS storage is preferred due to the thin provisioning capabilities.

Machine Creation Services (MCS) storage optimization

The Machine Creation Services (MCS) storage optimization feature is also known as MCS I/O. This feature is only available on Azure, GCP, XenServer, VMware, AWS, and SCVMM.

- The write-cache container is *file-based*, the same functionality found in Citrix Provisioning. For example, the Citrix Provisioning write cache file name is `D:\vdiskdif.vhdx` and the MCS I/O write cache file name is `D:\mcsdif.vhdx`.
- Achieve diagnostic improvements by including support for a Windows crash dump file written to the write-cache disk.
- MCS I/O retains the technology *cache in RAM with overflow to hard disk* to provide the most optimal multi-tier write cache solution. This functionality allows an administrator to balance between the cost in each tier, RAM and disk, and performance to meet the desired workload expectation.

Updating the write cache method from *disk-based* to *file-based* requires the following changes:

1. MCS I/O no longer supports RAM only cache. Specify a disk size during machine catalog creation.
2. The VM write cache disk is created and formatted automatically when booting a VM for the first time. Once the VM is up, the write cache file `mcsdif.vhdx` is written into the formatted volume `MCSWCDisk`.
3. The pagefile is redirected to this formatted volume, `MCSWCDisk`. As a result, this disk size considers the total amount of disk space. It includes the delta between the disk size and the generated workload plus the pagefile size. This is typically associated with VM RAM size.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable MCS storage optimization updates

To enable the MCS I/O storage optimization feature, upgrade the Cloud Connector and the VDA to the latest version of Citrix DaaS.

NOTE:

If you upgrade an existing deployment which has MCS I/O enabled, no additional configuration is required. The VDA and the Delivery Controller upgrade handle the MCS I/O upgrade.

For information on assigning a drive letter to write-back cache disk, see Assign a specific drive letter to MCS I/O write-back cache disk.

Prepare a master image on the hypervisor or cloud service

The master image contains the operating system, non-virtualized applications, VDA, and other software.

Good to know:

- A master image might also be known as a clone image, golden image, base VM, or base image. Host vendors and cloud service providers might use different terms.
- Ensure that the hypervisor or cloud service has enough processors, memory, and storage to accommodate the number of machines created.
- Configure the correct amount of hard disk space needed for desktops and applications. That value cannot be changed later or in the machine catalog.
- Remote PC Access machine catalogs do not use master images.
- Microsoft KMS activation considerations when using MCS: If your deployment includes 7.x VDAs with a XenServer 6.1 or 6.2, vSphere, or Microsoft System Center Virtual Machine Manager host, you do not need to manually rearm Microsoft Windows or Microsoft Office.

Install and configure the following software on the master image:

- Integration tools for your hypervisor (such as Citrix VM Tools, Hyper-V Integration Services, or VMware tools). If you omit this step, applications and desktops might not function correctly.
- A VDA. Citrix recommends installing the latest version of VDA to allow access to the newest features. Failure to install a VDA on the master image causes the catalog creation to fail.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Third-party tools as needed, such as antivirus software or electronic software distribution agents. Configure services with settings that are appropriate for users and the machine type (such as updating features).
- Third-party applications that you are not virtualizing. Citrix recommends virtualizing applications. Virtualizing reduces costs by eliminating having to update the master image after adding or reconfiguring an application. Also, fewer installed applications reduce the size of the master image hard disks, which saves storage costs.
- App-V clients with the recommended settings, if you plan to publish App-V applications. The App-V client is available from Microsoft.
- When using MCS, if you localize Microsoft Windows, install the locales and language packs. During provisioning, when a snapshot is created, the provisioned VMs use the installed locales and language packs.

IMPORTANT:

If you are using MCS, do not run Sysprep on master images.

To prepare a master image:

1. Using your hypervisor's management tool, create a master image and then install the operating system, and all service packs and updates. Specify the number of vCPUs. You can also specify the vCPU value if you create the machine catalog using PowerShell. You cannot specify the number of vCPUs when creating a catalog from Studio. Configure the amount of hard disk space needed for desktops and applications. That value cannot be changed later or in the catalog.
2. Ensure that the hard disk is attached at device location 0. Most standard master image templates configure this location by default, but some custom templates might not.
3. Install and configure the software listed above on the master image.
4. If you are not using MCS, join the master image to the domain where applications and desktops are members. Ensure that the master image is available on the host where the machines are created. If you are using MCS, joining the master image to a domain is not required. The provisioned machines are joined to the domain specified in the catalog creation wizard.
5. Citrix recommends that you create and name a snapshot of your master image so that it can be identified later. If you specify a master image rather than a snapshot when creating a catalog, the management interface creates a snapshot, but you cannot name it.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Volume licensing activation

MCS supports volume licensing activation to automate and manage the activation of Windows operating systems and Microsoft Office. The three models that MCS supports for volume licensing activation are:

- Key Management Service (KMS)
- Active Directory-based activation (ADBA)
- Multiple Activation Key (MAK)

You can change the activation setting after you create the machine catalog.

Key Management Service (KMS)

The KMS is a lightweight service that does not require a dedicated system and can easily be co-hosted on a system that provides other services. This functionality is supported on all Citrix supported Windows versions. During image preparation, MCS does the Microsoft Windows and Microsoft Office KMS rearm. You can skip rearm by running the command `Set-Provserviceconfigurationdata`. For more information on KMS activation, see Activate using Key Management Service.

NOTE:

All machine catalogs created after running the command `Set-Provserviceconfigurationdata` have the same setting as provided in the command.

Active Directory-based activation (ADBA)

ADBA enables you to activate machines through their domain connections. Machines are immediately activated when they join the domain. These machines remain activated as long as they remain joined to the domain and in contact with it. This functionality is supported on all Citrix supported Windows versions. For more information on Active directory-based activation, see Activate using Active Directory-based activation.

Multiple Activation Key (MAK)

MAK is a way of activating volume and authenticating the Windows system with the help of the Microsoft server. You must buy the MAK key from Microsoft which is assigned with a fixed number of activation counts. Every time a Windows system is activated, the activation count reduces. There are two ways of activating the system:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Online Activation: If the Windows system that you want to activate has internet access, the system automatically activates the Windows on installing the product key. This process reduces the activation count by 1 for the corresponding MAK.
- Offline Activation: If the Windows system is not able to connect to the internet to do the online activation, MCS gets a confirmation id and an installation id from the Microsoft server to get the Windows system activated. This way of activation is useful for non-persistent machine catalogs.

NOTE:

- MCS doesn't support Microsoft Office activation using MAK.
- The minimum VDA version required is 2303.

Key requirements

- The Delivery Controller™ must have internet access.
- Create a new catalog if the new image to be updated has a different MAK Key from the original.
- Install the MAK key on the master image. See Deploy MAK Activation for the steps to install MAK Key on a Windows System.
- If you are not using image preparation:

  a. Add the registry DWORD value `Manual` under `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SoftwareProtectionPlatform\Activation`.

  b. Set the value to `1`.

Activation Counts

To view the number of activations remaining for MAK Key or to check if a VM is consuming two or more activations, use the Volume Activation Management Tool (VAMT). See Install VAMT.

Activate the Windows system using MAK

To activate the Windows system using MAK:

1. Install the product key on the master image. This step consumes one activation count.
2. Create an MCS machine catalog.
3. If you aren't using image preparation:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

   a. Add the registry DWORD value `Manual` under `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SoftwareProtectionPlatform\Activation`.
   b. Set the value to `1`.

   This method disables the option of online activation.

4. Add VMs to the machine catalog.
5. Power on the VMs.
6. Depending on whether it's online or offline activation, the Windows system is activated.

   - If the activation is online, the Windows system is activated after the product key is installed.
   - If the activation is offline, MCS communicates with provisioned VMs to get the activation status of the Windows system. MCS then retrieves a confirmation id and an installed id from the Microsoft server. These IDs are used to activate the Windows system.

Troubleshooting

If the provisioned VM is not activated with the installed MAK Key, run `Get-ProvVM` or `Get-ProvScheme` command on a PowerShell window.

- The `Get-ProvScheme` command: See the parameter `WindowsActivationType` associated with the MCS machine catalog from the latest master image.
- The `Get-ProvVM` command. See the parameters `WindowsActivationType`, `WindowsActivationStatus`, `WindowsActivationStatusErrorCode`, and `WindowsActivationStatusError`.

You can check the error and verify the steps to resolve the issue.

Create a machine catalog using Studio

Before creating a catalog:

- Ensure that you have created a connection to the hypervisor, cloud service, other resource that hosts your machines.
- If you have created a master image to provision machines. Ensure that you have installed a VDA on that master image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

When you are using a cloud service or hypervisor to host VMs, the catalog creation wizard might contain extra pages specific to that host. For example, when using an Azure Resource Manager master image, the catalog creation wizard contains a **Storage and License Types** page. For host-specific information, see the specific articles as mentioned in Where to go next.

Launch the catalog creation wizard

1. Sign in to Citrix Cloud.
2. In the **DaaS** tile, click **Manage** to open Studio.
3. Select **Machine Catalogs** in the left pane.
4. If this is the first catalog being created, you are guided to the correct selection (such as "Set up the machines and create machine catalogs to run apps and desktops"). The catalog creation wizard opens.
5. If you already created a catalog and want to create another, follow these steps:

    a. To organize catalogs using folders, create folders under the default **Machine Catalogs** folder. For more information, see Create a catalog folder.

    b. Select the folder where you want to create the catalog, and then click **Create Machine Catalog**. The catalog creation wizard opens.

The wizard walks you through the pages described in the following sections. The pages you see may differ, depending on the selections you make, and the connection (to a host) you use. Hosts / virtualization resources lists information sources for the supported host types.

Select a machine type

Each catalog must contain machines of only one OS type. Select one of the following on the **Machine Type** page:

- **Multi-session OS:** A multi-session OS catalog provides hosted shared desktops. The machines can be running supported versions of the Windows or Linux operating systems, but the catalog cannot contain both Windows and Linux operating systems.
- **Single-session OS:** A single-session OS catalog provides VDI desktops that you can assign to different users.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Remote PC Access:** A Remote PC Access catalog provides users with remote access to their physical office desktop machines. Remote PC Access does not require a VPN to provide security.

Select machine management options

NOTE:

The page **Machine Management** does not appear if you select **Remote PC Access** on the **Machine Type** page.

The **Machine Management** page indicates how machines are managed and the tool that you want to use to deploy machines.

Select one of the options to indicate how machines must be power managed:

- **Machines that are power managed (for example, virtual machines or blade PCs)**: This option is available only if you already configured a connection to a hypervisor or cloud service.
- **Machines are not power managed (for example, physical machines)**

If you select the option **Machines that are power managed (for example, virtual machines or blade PCs)**, then select a tool to create VMs:

- **Citrix Provisioning™ Technology**
  - **Citrix Machine Creation Services (MCS)** Creates a catalog of VMs provisioned and imaged using MCS. MCS copies images cloned from a master image to those VMs.
  - **Citrix Provisioning Services (PVS)** Creates a catalog of VMs provisioned using MCS and imaged using PVS. Those VMs serve as PVS target devices and the PVS server can stream a single shared disk image to them.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- This option is available only for PVS sites registered with Citrix Cloud™ and is currently limited to Azure resources.
- While you create a Citrix Provisioning catalog on the **Target Device** page, you might see that in the drop-down menu to select the farm and site for the machines to be provisioned, there are farms and sites listed that no longer exist. As a workaround, you can run the PowerShell command `Unregister-HypPvsSite` to remove the farms and sites from the database. For information on the PowerShell command, see Unregister-HypPvsSite.

- **Other service or technology** A tool that manages machines already in the data center. Citrix recommends that you use Microsoft System Center Configuration Manager or another third-party application to ensure that the machines in the catalog are consistent.

NOTE:

For Linux OS machines, see Create Linux VDAs using Machine Creation Services (MCS).

Select a desktop experience

NOTE:

The options on the **Desktop Experience** page varies according to the machine type that you select on the **Machine Type** page.

- For **Multi-session OS** machines, users are assigned a random desktop each time they log in. You get the following options on the **Desktop Experience** page:
  - Save changes on the local disk of the machine hosting virtual desktops: Persistent
  - Discard all changes and clear virtual desktops when the user logs off: Non-persistent

NOTE:

For persistent multi-session machines, changes users make to the desktops will be saved and accessible to all authorized users.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For single-session OS machines, you get the following options on the **Desktop Experience** page:
  - Connect to a new (random) desktop each time the users log in.
  - Connect to the same (static) desktop each time the users log in.

  You can further decide whether changes made by users will be saved or discarded after they log off.

If you select **Save changes on the local disk of the machine hosting virtual desktops: Persistent**, the Fast Copy Clone or Full Copy Clone options are available for the **Virtual machine copy** mode on the **Virtual Machines** page. Otherwise, the **Virtual machine copy** mode is unavailable.

Select an image and a machine profile

NOTE:

- This page appears only if you select **Citrix Machine Creation Services (MCS)** on the **Machine Management** page.
- The options available on this page vary according to the hypervisor or cloud service.

Follow these steps to complete the settings on the page:

1. Select an image type for the machine catalog, and then select an image. Two types of images are available:
   - **Master image**: A snapshot or VM created as the master image. It undergoes automatic image preparation at the start of catalog creation. If needed, you can add a note for the selected image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- When you are using MCS, do not run Sysprep on master images.
- If you specify a master image rather than a snapshot, the management interface creates a snapshot, but you cannot name it.
- An error message appears if you select a snapshot or VM that is not compatible with the machine management technology you selected earlier in the wizard.
- To update images within an image node, select it in the tree, and then click the **Refresh** option at the top right corner. If you don't select any image node, clicking **Refresh** updates all images in the tree. To clear a selected node in the tree, hold **CTRL** and then click the node.

- **Prepared image**: An image that has undergone image preparation, ready for direct use in VM creation. Opting for prepared images rather than master images for catalog creation ensures faster and more reliable machine catalog creation, along with streamlined image lifecycle management. If needed, add a note for the selected prepared image.

  NOTE:

  - VMs created using prepared images don’t support hibernation.
  - Currently, creating catalogs using prepared images are available only in Amazon WorkSpaces Core, Azure and VMware environments.
  - Prepared images are required for creating catalogs in Amazon WorkSpaces Core environments.

  For more information about how to create prepared images, see Image management.

2. To inherit VM settings from a machine profile, select **Use a machine profile**, and then select a VM or ARM template spec (specific to Azure) to use as the machine profile.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Currently, using machine profiles is restricted to Azure, Amazon WorkSpaces Core, AWS, GCP, and VMware VMs.
- A machine profile is required for creating catalogs in Amazon WorkSpaces Core environments.

3. For VMWare deployments, when creating a machine catalog using a machine profile, you must specify the folder where you want to keep the virtual machines.

To provide the virtual machine folder location, on the catalog creation wizard, go to **Virtual Machines** page, and go to **Select a folder to place the machines** section and provide the virtual machine folder location. If not specified, the system considers the folder of the selected machine profile as the default location.

1. For AWS deployments, you can select a launch template as the machine profile.
2. Select the minimum functional level for the catalog. To enable the use of the latest product features, ensure that the master image has the latest VDA version installed.

Configure the machines

NOTE:

- The title of this page depends on what you selected on the **Machine Management** page: **Machines**, **Virtual Machines**, or **Machines and Users**.
- This page does not appear if you select **Remote PC Access** on the **Machine Type** page.
- You can create an empty catalog, which means the catalog contains no machines.

- **When using MCS to create machines:**
  - Specify how many virtual machines to create. Enter **0** (zero) if you do not want to create any. Later, to create VMs for an empty catalog, you can perform **Add machines**.
  - Choose the amount of memory (in MB) each VM has.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **IMPORTANT:**
>
> Each created VM has a hard disk. Its size is set in the master image; you cannot change the hard disk size in the catalog.

- If you indicate on the **Desktop Experience** page that user changes to static desktops should be saved on a separate Personal vDisk, then specify the virtual disk size in GB and the drive letter.
- If your deployment uses more than one zone (resource location), you can select a zone for the catalog.
- If you're creating static desktop VMs, select a virtual machine copy mode. See Virtual machine copy mode.
- If you're creating random non-persistent desktop VMs, you can enable and configure the write-back cache for temporary data on machines to improve I/O performance. For more information, see Configure cache for temporary data.

- **When using other tools to provide machines:**

  Add (or import a list of) machine account names. You can change the account name for a VM after you add or import it. If you have specified static machines on the **Desktop Experience** page, you can optionally specify the user name for use with each VM you add.

  > **TIP:**
  >
  > To add users, you can browse to the users or enter a semicolon-separated list of user names manually. If the users are in Active Directory, enter the names directly. If not, enter the names in this format: `<identity provider>:<user name>`. Example: `AzureAD:username`.

  After you add or import names, you can use the **Remove** button to delete names from the list while you are still on this wizard page.

- **When using other tools (not MCS):**

  An icon and tooltip for each machine added (or imported) help identify machines that might not be eligible to add to the catalog, or be unable to register with a Cloud Connector.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Virtual machine copy mode

The copy mode that you specify on the **Machines** page determines whether MCS creates thin (fast copy) or thick (full copy) clones from the master image. (Default = thin clones)

- Use fast copy clones for more efficient storage use and faster machine creation.
- Use full copy clones for better data recovery and migration support, with potentially reduced IOPS after the machines are created.

> **NOTE:**
>
> The Full Copy Clone approach is available only for provisioning persistent VMs on multi- or single-session OSs.

Configure cache for temporary data

When using MCS to manage random non-persistent machines in a catalog, you can enable write-back cache for machines to improve I/O performance.

Write-back cache is referred to as MCSIO. For more information, see this blog article.

PREREQUISITES

To enable write-back cache, the catalog must meet these requirements:

- Uses a connection that specifies storage for temporary data. For more information, see Connections and resources.
- VDAs must be at least version 7.9 and installed with a current MCSIO driver.

  > **NOTE:**
  >
  > You can install this driver when you install or upgrade a VDA. By default, that driver isn't installed.

- To enable drive letter assignment for disk caches, VMs must meet the following more requirements:
  - Operating System: Windows
  - VDA version: 2305 or later

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CONSIDERATIONS

- Write-back caches come in *Memory* cache and *Disk* cache. By default, their default values differ according to the connection type. Generally, the default values are sufficient for most cases; however, consider the space needed for:
  - Temporary data files created by Windows itself, including the Windows page file.
  - User profile data.
  - ShareFile data that is synced to users' sessions.
  - Data that might be created or copied by a session user or any applications users may install inside the session.

- When enabling the write-back cache for temporary data, use both a memory cache and a disk cache. Temporary data is first written to the memory cache. When the memory cache reaches the configured limit, the oldest data is moved to the disk cache. **Note:** Write-back caching using only a disk cache is no longer supported.
- The memory cache is part of the total amount of memory on each machine. Consider increasing the total amount of memory on each machine after enabling write-back cache.
- Changing **Disk cache size (GB)** from its default value can affect performance. The size must match user requirements and the load placed on the machine.

IMPORTANT:

If the disk cache runs out of space, the user's session becomes unusable.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If you clear the **Disk cache size** checkbox, no cache disk is created. In this case, specify a **Memory allocated to cache** value that is large enough to hold all of the temporary data. This is feasible only if large amounts of RAM are available for allocation to each VM.
- Do not enable caching if you intend to use this catalog to create AppDisks.
- You cannot change the cache values in a machine catalog after it is created.

Using CSV files to bulk add machines

If you use Studio, you can bulk add machines by using CSV files. The feature is available to all catalogs except catalogs created through MCS.

A general workflow to use CSV files to bulk add machines is as follows:

1. On the **Machines** page, select **Add CSV File**. The **Add Machines in Bulk** window appears.
2. Select **Download CSV Template**.
3. Fill out the template file.
4. Drag or browse to the file to upload it.
5. Select **Validate** to do validation checks on your import.
6. Select **Import** to complete.

For information about CSV file considerations, see Considerations when using CSV files to add machines.

You can also export machines from a catalog on the same Machines page. The exported CSV of machines can then be used as a template when adding machines in bulk. To export machines:

1. On the **Machines** page, select **Export to CSV file**. A CSV file containing a list of the machines is downloaded.
2. Open the CSV file to add or edit machines as needed. To add machines in bulk using the saved CSV file, see the previous section, Using CSV files to bulk add machines.

NOTE:

- This feature is not available for Remote PC Access catalogs.
- Export and import of machines in CSV files is only supported between catalogs of the same type.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Security

The **Security** page appears only if you are creating a machine catalog without assigning a machine profile in AWS virtualization environment. Use the **Security** page to configure the security groups for the VMs. This is also applicable when editing and cloning an existing machine catalog.

If you create a machine profile-based machine catalog, then the security group configurations are inherited from the machine profile and the **Security** page does not appear.

Configure NICs for the machines

The page **NICs** does not appear if you select **Remote PC Access** on the **Machine Type** page.

If you plan to use multiple NICs, associate a virtual network with each card. For example, you can assign one card to access a specific secure network, and another card to access a more commonly used network. You can also add or remove NICs from this page.

NOTE:

For VMware deployments, when creating a machine catalog using a machine profile, the catalog inherits the NIC configurations from the machine profile. In such cases, if the machine profile has multiple NICs with the same network, then Studio uses the network from the hosting unit for NIC configurations.

Add machine accounts

NOTE:

This page **Machine Accounts** appears only when you select **Remote PC Access** on the **Machine Type** page.

Add the Active Directory machine accounts or Organizational Units (OUs). Do not use a forward slash (/) in an OU name.

You can choose a previously configured power management connection or select not to use power management. If you want to use power management but a suitable connection has not been configured yet, you can create that connection later and then edit the machine catalog to update the power management settings.

You can also bulk add machines by using CSV files. A general workflow to do that is as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. On the **Machine Accounts** page, select **Add CSV File**. The **Add Machines in Bulk** window appears.
2. Select **Download CSV Template**.
3. Fill out the template file.
4. Drag or browse to the file to upload it.
5. Select **Validate** to do validation checks on your import.
6. Select **Import** to complete.

For information about CSV file considerations, see Considerations when using CSV files to add machines.

Configure identities for machines in the catalog

NOTE:

- The page **Machine Identities** appears only when you do not select **Remote PC Access** on the **Machine Type** page and select **Citrix Machine Creation Services (MCS)** on the **Machine Management** page.

Each machine in the catalog must have a unique identity. This page lets you configure identities for machines in the catalog. The machines are joined to the identity after they are provisioned. You cannot change the identity type after you create the catalog.

A general workflow to configure settings on this page is as follows:

1. Select an identity from the list.
2. Indicate whether to create accounts or use existing ones, and the location (domain) for those accounts.

You can select one of the following options:

- **On-premises Active Directory**: Machines owned by an organization and signed into with an Active Directory account that belongs to that organization. They exist on-premises.

  NOTE:

  By default, the domain where the resource (connection) resides is selected.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Microsoft Entra joined**: Machines owned by an organization and signed into with a Microsoft Entra account that belongs to that organization. They exist only in the cloud. For information about the requirements, limitations, and considerations, see Microsoft Entra joined.

  NOTE:

  - This option requires that the master image meets the operating system prerequisite. For more information, see the Microsoft documentation Microsoft Entra joined devices.

- **Microsoft Entra hybrid joined**. Machines owned by an organization and signed into with an Active Directory Domain Services account that belongs to that organization. They exist in the cloud and on-premises. For information about the requirements, limitations, and considerations, see Microsoft Entra hybrid joined.

  NOTE:

  - Before you can use Microsoft Entra hybrid join, make sure that your Azure environment meets the prerequisites. See Configure Microsoft Entra hybrid join.
  - This option requires that the master image meets the operating system prerequisite. For more information, see Microsoft Entra hybrid joined devices.

- **Non-domain-joined**. Machines not joined to any domain. For information about the requirements and limitations, see Non-domain-joined.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT:

- If you select **On-premises Active Directory** or **Microsoft Entra hybrid joined** as the identity type, each machine in the catalog must have a corresponding Active Directory computer account.
- The **Non-domain-joined** identity type requires version 1811 or later of the VDA as the minimum functional level for the catalog. To make it available, update the minimum functional level.
- The **Microsoft Entra joined** and **Microsoft Entra hybrid joined** identity types require version 2203 or later of the VDA as the minimum functional level for the catalog. To make them available, update the minimum functional level.
- A Microsoft Entra service account is mandatory when creating Microsoft Entra only or Microsoft Entra catalogs enrolled in Microsoft Intune for persistent and non-persistent VMs.

Before configuring machine identities, make sure that you have permission to create computer accounts in the OU where the machines reside. Each machine in the catalog must have a unique name. Then choose how to configure machine identities:

- If you create new machine accounts, specify the OU and the machine naming scheme. For more information, see Machine account naming scheme. When you create a catalog, an identity pool is created automatically to hold all machine identities that you defined for this catalog.
- If you use existing machine accounts, choose an existing identity pool in your environment.

NOTE:

Make sure that OU names do not use forward slashes (`/`).

When you create a catalog and select **Use existing identity pool** on the **Machine Identities** page, the service account behavior depends on the identity pool configuration:

- If the selected identity pool does not have a service account configured, selecting a stored service account on the **Domain credentials** page does not take effect. The **Add machines** operation can fail with an error indicating that the service account cannot be found. To avoid this, manually enter domain credentials on the **Domain credentials** page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If the selected identity pool has a service account configured, any service account selected on the **Domain credentials** page is ignored. The **Add machines** operation always uses the service account associated with the identity pool.

If you use existing accounts, browse to the accounts or click **Import** and specify a `.csv` file containing account names. The imported file content must use the format: `[ADComputerAccount] ADcomputeraccountname.domain`

Ensure that there are enough accounts for all the machines you are adding. Studio manages those accounts. Therefore, either allow that interface to reset the passwords for all the accounts or specify the account password, which must be the same for all accounts.

For catalogs containing physical or existing machines, select or import existing accounts and assign each machine to both an Active Directory computer account and to a user account.

Machine account naming scheme

Each machine in a catalog must have a unique name. You must specify a machine account naming scheme when creating a catalog. Use wildcards (hash marks) as placeholders for sequential numbers or letters that appear in the name.

When specifying a naming scheme, consider the following:

- The maximum number of characters allowed is 15.
- The naming scheme must contain at least one wildcard character. You must put all wildcards together.
- The entire name, including wildcards, must contain at least 2 but no more than 15 characters. It must include at least one non-numeric and one # (wildcard) character.
- The name must not include spaces or any of the following characters: `,~!@'$%\^&.(){\/*?"<>|=+[];:_".`.
- The name cannot end with a hyphen (-).
- The number of characters increases with the increase in the number of machine accounts. For example, if you create 1,000 machine accounts with the scheme "veryverylong#", the last account name created (veryverylong1000) contains 16 characters that exceed the number of maximum characters allowed.

You can indicate whether the sequential values are numbers (0-9) or letters (A-Z):

- **0-9**. If selected, the specified wildcards resolve to sequential numbers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> If there is only one wildcard (#), the account names start with 1. If there are two, the account names start with 01. If there are three, the account names start with 001, and so on.

- **A-Z**. If selected, the specified wildcards resolve to sequential letters.

For example, a naming scheme of PC-Sales-## (with **0-9** selected) results in accounts named PC-Sales-01, PC-Sales-02, PC-Sales-03, and so on.

Optionally, you can specify what the account names start with.

- If you select **0-9**, accounts are named sequentially, starting with the specified numbers. Enter one or more digits, depending on how many wildcards you use in the preceding field. For example, if you use two wildcards, enter two digits or more.
- If you select **A-Z**, accounts are named sequentially, starting with the specified letters. Enter one or more letters, depending on how many wildcards you use in the preceding field. For example, if you use two wildcards, enter two letters or more.

Add domain credentials

Enter the credentials of an administrator who has permission to perform account operations. Detailed steps are as follows:

1. Click Enter credentials. The Windows Security page appears.
2. In the User name field, enter the administrator's SamName, user name, or user SID. Depending on your input:
   - If you enter a SamName, the **Domain** field populates automatically.
   - If you enter a user name or SID, you can limit the user search to a specific domain by entering the domain name or SID in the **Domain** field.
3. Click **Check name** to check whether the user name is valid or unique.
4. In the **Password** field, enter the domain password of the administrator.
5. Click **Done**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If the identity type you selected in **Machine Identities** is **Microsoft Entra hybrid joined**, the credentials you enter must have been granted the `Write userCertificate` permission.

Select a WEM configuration set for Experience Optimization

NOTE:

The page **Experience Optimization** appears only when you have a Workspace Environment Management™ (WEM) entitlement.

Improve resource allocation and enhance system performance on your machines by specifying a WEM configuration set for the machine catalog.

Required permissions

By default, creating and managing configuration sets for machine catalogs requires the **WEM Full Administrator** role, along with one of the following roles:

- **Full Access Administrator**
- **Cloud Administrator**
- **Machine Catalog Administrator**

To allow other roles to manage configuration sets, assign them both the **Manage configuration sets** permission and the **WEM Full Administrator** role.

Prerequisites

Before binding a catalog to a configuration set, ensure that your **Workspace Environment Management (WEM)** service deployment is set up. Sign in to Citrix Cloud and launch the WEM service. For more information, see Get started with Workspace Environment Management service.

If you already use WEM, verify that the **WEM agent** is installed on each VDA and connected to Citrix Cloud so that the optimization settings can take effect.

Steps

Select an **Experience Optimization** option to apply to the machine catalog:

- **Apply default settings:** Select this option to apply the default optimization settings, including automatic CPU spike protection and intelligent CPU optimization.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Apply custom settings:** Select this option to create a configuration set for this machine catalog using the catalog name. After the configuration set is created, you can customize the optimization settings as needed. Alternatively, you can select an existing configuration set.

Upgrade VDA (optional)

IMPORTANT:

- To ensure a smooth upgrade, make sure that you meet the prerequisites and review known issues before upgrading VDAs to CR or LTSR CU versions. See Upgrade VDAs using Studio.
- When upgrading LTSR VDAs to LTSR Cumulative Update (CU) versions, make sure that the version of the VDA Upgrade Agents running on the VDAs is 7.36.0.7 or later. For more information, see Upgrade VDAs using Studio.

This feature applies to the following machine types:

- MCS-provisioned persistent machines. You deploy them using **Citrix Machine Creation Services** on the **Machine Management** page during catalog creation.
- Machines that are not created using MCS (for example, physical machines). You deploy them using **Other service or technology** on the **Machine Management** page during catalog creation.

For more information about the two options, see Machine management

On the **VDA Upgrade** page, select the VDA version to upgrade to. If specified, the VDAs in the catalog that have the VDA Upgrade Agent installed can upgrade to the selected version — immediately or at a scheduled time.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- This feature supports upgrading only to the latest VDA. The time at which you create a VDA upgrade schedule or upgrade a VDA determines the latest version of the VDA.
- After you configure VDA upgrade settings, it might take up to 15 minutes for the **VDA Upgrade** field to reflect the latest status. To show the **VDA Upgrade** column, click the Columns to display icon in the upper right corner, select **Machine Catalog > VDA Upgrade**, and click **Save**.

Choose a VDA track that suits your deployment:

IMPORTANT:

You can switch between the CR VDA and the LTSR VDA as long as you switch from an earlier version to a later version. You cannot switch from a later version to an earlier version because that is considered a downgrade. For example, you cannot downgrade from 2212 CR to 2203 LTSR (any CU) but you can upgrade from 2112 CR to 2203 LTSR (any CU).

- **Latest CR VDA**. Current Releases (CRs) deliver the latest and most innovative app, desktop, and server virtualization features and functionality.
- **Latest LTSR VDA**. Long Term Service Releases (LTSRs) are recommended for large enterprise production environments that prefer to keep the same base version for an extended period.

After catalog creation, you can upgrade VDAs as needed. For more information, see Upgrade VDAs.

If you want to enable VDA upgrade later, you can return to this page by editing the catalog after catalog creation. For more information, see Configure VDA upgrade settings by editing a catalog.

Review the settings

On the **Summary** page, review the settings you specified. Enter a name and description for the catalog. This information appears in Studio.

When you're done, select **Finish** to start the catalog creation.

In **Machine Catalogs**, the new catalog appears with an inline progress bar.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To view details of the creation progress:

1. Hover the mouse over the machine catalog.
2. In the tooltip that appears, click **View details**.

   A step-by-step progress graph appears where you can see the following:

   - History of steps
   - Progress and running time of the current step
   - Remaining steps

Create an MCS machine catalog using PowerShell commands

You can also create an MCS machine catalog using PowerShell commands. For more information, see:

- SDKs and APIs
- Manage Citrix DaaS using Remote PowerShell SDKs
- New-ProvScheme

Assign a specific drive letter to an MCS I/O write-back cache disk

You can assign a specific drive letter to an MCS I/O write-back cache disk. This implementation helps you to avoid conflicts between the drive letter of any applications that you use and the drive letter of MCS I/O write-back cache disk. To do this, you can use PowerShell commands. The supported hypervisors are Azure, GCP, VMware, SCVMM, and XenServer.

NOTE:

This feature requires VDA version 2305 or later.

Limitations

- Applicable to only Windows operating system
- Applicable drive letter for write-back cache disk: `E` to `Z`
- Not applicable when Azure temporary disk is used as a write-back cache disk
- Applicable only when you create a new machine catalog

Assign a drive letter to a write-back cache disk

To assign a drive letter to a write-back cache disk:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open the **PowerShell** window.
2. Run `asnp citrix*`.
3. Create an identity pool if not already created.
4. Create a provisioning scheme using the `New-ProvScheme` command with the property `WriteBackCacheDriveLetter`. For example:

```
New-ProvScheme -CleanOnBoot `

-HostingUnitName "<name>" `

-IdentityPoolName $schemeName `

-ProvisioningSchemeName $schemeName `

-InitialBatchSizeHint 1 `

-UseWriteBackCache -WriteBackCacheDiskSize 127
-WriteBackCacheMemorySize 256 -WriteBackCacheDriveLetter E `

-MasterImageVM "XDHyp:\HostingUnits\<name>\image.folder\abcd-
resources.resourcegroup\MCSIOMasterVm_OsDisk_1_d3e2d6352xxxxxxxx2130aa
145ec77.manageddisk" `

-NetworkMapping @{"0"="XDHyp:\\HostingUnits\\name\
\virtualprivatecloud.folder\\East US.region\
\virtualprivatecloud.folder\\abcd-resources.resourcegroup\\abcd-
resources-vnet.virtualprivatecloud\\default.network"} `

-ServiceOffering "XDHyp:\\HostingUnits\\<name>\\serviceoffering.folder\
\Standard_D2s_v5.serviceoffering" `

-CustomProperties '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" />

<Property xsi:type="StringProperty" Name="OsType" Value="Windows" />

<Property xsi:type="StringProperty" Name="StorageType"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value="Premium_LRS"/>

<Property xsi:type="StringProperty" Name="PersistWBC" Value="false" />

<Property xsi:type="StringProperty" Name="PersistOsDisk"
Value="false" />

<Property xsi:type="StringProperty" Name="PersistVm" Value="false" />

<Property xsi:type="StringProperty" Name="WBCDiskStorageType"
Value="Premium_LRS" />

group1" />

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client" />

<Property xsi:type="StringProperty" Name="SchemaVersion" Value="2" />

</CustomProperties>'
```

5. Finish creating the catalog.

Important consideration about setting custom properties

Custom properties must be set correctly at `New-ProvScheme` and `Set-ProvScheme` in GCP and Azure environments. If you specify a non-existing custom property or properties, you get the following error message, and the commands fail to run.

`Invalid property found: <invalid property>. Ensure that the CustomProperties parameter supports the property.`

Important consideration about setting ProvScheme parameters

When you use MCS to create a catalog, you get an error if you:

- Set the following `New-ProvScheme` parameters in unsupported hypervisors when you create a machine catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PARAMETER	SUPPORTED HYPERVISOR
`UseWriteBackCache`	VMware
	Hyper-V
	XenServer®
	Azure
	GCP
`DedicatedTenancy`	Azure
	GCP
	AWS
`TenancyType`	Azure
	GCP
	AWS
`UseFullDiskCloneProvisioning`	VMware
	Hyper-V
	XenServer

- Update the following `Set-ProvScheme` parameters after you create the machine catalog:
  - `CleanOnBoot`
  - `UseWriteBackCache`
  - `DedicatedTenancy`
  - `TenancyType`
  - `UseFullDiskCloneProvisioning`

Add SIDs while creating virtual machines

You can add the parameter `ADAccountSid` to uniquely identify the machines while creating new virtual machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To do this:

1. Create a catalog with the supported identity type.
2. Add machines to the catalog using `NewProvVM`. For example:

```
New-ProvVM  -ProvisioningSchemeName "name"  -ADAccountSid @("SID ")  -
RunAsynchronously
```

However, you cannot provision a machine with:

- An AD account that is not in the catalog identity pool
- An AD account that is not in available state

Validate configuration before creating an MCS machine catalog

You can validate configuration settings before creating an MCS machine catalog using the parameter `-validate` in `New-ProvScheme` command. After you run this PowerShell command with the parameter, you get an appropriate error message if there is an incorrect parameter used or a parameter has conflict with another parameter. You can then use the error message to resolve the issue and successfully create an MCS machine catalog using PowerShell. Currently, this feature is applicable to AWS, Azure, GCP, and VMware virtualization environments.

NOTE:

While validating, you must not create an actual MCS machine catalog. You must use the result of the command to fix the errors, and then create a successful catalog. Therefore, while running the `New-ProvScheme` command, use a fake identity pool name.

To validate the configuration, do the following steps:

1. Open a PowerShell window from the Delivery Controller host.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run `New-ProvScheme` command and use the parameter `-validate`. Provide a fake identity pool name for the command to work. For example,

```
$result =New-ProvScheme  -CleanOnBoot -HostingUnitName "vSanRg"
-IdentityPoolName``"mptmpcatalogdemo" -InitialBatchSizeHint 1  -
MasterImageVM "XDHyp:
\HostingUnits\vSanRg\Windows19MasterImage.``vm\Citrix_XD_NonMachineProf
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
ileWin19Machines.snapshot" -NetworkMapping @{"0"="XDHyp:
\HostingUnits\vSanRg\\VM Network.network"} -ProvisioningSchemeName`
`"MachineProfileW10Machines"  -Scope @()

-VMCpuCount 2  -VM

MemoryMB 6143 -MachineProfile "XDHyp:\HostingUnits\vSanRg\TRW-Win11-
tpm-BL-TEMPLATE.``template" -TenancyType Shared  -FunctionalLevel
"L7_20" -Validate

$result.TerminatingError | Format-List -Property *
```

Error message:

```
ErrorData    : {[[ValidationFailureCount, xxx], [InvalidMemoryValue,
The memory size provided 6143 must be a multiple of 4 MB and must be
greater than or equal to 4 MB.], [InconsistentGuestOsSetting, The
GuestOs setting - windows9_64Guest of the selected machine profile does
not match with the setting - windows2019srv_64Guest of master image.
Please select a machine profile that matches the GuestOs setting of the
master image.], [InconsistentVtpmSetting, The vTPM setting of the
selected machine profile does not match with the selected master image.
Please select a machine profile that matches the vTPM setting of the
master image.], [InconsistentFirmwareSetting, The firmware setting -
efi of the selected machine profile does not match with the setting -
bios of master image. Please select a machine profile that matches the
firmware setting of the master image ErrorId      : ValidationFailure

ErrorMessage : ValidationFailure

Operation    : ValidatingInputs
```

4. After validating the configuration setting, you can create an MCS machine catalog with a real identity pool name and correct parameters.

Onboard VMs to Azure Arc

Azure Arc enables organizations to manage resources such as VMs hosted anywhere as if they are running in Azure. With Azure Arc, you can use Azure services such as Azure Monitor for comprehensive visibility and proactive management of the resources.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To onboard VMs to Azure Arc, create an MCS machine catalog using the `New-ProvScheme` command. You can also update an existing catalog using the `Set-ProvScheme` command. Only the new VMs added to the catalog are onboarded to Azure Arc.

Currently, this feature is applicable to all Citrix on-premises hypervisors VMware, Nutanix and SCVMM.

Prerequisites

Consider the following before enabling Azure Arc onboarding on MCS catalog:

- Azure Resource Group with:
  - `Allows` accounts to read, create, and delete Arc servers.
  - `Allows` accounts to manage VM extensions, licenses, and private link scopes.
  - `Azure Connected Machine Resource Administrator` role assigned to the service principal at the resource group scope.

See Assign Azure roles using the Azure portal.

- Master image with
  - VDA: Later than 2311, excluding 2411.

    NOTE:

    Azure Arc Onboarding is not supported in Citrix Virtual Apps and Desktops 2411.

  - AzureConnectedMachineAgent agent installed. You might download the MSI from under Windows or Linux sections of Microsoft's documentation.

Steps to onboard VM to Azure Arc

1. Setup a service account with `AzureArcResourceManagement` capability.

   The service account is used for authentication or authorization by storing credentials to access identity providers like Microsoft Entra ID. Each service account is tied to a single identity provider.

   To create a new service account to access Azure AD with `AzureArcResourceManagement capability`, run:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-AcctServiceAccount -IdentityProviderType “AzureAD”
-IdentityProviderIdentifier “tenant-id” -AccountId “application-id”
-AccountSecret “application-secret” -Capabilities
“AzureArcResourceManagement”
```

The `application-id` must be of the same service principal that was assigned the Azure Connected Machine Resource Administrator role.

2. Assign the service account to the identity pool. For example:

```
Set-AcctIdentityPool -IdentityPoolUid “idn-pool-uid” -ServiceAccountUid
“service-account-uid”
```

3. Create or update an MCS catalog with the following Arc parameters:

   - `EnableAzureArcOnboarding`: Indicates whether Arc Onboarding needs to be enabled on the catalog.
   - `AzureArcSubscriptionId`: Indicates the Azure subscription where the Arc-connected VMs are created.
   - `AzureArcRegion`: Indicates the Azure region where the Arc-connected VMs are created.
   - `AzureArcResourceGroup`: Indicates the Azure resource group where the Arc-connected VMs are created. See Prerequisites for information on Azure Arc Resource Group.

   Example: To enable Azure Arc Onboarding for a new catalog:

```
`New-ProvScheme -ProvisioningSchemeName "demo" -MasterImageVM "XDHyp:
\HostingUnits\hosting-unit\masterVMName.vm\masterSnapshotName.snapshot"
-HostingUnitName “hosting-unit” -IdentityPoolName “identity-pool”`

-EnableAzureArcOnboarding -AzureArcSubscriptionId “azure-sub”
-AzureArcResourceGroup “azure-resourcegroup” - AzureArcRegion “azure-
region”
```

   Example: To enable Azure Arc Onboarding for an existing catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-ProvScheme -ProvisioningSchemeName "demo" -EnableAzureArcOnboarding
$true -AzureArcSubscriptionId “azure-sub” -AzureArcResourceGroup
“azure-resourcegroup” - AzureArcRegion “azure-region”
```

Example: To disable Azure Arc Onboarding for an existing catalog:

```
Set-ProvScheme -ProvisioningSchemeName "demo" -EnableAzureArcOnboarding
$false:
```

4. Add new machines to the catalog to onboard Arc.
5. After you power-on the VM, you must see the VM in the Azure portal under **AzureArcResourceGroup** as a connected machine.

Considerations

- Arc onboarding is currently supported for only new VMs. So, if you update an existing catalog using `Set-ProvScheme`, then only newly added VMs are onboarded to Arc when first powered on.
- The Arc Custom Properties are still supported for existing catalogs for backward compatibility. However, if you run `New-ProvScheme` with Arc CustomProperties such as `EnableAzureArcOnboarding`, then catalog creation fails.
- You must add all the parameters in `New-ProvScheme` and `Set-ProvScheme` if you configure `EnableAzureArcOnboarding` as `true`.

Troubleshooting

When creating SCVMM catalog using `New-ProvScheme`, you might get the following error:

```
Master Image/Machine Profile's VM's device id is different than the
NetworkMapping's device id '0'. Please provide a device id that matches
the master image/machine profile.
```

In that case, make sure you explicitly specify the `DeviceId` in `NetworkMapping` parameter of `New-ProvScheme`. For example:

```
New-ProvScheme -ProvisioningSchemeType "MCS" -InitialBatchSizeHint 1
-HostingUnitName $HostingUnitName `

            -IdentityPoolName $CatalogName -MasterImageVM $MasterImage
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-ProvisioningSchemeName $CatalogName `

            -VMCpuCount 2 -VMMemoryMB 4096  -EnableAzureArcOnboarding `

            -AzureArcSubscriptionId $AzureArcSubscription -AzureArcRegion
$AzureArcRegion `

            -AzureArcResourceGroup $AzureArcResourceGroup

            -NetworkMapping @{"FDDxxxxxx-xxxx-4xxx-9EBC-3xxxxxxxx"="XDHyp:
\HostingUnits\<hosting unit name>\abc.network"}
```

Follow-Me Tagging

Follow-Me Tagging enables tracking of individual end-user VM usage by applying hypervisor-level tags. These tags, labeled with the specific user and/or organization (using `citrix-user-upn` as the key and the User Principal Name (UPN) as the value), are automatically added by Citrix when a user is assigned to a VM and removed when the user is unassigned.

Advantages

This feature offers several advantages:

- **IT chargeback**: Facilitates filtering resource usage (Azure: NICs, OS, ID, WBC, Data disks, and VMs) (AWS EC2: EC2 instance, EBS volumes (OS, ID, WBC, and Data disks), and NICs) by tags, allowing for accurate chargeback to individual users or business units.

  NOTE:

  - For AWS EC2, activate the `citrix-user-upn` tag key as a cost allocation tag to make it appear in your billing report. See Activating AWS-generated tags cost allocation tags.
  - For Azure, you need not activate the `citrix-user-upn` tag to filter cost analysis reports by user to view detailed spending, that includes, monthly total spend, costs per individual resource, daily cost trends, costs by service, and detailed billing records.

- **Efficient user management**: Automates the removal of tags from resources when end-users are unassigned (for example, employment changes like termination or reorganization).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Enhanced security monitoring**: Helps identify VMs assigned to specific end-users for targeted security scans.

Applicability

Currently, follow-me tagging is applicable to:

- AWS EC2 and Azure environments
- Statically assigned machines running single-session OS
- Persistent and Non-persistent catalogs
- All supported machine identity joined catalogs
- Only MCS provisioned VMs
- Managed disks (for Azure) only

Limitations

- A brief synchronization period exists between end-user assignment and the appearance of the corresponding tag on the hypervisor's machine.
- MCS doesn’t retry tagging operations if the tagging operation fails due to issues like insufficient tagging permissions, hypervisor failures, or unavailable Cloud Connectors. Instead, MCS issues a warning on the provisioning scheme. This warning can be accessed using the PowerShell command `Get-ProvOperationEvent`.
- Tag operations are initiated exclusively when a catalog's tagging is enabled or disabled, or when a user is assigned to a VM.
- If you manually remove the follow-me tag from the NIC, the tag doesn’t apply to any newly created resources on the next power on.

Important considerations

Consider the following when using follow-me tagging in AWS EC2 environments:

- AWS specific limitations: See Tagging limitations for tagging limitations.
- Activate the tag for cost allocation. See Activating AWS-generated tags cost allocation tags.

Consider the following when using follow-me tagging in Azure environment:

- Azure specific limitations
- You can add only 50 tags per resource.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure follow-me tagging

You can configure the follow-me tagging using Studio and PowerShell.

Use Studio

In the Machine Catalog Setup wizard:

1. On the **Operating System** page, select **Single-session OS.**
2. On the **Machine Management** page:
   - Select **Machines that are power managed (for example, virtual machines or blade PCs).**
   - Select to deploy machines using **Citrix provisioning technology Citrix Machine Creation Services (MCS)**.
3. Complete the settings on the following pages.
4. On the **Virtual Machines** page, select **Apply follow-me tagging**.
5. Complete the catalog creation process.
6. To verify that the feature is enabled for the catalog, navigate to the **Details** page for the created catalog. The **Follow-me tagging** capability under **Machine** must show as **Enabled**.
7. From the left-pane, select **Delivery groups**, click **Create Delivery Group**. Add the created catalog to a delivery group and assign one or more users to the delivery group.

MCS automatically tags a VM in the catalog with the first user who logs on to the machine. Alternatively, users can be manually assigned to a machine instead of relying on the first logon.

You can also edit an existing catalog to configure the follow-me tagging.

1. Select the catalog you want to modify and click **Edit Machine Catalog**.
2. Navigate to the **Virtual Machines** section and select **Apply Follow-me Tagging**.
3. Click **Apply** and then **Save** to enable the feature for the existing catalog. New and existing VMs in this catalog are now tagged at the hypervisor when end users are assigned.

Use PowerShell

To configure follow-me tagging using PowerShell, use the `-HypervisorVMTagging` parameter with the `Set-BrokerCatalog` cmdlet and set it to `$true`.

Example script to enable tagging:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-BrokerCatalog -Name 'CatalogName' -HypervisorVMTagging $true
```

Example Script to check tagging status for a catalog:

```
Get-BrokerCatalog -Name "SS-S-P-Cat" | Select Name, SessionSupport,
AllocationType, ProvisioningType, HypervisorVMTagging
```

Check the value of `HypervisorVMTagging`. If follow-me tagging is enabled for the catalog, then the value of `HypervisorVMTagging` is `True`.

After enabling the follow-me tagging for the catalog, add the created catalog to a delivery group and assign one or more users to the delivery group.

Use follow-me tagging

After you enable follow-me tagging for a machine catalog and users are assigned to the VMs within that catalog, MCS automatically applies a hypervisor-level tag to the virtual machines. This tag is in the format `citrix-user-upn:<User Principal Name (UPN)>`. Use this tag within your hypervisor's billing and management console to track resource usage by specific end users.

To analyze costs for resources with specific tags in Azure:

1. Go to the **Cost Analysis** page on Azure Portal.
2. Add the **Tag** filter.
3. Use `citrix-user-upn` as the key.
4. Select one or more desired UPNs to track resource costs.
5. View the actual costs accumulated for the tagged resources.

Use the tag filtering with `citrix-user-upn` to:

- See a user's monthly total spending (Accumulated costs view).
- View all resources owned by a specific user and their costs (Cost by resources view).
- Detect unexpected increases in daily costs per user (Daily costs view).
- Identify which services a user is spending on, such as VMs or Storage (Cost by service view).
- Build detailed user-level billing records by filtering raw billing line items (Invoice details view).

To analyze costs for resources with cost allocation tags in AWS:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Activate the cost allocation tags (It takes up to 24 hours for it to get activated and to be visible in the Billing Report). Activate the cost allocation tags through EC2 billing console or thorough AWS cost explorer API, `UpdateCostAllocationTagsStatus`.
2. Add the cost allocation Tag Key and some value to the AWS resources.

Using these tags, generate the billing reports to view the cost incurred by resources as per the cost allocation tag key and specific values. You can view the report on monthly, daily, and hourly granularity.

When a user is unassigned from a machine, MCS automatically removes the corresponding tag from that VM.

Troubleshooting

- **Problem**: Tags are not appearing on the hypervisor after user assignment.
- **Cause**: There might be a sync-up delay, or MCS failed to perform tagging due to permissions issues, hypervisor failure, or unavailable Cloud Connectors.
- **Solution**:
  - Allow a few minutes for the tag to appear.
  - If the issue persists, check for warnings on the provisioning scheme using the PowerShell cmdlet `Get-ProvOperationEvent` to identify any errors encountered during tagging. Ensure that Citrix has the necessary tagging permissions on the hypervisor.
  - Check the tagging status. Run `Get-ProvVM` and check the `CustomMachineData` for the Boolean `IsFollowMeTagged`.

Image replication of additional storage for supported on-premises hypervisors

This feature enables efficient replication and management of image version specification instances across multiple storage locations supported by on-premises hypervisors.

Use cases

- You can replicate image versions to new or superseded storage locations, allowing virtual machines to be provisioned in additional locations either during or after the image preparation process.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- When a new image version is created and additional storage locations are specified, the prepared image version specification is automatically replicated to those designated storage locations.
- If there is a need to use an existing image version with a superseded or newly added storage locations, you can add an image version instance to replicate to the new storage location.
- When a hosting unit is added to an existing image version, along with additional storage, the prepared image version spec instance will be replicated to the specified additional storages within the target hosting unit.

PowerShell commands

- Add a new image instance that replicates a prepared image version spec to the specified storage location.

```
Add-ProvImageVersionSpecInstance -ImageVersionSpecUid <
ImageVersionSpecUid > -StorageIds "<StorageId1,StorageId2>"
-RunAsynchronously
```

- Remove an existing image version spec instance replica and not used by any existing VMs.

```
Remove-ProvImageVersionSpecInstance -ImageVersionSpecUid <
ImageVersionSpecUid >  -ImageInstanceUid < ImageInstanceUid >
-RunAsynchronously
```

- Get a list of image version specs instances.

```
Get-ProvImageVersionSpecInstance -ImageVersionSpecUid  <
ImageVersionSpecUid >
```

Where to go next

For information on creating specific hypervisor catalogs, see:

- Create an AWS catalog
- Create a Google Cloud Platform catalog
- Create a Microsoft Azure catalog
- Create a Microsoft System Center Virtual Machine Manager catalog
- Create a Nutanix catalog

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create a VMware catalog
- Create a XenServer catalog

If this is the first catalog created, you are guided to create a delivery group.

To review the entire configuration process, see Plan and build a deployment.

You can create a Citrix Provisioning catalog using Studio and PowerShell. This implementation provides you the following advantages:

- A single unified console to manage both MCS and Citrix Provisioning catalogs.
- Have new features for Citrix Provisioning catalogs, such as, identity management solution, on-demand provisioning and so on.

Currently, this feature is available only for Azure and VMware workloads. However, in VMware and XenServer environments, you can currently create the catalogs using only PowerShell commands. For more information, see Create Citrix Provisioning catalogs in Citrix Studio.

More information

- Citrix Virtual Apps and Desktops Image Management
- Create and manage connections and resources
- Identity pools of different machine identity join types
- Manage machine catalogs

Create a catalog of Amazon WorkSpaces Core Managed Instances

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Amazon WorkSpaces Core Managed Instances.

NOTE:

Currently, creation of catalogs of both persistent and non-persistent VMs (`CleanOnBoot` property is `True` or `False`) is supported.

Prerequistes

Before creating a catalog of Amazon WorkSpaces Core Managed Instances, you need to finish creating:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. A connection to Amazon WorkSpaces Core Managed Instances. See Connection to Amazon WorkSpaces Core Managed Instances
2. A prepared image. See Create a prepared image for Amazon WorkSpaces Core Managed Instances.

Network setting during image preparation

During image preparation, a preparation virtual machine (VM) is created based on the original VM. This preparation VM is disconnected from the network. To disconnect the network from the preparation VM, a network security group is created to deny all inbound and outbound traffic. This network security group persists and is reused. The network security group's name is `Citrix.XenDesktop.IsolationGroup-GUID`, where GUID is randomly generated.

A machine profile-based machine catalog

You can use a machine profile to capture the hardware properties from an EC2 instance (VM) or launch template version and apply them to the provisioned machines. Properties that are captured can include, for example, tenancy type, instance type, security groups, network mappings, EBS volume properties, EBS optimization, CPU options, hibernation capability, and other supported AWS configurations.

You can use an AWS EC2 Instance (VM) or AWS Launch Template version as the machine profile input.

NOTE:

- EBS volume properties are derived only from a machine profile.
- The Instance Metadata Service (IMDS) V2 is only supported and not IMDS V1. For information, see How Instance Metadata Service Version 2 works.

AWS tenancy

AWS provides the following tenancy options: shared tenancy (the default type) and dedicated tenancy. Shared tenancy means that multiple Amazon WorkSpaces Core instances from different customers might reside on the same piece of physical hardware. Dedicated tenancy means that your Amazon WorkSpaces Core instances run only on hardware with other instances that you have deployed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The dedicated instances are only supported (dedicated hosts are currently not supported). Other customers do not use the same piece of hardware.

Tenancy type is captured from machine profile

When you use MCS to create a catalog to provision machines in AWS, the tenancy type is captured from the machine profile.

- **Shared hardware**: This setting is suitable for most deployments. Multiple customers share pieces of hardware even though they do not interact with each other. Using shared hardware is the least expensive option for running your Amazon EC2 instances.
- **Dedicated instance**: This setting is more suitable for deployments with specific security or compliance requirements. With a dedicated instance, you still enjoy the benefits of having a host separate from other AWS customers but you do not pay for the entire host. You do not need to worry about the capacity of the host but you are charged at a higher rate for the instances. Additionally, Dedicated Instances provide limited support for Bring Your Own License (BYOL).

Flexible billing

Amazon WorkSpaces Core Managed Instances supports two billing modes:

BILLING MODE	DESCRIPTION
Monthly	Fixed, monthly flat-rate billing. Ideal for persistent desktops and predictable workloads.
Hourly	Pay-as-you-go billing. This is the AWS default configuration if no billing mode is explicitly specified.

These options provide flexibility for managing compute costs based on your workload's persistence and usage patterns.

This feature requires the use of the Amazon WorkSpaces billing service. By default, MCS uses this service to provision and manage instances, letting you benefit from more competitive flat-rate pricing for persistent workloads.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prerequisites and considerations

- AWS account configuration: Your AWS account must be configured to use the WorkSpaces billing service. While AWS accounts are switched by default, some customers may request AWS to remain on the legacy EC2 billing service for using WorkSpaces Core Managed Instances.

  NOTE:

  If your account is on the legacy EC2 billing service, the **Monthly** billing option is not available.

- Host connection: Flexible billing is only applicable to Amazon WorkSpaces Core host connections. It is not supported for standard AWS EC2 host connections.
- Spot instances: Spot instances are not supported with the WorkSpaces billing service.
- Mixed billing: An AWS account must use either WorkSpaces billing or EC2 billing for core managed instances. A mix of both within a single account is not supported.
- Compatibility: Only specific instance types, platform types (OS), and tenancy types are compatible with certain billing modes. MCS performs a preflight check to ensure your selections (Service Offering, Machine Profile, and Prepared Image) match the chosen billing mode.

See Create a machine catalog with a specific billing mode.

Create a catalog

A prepared image and a machine profile is required for creating catalogs of Amazon WorkSpaces Core Managed Instances. You can use an AWS VM Instance or AWS Launch Template version as the machine profile input.

You can create a catalog using:

- Studio
- PowerShell

Create a catalog using Studio

Create a machine catalog from the Images node

Use the **Create catalog** option in the **Images** node to create a catalog using the image version.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Alternatively, you can select the version when creating a catalog in the **Machine Catalogs** node, linking to the prepared image option in the catalog creation workflow. See Create a machine catalog from the Machine Catalogs node.

To create an MCS machine catalog from the **Images** node, do the following:

1. Select an image version and click **Create catalog**. Click **Next** on the **Introduction** page.
2. On the **Machine Management** and **Image** pages, the settings are pre-selected based on the selected image version. On the Image page, enter a note for the selected prepared image.
3. Complete the settings on the following pages.
4. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.
5. Go to the **Machine Catalogs** node to see the created machine catalog.

Create a machine catalog from the Machine Catalogs node

To create an MCS machine catalog from the Machine Catalogs node, do the following:

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears.
3. On the **Machine Type** page, select a machine type for the catalog, for example, **Multi-session OS**.
4. On the **Machine Management** page, select the following settings:
    a. Select **Machines that are power managed (for example, virtual machines or blade PCs)**.
    b. Select **Citrix provisioning technology**. Then, select **Citrix Machine Creation Services™**.
    c. In the **Resources** field, select the resources (Availability Zone or Local Zone) that you configured while creating the host connection and click **Next**.
5. On the **Desktop experience** page, select either random or static desktop that you want users to have when they log in. If a static desktop is selected, further specify whether you want to save changes that the user makes on the local disk (persistent or non-persistent).
6. On the **Image** page, click **Select an image** to select a prepared image for the machine catalog. Select the prepared version that you created. Click the image version name. To view more details about the selected image version, click the version number, which is underlined. Click **Done**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The machine profile associated with the prepared image appears and its hardware properties (for example, instance type, tenancy type, network mappings, security groups, volume properties) are used to create machines in the catalogs. To change the machine profile source to another VM or launch template version click the edit button.

7. On the **Virtual Machines** page:
    a. Enter the number of VMs for the catalog.
    b. The default machine specification is displayed, which is based on the machine profile. To change it, select the edit icon and select a machine specification.
8. On the **NICs** page, select the NICs (or ENIs) for the VMs.
9. On the **Machine Identities** page, configure the machine identity type for the machines in the catalog:
    a. To configure **domain-joined machines (on-premises Active Directory or Microsoft Entra hybrid joined)**, select the domain and create new AD accounts for the VMs to be created in this machine catalog. The provisioned VMs are joined to the domain selected. To provision **non-domain joined machines**, select the non-domain join option.
    b. Specify the account naming scheme for the new accounts to be created for the VMs.
10. On the **Domain credentials** page, click **Enter credentials** to provide the credentials for the selected domain. Enter admin-level username and password when prompted. You can also use a service account if you have domain credentials already saved previously by following our product docs.
11. Click through the remaining pages until the **Summary** page. Enter a name for the machine catalog and select **Finish** to create the machine catalog.

Limitations on creating a machine catalog in an AWS local zone

- Certain local zones only support certain hardware configurations (for example, Perth local zone does not support GP3 volumes, only GP2).
- Since only gp2 is universally supported across all local zones, and not all support gp3, ID disk creation defaults to using gp2 volume type.
- You must select a machine profile with hardware specifications that are supported in the desired local zone.
- Prepared image AMIs snapshots and ID disk snapshots defaults to being placed in the region, rather than the local zone (due to AWS limitations regarding visibility into EBS snapshot support in local zones).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Only local zones supporting full EC2 and EBS services are supported zones.

Create a catalog using PowerShell

Create a catalog using a prepared image version spec and machine profile

- Create an MCS non-persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$true] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

- Create an MCS persistent machine catalog from the prepared image version spec using the `New-ProvScheme` command. For example,

```
New-ProvScheme -ProvisioningSchemeName <string> -ImageVersionSpecUid
<Guid> -HostingUnitUid <Guid> -IdentityPoolUid <Guid> [-CleanOnBoot
$false] [-MachineProfile <string>] [-ProvisioningSchemeType “MCS”]
```

Example of the complete set of Powershell commands to create a catalog:

```
$Catalog = New-BrokerCatalog  -AllocationType "Random"  -IsRemotePC $False
 -MinimumFunctionalLevel "L7_20" -Name "wsccatalog" -PersistUserChanges
"Discard" -ProvisioningType "MCS" -Scope @() -SessionSupport
"MultiSession"

$IdentityPool = New-AcctIdentityPool  -AllowUnicode  -Domain "domainname"
-IdentityPoolName "wsccatalog" -IdentityType "ActiveDirectory"  -
NamingScheme "aws##" -NamingSchemeType "Numeric" -Scope @()

$PreparedImageVersionSpec = Get-ProvImageVersionSpec -ImageDefinitionName
image1 -ImageVersionNumber 1 -Filter "PreparationType -eq 'Mcs'"

$Task = New-ProvScheme -ProvisioningSchemeName wsccatalog
-ImageVersionSpecUid $PreparedImageVersionSpec.ImageVersionSpecUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-HostingUnitName wsc -IdentityPoolName wsccatalog -CleanOnBoot -Scope @()
-SecurityGroup @() -MachineProfile 'XdHyp:\HostingUnits\cvad-test-
scalestress\us-east-1a.availabilityzone\machine-profile-instance i
(i-0xxxxxxxx).vm' -RunAsynchronously

Get-ProvTask -TaskId $Task.TaskId

$ProvScheme = Get-ProvScheme -ProvisioningSchemeName wsccatalog

Set-BrokerCatalog -Name $Catalog.Name -ProvisioningSchemeId
$ProvScheme.ProvisioningSchemeUid
```

Update the machine profile

To update the machine profile on a catalog that was initially provisioned with a machine profile, do the following. You can also change the tenancy type and hibernation capability of the machine profile source while editing an MCS machine catalog.

1. Run `Set-ProvScheme` command. For example,

```
Set-ProvScheme `

-ProvisioningSchemeUid "<ID" `

-MachineProfile "XDHyp:\HostingUnits\abc\us-
east-1a.availabilityzone\citrix-cvad-machineprofile-instance
(i-0xxxxxxxx).vm"
```

Create a machine catalog with a specific billing mode

You can specify the billing mode while creating a machine catalog using only PowerShell currently.

USE POWERSHELL

To specify the billing mode through PowerShell, use the `CustomProperties` parameter in the `New-ProvScheme` command.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$custprop = "BillingMode,Monthly"

New-ProvScheme -ProvisioningSchemeName "MyCatalog" `

-ImageVersionSpecUid $ImageVersionSpecUid `

-HostingUnitName "wsc-unit" `

-IdentityPoolName "MyIdentityPool" `

-MachineProfile "XdHyp:\HostingUnits\wsc-unit\machine-profile
lt-123.launchtemplate\lt-123 (1).launchtemplateversion" `

-CustomProperties $custprop `

-CleanOnBoot
```

NOTE:

If the `BillingMode` property is omitted, the catalog defaults to `Hourly`.

Change the billing mode of an existing catalog

You can convert an existing catalog from `Monthly` to `Hourly`, or vice versa. This change can apply to both new and existing VMs in the catalog.

IMPORTANT CONSIDERATIONS FOR UPDATES

- Service window: Existing VMs must undergo a service window or power cycle to apply the billing change.
- Validation: MCS validates that the existing instance types and platforms are compatible with the new billing mode before applying the change.

UPDATE USING POWERSHELL

- To update the billing mode of only new VMs added to a catalog, update the billing mode custom property of the provisioning scheme:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$custprop = "BillingMode,Hourly"

Set-ProvScheme -ProvisioningSchemeName "MyCatalog" -CustomProperties
$custprop
```

- To update the billing mode of new and existing VMs in a catalog, create a new provisioning scheme version with the updated custom property, and apply the new version to all VMs:

```
$custprop = "BillingMode,Hourly"

New-ProvSchemeVersion -ProvisioningSchemeName "MyCatalog"
-CustomProperties $custprop

New-ProvSchemeHardwareUpdate -ProvisioningSchemeVersion 2 `

-StartsNow -AllVMs `

-MaxDurationInMinutes 100 `

-ProvisioningSchemeName "MyCatalog"
```

Monitor billing information

You can verify the billing mode for catalogs and individual virtual machines.

Run the following PowerShell commands to check your account's billing eligibility:

- Returns `BillingMode` as part of CustomProperties

```
Get-ProvScheme –ProvisioningSchemeName “"MyCatalog" "  | Select
 ProvisioningSchemeName,  CustomProperties
```

- Returns `BillingMode` as part of VMInfo

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-ProvVMDetails –ProvisioningSchemeName “"MyCatalog" "  | Select-
Object  -ExpandProperty VMInfo
```

Troubleshooting and validation

MCS includes preflight checks to prevent incompatible configurations. You may encounter the following errors during catalog creation or editing:

- **NoInstanceConfigFoundForBillingMode**: Occurs if the selected Service Offering (instance type), Tenancy, and Platform Type are not supported for the chosen billing mode.
- **Spot Instance Not Supported**: If you attempt to use Spot instances with a WorkSpaces host connection, validation fails.
- **EC2 billing restriction**: If your AWS account is on the legacy EC2 billing model, attempting to set a Monthly billing mode results in a validation error.

Create a catalog with launch template version using PowerShell

You can create an MCS machine catalog with a launch template version as a machine profile input. You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM.

On the AWS EC2 console, you can provide the instance configuration information of a launch template along with version number. When you specify the launch template version as a machine profile input while creating or updating a machine catalog, the properties from that version of the launch template are copied to the provisioned VDA VMs.

The following properties can be provided using machine profile input or explicitly as parameters in `New-ProvScheme` or `Set-ProvScheme`commands. If they are provided in `New-ProvScheme` or `Set-ProvScheme` commands, they take precedence over the machine profile values of these properties.

- Service Offering
- Networks

NOTE:

If service offering is not provided in the machine profile launch template or as a parameter in the `New-ProvScheme` command, you get an appropriate error.

To create a catalog using launch template version as a machine profile input:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Get the list of launch template versions of a launch template. For example:

```
XDHyp:\HostingUnits\test\test-mp-sard (lt-01xxxxx).launchtemplate> ls |
Select FullPath
```

4. Create an identity pool if not created. For example:

```
New-AcctIdentityPool `

-IdentityPoolName "abc11" `

-NamingScheme "abc1-##" `

-NamingSchemeType Numeric `

-Domain "citrix-xxxxxx.local" `

-ZoneUid "xxxxxxxx" `
```

5. Create a provisioning scheme with a launch template version as a machine profile input. For example:

```
New-ProvScheme `

-ProvisioningSchemeName "MPLT1" `

-HostingUnitUid "c7f71f6a-3f45-4xxx-xxxx-xxxxxxxxxx" `

-IdentityPoolUid "bf3a6ba2-1f80-4xxx-xxxx-xxxxxxxxx" `

-ImageVersionSpecUid ‘24dfb047-e867-527g-896c-25664xxxxx1t’ `

-CleanOnBoot `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-01xxxxx).launchtemplate\lt-01xxxxx (1).launchtemplateversion"
```

6. Register a provisioning scheme as a broker catalog. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-BrokerCatalog -Name "MPLT1" `

-AllocationType Random `

-Description "Machine profile catalog" `

-ProvisioningSchemeId fe7df345-244e-4xxxx-xxxxxxxxx `

-ProvisioningType Mcs `

-SessionSupport MultiSession `

-PersistUserChanges Discard
```

7. Complete creating the catalog.

Update the machine profile source

You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM. For example:

- To update the input of a machine profile catalog from a VM to a launch template version:

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-0bxxxxxxxxxxxx).launchtemplate\lt-0bxxxxxxxxxxxx
(1).launchtemplateversion"
```

- To update the input of a machine profile catalog from a launch template version to a VM:

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\sard-ue1a\us-
east-1a.availabilityzone\apollo-non-persistent-vda-win2022-2
(i-08xxxxxxxx).vm"
```

MCSIO enabled catalog

MCS Storage Optimization (MCSIO) improves the performance of the VM by caching disk operations in either memory or on a small, high-speed disk. You can create an MCSIO enabled non-persistent catalog using PowerShell commands. To create such a catalog, you must install the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

MCSIO driver while installing or upgrading the VDA during the preparation of the AMI instance. By default, that driver is not installed.

After an MCSIO AMI is prepared (when installing the VDA, select the option to include the MCSIO driver in the installation), you can create an MCSIO enabled non-persistent catalog.

NOTE:

The option to configure MCSIO with only disk cache (without memory cache) using Studio has been removed across all hypervisors and cloud service environments.

Create an MCSIO enabled catalog

The four parameters added to the New-ProvScheme PowerShell command are:

- `UseWriteBackCache`: Turns on caching (write-back cache) for the given provisioning scheme
- `WriteBackCacheDiskSize`: Specifies the size in GB of the temporary disk used for caching
- `WriteBackCacheMemorySize`: Specifies how much memory in MB to use for caching. This is an optional parameter.

NOTE:

- The value of `WriteBackCacheDiskSize` must be more than zero because at least 1 GB of cache disk storage is required. The cache disk size must not be bigger than the OS disk size.
- The value of `WriteBackCacheMemorySize` must be non-zero and less than the machine catalog memory size.

The custom properties that affect MCSIO are:

- `WBCDiskStorageType`: Defines the volume type, which is used for the temporary disk in Amazon WorkSpaces Core Managed Instances. This parameter takes a string argument in the format `volume-type[:iops][:throughput]`. The following are the volume types:
  - gp2: Do not use iops and throughput parameters for this volume type
  - gp3: Use iops and throughput parameters for this volume type
  - io1: Use only iops parameter for this volume type
  - io2: Use only iops parameter for this volume type

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The default volume type is **gp2**.

- `PersistWBC`: Controls whether to keep or discard the cache disk whenever the Amazon WorkSpaces Core Managed Instances is powered off. If set to `true`, the cache disk is kept. If set to `false` (the default), the cache disk is only created and kept while the AMI instance is powered on.
- `PersistOSDisk`: Controls whether to keep or discard the OS disk whenever the Amazon WorkSpaces Core Managed Instances is powered off. If set to `true`, the OS disk is kept. If set to `false` (the default), the OS disk is only created and kept while the AMI instance is powered on.

Perform the following steps in the PowerShell window to create an MCSIO enabled non-persistent catalog:

1. Open the PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a broker catalog and an identity pool.
4. Create the provisioning scheme. For example:

```
$HostingUnitUid = '0xxxx1d9-bbfc-xxxf-bxxb-exxxxxe008b2'

$MasterImageVM = 'XDHyp:\HostingUnits\ctx-test\aws-apollo-non-
persistent-multi-mcsio-vda-win2022 (ami-0bf1810488acbxxxb).template'

$NetworkMap = @{ 'NetworkPath' = 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\10.0.128.0`/17
(vpc-0fa6e41d72507fxxx).network' }

$SecurityGroup = $( 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\private.securitygroup' )

$ServiceOffering = 'XDHyp:\HostingUnits\ctx-test\T3 Medium
Instance.serviceoffering'

$CustomProperties = 'WBCDiskStorageType,gp3:6000:250;PersistWBC,false'

$provScheme = New-ProvScheme -ProvisioningSchemeName $CatalogName
-HostingUnitUid $HostingUnitUid `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-IdentityPoolUid $acctPool.IdentityPoolUid -CleanOnBoot `

- MasterImageVM $MasterImageVM `

-NetworkMap $NetworkMap `

-ServiceOffering $ServiceOffering `

-SecurityGroup $SecurityGroup `

-CustomProperties $CustomProperties `

-UseWriteBackCache -WriteBackCacheDiskSize 16 -WriteBackCacheMemorySize
256
```

5. Add VMs to the catalog.

Improve boot performance with MCSIO

You can improve the boot performance of VMs if you enable MCSIO and set `PersistWBC` and `PersistOSDisk` custom properties as `true`. With such a setting, VMs can boot faster because they do not need to initialize a new cache disk or to recreate a root disk from their template.

Encrypt OS and ID disks

You can create a catalog of VMs with AWS KMS keys (Customer managed key and AWS managed key) that can be used to encrypt OS disk and Identity Disk (ID).

- AWS managed keys are automatically rotated every year.
- Customer managed keys are optional for automatic rotation and can be managed manually.

You can see the following AWS documents for more information on KMS keys:

- AWS KMS concepts
- How automatic key rotation works

For encryption of OS and ID disks, configure one of the following:

- Use a prepared image that is encrypted (for example, an AMI created from an instance or snapshot that contains an EBS root volume encrypted with KMS key)
- Use a machine profile source (VM or launch template) that contains an encrypted EBS root volume.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations

Consider the following limitations:

- MCS currently supports only one disk on prepared image AMI.
- You cannot directly encrypt existing unencrypted EBS volumes or snapshots, or modify the KMS key of an existing encrypted volume. To do that, you must:

  a. Create a new snapshot of that volume.

  b. Create a new volume from that snapshot

  c. Encrypt the new volume.

See the following AWS documents:

- Encrypt unencrypted resources
- Limitations of automatic or default encryption of EBS volumes: Automatically encrypt existing and new Amazon EBS volumes.

Create a catalog with disk encryption

You can create an MCS machine catalog with disk encryption using:

- Prepared image (created using image management from master image that has encrypted disk)
- Machine profile

Considerations while using machine profile input are:

- The KMS key of the machine profile input takes precedence over the prepared image's KMS key.
- If no machine profile input is provided, then the KMS key of the prepared image AMI is used to encrypt the disks of catalog VMs.
- If the machine profile has Block Device Mappings present, then the block devices present in the prepared image template (AMI) and the machine profile must match. For example, if AMI has a device defined on `/dev/sda1`, then the Machine Profile must also have a device defined on `/dev/sda1`.
- If there is no key in the machine profile source and the prepared image is unencrypted, then disks of catalog VMs are not encrypted.
- When the prepared image is encrypted, a machine profile source VM or launch template must have an encrypted root volume to be considered a valid input.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Modify an existing catalog

You can modify an existing catalog using the `Set-ProvScheme` PowerShell command to have:

- A machine profile input with a volume containing a new KMS key.
- A prepared image created from the master image with encrypted AMI using image management.

Important considerations:

- The volumes of new VMs added to the catalog are encrypted with the new KMS key.
- To update the encryption settings when there is an existing machine profile, run `Set-ProvScheme` with a new machine profile.
- You cannot modify an existing catalog from having encrypted volumes to unencrypted volumes. You cannot do an image update from an encrypted prepared image AMI to an unencrypted prepared image AMI.

Enable NitroTPM and UEFI secure boot for VM instances

When creating a catalog, you can now select a prepared image (AMI) with NitroTPM and/or UEFI secure boot enabled. Accordingly, the provisioned VMs in the catalog are also enabled with NitroTPM and/or UEFI secure boot. This implementation ensures that the VMs are secured and trusted. For more information on NitroTPM and UEFI Secure Boot, see the Amazon documentation.

Limitations

- You can use both NitroTPM and Secure Boot currently in all AWS Regions (including the AWS GovCloud (US) Regions) except China.
- You cannot enable NitroTPM and UEFI secure boot on existing catalogs. If you want a catalog with NitroTPM and UEFI secure boot enabled, create a new catalog.

Key steps

1. Set up your AWS environment.
2. Create a connection to AWS.
3. Create a master image (AMI) enabled with NitroTPM and/or UEFI secure boot.
4. Create a prepared image from the master image. See Create a prepared image for Amazon WorkSpaces Core Managed Instances.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. Create a machine catalog by selecting the prepared image with NitroTPM and UEFI secure boot enabled in Citrix Studio catalog creation menu or when creating a Provisioning Scheme using PowerShell commands.

VMs added to the created catalog have NitoTPM and UEFI secure boot enabled.

Create an AMI that supports NitroTPM and UEFI secure boot

1. You can create an AMI from a VM that has NitroTPM and/or UEFI secure boot enabled.
   a. Create the instance from using the AWS marketplace images. Example, search for `TPM-Windows_Server-2022-English-Full-Base on the aws-marketplace`.
   b. Download single or multi session VDA.
   c. Create an AMI from that VM.
2. Use the register-image command:

   ```
   --boot-mode (string)

   --tpm-support (string)
   ```

   For more information, see register-image.

See the following AWS documents:

- Determine the supported boot modes of an EC2 instance type
- Requirements for using NitroTPM with Amazon EC2 instances/.

You can open a PowerShell window from the Delivery controller™ host to check if a specific:

- service offering supports NitroTPM or UEFI secure boot

  ```
  (Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
  Instance.serviceoffering”).AdditionalData.BootMode

  (Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
  Instance.serviceoffering”).AdditionalData.NitroTpmSupportVersions
  ```

- template supports NitroTPM or UEFI secure boot

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
(Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
-ResourceType “template -Id “ID”).AdditionalData.BootMode

(Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
-ResourceType “template -Id “ID”).AdditionalData.TpmSupport
```

Update the service offering of existing catalog

You can change the service offering of an existing catalog using `Set-ProvScheme`. The change applies to the newly added VMs. However, you get errors in the following scenarios:

AMIS BOOT MODE	AMI SUPPORTS NITRO TPM?	SERVICE OFFERING SUPPORTS NITROTPM AND UEFI SECURE BOOT?
UEFI	No	No
Legacy BIOS	Yes	No
UEFI	Yes	No
UEFI Preferred	Yes	No

Copy tags on VMs

You can copy tags on NICs, and disks (Identity disk, write back cache disk, and OS disk) that are specified in the machine profile to newly created VMs in an MCS machine catalog. You can specify these tags in any of the machine profile sources (AWS VM instance or AWS launch template version). This feature is applicable to persistent and non-persistent machine catalogs and VMs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- On the AWS EC2 console, you cannot see the **Tag Network Interfaces** values under the **Launch Template Version Resource Tags**. However, you can run the PowerShell command `aws ec2 describe-launch-template-versions --launch-template-id lt-0bb652503d45dcbcd --versions 12` to see the tag specifications.
- If a machine profile source (VM or launch template version) has two network interfaces (eni-1 and eni-2), and eni-1 has tag t1 and eni-2 has tag t2, then the VM gets both the two network interfaces' tags.

Filter VM instances using PowerShell

An AWS VM instance that you use as a machine profile VM must be compatible for the machine catalog to create and function correctly. To list the AWS VM instances that can be used as machine profile input VMs, you can use the `Get-HypInventoryItem` command. The command can page and filter the inventory of VMs available on a hosting unit.

Pagination:

Get-HypInventoryItem supports two modes of pagination:

- Paging mode uses the `-MaxRecords` and `-Skip` parameters to return sets of items:
  - `-MaxRecords`: The default is **1**. This controls how many items to return.
  - `-Skip`: The default is **0**. This controls how many items to skip from the absolute beginning (or absolute end) of the list in the hypervisor.
- Scrolling mode uses `-MaxRecords`, `-ForwardDirection`, and `-ContinuationToken` parameters to allow scrolling of the records:
  - `-ForwardDirection`: The default is **True**. This is used along with `-MaxRecords` to return either the next set of matching records or the previous set of matching records.
  - `-ContinuationToken`: The returns the items immediately after (or before if `ForwardDirection` is **false**) but not including the item given in the `ContinuationToken`.

Examples of pagination:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To return a single record of the machine template with the lowest name. The `AdditionalData` field has the `TotalItemsCount` and the `TotalFilteredItemsCount`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template
```

- To return 10 records of the machine template with the lowest name:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 10 | select Name
```

- To return an array of records ending with the highest name:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ForwardDirection $False -MaxRecords 10 | select
Name
```

- To return an array of records starting at the machine template associated with the given `ContinuationToken`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ContinuationToken "ami-07xxxxxxxxx"
-MaxRecords 10
```

Filtering:

The following additional optional parameters are supported for filtering. You can combine these parameters with the pagination options.

- `-ContainsName "my_name"`: If the given string matches part of an AMI name, then the AMI is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -ContainName ‘apollo’ | select
Name
```

- `-Tags '{ "Key0": "Value0", "Key1": "Value1", "Key2": "Value2" }'`: If an AMI has at least one of these tags, it is included in the `Get` result. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -Tags '{"opex owner": "Not
tagged"}' | select Name
```

NOTE:

Two tag values are supported. **Not Tagged** tag value matches items which do not have the given tag in their list of tags. **All values** tag value matches items which have the tag regardless of the value of the tag. Otherwise, the match happens only if the item has the tag and the value equals to what is given in the filter.

- `-Id "ami-0a2d913927e0352f3"`: If the AMI matches the given ID, it is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -Id ami-xxxxxxxxxxxx
```

Filtering on AdditionalData parameter:

The `AdditionalData` filter parameter lists templates or VMs based on their capability, service offering, or any property which is in AdditionalData. For example:

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200).AdditionalData
```

You can also add a `-Warn` parameter to indicate the incompatible VMs. The VMs are included with an `AdditionalData` field named **Warning**. For example:

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200 -Template "ami-015xxxxxxxx"
-Warn $true).AdditionalData
```

Where to go next

- For managing an Amazon Workspaces Core catalog, see Manage a catalog of Amazon WorkSpaces Core Managed Instances

© 1997–2026 Citrix Systems, Inc. All rights reserved.

More information

- AWS virtualization environments
- Connection to Amazon WorkSpaces Core Managed Instances
- Image management
- Create a prepared image for Amazon WorkSpaces Core Managed Instances
- For Amazon WorkSpaces Core GitHub PowerShell examples, see citrix-mcs-sdk-samples-Amazon WorkSpaces Core.

Create an Amulet Hotkey CoreStation machine catalog

Create machine catalogs describes the generic machine-catalog workflow. The following information covers Amulet Hotkey CoreStation specific details.

NOTE:

- Before creating an Amulet Hotkey CoreStation catalog, complete Connection to Amulet Hotkey CoreStation.
- Make sure to have one or more Amulet Hotkey CoreStation nodes available and install VDAs on those nodes.
- For information about creating the initial Amulet Hotkey CoreStation cartridge image, see the OS Deployment on CoreStation User Guide.

You can create an Amulet Hotkey CoreStation machine catalog using:

- Studio
- PowerShell commands

Using Studio

In the Machine Catalog Setup wizard:

1. On the **Operating System** page, select **Multi-session OS** or **Single-session OS**.
2. On the **Machine Management** page, select **Machines that are power managed and Another service or technology**.
3. On the **Virtual Machines** page, add machines and their Active Directory machine accounts. You can do either of the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Click **Add Machines** to add machines manually. The **Select VMs window** appears. Expand the Amulet Hotkey CoreStation enclosure connection you created earlier and select the nodes you want to add. Then add the associated machine account names.
- Click **Add CSV File** to bulk add machines. For information about using CSV files to add machines, see Use CSV files to bulk add machines to a catalog.

The **Scopes** and **Summary** pages do not contain Amulet Hotkey CoreStation-specific information.

Using PowerShell commands

Run `New-BrokerCatalog` and `New-BrokerMachine` PowerShell commands to create a broker catalog and import machines to the broker catalog.

For example:

```
New-BrokerCatalog -AllocationType "Random" -IsRemotePC $False
-MachinesArePhysical $False -MinimumFunctionalLevel "L7_20" -Name "BurMC"
-PersistUserChanges "OnLocal" -ProvisioningType "Manual" -Scope @()
-SessionSupport "MultiSession" -ZoneUid "e166e2cb-25dc-4578-bc07-
bcf2a82d1463"

New-BrokerMachine -CatalogUid 3 -HostedMachineId "c10n1"
-HypervisorConnectionUid 4 -IsReserved $False -MachineName
"S-1-5-21-2589939477-3963209805-1860259709-1121"
```

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To power manage, see Power manage Amulet Hotkey CoreStation VMs.

More information

- Create and manage connections and resources
- Connection to Amulet Hotkey CoreStation
- Create machine catalogs

Create an AWS EC2 catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to AWS EC2 virtualization environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Before creating an AWS catalog, you need to finish creating a connection to AWS. See Connection to AWS EC2.

Network setting during image preparation

During image preparation, a preparation virtual machine (VM) is created based on the original VM. This preparation VM is disconnected from the network. To disconnect the network from the preparation VM, a network security group is created to deny all inbound and outbound traffic. This network security group persists and is reused. The network security group's name is `Citrix.XenDesktop.IsolationGroup-GUID`, where GUID is randomly generated.

AWS tenancy

AWS provides the following tenancy options:

- Shared tenancy (the default type) and dedicated tenancy. Shared tenancy means that multiple Amazon EC2 instances from different customers might reside on the same piece of physical hardware.
- Dedicated tenancy means that your EC2 instances run only on hardware with other instances that you have deployed. Other customers do not use the same piece of hardware.

Requirements for provisioning to AWS hosts

- An imported BYOL (bring your own license) image (AMI). With dedicated hosts, use and manage your existing licenses.
- An allocation of dedicated hosts with sufficient utilization to satisfy provisioning requests.
- Enabling **auto-placement**.

Options to configure AWS tenancy

- **Use shared hardware**. This setting is suitable for most deployments. Multiple customers share pieces of hardware even though they do not interact with each other. Using shared hardware is the least expensive option for running your Amazon EC2 instances.
- **Use dedicated host**. An Amazon EC2 dedicated host is a physical server with EC2 instance capacity that is fully dedicated, letting you use existing per-socket or per-VM software licenses. Dedicated hosts have preset utilization based on instance type. For example, a single allocated dedicated host of C4 Large instance types is limited to running 16 instances. See the AWS site for more information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This setting is suitable for deployments with licensing restrictions or security requirements that need your use of a dedicated host. With a dedicated host, you own an entire physical host and are billed on an hourly basis. Owning that host lets you spin up as many EC2 instances as that host permits, without more charges.

- **Use dedicated instance**. This setting is more suitable for deployments with specific security or compliance requirements. With a dedicated instance, you still enjoy the benefits of having a host separate from other AWS customers but you do not pay for the entire host. You do not need to worry about the capacity of the host but you are charged at a higher rate for the instances.

NOTE:

You can delete any available preparation identity disk if there is no ongoing catalog creation or image update task.

To configure AWS tenancy using Studio, see Create a catalog using Studio and using PowerShell, see Configure AWS dedicated host tenancy using the PowerShell.

Tag AWS operational resources

An Amazon Machine Image (AMI) represents a type of virtual appliance used to create a virtual machine within the Amazon Cloud environment, commonly referred to as EC2. You use an AMI to deploy services that use the EC2 environment. When you create a catalog to provision machines using MCS for AWS, you select the **AMI** to act as the golden image for that catalog.

IMPORTANT:

Creating catalogs by using both a machine profile and a launch template is required for using operational resource tagging.

To create an AWS catalog, you must first create an AMI for the instance you want to be the golden image. MCS reads the tags from that instance and incorporates them into the launch template. The launch template tags are then applied to all Citrix® resources created in your AWS environment, including:

- Virtual Machines
- VM disks
- VM network interfaces

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- S3 buckets
- S3 objects
- Launch templates
- AMIs

You can tag operational resources using Studio and PowerShell while creating a catalog. For Studio, see Create a catalog using Studio (**Image** page). For PowerShell, see Tag operational resources using PowerShell.

Create a catalog

You can create a catalog using:

- Studio
- PowerShell

Create a catalog using Studio

1. Click **Machine Catalogs** on the left navigation pane.
2. Click **Create Machine Catalog**. The **Machine Catalog Setup** page appears.
3. On the **Machine Type** page, select a machine type for the catalog, for example, Multi-session OS.
4. On the **Machine Management** page, select the following settings:
    a. Select Machines that are power managed (for example, virtual machines or blade PCs).
    b. Select **Citrix provisioning technology**. Then, select **Citrix Machine Creation Services™**.
    c. In the **Resources** field, select the resources (Availability Zone or Local Zone) that you configured while creating the host connection and click **Next**.
5. On the **Desktop experience** page, select either random or static desktop that you want users to have when they log in.
6. On the **Image** page:
    a. Select a machine template that you want to use as the master image for all machines in the catalog.
    b. If you want VMs in the catalog to inherit configurations from a machine profile, select a machine profile. By default, the **Use a machine profile** checkbox is selected. To change the machine profile source to another VM or launch template version, click the edit button.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. If the machine template has two volumes, then the option **Provision a Data disk** is enabled by default. In this case, machine profiles are filtered with only those instances or launch templates with two volumes (that specifies the hardware properties, for example, block device mapping, volume type) for the two volumes, and launch templates with no volumes and block device mappings defined.

   If you clear the checkbox to provision a data disk, then machine profiles are filtered with only those launch templates with no volumes and block device mappings defined.

   For a machine profile-based MCS catalog, you can use the same master VM as the data disk source for the machine profile.

d. Select the **Apply machine tags to operational resources** checkbox to apply machine tags to operational resources. This option controls whether to apply machine tags to every item created in your AWS environment that facilitates provisioning of machines. Operational resources are created as byproducts of catalog creation. They include both temporary and persistent resources, such as preparation VM instances and AMI.

NOTE:

The **Security** page appears only if you are creating a machine catalog without assigning a machine profile.

7. On the **Virtual Machines** page:

   a. Enter the number of VMs for the catalog.

   b. The default machine specification is displayed, which is based on the machine profile. To change it, select the edit icon and select a machine specification.

   c. Configure the AWS tenancy. See Options to configure AWS tenancy.

   d. You can also configure a secondary VM when the primary machine size reaches full capacity. Click **Secondary size** (optional). In the **Secondary machine size** window, the VMs listed have both, Spot and Regular VM types. You may select up to 10 secondary machine sizes. Once the 10 VMs are selected, then the other VMs listed are disabled from further selection. Click **Next**. In the **Secondary machine size** blade, you can select multiple machine sizes and drag and drop to change the priority order. Click **Done**. The selected machine sizes show up in the Secondary size (optional). Click the edit icon to edit as needed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

8. The **Security** page appears only if you are creating a machine catalog without assigninga machine profile. Use the **Security** page to configure the security groups for the VMs. This is also applicable when editing and cloning an existing machine catalog.

   If you create a machine profile-based machine catalog, then the security group configurations are inherited from the machine profile and the **Security** page does not appear.
9. In the **NICs** page, select the NICs (or ENIs) for the VMs.
10. On the **Disk Settings** page, choose whether to enable write-back cache.
11. On the **Machine Identities** page, configure on-premises Active Directory or Microsoft Entra hybrid joined for the machines in the catalog by selecting the domain and creating new AD accounts for the VMs to be created in this machine catalog. The provisioned VMs are joined to the domain selected. Specify the account naming scheme for the new AD accounts to be created for the VMs. Click Next.
12. On the **Domain credentials** page, click **Enter credentials** to provide the credentials for the selected domain. Enter admin-level username and password when prompted. You can also use a service account if you have domain credentials already saved previously by following our product docs.
13. Click through the remaining pages until the **Summary** page. If you select to provision a data disk on the **Images** page, the value of **Use data disk** is set to **true** on the **Summary** page.Enter a name for the machine catalog and select **Finish** to create the machine catalog.

Limitations on creating a machine catalog in an AWS local zone

- Certain local zones only support certain hardware configurations (for example, Perth local zone does not support GP3 volumes, only GP2).
- Since only gp2 is universally supported across all local zones, and not all support gp3, ID disk creation defaults to using gp2 volume type.
- You must select a machine profile with hardware specifications that are supported in the desired local zone.
- Prepared image AMIs snapshots and ID disk snapshots defaults to being placed in the region, rather than the local zone (due to AWS limitations regarding visibility into EBS snapshot support in local zones).
- Only local zones supporting full EC2 and EBS services are supported zones.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog using PowerShell

Configure AWS dedicated host tenancy using the PowerShell

Alternatively, you can provision AWS dedicated hosts through PowerShell. Use the `New-ProvScheme` cmdlet with the parameter `TenancyType` set to `Host`.

Tag operational resources using PowerShell

To use PowerShell to tag resources:

1. Open a PowerShell window from the DDC host.
2. Run the command `asnp citrix` to load Citrix-specific PowerShell modules.

To tag a resource for a provisioned VM, use the custom property `AwsOperationalResourcesTagging`. Example:

```
New-ProvScheme -ProvisioningSchemeName test

-CustomProperties “AwsOperationalResourcesTagging,true”

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-01xxxxx).launchtemplate\lt-01xxxxx (1).launchtemplateversion"

... <Other <standard provscheme parameters>
```

MCSIO enabled catalog

MCS Storage Optimization (MCSIO) improves the performance of the VM by caching disk operations in either memory or on a small, high-speed disk. You can create an MCSIO enabled non-persistent catalog using PowerShell commands. To create such a catalog, you must install the MCSIO driver while installing or upgrading the VDA during the preparation of the AMI instance. By default, that driver is not installed.

After an MCSIO AMI is prepared (when installing the VDA, select the option to include the MCSIO driver in the installation), you can create an MCSIO enabled non-persistent catalog.

NOTE:

The option to configure MCSIO with only disk cache (without memory cache) using Studio has been removed across all hypervisors and cloud service environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create an MCSIO enabled catalog

The four parameters added to the New-ProvScheme PowerShell command are:

- `UseWriteBackCache`: Turns on caching (write-back cache) for the given provisioning scheme
- `WriteBackCacheDiskSize`: Specifies the size in GB of the temporary disk used for caching
- `WriteBackCacheMemorySize`: Specifies how much memory in MB to use for caching. This is an optional parameter.

NOTE:

- The value of `WriteBackCacheDiskSize` must be more than zero because at least 1 GB of cache disk storage is required. The cache disk size must not be bigger than the OS disk size.
- The value of `WriteBackCacheMemorySize` must be non-zero and less than the machine catalog memory size.

The custom properties that affect MCSIO are:

- `WBCDiskStorageType`: Defines the volume type, which is used for the temporary disk in AWS. This parameter takes a string argument in the format `volume-type[:iops][:throughput]`. The following are the volume types:
  - gp2: Do not use iops and throughput parameters for this volume type
  - gp3: Use iops and throughput parameters for this volume type
  - io1: Use only iops parameter for this volume type
  - io2: Use only iops parameter for this volume type

  The default volume type is **gp2**.
- `PersistWBC`: Controls whether to keep or discard the cache disk whenever the AWS instance is powered off. If set to `true`, the cache disk is kept. If set to `false` (the default), the cache disk is only created and kept while the AMI instance is powered on.
- `PersistOSDisk`: Controls whether to keep or discard the OS disk whenever the AWS instance is powered off. If set to `true`, the OS disk is kept. If set to `false` (the default), the OS disk is only created and kept while the AMI instance is powered on.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Perform the following steps in the PowerShell window to create an MCSIO enabled non-persistent catalog:

1. Open the PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a broker catalog and an identity pool.
4. Create the provisioning scheme. For example:

```
$HostingUnitUid = '0xxxx1d9-bbfc-xxxf-bxxb-exxxxxe008b2'

$MasterImageVM = 'XDHyp:\HostingUnits\ctx-test\aws-apollo-non-
persistent-multi-mcsio-vda-win2022 (ami-0bf1810488acbxxxb).template'

$NetworkMap = @{ 'NetworkPath' = 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\10.0.128.0`/17
(vpc-0fa6e41d72507fxxx).network' }

$SecurityGroup = $( 'XDHyp:\HostingUnits\ctx-test\us-
east-1a.availabilityzone\private.securitygroup' )

$ServiceOffering = 'XDHyp:\HostingUnits\ctx-test\T3 Medium
Instance.serviceoffering'

$CustomProperties = 'WBCDiskStorageType,gp3:6000:250;PersistWBC,false'

$provScheme = New-ProvScheme -ProvisioningSchemeName $CatalogName
-HostingUnitUid $HostingUnitUid `

-IdentityPoolUid $acctPool.IdentityPoolUid -CleanOnBoot `

- MasterImageVM $MasterImageVM `

-NetworkMap $NetworkMap `

-ServiceOffering $ServiceOffering `

-SecurityGroup $SecurityGroup `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-CustomProperties $CustomProperties `

-UseWriteBackCache -WriteBackCacheDiskSize 16 -WriteBackCacheMemorySize
256
```

5. Add VMs to the catalog.

Improve boot performance with MCSIO

You can improve the boot performance of VMs if you enable MCSIO and set `PersistWBC` and `PersistOSDisk` custom properties as `tru`e. With such a setting, VMs can boot faster because they do not need to initialize a new cache disk or to recreate a root disk from their template.

Create a machine profile-based machine catalog using PowerShell

You can use a machine profile to capture the hardware properties from an EC2 instance (VM) or launch template version and apply them to the provisioned machines. Properties that are captured can include, for example, EBS volume properties, instance type, EBS optimization, CPU options, tenancy type, hibernation capability, security groups, and other supported AWS configurations.

You can use an AWS EC2 Instance (VM) or AWS Launch Template version as the machine profile input.

NOTE:

EBS volume properties are derived only from a machine profile.

Important considerations

The important considerations while creating an MCS machine catalog:

- If you add machine hardware property parameters in the `New-ProvScheme` and `Set-ProvScheme` commands, then the values provided in the parameters overwrite the values in the machine profile.
- If you set `AwsCaptureInstanceProperties` as `true` and do not set `MachineProfile` property, then only IAM roles and tags are captured.
- You cannot set both `AwsCaptureInstanceProperties` and `MachineProfile` at the same time.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The `AwsCaptureInstanceProperties` is deprecated.

- If a machine profile is not provided, you must explicitly provide the values of the following properties:
  - Security Group
  - ENI or Virtual Network
- You can enable `AwsOperationalResourcesTagging` only if you enable `AwsCaptureInstanceProperties` or specify a machine profile.

The important consideration after creating an MCS machine catalog is:

- You cannot change a catalog from a machine profile-based to a non-machine profile-based catalog.

Configure security groups in a machine profile input

You can create an MCS machine catalog where the provisioned VMs are assigned security groups per ENI (Network Interface). To do this, use a machine profile input (EC2 instance or launch template) that has different security groups mapped to distinct ENIs. For example, if machine profile input has ENI A with SG 1 and ENI B with SG 2, then provisioned VMs must also have ENI A with SG 1 and ENI B with SG 2.

Retrieve network interface details

Run the following commands to get the list of network interface data records including the interface SubnetId, assigned security groups, and assigned networks.

```
(Get-HypInventoryItem -LiteralPath 'XdHyp:\HostingUnits\cvad-test' –
ResourceType vm). AdditionalData
```

NOTE:

MCS does not currently allow more than one network per network interface.

Create a machine catalog using a machine profile

To create a machine catalog using a machine profile:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create an identity pool if not already created. For example,

```
New-AcctIdentityPool -IdentityPoolName idPool -NamingScheme ms##
-Domain abcdf -NamingSchemeType Numeric
```

4. Run New-ProvScheme command. For example:

```
New-ProvScheme -ProvisioningSchemeName demet-test-1

-HostingUnitUid aa633238-9xxd-4cf6-80e8-232a758a1xx1

-IdentityPoolUid 34d5b088-e312-416f-907d-16573xxxxxc4

-CleanOnBoot

-MasterImageVM 'XDHyp:\HostingUnits\cvad-test-scalestress\citrix-demet-
ami.0 (ami-0ca813xxxxxx061ef).template'

-MachineProfile 'XdHyp:\HostingUnits\cvad-test-scalestress\us-
east-1a.availabilityzone\machine-profile-instance i (i-0xxxxxxxx).vm'
```

5. Complete creating the catalog.

Update the machine profile

To update the machine profile on a catalog that was initially provisioned with a machine profile, do the following. You can also change the tenancy type and hibernation capability of the machine profile source while editing an MCS machine catalog.

1. Run `Set-ProvScheme` command. For example,

```
Set-ProvScheme `

-ProvisioningSchemeUid "<ID" `

-MachineProfile "XDHyp:\HostingUnits\abc\us-
east-1a.availabilityzone\citrix-cvad-machineprofile-instance
(i-0xxxxxxxx).vm"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog with launch template version using PowerShell

You can create an MCS machine catalog with a launch template version as a machine profile input. You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM.

On the AWS EC2 console, you can provide the instance configuration information of a launch template along with version number. When you specify the launch template version as a machine profile input while creating or updating a machine catalog, the properties from that version of the launch template are copied to the provisioned VDA VMs.

The following properties can be provided using machine profile input or explicitly as parameters in `New-ProvScheme` or `Set-ProvScheme`commands. If they are provided in `New-ProvScheme` or `Set-ProvScheme` commands, they take precedence over the machine profile values of these properties.

- Service Offering
- Networks
- Tenancy Type

NOTE:

If service offering is not provided in the machine profile launch template or as a parameter in the `New-ProvScheme` command, you get an appropriate error.

To create a catalog using launch template version as a machine profile input:

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Get the list of launch template versions of a launch template. For example:

```
XDHyp:\HostingUnits\test\test-mp-sard (lt-01xxxxx).launchtemplate> ls |
Select FullPath
```

4. Create an identity pool if not created. For example:

```
New-AcctIdentityPool `

-IdentityPoolName "abc11" `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-NamingScheme "abc1-##" `

-NamingSchemeType Numeric `

-Domain "citrix-xxxxxx.local" `

-ZoneUid "xxxxxxxx" `
```

5. Create a provisioning scheme with a launch template version as a machine profile input. For example:

```
New-ProvScheme `

-ProvisioningSchemeName "MPLT1" `

-HostingUnitUid "c7f71f6a-3f45-4xxx-xxxx-xxxxxxxxxx" `

-IdentityPoolUid "bf3a6ba2-1f80-4xxx-xxxx-xxxxxxxxx" `

-MasterImageVM "XDHyp:\HostingUnits\xxxd-ue1a\apollo-non-persistent-
vda-win2022 (ami-0axxxxxxxxxx).template" `

-CleanOnBoot `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-01xxxxx).launchtemplate\lt-01xxxxx (1).launchtemplateversion"
```

6. Register a provisioning scheme as a broker catalog. For example:

```
New-BrokerCatalog -Name "MPLT1" `

-AllocationType Random `

-Description "Machine profile catalog" `

-ProvisioningSchemeId fe7df345-244e-4xxxx-xxxxxxxxx `

-ProvisioningType Mcs `

-SessionSupport MultiSession `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-PersistUserChanges Discard
```

7. Complete creating the catalog.

Update the machine profile source

You can also update the input of a machine profile catalog from a VM to a launch template version and from a launch template version to a VM. For example:

- To update the input of a machine profile catalog from a VM to a launch template version:

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\xxxx-ue1a\machineprofiletest
(lt-0bxxxxxxxxxxxx).launchtemplate\lt-0bxxxxxxxxxxx
(1).launchtemplateversion"
```

- To update the input of a machine profile catalog from a launch template version to a VM:

```
Set-ProvScheme -ProvisioningSchemeName "CloudServiceOfferingTest" `

-MachineProfile "XDHyp:\HostingUnits\sard-ue1a\us-
east-1a.availabilityzone\apollo-non-persistent-vda-win2022-2
(i-08xxxxxxxx).vm"
```

Encrypt OS, ID, and WBC disks

You can create a persistent and non-persistent catalog of VMs with AWS KMS keys (Customer managed key and AWS managed key) that can be used to encrypt OS disk, Identity Disk (ID), and write-back cache disk (WBC).

- AWS managed keys are automatically rotated every year.
- Customer managed keys are optional for automatic rotation and can be managed manually.

You can see the following AWS documents for more information on KMS keys:

- AWS KMS concepts
- How automatic key rotation works

For encryption of OS, ID, and WBC disks, configure one of the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Use a master image that is encrypted (for example, an AMI created from an instance or snapshot that contains an EBS root volume encrypted with KMS key)
- Use a machine profile source (VM or launch template) that contains an encrypted EBS root volume.

Limitations

Consider the following limitations:

- MCS currently supports only one disk on master image AMI.
- You cannot directly encrypt existing unencrypted EBS volumes or snapshots, or modify the KMS key of an existing encrypted volume. To do that, you must:
  a. Create a new snapshot of that volume.
  b. Create a new volume from that snapshot
  c. Encrypt the new volume.

See the following AWS documents:

- Encrypt unencrypted resources
- Limitations of automatic or default encryption of EBS volumes: Automatically encrypt existing and new Amazon EBS volumes.

Create a catalog with disk encryption

You can create an MCS machine catalog with disk encryption using:

- Master image
- Machine profile

Considerations while using machine profile input are:

- The KMS key of the machine profile input takes precedence over the master image's KMS key.
- If no machine profile input is provided, then the KMS key of the master image AMI is used to encrypt the disks of catalog VMs.
- If the machine profile has Block Device Mappings present, then the block devices present in the master image template (AMI) and the machine profile must match. For example, if AMI has a device defined on `/dev/sda1`, then the Machine Profile must also have a device defined on `/dev/sda1`.
- If there is no key in the machine profile source and the master image is unencrypted, then disks of catalog VMs are not encrypted.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- When the master image is encrypted, a machine profile source VM or launch template must have an encrypted root volume to be considered a valid input.

Modify an existing catalog

You can modify an existing catalog using the `Set-ProvScheme` PowerShell command to have:

- A machine profile input with a volume containing a new KMS key.
- A master image template AMI encrypted with a new KMS key.

Important considerations:

- The volumes of new VMs added to the catalog are encrypted with the new KMS key.
- To update the encryption settings when there is an existing machine profile, run `Set-ProvScheme` with a new machine profile.
- You cannot modify an existing catalog from having encrypted volumes to unencrypted volumes. You can't do an image update from an encrypted master AMI to an unencrypted master AMI.

Enable NitroTPM and UEFI secure boot for VM instances

When creating a catalog, you can now select a master image (AMI) with NitroTPM and/or UEFI secure boot enabled. Accordingly, the provisioned VMs in the catalog are also enabled with NitroTPM and/or UEFI secure boot. This implementation ensures that the VMs are secured and trusted. For more information on NitroTPM and UEFI Secure Boot, see the Amazon documentation.

Limitations

- You can use both NitroTPM and Secure Boot currently in all AWS Regions (including the AWS GovCloud (US) Regions) except China.
- You cannot enable NitroTPM and UEFI secure boot on existing catalogs. If you want a catalog with NitroTPM and UEFI secure boot enabled, create a new catalog.

Key steps

1. Set up your AWS environment.
2. Create a connection to AWS.
3. Create a master image (AMI) enabled with NitroTPM and/or UEFI secure boot.
4. Create a machine catalog by selecting the master image with NitroTPM and UEFI secure boot enabled in Web Studio catalog creation menu or when creating a Provisioning Scheme using PowerShell commands.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

VMs added to the created catalog have NitoTPM and UEFI secure boot enabled.

Create an AMI that supports NitroTPM and UEFI secure boot

1. You can create an AMI from a VM that has NitroTPM and/or UEFI secure boot enabled.
   a. Create the instance from using the AWS marketplace images. Example, search for `TPM-Windows_Server-2022-English-Full-Base on the aws-marketplace`.
   b. Download single or multi session VDA.
   c. Create an AMI from that VM.
2. Use the register-image command:

   ```
   --boot-mode (string)

   --tpm-support (string)
   ```

   For more information, see register-image.

See the following AWS documents:

- Determine the supported boot modes of an EC2 instance type
- Requirements for using NitroTPM with Amazon EC2 instances/.

You can open a PowerShell window from the Delivery controller™ host to check if a specific:

- service offering supports NitroTPM or UEFI secure boot

  ```
  (Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
  Instance.serviceoffering”).AdditionalData.BootMode

  (Get-Item -Path “XDHyp:\HostingUnits\aws\T3 Medium
  Instance.serviceoffering”).AdditionalData.NitroTpmSupportVersions
  ```

- template supports NitroTPM or UEFI secure boot

  ```
  (Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
  -ResourceType “template -Id “ID”).AdditionalData.BootMode
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
(Get-HypInventoryItem -LiteralPath “XDHyp:\HostingUnits\aws”
-ResourceType “template -Id “ID”).AdditionalData.TpmSupport
```

Update the service offering of existing catalog

You can change the service offering of an existing catalog using `Set-ProvScheme`. The change applies to the newly added VMs. However, you get errors in the following scenarios:

AMIS BOOT MODE	AMI SUPPORTS NITRO TPM?	SERVICE OFFERING SUPPORTS NITROTPM AND UEFI SECURE BOOT?
UEFI	No	No
Legacy BIOS	Yes	No
UEFI	Yes	No
UEFI Preferred	Yes	No

Provision a data disk on MCS created VM

A data disk allows storage of persistent data like event logs, security traces, and application data.

You can create and assign a persistent data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in AWS.

You can provision persistent data disks with the OS and ID disks. And, the source of the data disk must be the master image (AMI's secondary volume).

You can create both machine profile and non-machine profile-based MCS catalog. For machine profile-based MCS catalog, you can use the same master image VM as the data disk source for the machine profile.

Data disk properties

The provisioned VM's data disk derives:

- Size and device name from the AMI
- Volume type from the AMI if the machine profile is not provided

For machine profile based catalog,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If the data disk is in the machine profile template, then provisioned VM derives data disk properties such as tag, storage policy, and storage tier from machine profile.
- The machine profile template must also have a data disk at the same device index as that of the data disk from the AMI

For non-machine profile based catalog, hardware information is derived from the master image AMI.

The data disk is also encrypted with a KMS key and inherits the KMS key of the data disk from AMI or machine profile if the KMS key is provided. The KMS of the machine profile though, takes precedence. You cannot change the KMS of the data disk.

Limitations

The following operations are currently not supported:

- Provisioning of non-persistent data disks.
- Using a machine profile:
  - with no data disk when the AMI has one, or
  - at a different data disk index than that of the AMI
- Per-disk tagging at instance creation time.
- Data disk device name restrictions:
  - For Windows AMIs, place the data disk on xvd and not on xvd
  - For Linux AMIs, place the data disk on /dev/sd and not on /dev/sd
- Modifying existing catalogs and VMs to use data disks.
- Resetting of data disk.
- Updating an image, of an existing catalog, that has a data disk with an image that doesn't have a data disk. Only new VMs are updated with image contents and volume properties, while existing VMs are not updated.
- Provisioning WBC disk with data disk.

Create a catalog with data disk

You can create a catalog with data disk using Studio and PowerShell.

For Studio, see Create a catalog using Studio. Additionally, see the following important points:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create a master image (AMI) from a master VM with two volumes, one of the OS disk (root volume) and one for the data disk (secondary volume).
- For a machine profile-based MCS catalog, you can use the same master VM as the data disk source for the machine profile.
- During catalog creation in the Studio UI, select the AMI you created with two voumes as the master image
- The **Provision data disk** option is enabled by default.
- Select a machine profile with 2 volumes (instance or launch template) or 0 volumes (launch templates only) that specifies the hardware properites (for example, block device mapping, volume type) for the two volumes.
- You cannot provision a data disk when the master image (AMI) has:
  - One volume: In this case, machine profiles are filtered with only those instances or launch templates with 1 volume, and launch templates with no volumes and block device mappings defined.
  - More than 2 volumes: In this case, machine profiles are filtered with only those launch templates with no volumes and block device mappings defined
- Finish creating the catalog and data data disk will be provisioned for the VMs in the catalog

Use PowerShell SDK

1. Create a master image (AMI) from a master VM with a data disk in AWS.

   For a machine profile-based MCS catalog, you can use the same master VM as the data disk source for the machine profile.

2. Create an MCS machine catalog with data disk provisioned VMs using `New-ProvScheme` PowerShell command with `DataDiskPersistence` parameter value - `"Persistent"`. For example:

   ```
   New-ProvScheme  -CleanOnBoot -HostingUnitName "<HostingUnitName >"
   -IdentityPoolName "<IdentityPoolName >" -InitialBatchSizeHint 1
   -MasterImageVM "<Path to master image item with an additional disk >"
   -NetworkMapping <NetworkMapping > -ProvisioningSchemeName
   "<ProvisioningSchemeName >" -DataDisk "" -DataDiskPersistence
   "Persistent"  -Scope @() -VMCpuCount 4  -VMMemoryMB 6144  -TenancyType
   Shared  -FunctionalLevel "L7_20"
   ```

3. Add VMs to the catalog using the `New-ProvVM` PowerShell command.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Image update with data disk

You can update the image using `Publish-ProvMasterVMImage`, however, you cannot update an image of an existing catalog, containing a data disk with an image that doesn't have a data disk. After you update the image:

- For a persistent catalog:
  - new VMs in the catalog have updated OS disk and data disk. Existing VMs are not updated
- For a non-persistent catalog:
  - new VMs in the catalog have updated OS disk and data disk. Existing VMs' OS disk is updated on the next restart, while the data disk is not updated.

Delete data disk

If you delete the catalog, the data disk is deleted unless you use `forgetVM` or `purgeDBOnly` option. If you delete the VM, the data disk is deleted unless you use the `forgetVM` or `purgeDBOnly` option.

For on-demand provisioning catalogs, never delete the data disk.

Copy tags on VMs

You can copy tags on NICs, and disks (Identity disk, write back cache disk, and OS disk) that are specified in the machine profile to newly created VMs in an MCS machine catalog. You can specify these tags in any of the machine profile sources (AWS VM instance or AWS launch template version). This feature is applicable to persistent and non-persistent machine catalogs and VMs.

NOTE:

- On the AWS EC2 console, you cannot see the **Tag Network Interfaces** values under the **Launch Template Version Resource Tags**. However, you can run the PowerShell command `aws ec2 describe-launch-template-versions --launch-template-id lt-0bb652503d45dcbcd --versions 12` to see the tag specifications.
- If a machine profile source (VM or launch template version) has two network interfaces (eni-1 and eni-2), and eni-1 has tag t1 and eni-2 has tag t2, then the VM gets both the two network interfaces' tags.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Filter VM instances using PowerShell

An AWS VM instance that you use as a machine profile VM must be compatible for the machine catalog to create and function correctly. To list the AWS VM instances that can be used as machine profile input VMs, you can use the `Get-HypInventoryItem` command. The command can page and filter the inventory of VMs available on a hosting unit.

Pagination:

Get-HypInventoryItem supports two modes of pagination:

- Paging mode uses the `-MaxRecords` and `-Skip` parameters to return sets of items:
  - `-MaxRecords`: The default is **1**. This controls how many items to return.
  - `-Skip`: The default is **0**. This controls how many items to skip from the absolute beginning (or absolute end) of the list in the hypervisor.
- Scrolling mode uses `-MaxRecords`, `-ForwardDirection`, and `-ContinuationToken` parameters to allow scrolling of the records:
  - `-ForwardDirection`: The default is **True**. This is used along with `-MaxRecords` to return either the next set of matching records or the previous set of matching records.
  - `-ContinuationToken`: The returns the items immediately after (or before if `ForwardDirection` is **false**) but not including the item given in the `ContinuationToken`.

Examples of pagination:

- To return a single record of the machine template with the lowest name. The `AdditionalData` field has the `TotalItemsCount` and the `TotalFilteredItemsCount`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template
```

- To return 10 records of the machine template with the lowest name:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 10 | select Name
```

- To return an array of records ending with the highest name:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ForwardDirection $False -MaxRecords 10 | select
Name
```

- To return an array of records starting at the machine template associated with the given `ContinuationToken`:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -ContinuationToken "ami-07xxxxxxxxx"
-MaxRecords 10
```

Filtering:

The following additional optional parameters are supported for filtering. You can combine these parameters with the pagination options.

- `-ContainsName "my_name"`: If the given string matches part of an AMI name, then the AMI is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -ContainName ‘apollo’ | select
Name
```

- `-Tags '{ "Key0": "Value0", "Key1": "Value1", "Key2": "Value2" }'`: If an AMI has at least one of these tags, it is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -MaxRecords 100 -Tags '{"opex owner": "Not
tagged"}' | select Name
```

NOTE:

Two tag values are supported. **Not Tagged** tag value matches items which do not have the given tag in their list of tags. **All values** tag value matches items which have the tag regardless of the value of the tag. Otherwise, the match happens only if the item has the tag and the value equals to what is given in the filter.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `-Id "ami-0a2d913927e0352f3"`: If the AMI matches the given ID, it is included in the `Get` result. For example:

```
Get-HypInventoryItem -LiteralPath "XDHyp:\HostingUnits\ctx-test"
-ResourceType template -Id ami-xxxxxxxxxxxx
```

Filtering on AdditionalData parameter:

The `AdditionalData` filter parameter lists templates or VMs based on their capability, service offering, or any property which is in AdditionalData. For example:

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200).AdditionalData
```

You can also add a `-Warn` parameter to indicate the incompatible VMs. The VMs are included with an `AdditionalData` field named **Warning**. For example:

```
(Get-HypInventoryItem -ResourceType "launchtemplateversion" -LiteralPath
"XDHyp:\HostingUnits\aws" -MaxRecords 200 -Template "ami-015xxxxxxxx"
-Warn $true).AdditionalData
```

Backup SKU list for VMs

Public clouds can sometimes run out of capacity for a specific EC2 instance type (“primary SKU”). If the primary VM configuration is not available, then the VM cannot start resulting in loss of time and business disruption. To address such scenarios, provide a list of backup EC2 instance types (“backup SKUs”) that MCS can fall back to in the case of capacity-related issues.

Use a custom property `BackupVmConfiguration` while creating or updating an MCS machine catalog to provide a list of backup EC2 instance types (“Backup SKU List”).

If the primary EC2 instance fails, MCS attempts to fall back on the backup EC2 instance types in the order you specify. If MCS is unable to fall back on any of the provided backup EC2 instance types, an error message is displayed. You can then try powering on the primary EC2 instance again. If this fails, MCS retries the backup EC2 instance types.

The backup SKU list can have on-demand instance.

This feature is applicable to both persistent and non-persistent MCS machine catalogs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Important considerations

- You can provide multiple backup EC2 instance types in the backup SKU list.
- The backup SKU list must be unique.
- A backup EC2 instance cannot be the same as the primary EC2 instance.
- The backup EC2 instances must be valid AWS instance types.
- Do not specify duplicate service offerings. Example: `BackupVmConfiguration,t2.small|t3.small|t2.small` is not valid.
- The service offering specified in the list must be compatible with the machine catalog configuration. For example, if the catalog uses UEFI and the service offering specified in the backup list doesn't support it, then the catalog creation or update fails during preflight.
- You can modify the backup SKU list of an existing catalog using the `Set-ProvScheme` PowerShell command. You can modify existing VMs using the `Set-ProvVM` and `Set-ProvVMUpdateTimeWindow` PowerShell commands.

Configure backup EC2 instances

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a Broker catalog.
4. Create an identity pool.
5. Add a backup EC2 instance list using the custom property `BackupVmConfiguration` and create a provisioning scheme. For example:

```
$serviceOffering = "XDHyp:\HostingUnits\$hostingUnitName\T3 Medium
Instance.serviceoffering"

$customProperties =
"AwsCaptureInstanceProperties,false;AwsOperationalResourcesTagging,fals
e;BackupVmConfiguration,t2.small|t2.large|t3.small|t3.large;"

$createdProvScheme = New-ProvScheme -ProvisioningSchemeName
$provisioningSchemeName -HostingUnitName $hostingUnitName
-IdentityPoolName $provisioningSchemeName -NetworkMapping
$networkMapping -SecurityGroup $securityGroupPath -ServiceOffering
$serviceOffering -MasterImageVM $masterImageVm -CustomProperties
$customProperties
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Update the BrokerCatalog with the unique Id of the provisioning scheme.
7. Create and add VMs to the catalog.

You can also add backup EC2 instances using Studio:

On the **Virtual Machines** page, click **Secondary size** (optional). In the **Secondary machine size** window, the VMs listed have both, Spot and Regular VM types. You may select up to 10 secondary machine sizes. Once the 10 VMs are selected, then the other VMs listed are disabled from further selection. Click **Next**. In the **Secondary machine size** blade, you can select multiple machine sizes and drag and drop to change the priority order. Click **Done**. The selected machine sizes show up in the Secondary size (optional). Click the edit icon to edit as needed. See Create a catalog using Studio.

Create a catalog using AWS Spot instance

Compared to On-demand instances, Spot instances offer cost savings of up to 90%. Spot instances may be interrupted by Amazon EC2 if capacity becomes unavailable, making them suitable for non-critical applications and desktops only.

For information on Spot instances, see the AWS doc Spot Instances.

Additionally, you can use Spot instances as both primary EC2 instance type and backup EC2 instance. You can provide a list of backup EC2 instance types (“Backup SKUs” that can be On-demand and Spot instances) using PowerShell that MCS can fall back to in capacity-related issues.

Important considerations**

- You must create a catalog of Spot instances only with machine profile workflow.
- Only a persistent Spot instance request type is supported. A one-time Spot Instance request is not supported.
- Only the **Stop** and **Hibernate** interruption behaviors are supported.
- You can change the configuration of an existing catalog from On-demand to Spot instances and vice versa. However, changing an EC2 instance from On-demand to Spot is complex. See the AWS documentation Switch an EC2 instance from on-demand to spot pricing.
- When you delete a provisioned Spot instance, cancel the existing spot instance request. Or else, AWS creates a new Spot instance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Steps to create a catalog using AWS Spot instances

1. Create a machine profile source with Spot instance. For steps to create a Spot instance, see Create a Spot Instance request.
2. Create a machine catalog using a machine profile with `New-ProvScheme` PowerShell command. You can update a catalog using the `Set-ProvScheme` command.

Use Spot instances as backup SKU

You can use Spot instances as both primary EC2 instance type and backup EC2 instance. You can provide a list of backup EC2 instance types (“Backup SKUs” that can be On-demand and Spot instances) using PowerShell that MCS can fall back to in capacity-related issues.

NOTE:

You can specify duplicate Spot instances in the backup SKUs list. Example: `BackupVmConfiguration,t2.small:Spot|t2.small|t3.small` is valid.

Required permissions

You need the following permissions if you use Spot instance as a primary or backup EC2 instance:

- `ec2:DescribeSpotInstanceRequests`
- `ec2:CancelSpotInstanceRequests`

Configure backup Spot instances

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a Broker catalog.
4. Create an identity pool.
5. Add a backup EC2 instance list using the custom property `BackupVmConfiguration` and create a provisioning scheme. For example:

```
$serviceOffering \= "XDHyp:\\HostingUnits\\$hostingUnitName\\T3 Medium
Instance.serviceoffering"

$customProperties \=
"AwsCaptureInstanceProperties,false;AwsOperationalResourcesTagging,fals
e;BackupVmConfiguration,t2.small|t2.large|t3.small:Spot|t3.large:Spot"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$createdProvScheme \= New-ProvScheme \-ProvisioningSchemeName
$provisioningSchemeName \-HostingUnitName $hostingUnitName \-
IdentityPoolName $provisioningSchemeName \-NetworkMapping
$networkMapping \-SecurityGroup $securityGroupPath \-ServiceOffering
$serviceOffering \-MasterImageVM $masterImageVm \-CustomProperties
$customProperties
```

6. Update the BrokerCatalog with the unique Id of the provisioning scheme.
7. Create and add VMs to the catalog.

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage an AWS EC2 catalog.

More information

- Create and manage connections and resources
- Connection to AWS EC2
- Create machine catalogs

Create a Google Cloud Platform catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Google cloud environments.

NOTE:

Before creating a Google cloud platform (GCP) catalog, you need to finish creating a connection to GCP. See Connection to Google cloud environments.

Prepare a master VM instance and a persistent disk

TIP:

Persistent disk is the Google Cloud term for virtual disk.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To prepare your master VM instance, create and configure a VM instance with properties that match the configuration you want for the cloned VDA instances in your planned machine catalog. The configuration does not apply only to the instance size and type. It also includes instance attributes such as metadata, tags, GPU assignments, network tags, and service account properties.

As part of the mastering process, MCS uses your master VM instance to create the Google Cloud *instance template*. The instance template is then used to create the cloned VDA instances that comprise the machine catalog. Cloned instances inherit the properties (except the VPC, subnet, and persistent disk properties) of the master VM instance from which the instance template was created.

After configuring the properties of the master VM instance to your specifics, start the instance and then prepare the persistent disk for the instance.

We recommend that you manually create a snapshot of the disk or an image of the disk. Doing so lets you use a meaningful naming convention to track versions, gives you more options to manage earlier versions of your master image, and saves time for machine catalog creation. If you do not create your own snapshot, MCS creates a temporary snapshot for you (which is deleted at the end of the provisioning process). Manually creating a multi-regional snapshot of the OS disk or image also allows you to use the same master image for machine catalogs in different GCP regions.

Enable zone selection

Citrix DaaS™ supports zone selection. With zone selection, you specify the zones where you want to create VMs. With zone selection, administrators can place sole tenant nodes across zones of their choice. To configure sole tenancy, you must complete the following on Google Cloud:

- Reserve a Google Cloud sole-tenant node
- Create the VDA master image

Reserve a Google Cloud sole-tenant node

To reserve a sole-tenant node, refer to the Google Cloud documentation.

IMPORTANT:

A node template is used to indicate performance characteristics of the system that is reserved in the node group. Those characteristics include the number of vGPUs, the amount of memory allocated to the node, and the machine type used for machines created on the node. For more information see the Google Cloud documentation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create the VDA master image

To deploy machines on the sole-tenant node successfully, you need to take extra steps when creating a master VM image. Machine instances on Google Cloud have a property called *node affinity labels*. Instances used as master images for catalogs deployed to the sole-tenant node require a *node affinity label* that matches the name of the **target node group**. To achieve this, keep the following in mind:

- For a new instance, set the label in the Google Cloud console when creating an instance. For details, see Provision a sole-tenant VM.
- For an existing instance, set the label by using the **gcloud** command line. For details, see Configure node affinity labels.

NOTE:

If you intend to use sole tenancy with a shared VPC, see Shared Virtual Private Cloud.

Create a machine catalog

NOTE:

Create your resources before you create a machine catalog. Use the naming conventions established by Google Cloud when configuring machine catalogs. See Bucket and object naming guidelines for more information.

You can create a machine catalog in two ways:

- Studio
- PowerShell. See Manage Citrix DaaS using Remote PowerShell SDKs. For information on how to implement specific features using PowerShell, see Use PowerShell

Create a machine catalog using Studio

Follow the guidance in Create machine catalogs. The following description is unique to Google Cloud catalogs.

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select **Create Machine Catalog** in the action bar.
3. On the **Machine Type** page, select **Multi-session OS** and then select **Next**. Citrix DaaS also supports single-session OS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. On the **Machine Management** page, select the **Machines that are power managed** and the **Citrix Machine Creation Services™** options and then select **Next**. If there are multiple resources, select one from the menu.
5. On the **Image** page, complete these steps as needed, and then click **Next**.

    a. Select the master image. You can select the following image types:

    - Virtual Machine (whose regions are the same as the selected hosting units).
    - Snapshots (support multi-region snapshots).
    - OS image (support multi-region public and non-public images). If you want to use the sole tenancy functionality, be sure to select an image whose node group property is correctly configured. See Enable zone selection.

    b. On the **Select a machine profile** page, select resources from **Virtual machine** tab or from **Instance templates** tab.

    NOTE:

    - Currently, VMs in this catalog inherit the storage, machine type, and disk encryption, settings from the selected machine profile.
    - If you select an instance template as the machine profile, then all the zones are selected by default. You can select the zones as required.

    c. Select the minimum functional level for the catalog.

6. On the **Storage** page, select the type of storage used to contain the operating system for this machine catalog. Each of the following storage options has unique price and performance characteristics. An identity disk is always created using the zonal standard persistent disk.

    - Standard persistent disk
    - Balanced persistent disk
    - SSD persistent disk

    For details about Google Cloud storage options, see Storage options.

7. On the **Virtual Machines** page, specify how many VMs you want to create, view the detailed specification of the VMs, select the Google Cloud machine type, and then select **Next**. If you

© 1997–2026 Citrix Systems, Inc. All rights reserved.

use sole tenant node groups for machine catalogs, be sure to select **only** the zones where reserved sole tenant nodes are available. See Enable zone selection.

NOTE

.

Google Cloud machine type is automatically selected based on the machine profile chosen. You can select a different machine type if necessary.

8. On the **Disk Settings** page, you can configure the following settings:

   - Choose whether to enable write-back cache. After enabling write-back cache, you can do the following:

     - Configure the size of the disk and RAM used for caching temporary data. For more information, see Configure cache for temporary data.
     - Select the storage type for the write-back cache disk. The following storage options are available to use for the write-back cache disk:

       - Standard persistent disk
       - Balanced persistent disk
       - SSD persistent disk

       For details about Google Cloud storage options, see Storage options.
     - Select the type for the write-back cache disk.

       - **Use non-persistent write-back cache disk**. If selected, the write-back cache disk does not persist for the provisioned VMs. The disk is deleted during power cycles and any data redirected to the disk will be lost.
       - **Use persistent write-back cache disk**. If selected, the write-back cache disk persists for the provisioned VMs. Enabling this option increases your storage costs.

   - When MCS storage optimization (MCS I/O) is enabled, you can do either of the following:

     - Choose whether to retain system disks for VDAs during power cycles. For more information, see Enabling MCS storage optimization updates.
     - Update the memory and disk cache sizes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Choose whether to use your own key to protect disk contents. To use the feature, you must first create your own Customer Managed Encryption Keys (CMEKs). For more information, see Use Customer Managed Encryption Keys (CMEK).

  NOTE:

  It is available only in the Studio interface.

  After creating the keys, you can select one of those keys from the list. You cannot change the key after you create the catalog. Google Cloud does not support rotating keys on existing persistent disks or images. Therefore, after you provision a catalog, the catalog is tied to a specific version of the key. If that key is disabled or destroyed, the instances and disks encrypted with it become unusable until the key is reenabled or restored.

  The Customer-Managed Encryption Key (CMEK) settings follow a priority sequence as below:

  - Customized CMEK of a catalog takes the highest priority.
  - If the selected machine profile is encrypted, the CMEK settings automatically use the machine profile's CMEK as the next priority.
  - If the selected machine profile is not encrypted, the CMEK settings automatically use the master image's CMEK.

9. On the **Machine Identities** page, select an Active Directory account and then select **Next**.
   - If you select **Create new Active Directory accounts**, select a domain and then enter the sequence of characters representing the naming scheme for the provisioned VM computer accounts created in the Active Directory. The account naming scheme can contain 1–64 characters, and cannot contain blank spaces, or non-ASCII or special characters.
   - If you select **Use existing Active Directory accounts**, select **Browse** to navigate to the existing Active Directory computer accounts for the selected machines.
10. On the **Domain Credentials** page, select **Enter credentials**, type the user name and password, select **Save**, and then select **Next**.
    - The credential you type must have permissions to perform Active Directory account operations.
11. On the **Scopes** page, select scopes for the machine catalog and then select **Next**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You can select optional scopes or select **custom scope** to customize scopes as needed.

12. On the **Summary** page, confirm the information, specify a name for the catalog, and then select **Finish**.

> **NOTE:**
>
> The catalog name can contain 1–39 characters, and cannot contain only blank spaces or the characters `\ / ; : # . * ? = < > | [ ] { } " ' ( ) ' )`.

Machine catalog creation might take a long time to complete. When it completes, the catalog is listed. You can verify that the machines are created on the target node groups in the Google Cloud console.

Import manually created Google Cloud machines

Using this feature, you can:

- Import manually created Google Cloud multi-session OS machines into a Citrix DaaS catalog.
- Remove manually created Google Cloud multi-session OS machines from a Citrix DaaS catalog.
- Use existing Citrix DaaS power management capabilities to power manage Google Cloud Windows multi-session OS machines. For example, set a restart schedule for those machines.

This functionality does not require changes to an existing Citrix DaaS provisioning workflow, nor the removal of any existing feature.

It is recommended that you use MCS to provision machines in Studio instead of importing manually created Google Cloud machines.

Shared Virtual Private Cloud

Shared Virtual Private Clouds (VPCs) comprise a host project, from which the shared subnets are made available, and one or more service projects that use the resource. Shared VPCs are desirable options for larger installations because they provide centralized control, usage, and administration of shared corporate Google cloud resources. For more information, see the Google Documentation site.

With this feature, Machine Creation Services (MCS) supports provisioning and managing machine catalogs deployed to Shared VPCs. This support, which is functionally equivalent to the support currently provided in local VPCs, differs in two areas:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You must grant extra permissions to the Service Account used to create the host connection. This process allows MCS to access and use Shared VPC Resources. See New permissions required.
- You must create two firewall rules, one each for ingress and egress. These firewall rules are used during the image mastering process. See Firewall Rules.

For information on configuring shared VPC, see Configure the shared VPC.

New permissions required

A Google Cloud service account with specific permissions is required when creating the host connection. These additional permissions must be granted to any service accounts used to create Shared VPC based host connections.

TIP:

These additional permissions are not new to Citrix DaaS. They are used to facilitate the implementation of local VPCs. With Shared VPCs, these additional permissions allow access to other shared VPC resources.

A maximum of four extra permissions must be granted to the service account associated with the host connection to support Shared VPC:

- **compute.firewalls.list** - This permission is mandatory. It allows MCS to retrieve the list of firewall rules present on the Shared VPC.
- **compute.networks.list** - This permission is mandatory. It allows MCS to identify the Shared VPC networks available to the service account.
- **compute.subnetworks.list** – This permission is optional depending on how you use VPCs. It allows MCS to identify the subnets within the visible Shared VPCs. This permission is already required when using local VPCs but must also be assigned in the Shared VPC host project.
- **compute.subnetworks.use** - This permission is optional depending on how you use VPCs. It is necessary to use subnet resources in the provisioned machine catalogs. This permission is already required for using local VPCs but must also be assigned in the Shared VPC host project.

When using these permissions, consider that there are different approaches based on the type of permission used to create the machine catalog:

- Project-level permission:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - Allows access to all Shared VPCs within the host project.
  - Requires the permissions `compute.subnetworks.list` and `compute.subnetworks.use` must be assigned to the service account.

- Subnet-level permission:
  - Allows access to specific subnets within the Shared VPC.
  - Permissions `compute.subnetworks.list` and `compute.subnetworks.use` are intrinsic to the subnet level assignment and therefore do not need to be assigned directly to the service account.

Select the approach that matches your organizational needs and security standards.

TIP:

For more information about the differences between project-level and subnet-level permissions, see Service Project Admins.

Firewall Rules

During the preparation of a machine catalog, a machine image is prepared to serve as the master image system disk for the catalog. When this process occurs, the disk is temporarily attached to a virtual machine. This VM must run in an isolated environment that prevents all inbound and outbound network traffic. This is accomplished through a pair of deny-all firewall rules; one for ingress and one for egress traffic. When using Google Cloud local VPCs, MCS creates this firewall in the local network and applies it to the machine for mastering. After mastering completes, the firewall rule is removed from the image.

We recommend keeping the number of new permissions required to use Shared VPCs to a minimum. Shared VPCs are higher-level corporate resources and typically have more rigid security protocols in place. For this reason, create a pair of firewall rules in the host project on the shared VPC resources, one for ingress and one for egress. Assign the highest priority to them. Apply a new target tag to each of these rules, using the following value:

`citrix-provisioning-quarantine-firewall`

When MCS creates or updates a machine catalog, it searches for firewall rules containing this target tag. It then examines the rules for correctness and applies them to the machine used to prepare the master image for the catalog. If the firewall rules are not found, or the rules are found but the rules or their priorities are incorrect, a message similar to the following appears:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"Unable to find valid INGRESS and EGRESS quarantine firewall rules for VPC <name> in project <project>. " Please ensure you have created 'deny all' firewall rules with the network tag ‘citrix-provisioning-quarantine-firewall' and proper priority." "Refer to Citrix Documentation for details."
```

Configure the shared VPC

Before adding the Shared VPC as a host connection in Citrix DaaS's Studio, complete the following steps to add service accounts from the project you intend to provision into:

1. Create an IAM role.
2. Add a service account to the host project IAM role.
3. Add the cloud build service account to the shared VPC.
4. Create firewall rules.

CREATE AN IAM ROLE

Determine the access level of the role:

- *Project level access*, or
- A more restricted model using *subnet level access*.

Project level access for IAM role. For the project level IAM role, include the following permissions:

- compute.firewalls.list
- compute.networks.list
- compute.subnetworks.list
- compute.subnetworks.use

To create a project level IAM role:

1. In the Google Cloud console, navigate to **IAM & Admin > Roles**.
2. On the **Roles** page, select **CREATE ROLE**.
3. On the **Create Role** page, specify the role name. Select **ADD PERMISSIONS**.
    a. On the **Add permissions** page, add permissions to the role, individually. To add a permission, type the name of the permission in the **Filter table** field. Select the permission and then select **ADD**.
    b. Select **CREATE**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Subnet-level IAM role. This role omits the addition of the permissions `compute.subnetworks.list` and `compute.subnetworks.use` after selecting **CREATE ROLE**. For this IAM access level, the permissions `compute.firewalls.list` and `compute.networks.list` must be applied to the new role.

To create a subnet level IAM role:

1. In the Google Cloud console, navigate to **VPC network** > **Shared VPC**. The **Shared VPC** page appears, displaying the subnets of the Shared VPC networks that the host project contains.
2. On the **Shared VPC** page, select the subnet that you want to access.
3. In the top-right corner, select **ADD MEMBER** to add a service account.
4. On the **Add members** page, complete these steps:
    a. In the **New members** field, type the name of your service account and then select your service account in the menu.
    b. Select the **Select a role** field and then **Compute Network User**.
    c. Select **SAVE**.
5. In the Google Cloud console, navigate to **IAM & Admin** > **Roles**.
6. On the **Roles** page, select **CREATE ROLE**.
7. On the **Create Role** page, specify the role name. Select **ADD PERMISSIONS**.
    a. On the **Add permissions** page, add permissions to the role, individually. To add a permission, type the name of the permission in the **Filter table** field. Select the permission, and then select **ADD**.
    b. Select **CREATE**.

ADD A SERVICE ACCOUNT TO THE HOST PROJECT IAM ROLE

After creating an IAM role, do the following steps to add a service account for the host project:

1. In the Google Cloud console, navigate to the host project and then to **IAM & Admin > IAM**.
2. On the **IAM** page, select **ADD** to add a service account.
3. On the **Add members** page:
    a. In the **New members** field, type the name of your service account and then select your service account in the menu.
    b. Select a role field, type the IAM role you created, and then select the role in the menu.
    c. Select **SAVE**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The service account is now configured for the host project.

ADD THE CLOUD BUILD SERVICE ACCOUNT TO THE SHARED VPC

Every Google Cloud subscription has a service account that is named after the project ID number, followed by `cloudbuild.gserviceaccount`. For example: `705794712345@cloudbuild.gserviceaccount`.

You can determine the project ID number for your project by navigating to **Cloud overview > Dashboard** in the Google Cloud console. The project ID and project number are displayed on the project Dashboard Project info card:

Perform the following steps to add the Cloud Build service account to the Shared VPC:

1. In the Google Cloud console, navigate to the host project and then to **IAM & Admin** > **IAM**.
2. On the **Permissions** page, select **ADD** to add an account.
3. On the **Add members** page, complete these steps:
    a. In the **New members** field, type the name of the Cloud Build service account and then select your service account in the menu.
    b. Select the **Select a role** field, type `Computer Network User`, and then select the role in the menu.
    c. Select **SAVE**.

CREATE FIREWALL RULES

As part of the mastering process, MCS copies the selected machine image and uses it to prepare the master image system disk for the catalog. During mastering, MCS attaches the disk to a temporary virtual machine, which then runs preparation scripts. This VM must run in an isolated environment that prohibits all inbound and outbound network traffic.

To create an isolated environment, MCS requires two *deny all* firewall rules (an ingress rule and an egress rule). Therefore, create two firewall rules (Ingress and Egress) in the *Host Project* as follows:

1. In the Google Cloud console, navigate to the host project and then to **VPC network > Firewall**.
2. On the **Firewall** page, select **CREATE FIREWALL RULE**.
3. On the **Create a firewall rule** page, complete the following:
    - **Name**. Type a name for the rule.
    - **Network**. Select the Shared VPC network to which the ingress firewall rule applies.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Priority**. The smaller the value is, the higher the priority of the rule is. We recommend a small value (for example, 10).
- **Direction of traffic**. Select **Ingress**.
- **Action on match**. Select **Deny**.
- **Targets**. Use the default, **Specified target tags**.
- **Target tags**. Type `citrix-provisioning-quarantine-firewall`.
- **Source filter**. Use the default, **IP ranges**.
- **Source IP ranges**. Type a range that matches all traffic. Type `0.0.0.0/0`.
- **Protocols and ports**. Select **Deny all**.

4. Select **CREATE** to create the rule.
5. Repeat the steps to create another rule. For **Direction of traffic**, select **Egress**.

Use Customer Managed Encryption Keys (CMEK)

NOTE:

Support for CMEK in GCP is currently under Preview.

You can use Customer Managed Encryption Keys (CMEK) for MCS catalogs. When using this functionality, you assign the Google Cloud Key Management Service `CryptoKey Encrypter/Decrypter` role to the Compute Engine Service Agent. Citrix DaaS account must have the correct permissions in the project where the key is stored. See Assign permissions to Citrix DaaS account. Refer to Helping to protect resources by using Cloud KMS keys for more information.

Your Compute Engine Service Agent is in the following form: `service-<Project_Number>@compute-system.iam.gserviceaccount.com`. This form is different than the default Compute Engine Service Account.

NOTE:

This Compute Engine Service Account might not appear in the Google Console **IAM Permissions** display. In such cases, use the `gcloud` command as described in Helping to protect resources by using Cloud KMS keys.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Assign permissions to Citrix DaaS account

Google Cloud KMS permissions can be configured in various ways. You can either provide *project level* KMS permissions or *resource level* KMS permissions. See Permissions and roles for more information.

PROJECT LEVEL KMS PERMISSIONS

One option is to provide Citrix DaaS account with project-level permissions to browse Cloud KMS resources. To do this, create a custom role, and add the following permissions:

- `cloudkms.keyRings.list`
- `cloudkms.keyRings.get`
- `cloudkms.cryptokeys.list`
- `cloudkms.cryptokeys.get`

Assign this custom role to your Citrix DaaS account. This allows you to browse regional keys in the relevant project in the inventory.

RESOURCE LEVEL KMS PERMISSIONS

For the other option, resource level permissions, in the Google Cloud console, browse to the `cryptoKey` you use for MCS provisioning. Add Citrix DaaS account to a key ring or a key that you use for catalog provisioning.

TIP:

With this option, you cannot browse regional keys for your project in the inventory because Citrix DaaS account does not have project-level list permissions on the Cloud KMS resources. However, you can still provision a catalog using CMEK by specifying the correct `cryptoKeyId` in the `ProvScheme` custom properties. See Create a catalog with CMEK using custom properties.

Rotating customer managed keys

Google Cloud does not support rotating keys on existing persistent disks or images. Once a machine is provisioned it is tied to the key version in use at the time it was created. However, a new version of the key can be created and that new key is used for newly provisioned machines or resources created when a catalog is updated with a new master image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT CONSIDERATIONS ABOUT KEY RINGS

Key rings cannot be renamed or deleted. Also, you might incur unforeseen charges when configuring them. When deleting or removing a key ring, Google Cloud displays an error message:

```
Sorry, you can't delete or rename keys or key rings. We were concerned
about the security implications of allowing multiple keys or key versions
over time to have the same resource name, so we decided to make names
immutable. (And you can't delete them, because we wouldn't be able to do a
true deletion--there would still have to be a tombstone tracking that this
name had been used and couldn't be reused).

We're aware that this can make things untidy, but we have no immediate
plans to change this.

If you want to avoid getting billed for a key or otherwise make it
unavailable, you can do so by deleting all the key versions; neither keys
nor key rings are billed for, just the active key versions within the
keys.
```

TIP:

For more information, see Editing or deleting a key ring from the console.

Uniform bucket-level access compatibility

Citrix DaaS is compatible with uniform bucket-level access control policy on Google Cloud. This functionality augments the use of IAM policy that grants permissions to a service account to allow for the manipulation of resources, including storage buckets. With uniform bucket level access control, Citrix DaaS allows you to use an access control list (ACL) to control access to storage buckets or objects stored in them. See Uniform bucket-level access for overview information about Google Cloud uniform bucket-level access. For configuration information, see Require uniform bucket-level access.

Use PowerShell

This section details how to do the following tasks using PowerShell:

- Create a catalog with persistent write-back cache disk
- Improve boot performance with MCSIO
- Create a catalog with CMEK using custom properties

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create a machine catalog using a machine profile
- Create a machine catalog with machine profile as an instance template
- Create a catalog with shielded VM
- Create Windows 11 VMs on the sole-tenant node
- VMs and disks with inherited labels

Create a catalog with persistent write-back cache disk

To configure a catalog with persistent write-back cache disk, use the PowerShell command `New-ProvScheme CustomProperties`.

TIP:

Use the PowerShell parameter `New-ProvScheme CustomProperties` only for cloud-based hosting connections. If you want to provision machines using a persistent write-back cache disk for an on-premises solution (for example, XenServer®) PowerShell is not needed because the disk persists automatically.

This command supports an extra property, `PersistWBC`, used to determine how the write-back cache disk persists for MCS provisioned machines. The `PersistWBC` property is only used when the `UseWriteBackCache` parameter is specified, and when the `WriteBackCacheDiskSize` parameter is set to indicate that a disk is created.

NOTE:

This behavior applies to both Azure and GCP where the default MCSIO write-back cache disk is deleted and re-created when power cycling. You can choose to persist the disk to avoid the deletion and recreation of MCSIO write-back cache disk.

Examples of properties found in the `CustomProperties` parameter before supporting `PersistWBC` include:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />

</CustomProperties>
```

NOTE:

This example only applies to Azure. The properties are different in GCP environment.

When using these properties, consider that they contain default values if the properties are omitted from the `CustomProperties` parameter. The `PersistWBC` property has two possible values: **true** or **false**.

Setting the `PersistWBC` property to **true** does not delete the write-back cache disk when the Citrix DaaS administrator shuts down the machine from the management interface.

Setting the `PersistWBC` property to **false** deletes the write-back cache disk when the Citrix DaaS administrator shuts down the machine from the management interface.

NOTE:

If the `PersistWBC` property is omitted, the property defaults to **false** and the write-back cache is deleted when the machine is shut down from the management interface.

For example, using the `CustomProperties` parameter to set `PersistWBC` to true:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />

<Property xsi:type="StringProperty" Name="PersistWBC" Value="true" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>
```

IMPORTANT:

The `PersistWBC` property can only be set using the `New-ProvScheme` PowerShell cmdlet. Attempting to alter the `CustomProperties` of a provisioning scheme after creation has no impact on the machine catalog and the persistence of the write-back cache disk when a machine is shut down.

For example, set `New-ProvScheme` to use the write-back cache while setting the `PersistWBC` property to true:

```
New-ProvScheme

-CleanOnBoot

-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" /><Property xsi:type=`"StringProperty`"
Name=`"StorageAccountType`" Value=`"Premium_LRS`" /><Property
xsi:type=`"StringProperty`" Name=`"ResourceGroups`"
Value=`"benvaldev5RG3`" /><Property xsi:type=`"StringProperty`"
Name=`"PersistWBC`" Value=`"true`" /></CustomProperties>"

-HostingUnitName "adSubnetScale1"

-IdentityPoolName "BV-WBC1-CAT1"

-MasterImageVM "XDHyp:
\HostingUnits\adSubnetScale1\image.folder\GoldImages.resourcegroup\W10MCSI
O-01_OsDisk_1_a940e6f5bab349019d57ccef65d2c7e3.manageddisk"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\adSubnetScale1\
\virtualprivatecloud.folder\CloudScale02.resourcegroup\adVNET.virtualpriva
tecloud\adSubnetScale1.network"}

-ProvisioningSchemeName "BV-WBC1-CAT1"

-ServiceOffering "XDHyp:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
\HostingUnits\adSubnetScale1\serviceoffering.folder\Standard_D2s_v3.servic
eoffering"

-UseWriteBackCache

-WriteBackCacheDiskSize 127

-WriteBackCacheMemorySize 256
```

Improve boot performance with MCSIO

You can improve boot performance for Azure and GCP managed disks when MCSIO is enabled. Use the PowerShell `PersistOSDisk` custom property in the `New-ProvScheme` command to configure this feature. Options associated with `New-ProvScheme` include:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="Resource``````````````Groups"
Value="benvaldev5RG3" />

<Property xsi:type="StringProperty" Name="PersistOsDisk" Value="true" />

</CustomProperties>
```

To enable this feature, set the `PersistOSDisk` custom property to **true**. For example:

```
New-ProvScheme

-CleanOnBoot

-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" /><Property xsi:type=`"StringProperty`"
Name=`"StorageAccountType`" Value=`"Premium_LRS`" /><Property
xsi:type=`"StringProperty`" Name=`"ResourceGroups`"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value=`"benvaldev5RG3`" /><Property xsi:type=`"StringProperty`"
Name=`"PersistOsDisk`" Value=`"true`" /></CustomProperties>"

-HostingUnitName "adSubnetScale1"

-IdentityPoolName "BV-WBC1-CAT1"

-MasterImageVM "XDHyp:
\HostingUnits\adSubnetScale1\image.folder\GoldImages.resourcegroup\W10MCSI
O-01_OsDisk_1_a940e6f5bab349019d57ccef65d2c7e3.manageddisk"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\adSubnetScale1\
\virtualprivatecloud.folder\CloudScale02.resourcegroup\adVNET.virtualpriva
tecloud\adSubnetScale1.network"}

-ProvisioningSchemeName "BV-WBC1-CAT1"

-ServiceOffering "XDHyp:
\HostingUnits\adSubnetScale1\serviceoffering.folder\Standard_D2s_v3.servic
eoffering"

-UseWriteBackCache

-WriteBackCacheDiskSize 127

-WriteBackCacheMemorySize 256
```

Create a catalog with CMEK using custom properties

When creating your Provisioning Scheme via PowerShell, specify a `CryptoKeyId` property in `ProvScheme CustomProperties`. For example:

```
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

    <Property xsi:type="StringProperty" Name="CryptoKeyId"
Value="<yourCryptoKeyId>" />

</CustomProperties>'
```

The `cryptoKeyId` must be specified in the following format:

`projectId:location:keyRingName:cryptoKeyName`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example, if you'd like to use the key `my-example-key` in key ring `my-example-key-ring` in the region `us-east1` and project with ID `my-example-project-1`, your `ProvScheme` custom settings would resemble:

```
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

    <Property xsi:type="StringProperty" Name="CryptoKeyId" Value="my-
example-project-1:us-east1:my-example-key-ring:my-example-key" />

</CustomProperties>'
```

All MCS provisioned disks and images related to this provisioning scheme use this customer managed encryption key.

TIP:

If you use global keys, the customer properties location must say `global` and not the **region** name, which in the example above is **us-east1**. For example: `<Property xsi:type="StringProperty" Name="CryptoKeyId" Value="my-example-project-1:global:my-example-key-ring:my-example-key" />`.

Create a machine catalog using a machine profile

When you create a catalog to provision machines using Machine Creation Services (MCS), you can use a machine profile to capture the hardware properties from a virtual machine and apply them to newly provisioned VMs in the catalog. When `MachineProfile` parameter is not used, the hardware properties are captured from the master image VM or snapshot. Some properties you define explicitly, for example, `StorageType`, `CatalogZones` and `CryptoKeyId` are ignored from machine profile.

- To create a catalog with a machine profile, use the `New-ProvScheme` command. For example, `New-ProvScheme –MachineProfile “path to VM”`. If you do not specify the `MachineProfile` parameter, hardware properties are captured from the master image VM.
- To update a catalog with a new machine profile, use the `Set-ProvScheme` command. For example, `Set-ProvScheme –MachineProfile “path to new VM”`. This command does not change the machine profile of the existing VMs in the catalog. Only the newly created VMs added to the catalog have the new machine profile.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You can also update the master image, however, when you update the master image, the hardware properties are not updated. If you want to update the hardware properties, you need to update the machine profile using `Set-ProvScheme` command. These changes will only apply to the new machines in the catalog. For updating the hardware properties of an existing machine, you can use the command `Set-ProvVMUpdateTimeWindow` with `-StartsNow` and `-DurationInMinutes -1` parameters.

  NOTE:

  - `StartsNow` indicates that the scheduled start time is the current time.
  - `DurationInMinutes` with a negative number (for example, –1) indicates no upper bound on the schedule's time window.

Create a machine catalog with machine profile as an instance template

You can select a GCP instance template as an input for the machine profile. Instance templates are lightweight resources in GCP, therefore, are very cost effective.

Create a new machine catalog with machine profile as an instance template

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Find an instance template in your GCP project using the following command:

```
cd XDHyp:\HostingUnits\<HostingUnitName>\instanceTemplates.folder
```

4. Create a new machine catalog with machine profile as an instance template using NewProvScheme command:

```
New-ProvScheme -ProvisioningSchemeName <CatalogName>  -HostingUnitName
<HostingUnitName> -IdentityPoolName <identity pool name> -MasterImageVM

XDHyp:\HostingUnits\<HostingUnitName>\Base.vm\Base.snapshot
-MachineProfile XDHyp:
\HostingUnits\<HostingUnitName>\instanceTemplates.folder\mytemplate.tem
plate
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information on the New-ProvScheme command, see `<https://developer-docs.citrix.com/projects/citrix-daas-sdk/en/latest/MachineCreation/New-ProvScheme/>`.

5. Finish creating the machine catalog using PowerShell commands.

Update a machine catalog to have an instance template as machine profile

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run the following command:

```
Set-ProvScheme -ProvisioningSchemeName  <CatalogName> -MachineProfile
XDHyp:
\HostingUnits\<HostingUnitName>\instanceTemplates.folder\<TemplateName>
.template
```

For information on the Set-ProvScheme command, see `<https://developer-docs.citrix.com/projects/citrix-daas-sdk/en/latest/MachineCreation/Set-ProvScheme/>`.

Create a catalog with shielded VM

You can create an MCS machine catalog with shielded VM properties. A shielded virtual machine is hardened by a set of security controls that provide verifiable integrity of your Compute Engine instances, using advanced platform security capabilities like secure boot, a virtual trusted platform module, UEFI firmware and integrity monitoring.

MCS supports creating the catalog using the machine profile workflow. If you use machine profile workflow, then you must enable the shielded VM properties of a VM instance. You can then use this VM instance as a machine profile input.

Create an MCS machine catalog with shielded VM

1. Enable shielded VM options of a VM instance in Google Cloud console. See Quickstart: Enable Shielded VM options.
2. Create an MCS machine catalog with machine profile workflow by using the VM instance.
    a. Open a PowerShell window
    b. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
    c. Create an identity pool if not already created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

d. Run the `New-ProvScheme` command. For example:

```
New-ProvScheme -ProvisioningSchemeName <catalog-name>

-HostingUnitName gcp-hostint-unit

-MasterImageVM XDHyp:\HostingUnits\gcp-hostint-unit\catalog-vda.vm

-MachineProfile XDHyp:\HostingUnits\gcp-hostint-unit\catalog-
machine.vm
```

3. Finish creating the machine catalog.

Update a machine catalog with a new machine profile

1. Run the `Set-ProvScheme` command. For example:

```
Set-ProvScheme -ProvisioningSchemeName <catalog-name>

-MasterImageVM XDHyp:\HostingUnits\<hostin-unit>\catalog-vda.vm

-MachineProfile "DHyp:\HostingUnits\<hostin-unit>\catalog-machine.vm
```

To apply the change done in `Set-ProvScheme` to the existing VMs, run the `Set-ProvVMUpdateTimeWindow` command.

1. Run `Set-ProvVMUpdateTimeWindow` command. For example:

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName my-catalog -VMName
<List-Of-Vm-Names> -StartsNow -DurationInMinutes -1
```

2. Restart the VMs.

Create Windows 11 VMs on the sole-tenant node

You can create Windows 11 VMs in GCP. However, if you install Windows 11 on the master image, then you must enable vTPM during the master image creation process. Also, you must enable vTPM on the machine profile source (VM or instance template).

The key steps to create Windows 11 VMs on the sole-tenant node are:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Set up the Google Cloud virtualization environments. For information, see Google Cloud environments.
2. Install VDA. See Install VDAs.
3. Create a connection to Google cloud environments. For information, see Connection to Google cloud environments.
4. Create a Windows 11 Bring Your Own License (BYOL) master image and import the image to Google Cloud. See Create a Windows 11 BYOL master image.
5. Create the machine profile source: Provision VM on the sole-tenant node and enable the vTPM of the source machine profile. See Provision VM on sole-tenant node.
6. Create an MCS machine catalog using the Windows 11 machine profile source enabled with vTPM. The machine profile source must have the same instance type as described in the sole-tenant node. See Create an MCS machine catalog using the Windows 11 machine profile source.

Create a Windows 11 BYOL master image

There are two option to create a Windows 11 BYOL master image and import the master image to Google Cloud:

- Use Google Cloud Cloud Build Tools
- Create the master image on any other hypervisor

USE GOOGLE CLOUD CLOUD BUILD TOOLS

1. Upload the Windows 11 ISO, GCP SDK, .NET framework and PowerShell installer files to the GCP storage bucket.
2. Provide the file location in the cloud build `.yaml` file as parameter.
3. Run the following Cloud Build from the command line to build the final Windows 11 image. GCP bootstraps and creates the master image in the selected project using Daisy workflow in GCP and the master image is imported into GCP.

```
gcloud compute instances import INSTANCE-NAME--source-uri=gs://BUCKET/
IMAGE-OVF-FILE.ovf --guest-os-features=UEFI_COMPATIBLE --byol --
machine-type=MACHINE-TYPE --zone=ZONE
```

NOTE:

Replace all the capital letter text with the actual resource details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For the complete information, see Create custom Windows BYOL images.

CREATE THE MASTER IMAGE ON ANY OTHER HYPERVISOR

1. Create the Windows 11 master image using any other hypervisor.
2. Export the master image in an OVF format to the local machine.
3. Upload the OVF files to the GCP storage bucket using the local gcloud CLI.

   ```
   gsutil cp LOCAL_IMAGE_PATH_OVF_FILES gs://BUCKET_NAME/
   ```

4. Run the following Cloud Build from the command line to build the final Windows 11 image. GCP bootstraps and creates the master image in the selected project using Daisy workflow in GCP and the master image is imported into GCP.

   ```
   gcloud compute instances import INSTANCE-NAME --source-uri=gs://BUCKET/
   IMAGE-OVF-FILE.ovf --guest-os-features=UEFI_COMPATIBLE --byol --
   machine-type=MACHINE-TYPE --zone=ZONE
   ```

   NOTE:

   Replace all the capital letter text with the actual resource details.

Provision VM on sole-tenant node

Use sole-tenant nodes to keep your VMs physically separated from VMs in other projects, or to group your VMs together on the same host hardware. For information on the sole-tenant node, see the GCP document Sole-tenancy overview.

For provisioning a VM (machine profile source) on the sole-tenant node, see the GCP document Provision VMs on sole-tenant nodes.

NOTE:

- Select the same Instance type and region as the node group.
- Enable vTPM in the Shielded VM section. For more information, see Quickstart: Enable Shielded VM options.
- Disable the Bitlocker on the source VM.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create an MCS machine catalog using the Windows 11 machine profile source

You can create an MCS machine catalog to create Windows 11 VMs using Studio or PowerShell commands.

NOTE:

- For the master image, select the Windows 11 Snapshot or VM.
- For the machine profile source, select the Windows 11 VM as machine profile. The machine profile source must have the same instance type as described in the sole-tenant node.

For information on using Studio, see Create a machine catalog using Studio.

For information on PowerShell commands, see Create a machine catalog using a machine profile.

After you create the catalog and power on the VMs, you can see the Windows 11 VMs running on the sole tenant node on the Google Cloud console.

VMs and disks with inherited labels

MCS machine catalog VMs and disks (Identity Disk, Write-cache Back Disk, and OS disk) can inherit the labels of a machine profile source (GCP VM instance or instance template). You can use the labels to distinguish instances owned by different teams (for example, team:research and team:analytics), and further use it for cost accounting or budgeting. For more information on labels, see the GCP document Organize resources using labels.

You can create a new catalog, update an existing catalog, and update existing VMs to inherit the labels using the machine profile source.

This feature is applicable to persistent and non-persistent MCS machine catalogs.

You can do the following:

- Create a catalog with inherited labels
- Update an existing catalog with inherited labels
- Update existing VMs with inherited labels
- Retrieve information for VM and boot disk labels
- Remove a VM

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog with inherited labels

To create an MCS machine catalog where VMs and disk inherit labels from the machine profile source, do the following:

1. Create a machine profile source (VM instance or instance template) with labels. For information on creating VMs with labels, see the GCP document Create resources with labels. An Instance template is created from the VM and takes the labels defined in the VM.
2. Create an MCS catalog using Studio or PowerShell commands.
3. If using Studio, on the **Image** page, select **Use a machine profile**, and then select the VM or template.
4. If using PowerShell commands, do the following:

    a. Open the PowerShell window.

    b. Run asnp citrix*.

    c. Create an identity pool. The identity pool is a container for the Active Directory (AD) accounts for the VMs to be created.

    d. Create the required AD computer accounts in Active Directory.

    e. Run the `New-ProvScheme` command to create a catalog. For example:

    New-ProvScheme with template as machine profile input (Persistent catalog):

    ```
    New-ProvScheme `

    -ProvisioningSchemeName "catalog-name" `

    -HostingUnitUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

    -IdentityPoolUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

    -MasterImageVM "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `

    -MachineProfile "XDHyp:\HostingUnits\hosting-unit-
    name\instanceTemplates.folder\instance-template-name.template" `
    ```

    New-ProvScheme with instance template as machine profile input (Non-Persistent catalog):

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-ProvScheme `

-ProvisioningSchemeName "catalog-name" `

-HostingUnitUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-IdentityPoolUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-MasterImageVM "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `

-MachineProfile "XDHyp:\HostingUnits\hosting-unit-
name\instanceTemplates.folder\instance-template-name.template" `

-CleanOnBoot
```

New-ProvScheme with VM instance as machine profile input (Persistent catalog):

```
New-ProvScheme `

-ProvisioningSchemeName "catalog-name" `

-HostingUnitUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-IdentityPoolUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-MasterImageVM "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `

-MachineProfile "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `
```

New-ProvScheme with VM instance as machine profile input (Non-Persistent catalog):

```
New-ProvScheme `

-ProvisioningSchemeName "catalog-name" `

-HostingUnitUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-IdentityPoolUid "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx" `

-MasterImageVM "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-MachineProfile "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `

-CleanOnBoot
```

f. Register provisioning scheme as a broker catalog.

g. Add VMs to the catalog.

Update an existing catalog with inherited labels

To update an existing catalog to have a new machine profile, run the Set-ProvScheme command. After you run the command, all the new VMs added to the catalog have the labels of the new machine profile source. The non-persistent catalog is updated on the next power on.

For example:

Set-ProvScheme with instance template as machine profile input:

```
Set-ProvScheme `

-ProvisioningSchemeName "catalog-name" `

-MachineProfile "XDHyp:\HostingUnits\hosting-unit-
name\instanceTemplates.folder\instance-template-name.template" `
```

Set-ProvScheme with VM instance as machine profile input:

```
Set-ProvScheme `

-ProvisioningSchemeName "catalog-name" `

-MachineProfile "XDHyp:\HostingUnits\hosting-unit-name\vm-name.vm" `
```

Update existing VMs with inherited labels

To update existing VMs with the updated machine profile source, run the following commands:

1. `Set-ProvScheme`
2. `Set-ProvVMUpdateTimeWindow`. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName my-catalog -VMName
<List-Of-Vm-Names> -StartsNow -DurationInMinutes -1
```

3. Restart the VMs.

Retrieve information for VM and boot disk labels

After creating the VMs, you can get the information of the VM and boot disk label using the `Get-Item` command with the `AdditionalData` parameter.

For retrieving information of the VM label, run the following command:

```
(Get-Item XDHyp:\HostingUnits\hosting-unit-
name\vm_name.vm).AdditionalData.Tags
```

For retrieving information of the boot disk label, run the following command:

```
(Get-Item XDHyp:\HostingUnits\hosting-unit-name\vm_name.vm\bootdisk-
name.attacheddisk).AdditionalData.Tags
```

NOTE:

To maintain consistency across the various hypervisors, we have used the term Tags to display GCP labels.

Remove a VM

You can choose to remove a VM from a catalog but not delete the VM from the GCP. In this case, the Citrix labels are only removed from the VM. All other added labels are not deleted from the VM. You can remove a VM from Studio or use PowerShell commands.

USING STUDIO

1. Select and right-click the VM.
2. Click **Delete**.
3. Select **Remove the virtual machines from the catalog but do not delete the virtual machines**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

USING POWERSHELL COMMANDS

Run `Remove-ProvVM` with `ForgetVM` parameter. For more information, see the SDK doc Remove-ProvVM.

Google Cloud Marketplace

You can browse and select images offered by Citrix on Google Cloud Marketplace to create machine catalogs. Currently, MCS supports only the machine profile workflow for this feature.

To search for Citrix VDA VM product through Google Cloud Marketplace, go to `<https://console.cloud.google.com/marketplace/>`.

You can use a custom image or a Citrix ready® image on Google Cloud Marketplace to update an image of a machine catalog.

NOTE:

If the machine profile does not contain storage type information, the value is derived from custom properties.

The supported Google Cloud Marketplace images are:

- Windows 2019 Single Session
- Windows 2019 Multi Session
- Ubuntu

Example of using a Citrix ready image as a source for creating a machine catalog:

```
New-ProvScheme -ProvisioningSchemeName GCPCatalog \

-HostingUnitName GcpHu -IdentityPoolName gcpPool -CleanOnBoot \

-MasterImageVM XDHyp:\HostingUnits\GcpHu\images.folder\citrix-daas-
win2019-single-vda-v20220819.publicimage \

-MachineProfile XDHyp:\HostingUnits\GcpHu\Base.vm
```

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To manage catalogs, see Manage machine catalogs and Manage a Google Cloud Platform catalog.

More information

- Create and manage connections and resources
- Connection to Google cloud environments
- Create machine catalogs

Create an HPE Moonshot machine catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to HPE Moonshot environments.

NOTE:

- Create a connection to HPE Moonshot
- Make sure to have one or more HPE Moonshot nodes available and install VDAs on those nodes.
- For information about creating the initial HPE Moonshot cartridge image, see the OS Deployment on Moonshot User Guide.

You can create an HPE Moonshot machine catalog using:

- Studio
- PowerShell commands

Create a machine catalog using Studio

In the **Machine Catalog Setup** wizard:

1. On the **Operating System** page, select **Multi-session OS** or **Single-session OS**.
2. On the **Machine Management** page, select **Machines that are power managed** and **Another service or technology**.
3. On the **Virtual Machines** page, add machines and their Active Directory machine accounts. You can do either of the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Click **Add Machines** to add machines manually. The **Select VMs** window appears. Expand the HPE Moonshot chassis connection you created earlier and select the nodes (VMs) you want to add. Then add the associated machine account names.
- Click **Add CSV File** to bulk add machines. For information about using CSV files to add machines, see Use CSV files to bulk add machines to a catalog.

The **Scopes** and **Summary** pages do not contain HPE Moonshot-specific information.

Create a machine catalog using PowerShell commands

Run the `New-BrokerCatalog` and `New-BrokerMachine` PowerShell commands to create a broker catalog and import machines to the broker catalog.

For example:

```
New-BrokerCatalog -AllocationType "Random" -IsRemotePC $False
-MachinesArePhysical $False -MinimumFunctionalLevel "L7_20" -Name "BurMC"
-PersistUserChanges "OnLocal" -ProvisioningType "Manual" -Scope @()
-SessionSupport "MultiSession" -ZoneUid "e166e2cb-25dc-4578-bc07-
bcf2a82d1463"

New-BrokerMachine -CatalogUid 3 -HostedMachineId "c10n1"
-HypervisorConnectionUid 4 -IsReserved $False -MachineName
"S-1-5-21-2589939477-3963209805-1860259709-1121"
```

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage an HPE Moonshot catalog.

More information

- Create and manage connections and resources
- Connection to HPE Moonshot
- Create machine catalogs

Create a Microsoft Azure catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Microsoft Azure Resource Manager cloud environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Before creating a Microsoft Azure catalog, you need to finish creating a connection to Microsoft Azure. See Connection to Microsoft Azure.

Create a machine catalog

You can create a machine catalog in two ways:

- Studio.
- PowerShell. See Manage Citrix DaaS using Remote PowerShell SDKs. For information on how to implement specific features using PowerShell, see Use PowerShell.

Create a machine catalog using an Azure Resource Manager image in Studio

This information is a supplement to the guidance in Create machine catalogs.

An image can be a disk, snapshot, or an image version of an image definition inside the Azure Compute Gallery that is used to create the VMs in a machine catalog.

Before creating the machine catalog, create an image in Azure Resource Manager.

NOTE:

- Use of unmanaged disk to provision VM is deprecated.
- Support for using a master image from a region different from that configured in the host connection is deprecated. Use Azure Compute Gallery to replicate the master image to the desired region.

When creating an MCS machine catalog, a temporary VM is created based on the original VM to perform preparation tasks such as enabling DHCP and license rearm. This temporary VM is called a preparation VM. The name of this preparation VM follows the format **Preparati-84x9n**, where the last five characters are randomly generated to avoid duplication. The naming convention for this preparation VM is fixed and cannot be customized. After the preparation tasks are completed, the preparation VM is destroyed.

To disconnect the network from the preparation VM, a network security group is created to deny all inbound and outbound traffic. The network security group is created automatically once per catalog. The network security group's name is `Citrix-Deny-All-a3pgu-GUID`, where GUID is

© 1997–2026 Citrix Systems, Inc. All rights reserved.

randomly generated. For example, `Citrix-Deny-All-a3pgu-3f161981-28e2-4223-b797-88b04d336dd1`.

In the machine catalog creation wizard:

1. The **Machine Type** and **Machine Management** pages do not contain Azure-specific information. Follow the guidance in the Create machine catalogs article.
2. On the **Image** page, select an image that you want to use as the master image for all machines in the catalog. The **Select an image** wizard appears. Follow these steps to select an image:

   a. (Applicable only to connections configured with shared images within or across tenants) Select a subscription where the image resides.

   b. Select a resource group.

   c. Navigate to the Azure managed disk, Azure Compute Gallery, or Azure image version.

   When selecting an image, consider the following:

   - Verify that a Citrix VDA is installed on the image.
   - If you select a disk attached to a VM, you must shut down the VM before proceeding to the next step.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The subscription corresponding to the connection (host) that created the machines in the catalog is denoted with a green dot. The other subscriptions are those that have the Azure Compute Gallery shared with that subscription. In those subscriptions, only shared galleries are shown. For information about how to configure shared subscriptions, see Share images within a tenant (across subscriptions) and Share images across tenants.
- You can create a provisioning scheme using ephemeral OS disk on Windows with Trusted Launch. When you select an image with Trusted Launch, then you must select a machine profile with Trusted Launch that is enabled with vTPM. To create machine catalogs using ephemeral OS disk, see How to create machines using ephemeral OS disks.
- When image replication is in progress, you can proceed and select the image as the master image and complete the setup. However, catalog creation might take longer to complete while the image is being replicated. MCS requires the replication to complete within an hour starting from catalog creation. If the replication times out, catalog creation fails. You can verify the replication status in Azure. Try again if the replication is still pending or after the replication completes.
- You can provision a Gen2 VM catalog by using a Gen2 image to improve boot time performance. However, creating a Gen2 machine catalog using a Gen1 image is not supported. Similarly, creating a Gen1 machine catalog using a Gen2 image is also not supported. Also, any older image that does not have generation information is a Gen1 image.

Choose whether you want VMs in the catalog to inherit configurations from a machine profile. By default, the **Use a machine profile (mandatory for Microsoft Entra ID)** checkbox is selected. Click **Select a machine profile** to browse to a VM or an ARM template spec from a list of resource groups.

Examples of configurations that VMs can inherit from a machine profile include:

- Accelerated networking
- Boot diagnostics
- Host disk caching (relating to OS and MCSIO disks)
- Machine size (unless otherwise specified)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Tags placed on the VM

NOTE:

- When you select a master image for machine catalogs in Azure, the machine profile is filtered based on the master image you selected. For example, the machine profile is filtered based on the Windows OS, security type, hibernation support, and disk encryption set ID of the master image.
- Using a machine profile with Trusted Launch as **Security Type** is mandatory when you select an image or snapshot that has Trusted Launch enabled. You can then enable or disable SecureBoot and vTPM by specifying their values in the Machine Profile. For information about Azure Trusted Launch, see `<https://docs.microsoft.com/en-us/azure/virtual-machines/trusted-launch>`.

Validate the ARM template spec to make sure whether it can be used as a machine profile to create a machine catalog. For information on creating an Azure template spec, see Create an Azure template spec.

There are two ways to validate the ARM template spec:

- After you select the ARM template spec from the resource group list, click **Next**. Error messages appear if the ARM template spec has errors.
- Run one of the following PowerShell commands:
  - `Test-ProvInventoryItem -HostingUnitName <string> -InventoryPath <string>`
  - `Test-ProvInventoryItem -HostingUnitUid <Guid> -InventoryPath <string>`

  For example:

```
Test-ProvInventoryItem -HostingUnitName "we-vdi0101-d-vnet"
-InventoryPath machineprofile.folder/vdi01-d-rg.resourcegroup/VDD-
templ-spec.templatespec/1.5.templatespecversion
```

After you create the catalog, you can view the configurations that the image inherits from the machine profile. On the **Machine Catalogs** node, select the catalog to view its details in the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

lower pane. Then, click the **Template Properties** tab to view machine profile properties. The **Tags** section displays up to three tags. To view all tags placed on the VM, click **View all**.

If you want MCS to provision VMs on an Azure dedicated host, enable the **Use a host group** checkbox and then select a host group from the list. A host group is a resource that represents a collection of dedicated hosts. A dedicated host is a service that provides physical servers that host one or more virtual machines. Your server is dedicated to your Azure subscription, not shared with other subscribers. When you use a dedicated host, Azure ensures that your VMs are the only machines running on that host. This feature is suitable for scenarios where you must meet regulatory or internal security requirements. To learn more about host groups and considerations for using them, see Provision VMs on Azure dedicated hosts.

IMPORTANT:

- Only host groups that have Azure auto-placement enabled are shown.
- Using a host group changes the **Virtual Machines** page offered later in the wizard. Only machine sizes that the selected host group contains are shown on that page. Also, Availability Zones are selected automatically and not available for selection.

3. The **Storage and License Types** page appears only when you use an Azure Resource Manager image.

   - Select the **Storage redundancy type**:
     - Local redundant storage (LRS): LRS allows you to choose from all available storage types. When using LRS, Azure deploys the Virtual Machines (VMs) exclusively within the specified availability zone.
     - Zone redundant storage (ZRS): ZRS allows for greater flexibility in VM placement, as Azure can launch VMs in any available zone. This is a key advantage over Local Redundant Storage (LRS), ensuring VM availability even if the disk's original zone becomes inaccessible. ZRS, however, is only compatible with Premium SSD and Standard SSD storage types.
   - Select the **Storage types** to use for the machine catalog: The storage type determines which machine sizes are offered on the **Virtual Machines** page of the wizard.
     - **Premium SSD**. Offers a high-performance, low-latency disk storage option suitable for VMs with I/O-intensive workloads.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - **Standard SSD**. Offers a cost-effective storage option that is suitable for workloads that require consistent performance at lower IOPS levels.
  - **Standard HDD**. Offers a reliable, low-cost disk storage option suitable for VMs that run latency-insensitive workloads.

- Select the **Use Azure ephemeral OS disk**. Azure ephemeral OS disk offers a cost-effective storage option that reuses the local disk of the VMs to host the operating system disk. Alternatively, you can use PowerShell to create machines that use ephemeral OS disks. For more information, see Azure ephemeral disks. Consider the following when using an ephemeral OS disk:
  - Azure ephemeral OS disk and MCS I/O cannot be enabled at the same time.
  - To update machines that use ephemeral OS disks, you must select an image whose size does not exceed the size of the VM's cache disk or temporary disk.
  - You cannot use the **Retain VM and system disk during power cycles** option offered later in the wizard.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The identity disk is always created using Standard SSD irrespective of the storage type that you choose.
- If you select **ZRS** as the **Storage redundancy**, you get the option to only select **Premium SSD** and **Standard SSD**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For details about Azure storage types and storage replication, see the following:

- [Introduction to Azure Storage](https://docs.microsoft.com/en-us/azure/storage/common/storage-introduction/)
- [Azure premium storage: Design for high performance](https://docs.microsoft.com/en-us/azure/virtual-machines/premium-storage-performance/)
- [Azure Storage redundancy](https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy/)

Select whether to use existing Windows licenses or Linux licenses:

- Windows licenses: Using Windows licenses along with Windows images (Azure platform support images or custom images) lets you run Windows VMs in Azure at a reduced cost. There are two types of licenses:

    - **Windows Server license**. Lets you use your Windows Server or Azure Windows Server licenses, allowing you to use Azure Hybrid Benefits. For details, see `<https://azure.microsoft.com/en-us/pricing/hybrid-benefit/>`. Azure Hybrid Benefit reduces the cost of running VMs in Azure to the base compute rate, waiving the cost of extra Windows Server licenses from the Azure gallery.

    - **Windows Client license**. Lets you bring your Windows 10 and Windows 11 licenses to Azure, allowing you to run Windows 10 and Windows 11 VMs in Azure without the need for extra licenses. For details, see [Client Access Licenses and Management Licenses](https://www.microsoft.com/en-us/licensing/product-licensing/client-access-license).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Linux licenses: With bring-your-own-subscription (BYOS) Linux licenses, you do not have to pay for the software. The BYOS charge only includes the compute hardware fee. There are two types of licenses:

    - **RHEL_BYOS**: To use RHEL_BYOS type successfully, enable Red Hat Cloud Access on your Azure subscription.

    - **SLES_BYOS**: The BYOS versions of SLES include support from SUSE.

See the following:

- [Verify the Windows license](#verify-the-windows-license)

- [Configure the Linux license](#configure-the-linux-license)

See the following documents to understand License types and their benefits:

- `<https://docs.microsoft.com/en-us/dotnet/api/microsoft.azure.management.compute.models.virtualmachine.licensetype?view=azure-dotnet>`

- `<https://docs.microsoft.com/en-us/azure/virtual-machines/linux/azure-hybrid-benefit-linux>`

Azure Compute Gallery is a repository for managing and sharing images. It lets you make your images available throughout your organization. We recommend that you store an image in Azure Compute Gallery when creating

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
large non-persistent machine catalogs because doing that enables faster
resets of VDA OS disks. After you select **Place prepared image in Azure
Compute Gallery**, the **Azure Compute Gallery settings** section appears,
letting you specify more Azure Computer Gallery settings:

-  **Ratio of virtual machines to image replicas**. Lets you specify the
ratio of virtual machines to image replicas that you want Azure to keep.
By default, Azure keeps a single image replica for every 40 non-persistent
machines. For persistent machines, that number defaults to 1,000.

-  **Maximum replica count**. Lets you specify the maximum number of image
replicas that you want Azure to keep. The default is 100.

For information on Azure Compute Gallery, see [Azure Compute Gallery]
(#azure-compute-gallery).

> **Note:**

>

> A gallery is created in ACG to store the image. This gallery is
accessible only to MCS for VM creation and doesn't appear on the **Select
an image** page.
```

1. On the **Virtual Machines** page, indicate how many VMs you want to create and the machine size. After catalog creation, you can change the machine size by editing the catalog.

   You can now configure a secondary VM when the primary machine size reaches full capacity. To configure secondary VM sizes, click **Secondary size (optional)**.

   a. In the **Secondary machine size** window, the VMs listed have both, Spot and Regular VM types. You may select up to 10 secondary machines sizes. Once the 10 VMs are selected, then the other VMs listed are disabled from further selection.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. Click **Next**. In the **Secondary machine size** blade, you can select multiple machine sizes and drag and drop to change the priority order. Click **Done**. The selected machine sizes show up in the **Secondary size (optional)**. Click the edit icon to edit as needed.

NOTE:

- If the Temporary Disk Size property is set for a primary VM then, only the secondary VMs with Temporary Disk Size property set are listed.
- If the Temporary Disk Size property is not set for a primary VM then, the secondary VMs without Temporary Disk Size property are listed.
- If you modify the primary VM, you must re-configure the secondary VM.
- Machine profiles are mandatory for secondary machine sizes.
- The secondary VM sizes which do not support spot are shown only when one of the following condition is matched; otherwise, all secondary VM sizes are shown:
- The primary VM size does not support spot
- The primary VM size supports spot but MP does not support spot
- The machine profile supports hibernation

2. The **NICs** page does not contain Azure-specific information. Follow the guidance in the Create machine catalogs article.
3. On the **Disk Settings** page, choose whether to enable write-back cache. With the MCS storage optimization feature enabled, you can configure the following settings when creating a catalog.

   After enabling write-back cache, you can do the following:

   - Configure the size of the disk and RAM used for caching temporary data. For more information, see Configure cache for temporary data.
   - Select the storage type for the write-back cache disk. The following storage options are available to use for the write-back cache disk:
     - Premium SSD
     - Standard SSD
     - Standard HDD

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> If you select **ZRS** as **Storage redundancy** on the **Storage and License Types** page, then write-back cache disk storage redundancy is set as ZRS by default.

- Choose whether you want the write-back cache disk to persist for the provisioned VMs. Select **Enable write-back cache** to make the options available. By default, **Use non-persistent write-back cache disk** is selected.
- Select the type for the write-back cache disk.
  - **Use non-persistent write-back cache disk**. If selected, the write-back cache disk is deleted during power cycles. Any data redirected to it will be lost. If the VM's temporary disk has sufficient space, it is used to host the write-back cache disk to reduce your costs. After catalog creation, you can check whether the provisioned machines use the temporary disk. To do so, click the catalog and verify the information on the **Template Properties** tab. If the temporary disk is used, you see **Non-persistent Write-back Cache Disk** and its value is **Yes (using VM's temporary disk)**. If not, you see **Non-persistent Write-back Cache Disk** and its value is **No (not using VM's temporary disk)**.
  - **Use persistent write-back cache disk**. If selected, the write-back cache disk persists for the provisioned VMs. Enabling the option increases your storage costs.

> **NOTE:**
>
> A catalog automatically uses Azure Temp Disk for WBC disk if all the following criteria are met:

  - MCSIO is enabled.
  - The WBC disk is non-persistent.
  - The VM size includes a Temp Disk large enough for the WBC disk.
  - No drive letter is specified for the WBC disk. This feature applies to both catalog creation and editing, helping reduce your storage costs.

- Choose whether to retain VMs and system disks for VDAs during power cycles.

  Retain VM and system disk during power cycles. Available when you've selected **Enable write-back cache**. By default, VMs and the system disks are deleted on shutdown

© 1997–2026 Citrix Systems, Inc. All rights reserved.

and recreated on startup. If you want to reduce VM restart times, select this option. Keep in mind that enabling this option also increases storage costs.

- Choose whether to **Enable storage cost saving**. If enabled, save storage costs by downgrading the storage disk to Standard HDD when the VM shuts down. The VM switches to its original settings on restart. The option applies to both storage and write-back cache disks. Alternatively, you can also use PowerShell. See Change the storage type to a lower tier when a VM is shut down.

  NOTE:

  Microsoft imposes restrictions on changing the storage type during VM shutdown. It's also possible that Microsoft will block storage type changes in the future. For more information, see this Microsoft article.

- Choose whether to encrypt data on machines in this catalog and which encryption key to use. Server-side encryption with a customer-managed key (CMK) lets you manage encryption at a managed disk level and protect data on the machines in the catalog. Default settings are inherited from either the machine profile or the master image, with the profile taking priority:

  - If you're using a *machine profile* with a *CMK*, the **Use the following key to encrypt data on each machine** option is auto-selected and defaults to the key from the *machine profile*.
  - If you're using a *machine profile* with a Platform Managed Key (PMK) and the *master image* is *CMK* encrypted, the **Use the following key to encrypt data on each machine** option is auto-selected and defaults to the key from the master image.
  - If you're *not* using a *machine profile* and the *master image* is *CMK* encrypted, the **Use the following key to encrypt data on each machine** option is auto-selected and defaults to the key from the *master image*.

For more information, see Azure server side encryption.

4. On the **Resource Group** page, choose whether to create resource groups or use existing groups.

   - If you choose to create resource groups, select **Next**.
   - If you choose to use existing resource groups, select groups from the **Available Provisioning Resource Groups** list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> Select enough groups to accommodate the machines you're creating in the catalog. A message appears if you choose too few. You might want to select more than the minimum required if you plan to add more VMs to the catalog later. You can't add more resource groups to a catalog after the catalog is created.

For more information, see Azure resource groups.

5. On the **Machine Identities** page, choose an identity type and configure identities for machines in this catalog. If you select the VMs as **Microsoft Entra joined**, you can add them to a Microsoft Entra security group. Detailed steps are as follows:

   a. From the **Identity type** field, select **Microsoft Entra joined**.

   b. Click **Select service account** and select a service account with the **Microsoft Entra security group management** capability.

   c. Click **Microsoft Entra security group: Create new**.

   > **NOTE:**
   >
   > **Create new** is dimmed if the selected service account lacks the **Microsoft Entra security group management** capability.

   d. Enter a group name, and then click **Create**.

   e. To add the security group to an assigned security group, select **Join an assigned security group as a member**, and then click **Select a group** to choose an assigned group to join.

   f. Enter the machine account naming scheme for the VMs.

   After catalog creation, Citrix DaaS™ accesses Azure using the service account you selected and creates the security group and a dynamic membership rule for the group. Based on the rule, VMs with the naming scheme specified in this catalog are automatically added to the security group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

> **NOTE:**
>
> To rename the Microsoft Entra security group after catalog creation, edit the catalog and go to **Microsoft Entra Security Group** from the left navigation. Names of Microsoft Entra security groups must not contain the following characters: `@ " \ / ; : # . * ? = < > | [ ] ( ) '`.

6. On the **Domain Credentials** page, follow the guidance in the Create Machine Catalogs article to complete settings.
7. On the **Summary** page, review the settings you specified, and click **Finish**.

> **TIP:**
>
> You can view the estimated monthly cost for the virtual machines in this machine catalog based on Azure's public list price. If the connection hosting the catalog has the `Microsoft.Consumption/pricesheets/read` permission in Azure, the estimate is calculated using your organization's contracted pricing instead.

Select the cost estimate to see detailed information. For a more accurate estimate, adjust settings such as daily power-on hours, workdays per week, and savings options based on your usage.

Create an Azure template spec

You can create an Azure template spec in the Azure portal and use it in Studio and PowerShell commands to create or update an MCS machine catalog.

To create an Azure template spec for an existing VM:

1. Go to the Azure portal. Select a resource group, and then select the VM and network interface. From the **…** menu on the top, click **Export template**.
2. Clear the **Include parameters** checkbox if you want to create a template spec for catalog provisioning. Verify in the JSON file that the `parameters` and `variables` sections are:

```
"parameters": {},

"variables": {}
```

3. Click **Download** to save the template as JSON file.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. On the Azure portal, select **Template specs** and click **Import Template**.
5. Browse and import the machine profile (in JSON) saved on your computer.
6. Provide the **Name**, **Subscription**, **Resource Group**, **Location**, and **Version**. Click **Next: Edit Template**.
7. Create **Review+Create** and create the template spec.
8. On the **Template Specs** page, verify the template spec you created. Click the template spec. On the left panel, click **Versions**.
9. You can create a new version by clicking **Create new version**. Specify a new version number, make changes to the current template spec, and click **Review + Create** to create the new version of the template spec.

You can get information about the template spec and template version using the following PowerShell commands:

- To get information about the template spec, run:

```
get-item XDHyp:
\HostingUnits\East\machineprofile.folder\abc.resourcegroup\bggTemplateS
pec.templatespec
```

- To get information about the template spec version, run:

```
get-item XDHyp:
\HostingUnits\East\machineprofile.folder\abc.resourcegroup\bggTemplateS
pec.templatespec\bgg1.0.templatespecversion
```

Use a template spec in creating or updating a catalog

You can create or update an MCS machine catalog using a template spec as a machine profile input. To do this, you can:

- Use Studio. See Create a machine catalog using an Azure Resource Manager image in Studio.
- Use PowerShell. See Use template spec in creating or updating a catalog using PowerShell

Export a machine profile to a JSON file

You can export the machine profile used by a catalog into a JSON file. This function enables you to customize the profile and import it into Azure as an ARM Template spec for future provisioning.

1. On the **Machine Catalogs** page, select a machine catalog to view details in the lower pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Click the **Template Properties** tab to view machine profile properties and click **Export**.
3. Specify a path on your local computer to save the machine profile as a JSON file.

Import a machine profile as an ARM Template spec in Azure

1. On the Azure portal, select **Template specs** and click **Import Template**.
2. Browse and import the machine profile (in JSON) saved on your computer.
3. Provide the **Name**, **Subscription**, **Resource Group**, **Location**, and **Version** for the importing template and click **Review + Create**. The template is validated and imported successfully. The imported template is listed in the **Template specs**.

When you create machine catalogs using machine profiles, you can see this template when choosing profiles. For more information, see Use a template spec in creating or updating a catalog.

Provision machines into specified Availability Zones

You can provision machines into specific Availability Zones in Azure environments. You can achieve that using Studio or PowerShell.

NOTE:

- If no zones are specified, MCS lets Azure place the machines within the region. If more than one zone is specified, MCS randomly distributes the machines across them.
- If you select ZRS as Storage redundancy on the Storage and License Types page, then you get a warning suggesting to clear the zone selection and let Azure manage the VM availability zones. You get the warning only if you select a machine profile or host group that has availability zones.

Configure Availability Zones in Studio

When creating a machine catalog, you can specify Availability Zones into which you want to provision machines. On the **Virtual Machines** page, select one or more Availability Zones where you want to create machines.

There are two reasons that no Availability Zones are available: The region has no Availability Zones or the selected machine size is unavailable.

For information on configuring using PowerShell command, see Configure Availability Zones using PowerShell.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure ephemeral disks

An Azure ephemeral disk allows you to repurpose the cache disk, temporary disk, or NVMe disk to store the OS disk for an Azure-enabled virtual machine. This functionality is useful for Azure environments that require a higher performant SSD disk over a standard HDD disk. For information on creating a catalog with an Azure ephemeral disk, see Create a catalog with an Azure ephemeral disk.

NOTE:

Persistent catalogs do not support ephemeral OS disks.

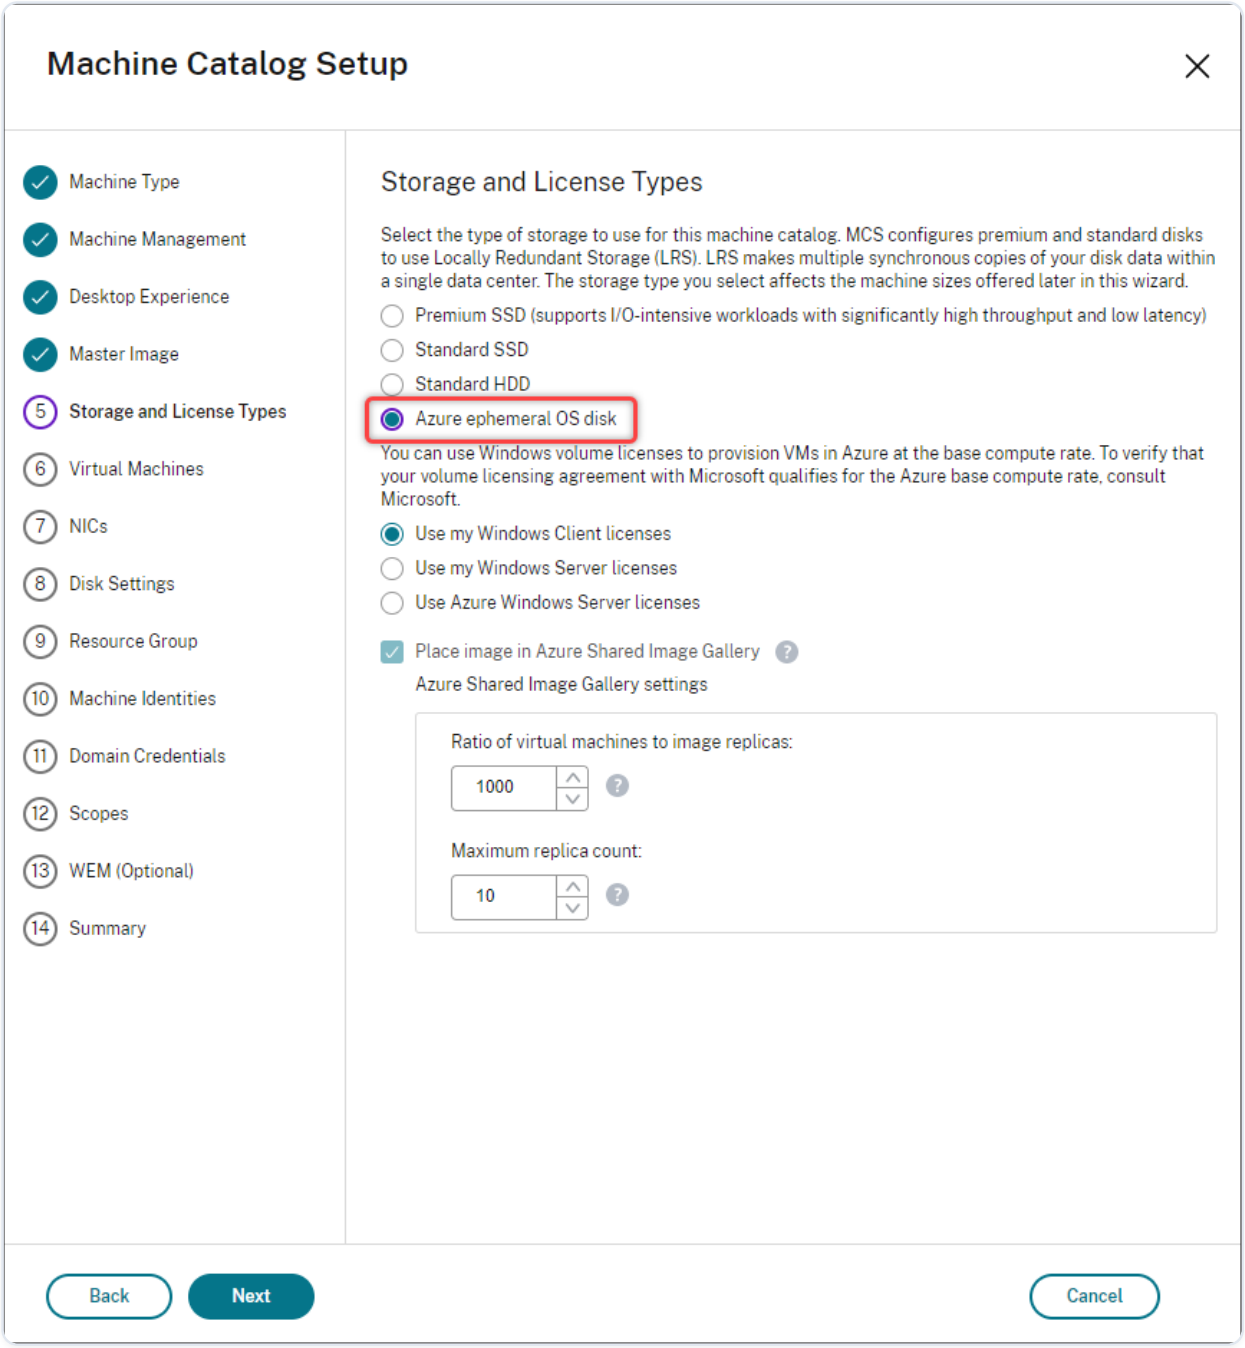
Ephemeral OS disks require that your provisioning scheme use managed disks and an Azure Compute Gallery. For more information, see Azure shared image gallery.

Store an ephemeral OS temporary disk

You have the option of storing an ephemeral OS disk on the VM temp disk, a resource disk, or an NVMe disk. This functionality enables you to use an ephemeral OS disk with a VM that either doesn't have a cache, or has insufficient cache. Such VMs have a temp disk, resource disk, or NVMe disk to store an ephemeral OS disk, such as `Ddv4`.

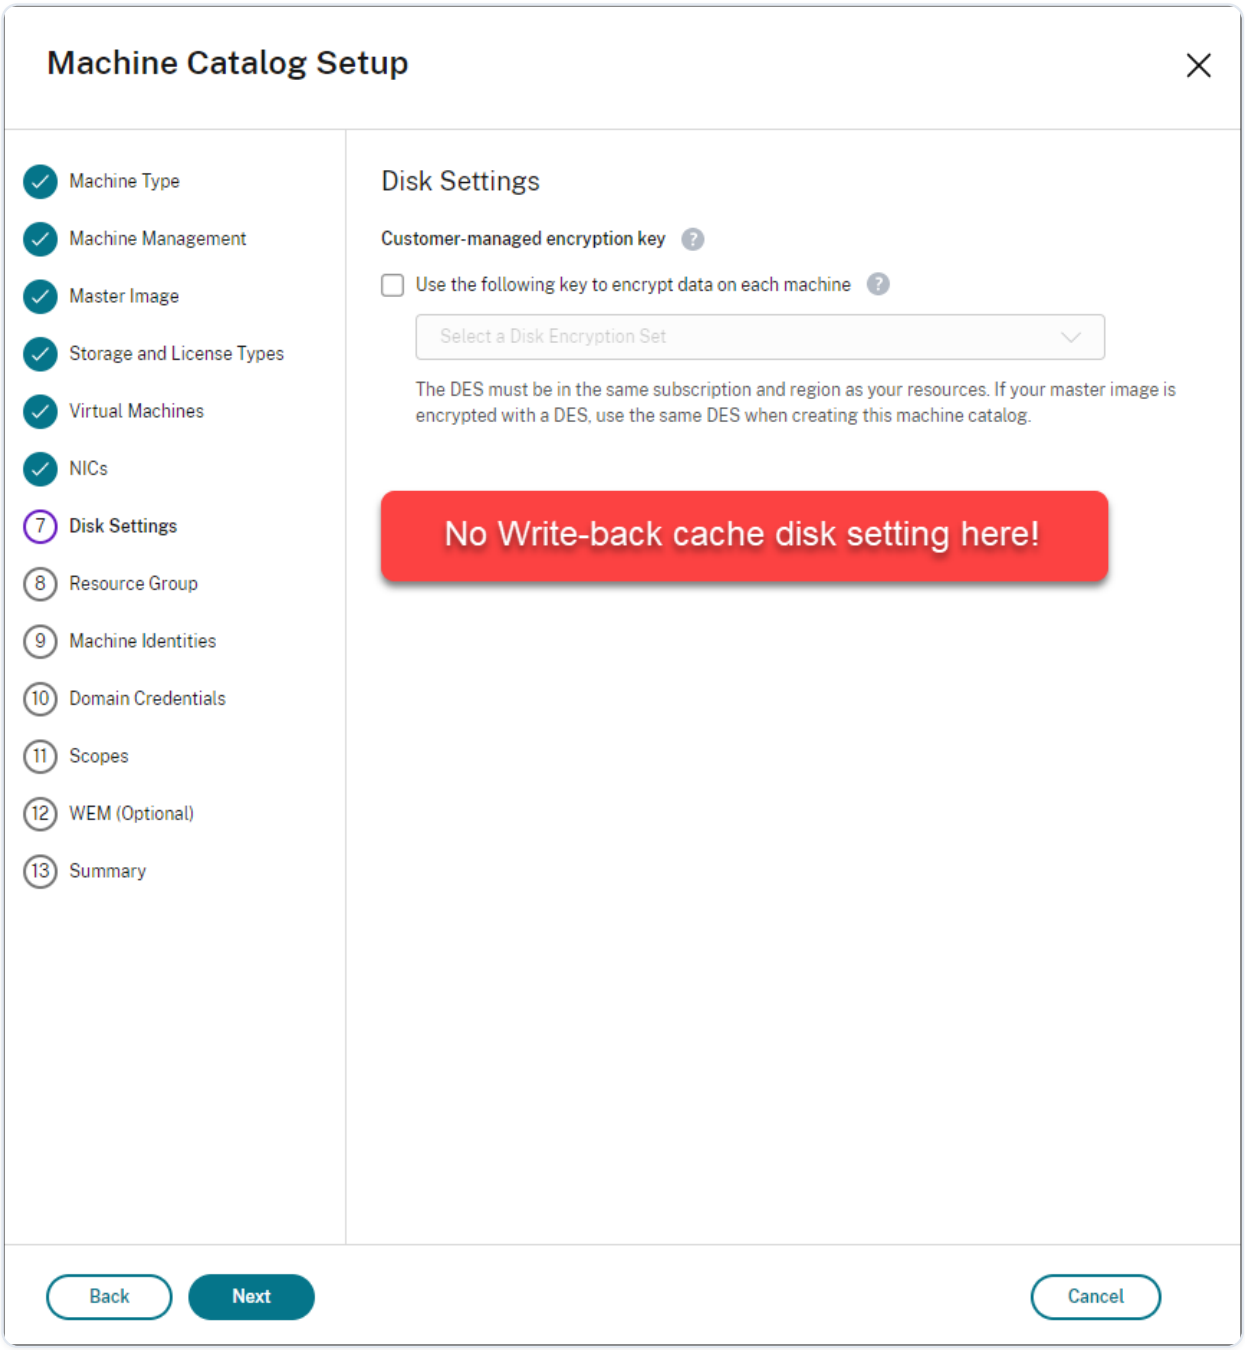
Consider the following:

- An ephemeral disk is stored either in the VM cache disk, or the VMs temporary (resource) disk or the NVMe disk. The cache disk is preferred over the temporary disk, unless the cache disk is not large enough to hold the contents of the OS disk.
- For updates, a new image that is larger than the cache disk but smaller than the temp disk results in replacing the ephemeral OS disk with the VM's temp disk.



Azure ephemeral disk and Machine Creation Services (MCS) storage optimization (MCS I/O)

Azure ephemeral OS disk and MCS I/O cannot be enabled at the same time.



The important considerations are as follows:

- You cannot create a machine catalog with both ephemeral OS disk and MCS I/O enabled at the same time.
- In the **Machine Catalog Setup** wizard, if you select **Azure ephemeral OS disk** on the **Storage and License Types** page, you do not get the option for write-back cache disk settings on the **Disk Settings** page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The PowerShell parameters (`UseWriteBackCache` and `UseEphemeralOsDisk`) set to **true** in `New-ProvScheme` or `Set-ProvScheme` fails with proper error message.
- For existing machine catalogs created with both features enabled, you can still:
  - update a machine catalog.
  - add or delete VMs.
  - delete a machine catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure Compute Gallery

Use Azure Compute Gallery (formerly Shared Image Gallery) as a published image repository for MCS provisioned machines in Azure. You can store a published image in the gallery to accelerate the creation and hydration of OS disks, improving start and application launch times for non-persistent VMs. Azure Compute Gallery contains the following three elements:

- Gallery: Images are stored here. MCS creates one gallery for each machine catalog.
- Gallery Image Definition: This definition includes information (operating system type and state, Azure region) about the published image. MCS creates one image definition for each image created for the catalog.
- Gallery Image Version: Each image in an Azure Compute Gallery can have multiple versions, and each version can have multiple replicas in different regions. Each replica is a full copy of the published image. Citrix DaaS creates one Standard_LRS image version (version 1.0.0) for each image with the appropriate number of replicas in the catalog's region, based on the number of machines in the catalog, the configured replica ratio, and the configured replica maximum.

NOTE:

Azure Compute Gallery functionality is only compatible with managed disks. It is not available for legacy machine catalogs.

For more information, see Azure shared image gallery overview.

Access images from Azure Compute Gallery

When selecting an image to use for creating a machine catalog, you can select images you created in the Azure Compute Gallery. These images appear in the list of images on the **Image** page of the Machine Catalog Setup wizard.

For these images to appear, you must:

1. Set up Citrix DaaS.
2. Connect to the Azure Resource Manager.
3. In the Azure portal, create a resource group. For details, see Create an Azure Shared Image Gallery using the portal.
4. In the resource group, create an Azure Compute Gallery.
5. In the Azure Compute Gallery, create an image definition.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. In the image definition, create an image version.

For information on configuring the Azure Compute Gallery, see Configure Azure Compute Gallery.

Conditions for Azure temporary disk to be eligible for write-back cache disk

You can use the Azure temporary disk as write-back cache disk only if all the following conditions are satisfied:

- The write-back cache disk must non-persist as the Azure temporary disk is not appropriate for persistent data.
- The chosen Azure VM size must include a temporary disk.
- The ephemeral OS disk is not required to be enabled.
- Accept to place the write-back cache file on Azure temporary disk.
- The Azure temporary disk size must be greater than the total size of (write-back cache disk size + reserved space for paging file + 1 GB buffer space).

Non-persistent write-back cache disk scenarios

The following table describes three different scenarios when a temporary disk is used for write-back cache while creating a machine catalog.

SCENARIO	OUTCOME
All conditions to use a temporary disk for write-back cache are satisfied.	The WBC file `mcsdif.vhdx` is placed on the temporary disk.
Temporary disk has insufficient space for write-back cache usage.	A VHD disk 'MCSWCDisk' is created and WBC file `mcsdif.vhdx` is placed on this disk.
Temporary disk has sufficient space for write-back cache usage but `UseTempDiskForWBC` is set to false.	A VHD disk 'MCSWCDisk' is created and WBC file `mcsdif.vhdx` is placed on this disk.

See the following PowerShell topics:

- Create a machine catalog with non-persistent write-back cache disk
- Create a machine catalog with persistent write-back cache disk

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure server-side encryption

Citrix DaaS supports customer-managed encryption keys for Azure managed disks through Azure Key Vault. With this support you can manage your organizational and compliance requirements by encrypting the managed disks of your machine catalog using your own encryption key. For more information, see Server-side encryption of Azure Disk Storage.

When using this feature for managed disks:

- To change the key that the disk is encrypted with, you change the current key in the `DiskEncryptionSet`. All resources associated with that `DiskEncryptionSet` change to be encrypted with the new key.
- When you disable or delete your key, any VMs with disks using that key automatically shut down. After shutting down, the VMs are not usable unless the key is enabled again or you assign a new key. Any catalog using the key cannot be powered on, and you cannot add VMs to it.

Important considerations when using customer-managed encryption keys

Consider the following when using this feature:

- All resources related to your customer-managed keys (Azure Key Vaults, disk encryption sets, VMs, disks, and snapshots) must reside in the same subscription and region.
- Disks, snapshots, and images encrypted with customer-managed keys cannot move to another resource group and subscription.
- Refer to the Microsoft site for limitations on disk encryption sets per region.

NOTE:

See Quickstart: Create a Key Vault using the Azure portal for information on configuring Azure server-side encryption.

Azure Customer-managed encryption key

When creating a machine catalog, you can choose whether to encrypt data on the machines provisioned in the catalog. Server-side encryption with a customer-managed encryption key lets you manage encryption at a managed disk level and protect data on the machines in the catalog. A Disk Encryption Set (DES) represents a customer-managed key. To use this feature, you must first create your DES in Azure. A DES is in the following format:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `/subscriptions/12345678-1234-1234-1234-123456789012/resourceGroups/Sample-RG/providers/Microsoft.Compute/diskEncryptionSets/SampleEncryptionSet`

Select a DES from the list. The DES you select must be in the same subscription and region as your resources.

If you create a catalog with an encryption key and later disable the corresponding DES in Azure, you can no longer power on the machines in the catalog or add machines to it.

See Create a machine catalog with customer-managed key.

Azure disk encryption at host

You can create an MCS machine catalog with encryption at host capability. Currently, MCS supports only the machine profile workflow for this feature. You can use a VM or a template spec as an input for a machine profile.

This encryption method does not encrypt the data through the Azure storage. The server hosting the VM encrypts the data and then the encrypted data flows through the Azure storage server. Hence, this method of encryption encrypts data end to end.

Restrictions:

Azure disk encryption at the host is:

- Not supported for all Azure machine sizes
- Incompatible with Azure disk encryption

For more information, see:

- Create a machine catalog with encryption at host capability.
- Retrieve encryption at host information from a machine profile

Double encryption on managed disk

You can create a machine catalog with double encryption. Any catalogs created with this feature have all disks server side encrypted with both platform and customer-managed keys. You own and maintain the Azure Key Vault, Encryption Key, and the Disk Encryption Sets (DES).

Double encryption is platform-side encryption (default) and customer-managed encryption (CMEK). Therefore, if you are a high security sensitive customer who is concerned about the risk associated with any encryption algorithm, implementation, or a compromised key, you can opt for this double

© 1997–2026 Citrix Systems, Inc. All rights reserved.

encryption. Persistent OS and data disks, snapshots, and images are all encrypted at rest with double encryption.

NOTE:

- You can create and update a machine catalog with double encryption using Studio and PowerShell commands.
- You can use non-machine profile-based workflow or machine profile-based workflow for creating or updating a machine catalog with double encryption.
- If you use non-machine profile-based workflow to create a machine catalog, you can reuse the stored `DiskEncryptionSetId`.
- If you use a machine profile, you can use a VM or template spec as a machine profile input.

Limitations

- Double encryption is not supported for Ultra Disks or Premium SSD v2 disks.
- Double encryption is not supported on unmanaged disks.
- If you disable a Disk Encryption Set key associated with a catalog, then the VMs of the catalog are disabled.
- All resources related to your customer-managed keys (Azure Key Vaults, disk encryption sets, VMs, disks, and snapshots) must be in the same subscription and region.
- You can only create up to 50 disk encryption sets per region per subscription.

See the following PowerShell topics:

- Create a machine catalog with double encryption
- Convert an unencrypted catalog to use double encryption
- Verify the catalog is double encrypted

Azure resource groups

Azure provisioning resource groups provide a way to provision the VMs that provide applications and desktops to users. You can create a resource group or use an existing resource group to provision VMs in an MCS machine catalog. You can use the same resource group in multiple machine catalogs. For information about Azure resource groups, see the Microsoft documentation.

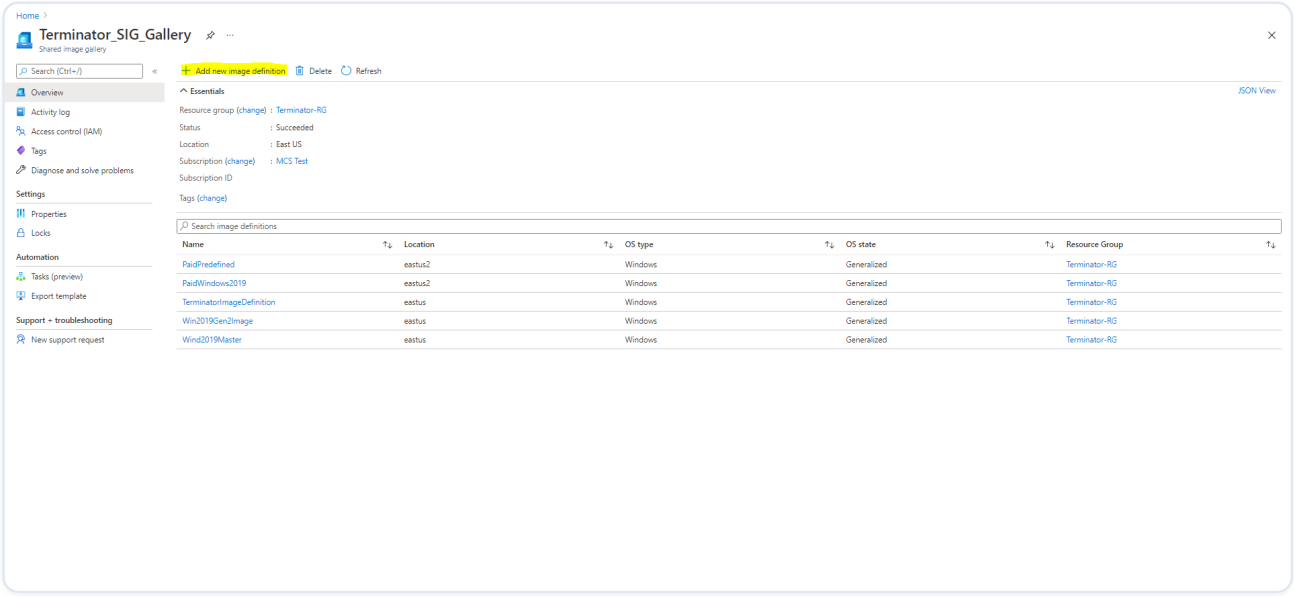
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Azure Resource Group Usage

There is no limit on the number of virtual machines, managed disks, snapshots, and images per Azure Resource Group. (The limit of 240 VMs per 800 managed disks per Azure Resource Group has been removed.)

- When using a full-scope service principal to create a machine catalog, MCS creates only one Azure Resource Group and uses that group for the catalog.
- When using a narrow scope service principal to create a machine catalog, you must supply an empty, pre-created Azure Resource Group for the catalog.

Azure Marketplace

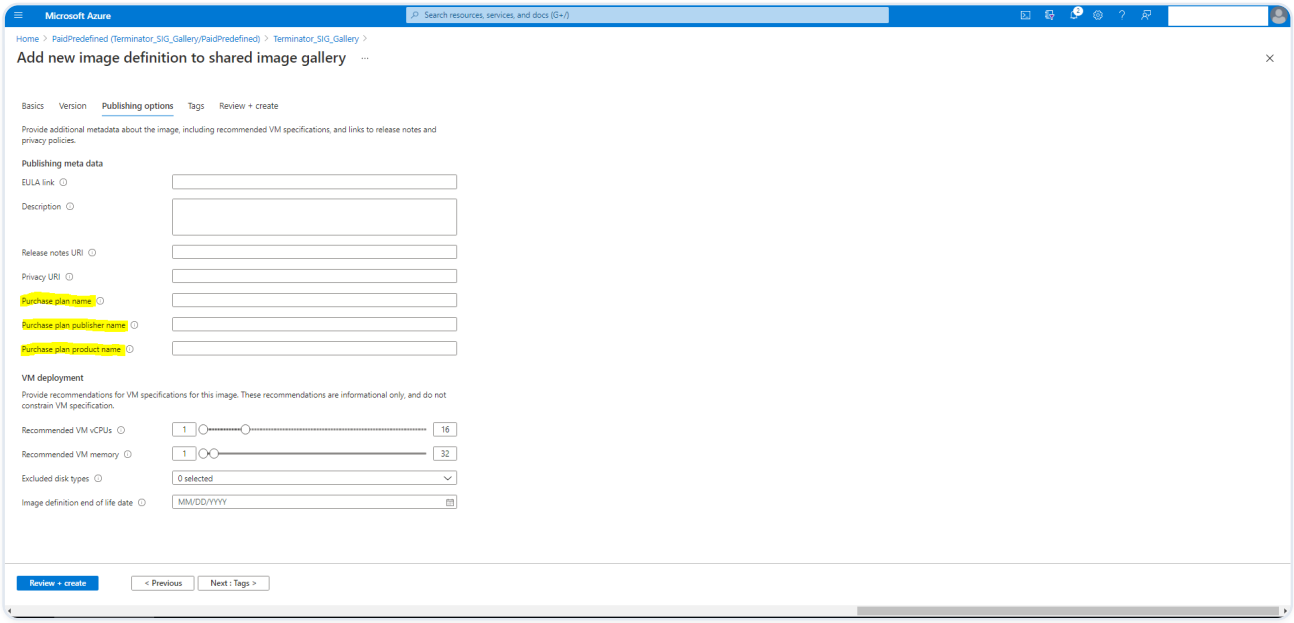


Citrix DaaS supports using a master image on Azure that contains plan information to create a machine catalog. For more information, see Microsoft Azure Marketplace.

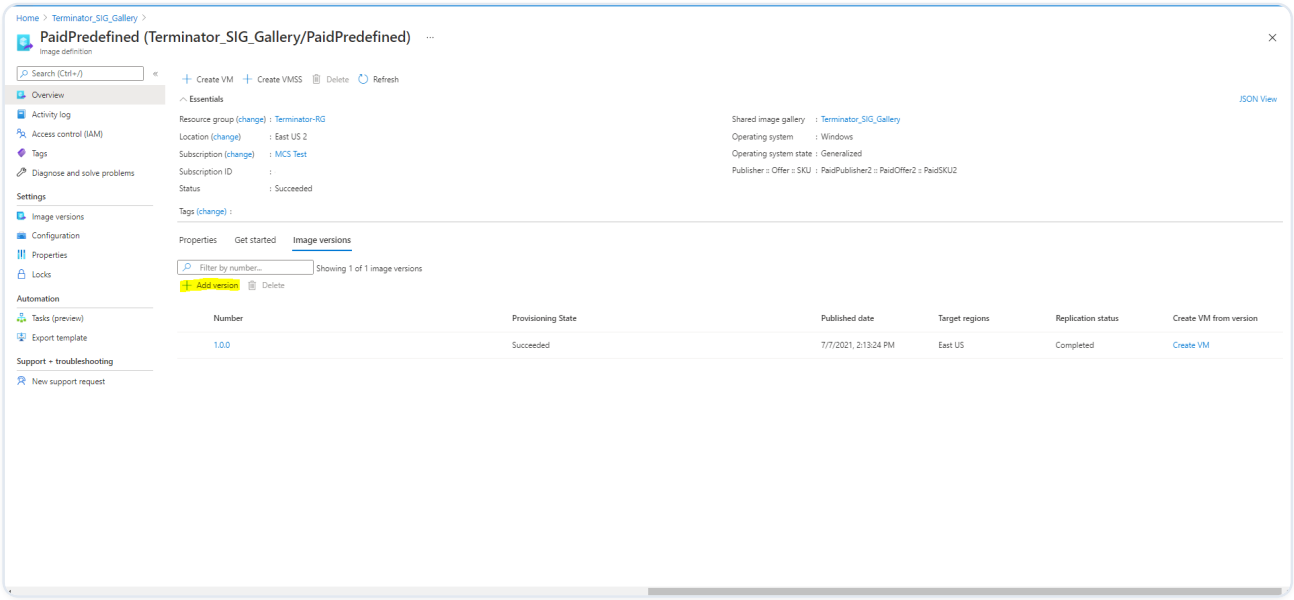
TIP:

Some images found on the Azure Marketplace, like the standard Windows Server image, do not append plan information. Citrix DaaS feature is for paid images.

Ensure that the image created in Azure Compute Gallery contains Azure plan information



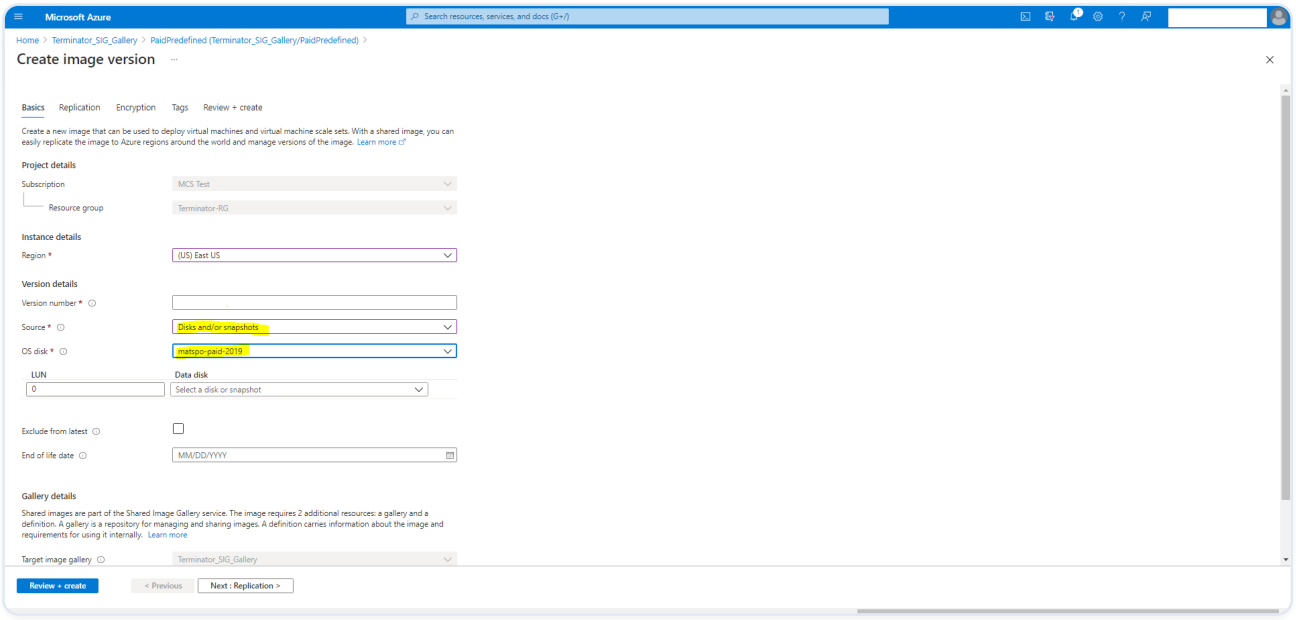
Use the procedure in this section to view Azure Compute Gallery images in Studio. These images can optionally be used for a master image. To put the image into an Azure Compute Gallery, create an image definition in a gallery.



In the **Publishing options** page, verify the purchase plan information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The purchase plan information fields are initially empty. Populate those fields with the purchase plan information used for the image. Failure to populate purchase plan information can cause the machine catalog process to fail.



After verifying the purchase plan information, create an image version within the definition. This is used as the master image. Click **Add version**:

In the **Version details** section, select the image snapshot or managed disk as the source:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Provision catalog VMs with Azure Monitor Agent installed

Azure monitoring is a service which you can use to collect, analyze, and act on telemetry data from your Azure and on-premises environments.

Azure Monitor Agent (AMA) collects monitoring data from compute resources like virtual machines and delivers the data to Azure monitor. It currently supports the collection of Event Logs, Syslog, and Performance metrics and sends it to Azure Monitor Metrics and Azure Monitor Logs data sources.

To enable monitoring by uniquely identifying the VMs in monitoring data, you can provision the VMs of an MCS machine catalog with AMA installed as an extension.

Requirements

- Permissions: Ensure that you have the minimum Azure permissions as specified in About Azure permissions and the following permissions to use Azure Monitor:
  - `Microsoft.Compute/virtualMachines/extensions/read`
  - `Microsoft.Compute/virtualMachines/extensions/write`
  - `Microsoft.Insights/DataCollectionRuleAssociations/Read`
  - `Microsoft.Insights/dataCollectionRuleAssociations/write`
  - `Microsoft.Insights/DataCollectionRules/Read`
- Data Collection Rule: Set up a data collection rule in the Azure portal. For information about setting up a DCR, see Create a data collection rule. A DCR is platform specific (Windows or Linux). Ensure that you create a DCR as per the required platform. The AMA uses Data

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Collection Rules (DCR) to manage the mapping between the resources, such as VMs, and data sources, like Azure Monitor Metrics and Azure Monitor Logs.

- Default Workspace: Create a workspace in the Azure portal. For information on creating a workspace, see Create a Log Analytics workspace. When you collect logs and data, the information is stored in a workspace. A workspace has a unique workspace ID and resource ID. The workspace name must be unique for a given resource group. After you create a workspace, configure data sources and solutions to store their data in the workspace.
- Whitelisted the monitor extension: The extensions `AzureMonitorWindowsAgent` and `AzureMonitorLinuxAgent` are Citrix defined whitelisted extensions. To view the list of whitelisted extensions, use the PowerShell command, `Get-ProvMetadataConfiguration`.
- Master Image: Microsoft recommends removing extensions from an existing machine before creating a new machine from it. If the extensions are not removed, it might lead to leftover files and unexpected behavior. For more information, see If the VM is recreated from an existing VM.

For information on creating a catalog with AMA enabled using PowerShell, see Provision catalog VMs with AMA enabled.

Azure confidential VMs

Azure confidential computing VMs ensure that your virtual desktop is encrypted in memory and protected in use.

You can use MCS to create a catalog with Azure confidential VMs. You must use the machine profile workflow to create such a catalog. You can use both VM and ARM template spec as a machine profile input.

You can also use a confidential VM type Azure master image and a confidential VM type Azure machine profile to create a prepared image, and then use this prepared image to create an MCS catalog.

Important considerations for confidential VMs

The important considerations for supported VM sizes and creating machine catalog with confidential VMs are as follows:

- To check the VM sizes supported by Confidential VMs, see Sizes.
- Create machine catalogs with confidential VMs.
    - You can create a machine catalog with Azure Confidential VMs using Studio and PowerShell commands.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You must use machine profile-based workflow for creating a machine catalog with Azure Confidential VMs. You can use a VM or template spec as a machine profile input.
- The master image and the machine profile input must be both enabled with the same confidential security type. Different Azure resources use different labels to indicate the confidential VM type.

  For Azure snapshot, managed disk or virtual machine, the security types are:

  - ConfidentialVM_DiskEncryptedWithCustomerKey.
  - ConfidentialVM_DiskEncryptedWithPlatformKey.
  - ConfidentialVM_VMGuestStateOnlyEncryptedWithPlatformKey

  For Azure ARM template spec version, the security types are:

  - VMGuestStateOnly: Confidential VM with only VM guest state encrypted
  - DiskWithVMGuestState: Confidential VM with both OS disk and VM guest state encrypted with platform managed key or customer managed key. Both normal and Ephemeral OS disk can be encrypted.
- You can get confidential VM information of various resource types such as managed disk, snapshot, Azure Compute Gallery image, VM, and ARM template spec using the AdditionalData parameter. For example:

  ```
  PS C:\Users\username> (get-item XDHyp:
  \HostingUnits\mynetwork\image.folder\username-dev-testing-
  rg.resourcegroup\username-dev-tsvda.vm).AdditionalData
  ```

  The additional data fields are:

- DiskSecurityType
- ConfidentialVMDiskEncryptionSetId
- DiskSecurityProfiles

  To get the confidential computing property of a machine size, run the following command: `(Get-Item -path "XDHyp:\Connections\my-connection-name\East US.region\serviceoffering.folder\abc.serviceoffering").AdditionalData`

  The additional data field is `ConfidentialComputingType`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You cannot change the master image or machine profile from confidential to non-confidential security type, or from non-confidential to confidential security type.
- You get appropriate error messages for any incorrect configuration.

Prepare master images and machine profiles

Before creating a set of confidential VMs, follow these steps to prepare a master image and a machine profile for them:

1. In the Azure portal, create a confidential VM with specific settings, such as:
   - **Security Type**: Confidential virtual machines
   - **Confidential OS disk encryption**: Enabled.
   - **Key management**: Confidential disk encryption with a platform-managed key For more information about creating confidential VMs, see this Microsoft article.
2. Prepare the master image on the VM created. Install the necessary applications and VDA on the created VM.

   NOTE:

   Creating confidential VMs using VHD is not supported. Instead, use Azure Compute Gallery, managed disks, or snapshots for this purpose.

3. Create the machine profile using either of these ways:
   - Use the existing VM created in step 1 if it possesses the needed machine properties.
   - If you opt for an ARM template spec as the machine profile, create the template spec as needed. Specifically, configure parameters that meet your confidential VM requirements, such as *SecurityEncryptionType* and *diskEncryptionSet* (for customer-managed key). For more information, see Create an Azure template spec.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Ensure the master image and the machine profile have the same security key type.
- To create confidential VMs requiring confidential OS disk encryption with a customer-managed key, make sure that the disk encryption set IDs in both the master image and the machine profile are identical.

If you want to use a confidential VM type prepared image to create an MCS catalog, then create a prepared image using the confidential VM type master image and a confidential VM type machine profile. See Create an image definition and initial image version for information on creating prepared images.

Create confidential VMs using Studio or PowerShell commands

To create a set of confidential VMs, create a machine catalog using a master image and a machine profile derived from a desired confidential VM.

To create the catalog using Studio, follow the steps described in Create machine catalogs. Keep the following considerations in mind:

- On the **Image** page, select a master image and a machine profile you've prepared for the confidential VM creation. The machine profile selection is mandatory and only profiles that match the same security encryption type as the selected master image are available for selection.
- On the **Virtual Machines** page, only machine sizes that support confidential VMs appear for selection.
- On the **Disk Settings** page, you can't specify the disk encryption set because it's inherited from the selected machine profile.

Boot Integrity Monitoring

If your VM has Secure Boot and virtual Trusted Platform Module (vTPM) enabled, and GuestAttestation extension installed, Microsoft Defender for Cloud can remotely validate that your VM boots in a healthy way. This monitoring is called Boot Integrity Monitoring. For more information on Boot Integrity Monitoring, see Boot integrity monitoring overview.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

You can enable Boot Integrity Monitoring for MCS machine catalog VMs (persistent and non-persistent VMs) using a machine profile (VM or template spec). Boot Integrity Monitoring is only supported for Trusted Launch and Confidential VMs.

You can update an existing catalog to use boot integrity using `Set-ProvScheme to point to a boot integrity enabled machine profile. New VMs added to the catalog are then enabled with integrity monitoring.

You can also update an existing VM in a catalog using `Set-ProvVmUpdateTimeWindow`, `Set-ProvVm`, or Maintenance Cycles.

You can convert a:

- VM without integrity monitoring to have integrity monitoring.
- VM with integrity monitoring to without integrity monitoring.

Create machine catalog enabled with integrity monitoring

Ensure that you have the following permissions:

- `Microsoft.Compute/virtualMachines/extensions/read`
- `Microsoft.Compute/virtualMachines/extensions/write`

Do the following to create an MCS machine catalog enabled with integrity monitoring:

1. Create a machine profile (VM or template spec) with `GuestAttestation` extension.
2. Create an MCS machine catalog using the machine profile input using the Full configuration interface or PowerShell commands.

   NOTE:

   You can check the `GuestAttestationExtensionEnabled` status of a VM or template spec using the `Get-Item` PowerShell command with the `AdditionalData parameter`.

3. Add VMs to the catalog.

Create a machine profile enabled with GuestAttestation extension

Create a VM or template spec as a machine profile input with integrity monitoring enabled, which implies `GuestAttestation` extension is installed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create a VM with integrity monitoring enabled, do the following:

1. Sign in to the Azure portal.
2. If you are creating a new VM:
    a. Select **Security type** as **Trusted launch virtual machines** or **Confidential virtual machines**.
    b. Click **Configure security features** and select **Integrity monitoring** checkbox.

    NOTE:

    For integrity monitoring, you must enable Secure Boot and vTPM.

3. On the **Overview** page, go to the **Security type** section and verify that the Security type is Trusted Launch or Confidential virtual machines and Integrity monitoring is enabled.
4. Navigate to the **Extensions + applications** page to verify that `GuestAttestation` is installed.

To enable integrity monitoring of an existing VM, see Enable integrity monitoring-Azure portal.

To create a template spec with `GuestAttestation` extension installed:

1. You can install GuestAttestation using a template spec. See Enable integrity monitoring-template spec.

    NOTE:

    In this template spec, under **Settings**, you can configure the endpoints to use for attestation. If you do not configure, then Azure decides what endpoints to configure.

Create a catalog of on-demand capacity reservation VMs

On-demand capacity reservation enables you to reserve compute capacity in an Azure region or an Availability Zone for any duration of time. For more information on Azure on-demand capacity reservation, see the Microsoft documentation On-demand Capacity Reservation.

You can create an MCS machine catalog of Azure VMs with on-demand capacity reservation using a machine profile (VM or template spec). You can also update an existing machine catalog and existing VMs to have or remove on-demand capacity reservation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This feature is applicable to persistent and non-persistent machine catalogs.

Limitations

This feature is not applicable to:

- Spot VMs
- Host group
- Hibernation enabled VMs

For more information on limitations, see the Microsoft documentation Limitations and restrictions.

Required permission

You need the following permission for creating a catalog of on-demand capacity reservation VMs:

`Microsoft.Compute/capacityReservationGroups/deploy/action`

Steps to create a catalog of on-demand capacity reservation VMs

1. Create a machine profile source (VM or ARM template spec). For creating a VM or an ARM template spec, see Associate a VM to a Capacity Reservation group.
2. Run the following PowerShell command to check if a machine profile has on-demand capacity reservation enabled or not. If the machine profile is enabled with on-demand capacity reservation, then you get the `capacityReservationGroup id`.

   For example,

   If the machine profile source is a VM, run the following command:

   ```
   (Get-Item "XDHyp:\HostingUnits\azure-res-
   conn2\machineprofile.folder\fifthcolumn.resourcegroup\demand-
   capacity.vm").AdditionalData
   ```

   If the machine profile source is a template spec, run the following command:

   ```
   (Get-Item "XDHyp:\HostingUnits\azure-res-
   conn2\machineprofile.folder\fifthcolumn.resourcegroup\fc-aeh-
   templatespec.templatespec\14.0.0-capacity-
   reservation.templatespecversion").AdditionalData
   ```

3. Create a machine catalog using a machine profile using Studio or PowerShell commands.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

You can update a catalog using the `Set-ProvScheme` command. You can also update existing VMs using the PowerShell command `Set-ProvVmUpdateTimeWindow`. The machine profile is updated on the next power on.

Nested virtualization

If you configure the master VM with nested virtualization enabled, then all VMs in the MCS machine catalog created using that master VM has nested virtualization enabled. This feature is applicable to both persistent and non-persistent VMs. You can update an existing MCS machine catalog and existing VMs to have nested virtualization through image update.

Currently, only Dv3 and Ev3 VM sizes support nested virtualization.

For information on nested virtualization, see the Microsoft blog Nested Virtualization in Azure.

NVMe-only SKUs

Typically, the older generations of general purpose, memory optimized, and compute optimized VMs (D/Ev5 or Fv2 and older) support SCSI. The newer generations (Da/Ea/Fav6 and newer) typically support only the NVMe storage interface. MCS supports the NVMe storage controller type to support the new VM SKUs on Azure.

For information on NVMe, see the Microsoft documentation General FAQ for NVMe.

You can create an MCS catalog using a service offering that:

- supports both SCSI and NVMe, see Create a catalog using a service offering that supports both SCSI and NVMe
- supports only NVMe, see Create a catalog using a service offering that supports only NVMe

Limitations

- All service offerings that support NVMe, do not support Trusted Launch at the same time.
- NVMe isn't supported for Gen 1 VMs.
- Some OS images might not support NVMe. In that case, the NVMe option is grayed out on the Azure UI.

Create a catalog using a service offering that supports both SCSI and NVMe

1. Create a VM to be used as a master image.

    a. Use a marketplace image that supports NVMe. A list of Azure Marketplace images that support NVMe can be found at Supported OS images for remote NVMe.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. Take a snapshot of the OS Disk of the VM to use in the `MasterImageVM` parameter of the `New-ProvScheme` command or use the managed disk directly.

   Check whether your master image supports NVMe or not using one of the following ways:

   - Check the `SupportedDiskControllerTypes` in the `AdditionalData` field of `Get-Item`. For example:

     ```
     (get-item XDHyp:
     \HostingUnits\mynetwork\image.folder\abc.resourcegroup\deg-
     snapshot).AdditionalData
     ```

     The `SupportedDiskControllerTypes` must be `SCSI, NVMe`.

   - Use Azure CLI and PowerShell

2. Use a service offering that supports both NVMe and SCSI.
3. Use a VM or template spec as a machine profile that has NVMe enabled. Take any VM that has `DiskControllerType` set to NVMe. Use the VM directly as a machine profile or export template and use the template spec as a machine profile.

Create a catalog using a service offering that supports only NVMe

1. Create a VM to be used as a master image. Use a marketplace image that supports NVMe. A list of Azure Marketplace images that support NVMe can be found at Supported OS images for remote NVMe.
2. Use a service offering that supports only NVMe.

> **NOTE:**
>
> As the service offering supports NVMe, you do not need a machine profile with `DiskControllerType` set to `NVMe` to enable NVMe on the catalog. However, if you use a machine profile, it must have the `DiskControllerType` either set to `NVMe` or must have it blank or not specified.

Modify existing persistent VMs

NVMe configuration cannot be changed on a VM once it is created. The way to change NVMe configuration for a persistent VM is to redeploy the VM. The logic to do this is:

1. Save the current state of the VM.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. After powering on an existing VM, detect whether the VM requires redeployment.

    a. If the configuration change is from NVMe to NVMe or SCSI to SCSI, redeployment of the VM is not required.

    b. If the configuration change is from SCSI to NVMe and conversely, redeploy and recreate the VM.

Use PowerShell

This section details how to do the following tasks using PowerShell:

- Use template spec in creating or updating a catalog using PowerShell
- Enable Azure VM extensions
- Machine catalogs with Trusted Launch
- Use machine profile property values
- Configure Availability Zones using PowerShell
- Provision VMs on Azure dedicated hosts
- Configure storage types
- Enable zone-redundant storage
- Capture diagnostic settings on VMs and NICs from a machine profile
- Verify the Windows license
- Configure the Linux license
- Create a machine catalog with an Azure ephemeral disk
- Configure Azure Compute Gallery
- Create or update a catalog with multiple NICs per VM
- Create a machine catalog with non-persistent write-back cache disk
- Create a machine catalog with persistent write-back cache disk
- Improve boot performance with MCSIO
- Create a machine catalog with customer-managed encryption key
- Create a machine catalog with encryption at host capability
- Create a machine catalog with double encryption
- Page file location determination
- Page file setting scenarios

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Specify page file setting
- Modify page file settings
- Provision catalog VMs with AMA enabled
- Create a catalog using Azure Spot VMs
- Configure backup VM sizes
- Copy tags on all resources

Use template spec in creating or updating a catalog using PowerShell

You can create or update an MCS machine catalog using a template spec as a machine profile input. To do this, you can use Studio or PowerShell commands.

For Studio interface, see Create a machine catalog using an Azure Resource Manager image in Studio interface.

Using PowerShell commands:

1. Open the **PowerShell** window.
2. Run `asnp citrix*`.
3. Create or update a catalog.
    - To create a catalog:
        a. Use the `New-ProvScheme` command with a template spec as a machine profile input. For example:

```
New-ProvScheme -MasterImageVM "XDHyp:/HostingUnits/azure/
image.folder/fgthj.resourcegroup/nab-ws-
vda_OsDisk_1_xxxxxxxxxxa.manageddisk"

MachineProfile "XDHyp:/HostingUnits/azure/machineprofile.folder/
fgthj.resourcegroup/test.templatespec/V1.templatespecversion"

-ProvisioningSchemeName <String>

-HostingUnitName <String>

-IdentityPoolName <String>

[-ServiceOffering <String>][-CustomProperties <String>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
[<CommonParameters>]
```

b. Finish creating the catalog.

- To update a catalog, use `Set-ProvScheme` command with a template spec as a machine profile input. For example:

```
Set-ProvScheme -MasterImageVm 'XDHyp://Connections/Azure/East
Us.region/vm.folder/MasterDisk.vm'

MachineProfile 'XDHyp:/HostingUnits/azure/machineprofile.folder/
fgthj.resourcegroup/testing.templatespec/V1.templatespecversion'

[-ProvisioningSchemeName] <String>

[-CustomProperties <String>][-ServiceOffering <String>] [-PassThru]

[<CommonParameters>]
```

Enable Azure VM extensions

After you select the ARM template spec, run the following PowerShell commands to work with Azure VM extensions:

- To view the list of supported Azure VM extensions: `Get-ProvMetadataConfiguration`
- To add more VM extensions: `Add-ProvMetadataConfiguration`. For example, `Add-ProvMetadataConfiguration -PluginType "AzureRM" -ConfigurationName "Extension" -ConfigurationValue "CustomScriptExtension"`

  If you try to add any of the following, the command fails with an error message:

  - Citrix defined extension.
  - Existing user defined extension.
  - Unsupported configuration keys. Currently, the supported configuration key is `Extension`.
- To remove extensions from the list: `Remove-ProvMetadataConfiguration`. You can remove the extensions that you added.

Machine catalogs with Trusted Launch

To successfully create a machine catalog with Trusted Launch, use:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- A master image enabled with Trusted Launch. You must use a machine profile, however, it is not necessary for the machine profile to be Trusted Launch enabled. If you use a master image enabled with Trusted Launch and a machine profile not enabled with Trusted Launch, you get a warning message because of the mismatched Trusted Launch configuration between master image and machine profile.
- A VM size that supports Trusted Launch.
- A Windows VM version that supports Trusted Launch. Currently, Windows 10, Windows 11, Windows Server 2016, 2019, and 2022 support Trusted Launch.

To view the Citrix DaaS offering inventory items, and to determine whether the VM size supports Trusted Launch, run the following command:

1. Open a PowerShell window.
2. Run **asnp citrix*** to load the Citrix-specific PowerShell modules.
3. Run the following command:

   ```
   $s = (ls XDHyp:\HostingUnits\<name of hosting
   unit>\serviceoffering.folder\"<VM size>".serviceoffering)
   ```

4. Run `$s | select -ExpandProperty Additionaldata`
5. Check the value of the `SupportsTrustedLaunch` attribute.
   - If `SupportsTrustedLaunch` is **True**, the VM size supports Trusted Launch.
   - If `SupportsTrustedLaunch` is **False**, the VM size does not support Trusted Launch.

As per Azure's PowerShell, you can use the following command to determine the VM sizes that support Trusted Launch:

```
(Get-AzComputeResourceSku | where {$_.Locations.Contains($region) -and
($_.Name -eq "<VM size>") })[0].Capabilities
```

The following are examples that describe whether the VM size supports Trusted Launch after you run the Azure PowerShell command.

- *Example 1*: If the Azure VM supports only Generation 1, that VM does not support Trusted Launch. Therefore, the `TrustedLaunchDisabled` capability is not displayed after you run the Azure PowerShell command.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- *Example 2*: If the Azure VM supports only Generation 2 and the `TrustedLaunchDisabled` capability is **True**, the Generation 2 VM size is not supported for Trusted Launch.
- *Example 3*: If the Azure VM supports only Generation 2 and the `TrustedLaunchDisabled` capability is not displayed after you run the PowerShell command, the Generation 2 VM size is supported for Trusted Launch.

For more information on Trusted Launch for Azure virtual machines, see the Microsoft document Trusted launch for Azure virtual machines.

Create a machine catalog with Trusted Launch

1. Create a master image enabled with Trusted Launch. See the Microsoft documentation Trusted launch VM Images.
2. Create a VM or template spec with security type as **trusted launch virtual machines**. For more information on creating a VM or template spec, see the Microsoft document Deploy a trusted launch VM.
3. Create a machine catalog using Studio or PowerShell commands.
   - If you want to use Studio, see Create a machine catalog using an Azure Resource Manager image in Studio.
   - If you want to use PowerShell commands, use the `New-ProvScheme` command with the VM or the template spec as a machine profile input.

     Example of `New-ProvScheme` with VM as machine profile input:

     ```
     New-ProvScheme -CleanOnBoot -HostingUnitName "name"
     -IdentityPoolName "name" -InitialBatchSizeHint 1

     -MasterImageVM "XDHyp:/HostingUnits/azure/image.folder/
     fgthj.resourcegroup/nab-ws-vda_OsDisk_1_xxxxxxxxxxa.manageddisk"

     -MachineProfile "XDHyp:
     \HostingUnits\<adnet>\machineprofile.folder\<def.resourcegroup>\<mac
     hine profile vm.vm>"

     -ProvisioningSchemeName <String>

     -HostingUnitName <String>

     -IdentityPoolName <String>
     ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
[-ServiceOffering <String>][-CustomProperties <String>]

[<CommonParameters>]
```

Example of `New-ProvScheme` with template spec as machine profile input:

```
New-ProvScheme -CleanOnBoot -HostingUnitName "name"
-IdentityPoolName "name" -InitialBatchSizeHint 1

-MasterImageVM "XDHyp:/HostingUnits/azure/image.folder/
fgthj.resourcegroup/nab-ws-vda_OsDisk_1_xxxxxxxxxxa.manageddisk"

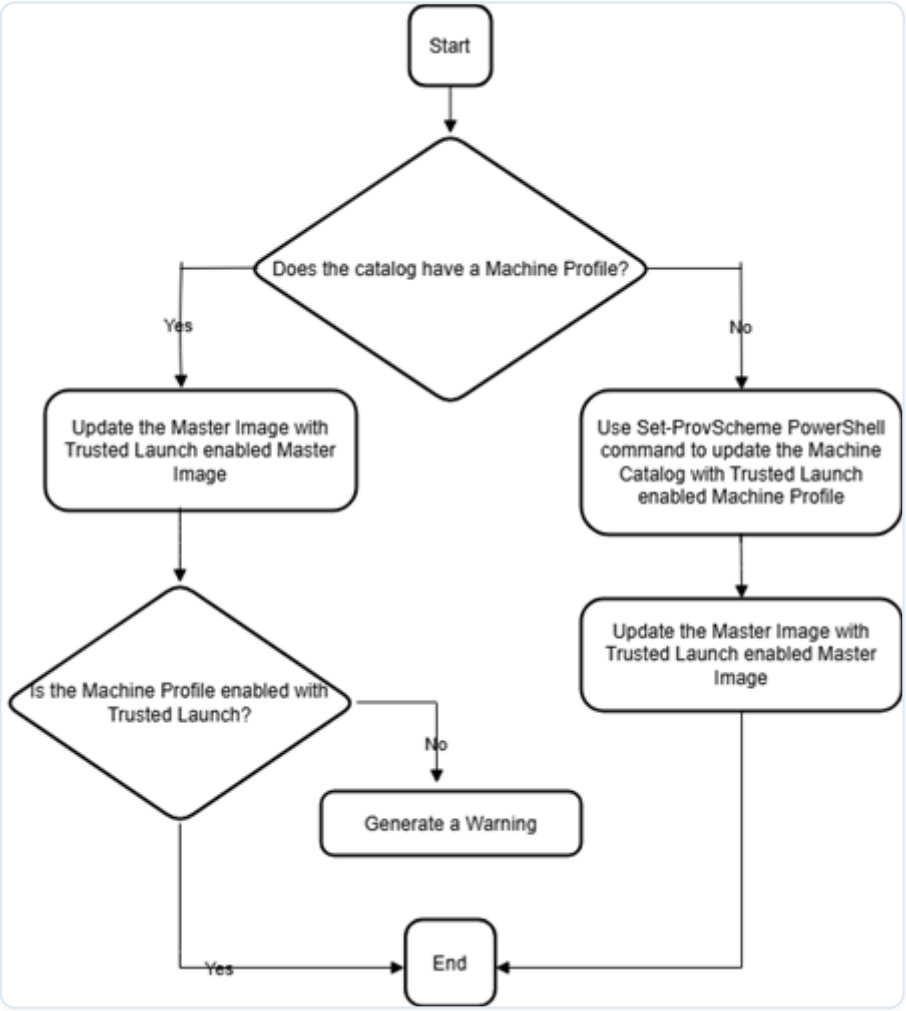
MachineProfile "XDHyp:/HostingUnits/azure/machineprofile.folder/
fgthj.resourcegroup/test.templatespec/V1.templatespecversion"

-ProvisioningSchemeName <String>

-HostingUnitName <String>

-IdentityPoolName <String>

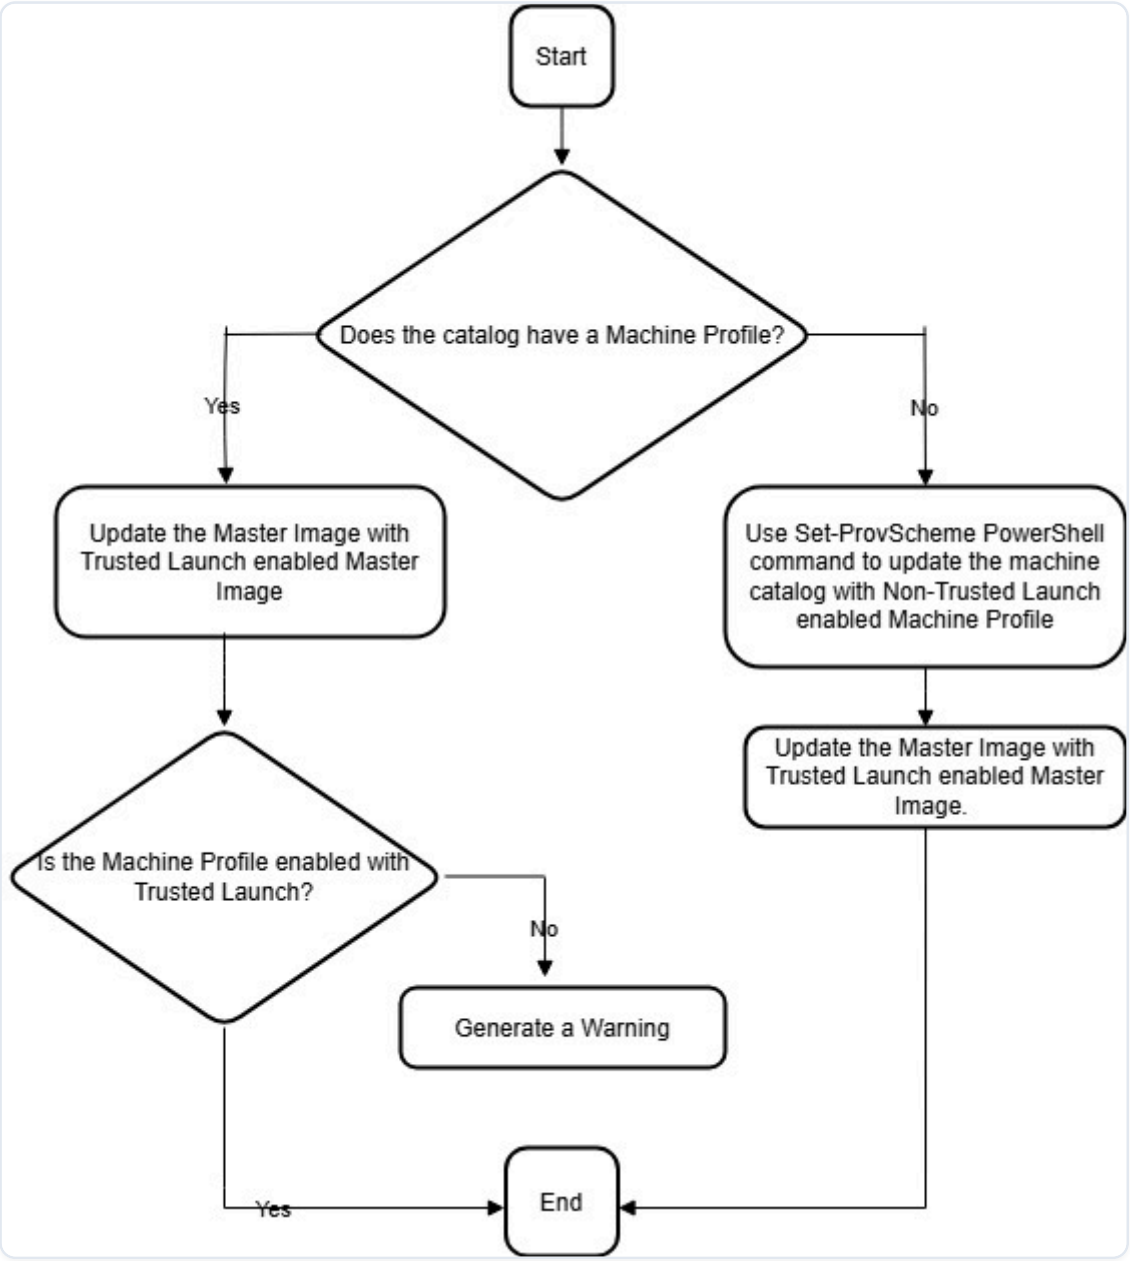
[-ServiceOffering <String>][-CustomProperties <String>]



[<CommonParameters>]
```

Update a machine catalog with Trusted Launch

You can update both persistent and non-persistent machine catalogs:



For persistent machine catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For non-persistent machine catalog:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Errors while creating machine catalogs with Trusted Launch

You get appropriate errors in the following scenarios while creating a machine catalog with Trusted Launch:

SCENARIO	ERROR
If you select a machine profile while creating an unmanaged catalog	`MachineProfileNotSupportedForUnmanagedCatalog`
If you select a machine profile that supports Trusted Launch while creating a catalog with unmanaged disk as the master image	`SecurityTypeNotSupportedForUnmanagedDisk`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SCENARIO	ERROR
If you select a machine profile with a security type different from the security type of the master image	`SecurityTypeConflictBetweenMasterImageAndMachineProfile`
If you select a VM size that does not support Trusted Launch but use a master image that supports Trusted Launch while creating a catalog	`MachineSizeNotSupportTrustedLaunch`

Use machine profile property values

The machine catalog uses the following properties that are defined in the custom properties:

- Availability zone
- Dedicated Host Group Id
- Disk Encryption Set Id
- OS type
- License type
- Storage type

If these custom properties are not defined explicitly, then the property values are set from the ARM template spec or VM, whichever is used as the machine profile. In addition, if `ServiceOffering` is not specified, then it is set from the machine profile.

NOTE:

If some of the properties are missing from the machine profile and not defined in the custom properties, then the default values of the properties take place wherever applicable.

The following section describes some scenarios at `New-ProvScheme` and `Set-ProvScheme` when `CustomProperties` either have all the properties defined or values are derived from the MachineProfile.

- New-ProvScheme Scenarios
  - MachineProfile has all the properties and CustomProperties are not defined. Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`New-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpA.vm"`

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<mpA-value>"/>

<Property xsi:type="StringProperty" Name="OSType" Value="<mpA-
value>"/>

<Property xsi:type="StringProperty" Name="LicenseType" Value="<mpA-
value>"/>

<Property xsi:type="StringProperty" Name="DiskEncryptionSetId"
Value="<mpA-value>"/>

<Property xsi:type="StringProperty" Name="DedicatedHostGroupId"
Value="<mpA-value>"/>

<Property xsi:type="StringProperty" Name="Zones" Value="<mpA-
value>"/>

</CustomProperties>
```

- MachineProfile has some properties and CustomProperties are not defined. Example: MachineProfile only has LicenseType and OsType.

`New-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpA.vm"`

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="OSType" Value="<mpA-
value>"/>

<Property xsi:type="StringProperty" Name="LicenseType" Value="<mpA-
value>"/>

</CustomProperties>
```

- Both MachineProfile and CustomProperties define all properties. Example:

  `New-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpA.vm" -CustomProperties $CustomPropertiesA`

  Custom properties take priority. The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="OSType"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="LicenseType"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="DiskEncryptionSetId"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="DedicatedHostGroupId"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="Zones"
Value="<CustomPropertiesA-value>"/>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>
```

- Some properties are defined in MachineProfile and some properties are defined in CustomProperties. Example:
  - CustomProperties define LicenseType and StorageAccountType
  - MachineProfile define LicenseType, OsType, and Zones

`New-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpA.vm" -CustomProperties $CustomPropertiesA`

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="OSType" Value="<mpA-
value>"/>

<Property xsi:type="StringProperty" Name="LicenseType"
Value="<CustomPropertiesA-value>"/>

<Property xsi:type="StringProperty" Name="Zones" Value="<mpA-
value>"/>

</CustomProperties>
```

- Some properties are defined in MachineProfile and some properties are defined in CustomProperties. In addition, ServiceOffering is not defined. Example:
  - CustomProperties define StorageType
  - MachineProfile define LicenseType

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-ProvScheme -MachineProfile "XDHyp:
\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mp
.vm"

-ServiceOffering "XDHyp:
\HostingUnits\azureunit\serviceoffering.folder\<explicit-machine-
size>.serviceoffering"
```

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select ServiceOffering

serviceoffering.folder\<explicit-machine-size>.serviceoffering

Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="explicit-storage-type"/>

<Property xsi:type="StringProperty" Name="LicenseType" Value="value-
from-machineprofile"/>

</CustomProperties>
```

- If the OsType is in neither in the CustomProperties nor in the MachineProfile, then:
  - The value is read from the master image.
  - If the master image is an unmanaged disk, the OsType is set to Windows. Example:

`New-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpA.vm" -MasterImageVM "XDHyp:\HostingUnits\azureunit\image.folder\linux-master-image.manageddisk"`

The value from the master image is written to the custom properties, in this case Linux.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="OSType" Value="Linux"/>

</CustomProperties>
```

- Set-ProvScheme Scenarios
  - An existing catalog with:
    - CustomProperties for `StorageAccountType` and OsType
    - MachineProfile `mpA.vm` that defines zones
  - Updates:
    - MachineProfile mpB.vm that defines StorageAccountType
    - A new set of custom properties $CustomPropertiesB that defines LicenseType and OsType

  `Set-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpB.vm" -CustomProperties $CustomPropertiesB`

  The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<mpB-value>"/>

<Property xsi:type="StringProperty" Name="OSType"
Value="<CustomPropertiesB-value>"/>

<Property xsi:type="StringProperty" Name="LicenseType"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value="<CustomPropertiesB-value>"/>

    </CustomProperties>
```

- An existing catalog with:
  - CustomProperties for `StorageAccountType` and OsType
  - MachineProfile `mpA.vm` that defines StorageAccountType and LicenseType
- Updates:
  - A new set of custom properties $CustomPropertiesB that defines StorageAccountType and OsType.

`Set-ProvScheme -CustomProperties $CustomPropertiesB`

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<CustomPropertiesB-value>"/>

<Property xsi:type="StringProperty" Name="OSType"
Value="<CustomPropertiesB-value>"/>

<Property xsi:type="StringProperty" Name="LicenseType" Value="<mp-A-
value>"/>

</CustomProperties>
```

- An existing catalog with:
  - CustomProperties for `StorageAccountType` and OsType
  - MachineProfile `mpA.vm` that defines Zones
- Updates:
  - A MachineProfile mpB.vm that defines StorageAccountType and LicenseType

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `ServiceOffering` is not specified

`Set-ProvScheme -MachineProfile "XDHyp:\HostingUnits\azureunit\machineprofile.folder\azure.resourcegroup\mpB.vm"`

The following values are set as custom properties for the catalog:

```
Get-ProvScheme | select ServiceOffering

serviceoffering.folder\<value-from-machineprofile>.serviceoffering

Get-ProvScheme | select CustomProperties

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="<mpB-value>"/>

<Property xsi:type="StringProperty" Name="OSType" Value="<prior-
CustomProperties-value>"/>

<Property xsi:type="StringProperty" Name="LicenseType" Value="<mpB-
value>"/>

</CustomProperties>
```

Configure Availability Zones using PowerShell

Using PowerShell, you can view the Citrix DaaS offering inventory items by using `Get-Item`. For example, to view the *Eastern US region* `Standard_B1ls` service offering:

```
$serviceOffering = Get-Item -path "XDHyp:\Connections\my-connection-
name\East US.region\serviceoffering.folder\Standard_B1ls.serviceoffering"
```

To view the zones, use the `AdditionalData` parameter for the item:

`$serviceOffering.AdditionalData`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If Availability Zones are not specified, there is no change in how machines are provisioned.

To configure Availability Zones through PowerShell, use the **Zones** custom property available with the `New-ProvScheme` operation. The **Zones** property defines a list of Availability Zones to provision machines into. Those zones can include one or more Availability Zones. For example, `<Property xsi:type="StringProperty" Name="Zones" Value="1, 3"/>` for Zones 1 and 3.

Use the `Set-ProvScheme` command to update the zones for a provisioning scheme.

If an invalid zone is provided, the provisioning scheme is not updated, and an error message appears providing instructions on how to fix the invalid command.

TIP:

If you specify an invalid custom property, the provisioning scheme is not updated and a relevant error message appears.

Outcome of using host groups and Azure availability zones at the same time

There is a pre-flight check to assess whether the creation of a machine catalog will be successful based on the availability zone specified in the custom property and the host group's zone. Catalog creation fails if the availability zone custom property does not match the host group's zone.

For information on configuring availability zones through PowerShell, see Configuring Availability Zones through PowerShell.

For information on Azure dedicated hosts, see Azure dedicated hosts.

The following table describes the various combinations of availability zone and host group zone and which ones result in successful or failed creation of a machine catalog.

HOST GROUP ZONE	AVAILABILITY ZONE IN CUSTOM PROPERTY	MACHINE CATALOG CREATION OUTCOME
Specified. For example, host group is in Zone 1	Not specified	Successful. Machines are created in the host group's zone
Specified. For example, host group is in Zone 1	Same zone as host group zone. For example, zone in the custom property is set to 1	Successful. Machines are created in Zone 1

© 1997–2026 Citrix Systems, Inc. All rights reserved.

HOST GROUP ZONE	AVAILABILITY ZONE IN CUSTOM PROPERTY	MACHINE CATALOG CREATION OUTCOME
Specified. For example, host group is in Zone 1	Different from the host group zone. For example, zone in the custom property is set to 2	As the specified availability zone and the host group's zone do not match, catalog creation fails with a relevant error during pre-flight checks
Specified. For example, host group is in Zone 1	Multiple zones specified. For example, zones in the custom properties are set to 1,2 or 2,3	As the specified availability zone and the host group's zone do not match, catalog creation fails with a relevant error during pre-flight checks
Not specified. For example, zone of the host group is `None`	Not specified	As the specified availability zone and the host group's zone match (that is, no zone), catalog creation is successful. Machines are not created in any zone
Not specified. For example, zone of the host group is `None`	Specified. For example, zones in the custom property are set to one or multiple zones	Because the specified availability zone and the host group's zone do not match, catalog creation fails with a relevant error during pre-flight checks

Provision VMs on Azure dedicated hosts

You can use MCS to provision VMs on Azure dedicated hosts. Before provisioning VMs on Azure dedicated hosts:

- Create a host group.
- Create hosts in that host group.
- Ensure that there is sufficient host capacity reserved for creating catalogs and virtual machines.

You can create a catalog of machines with host tenancy defined through the following PowerShell script:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-ProvScheme <otherParameters> -CustomProperties '<CustomProperties
xmlns="http://schemas.citrix.com/2014/xd/machinecreation"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

 <Property xsi:type="StringProperty" Name="HostGroupId"
Value="myResourceGroup/myHostGroup" />

 ...other Custom Properties...

 </CustomProperties>
```

When using MCS to provision virtual machines on Azure dedicated hosts, consider:

- A *Dedicated host* is a catalog property and cannot be changed once the catalog is created. Dedicated tenancy is currently not supported on Azure.
- A pre-configured Azure host group, in the region of the hosting unit, is required when using the `HostGroupId` parameter.
- Azure auto-placement is required. This functionality makes a request to onboard the subscription associated with the host group. For more information, see VM Scale Set on Azure Dedicated Hosts - Public Preview. If auto-placement is not enabled, MCS throws an error during catalog creation.

Configure storage types

Select different storage types for virtual machines in Azure environments that use MCS. For target VMs, MCS supports:

- OS disk: premium SSD, SSD, or HDD
- Write-back cache disk: premium SSD, SSD, or HDD

When using these storage types, consider the following:

- Ensure that your VM supports the selected storage type.
- If your configuration uses an Azure ephemeral disk, you do not get the option for write-back cache disk setting.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TIP:

`StorageType` is configured for an OS type and storage account. `WBCDiskStorageType` is configured for write-back cache storage type. For a normal catalog, `StorageType` is required. If `WBCDiskStorageType` is not configured, the `StorageType` is used as the default for `WBCDiskStorageType`.

If WBCDiskStorageType is not configured, then StorageType is used as the default for WBCDiskStorageType

Configure storage types for VMs

To configure storage types for VMs, use the `StorageType` parameter in `New-ProvScheme`. To update the value of the `StorageType` parameter in an existing catalog to one of the supported storage types use `Set-ProvScheme` command.

The following is an example set of the `CustomProperties` parameter in a provisioning scheme:

```
Set-ProvScheme -ProvisioningSchemeName catalog-name -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client" />

</CustomProperties>'
```

Enable zone-redundant storage

You can select zone-redundant storage during catalog creation. It synchronously replicates your Azure managed disk across multiple availability zones, which allows you to recover from a failure in one zone by utilizing the redundancy in others.

You can specify **Premium_ZRS** and **StandardSSD_ZRS** in the storage type custom properties. ZRS storage can be set using existing custom properties or through the **MachineProfile** template. ZRS storage is also supported with `Set-ProvVMUpdateTimeWindow` command with

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`-StartsNow` and `-DurationInMinutes -1` parameters. You can change existing VMs from LRS to ZRS storage.

NOTE:

- `StartsNow` indicates that the scheduled start time is the current time.
- `DurationInMinutes` with a negative number (for example, –1) indicates no upper bound on the schedule's time window.

Limitations:

- Supported only for managed disks
- Supported only with premium and standard solid-state drives (SSD)
- Not supported with `StorageTypeAtShutdown`
- Available only in certain regions.
- Performance of Azure drops when creating ZRS disks at scale. Therefore, for the first power on, turn on the machines in smaller batches (less than 300 machines at a time)

Set zone-redundant storage as the disk storage type

You can select zone-redundant storage during the initial catalog creation, or you can update your storage type in an existing catalog.

Select zone-redundant storage using PowerShell commands

When creating a new catalog in Azure using the `New-ProvScheme` PowerShell command, use `Standard_ZRS` as the value in the `StorageAccountType`. For example:

```
<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="StandardSSD_ZRS" />
```

When setting this value, it is validated by a dynamic API that determines if it can be used properly. The following exceptions can occur if the use of ZRS is not valid for your catalog:

- **StorageTypeAtShutdownNotSupportedForZrsDisks**: The StorageTypeAtShutdown custom property cannot be used with ZRS storage.
- **StorageAccountTypeNotSupportedInRegion**: This exception occurs if you try to use ZRS Storage in an Azure Region that does not support ZRS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **ZrsRequiresManagedDisks**: You can use zone-redundant storage only with managed disks.

You can set the disk storage type using the following custom properties:

- `StorageType`
- `WBCDiskStorageType`
- `IdentityDiskStorageType`

NOTE:

During catalog creation, the machine profile's OS disk `StorageType` is used if the custom properties are not set.

Capture diagnostic settings on VMs and NICs from a machine profile

You can capture diagnostic settings on VMs and NICs from a machine profile while creating a machine catalog, updating an existing machine catalog, and updating existing VMs.

You can create a VM or template spec as a machine profile source.

Key steps

1. Set up required IDs in Azure. You must provide these IDs in the template spec.
    - Storage account
    - Log analytics workspace
    - Event hub namespace with the standard tier pricing
2. Create machine profile source.
3. Create a new machine catalog, update an existing catalog, or update existing VMs.

Set up required IDs in Azure

Set up one of the following in Azure:

- Storage account
- Log analytics workspace
- Event hub namespace with the Standard tier pricing

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SET UP A STORAGE ACCOUNT

Create a standard storage account in Azure. In the template spec, give the full resourceId for the storage account as the `storageAccountId`.

Once VMs are set up to log data to the storage account, the data can be found under the `insights-metrics-pt1m` container.

SET UP A LOG ANALYTICS WORKSPACE

Create a log analytics workspace. In the template spec, give the full resourceId for the log analytics workspace as the workspaceId.

Once VMs are set up to log data to the workspace, data can be queried under Logs in Azure. You can run the following command in Azure under Logs to show a count of all the metrics logged by a resource:

```
AzureMetrics | summarize Count=count() by ResourceId
```

SET UP AN EVENT HUB

Do the following to set up an event hub in the Azure portal:

1. Create an event hub namespace with the standard tier pricing.
2. Create an event hub underneath the namespace.
3. Navigate to **Capture** under the event hub. Switch ON the toggle to capture with the Avro output type.
4. Create a new container in an existing storage account to capture the logs.
5. In the template spec, specify the `eventHubAuthorizationRuleId` in the following format: `/subscriptions/093f4c12-704b-4b1d-8339-f339e7557f60/resourcegroups/matspo/providers/Microsoft.EventHub/namespaces/matspoeventhub/authorizationrules/RootManageSharedAccessKey`
6. Specify the name of the event hub.

Once VMs are set up to log data to the event hub, the data is captured into the configured storage container.

Create a machine profile source

You can create a VM or template spec as a machine profile source.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE A VM BASED MACHINE PROFILE WITH DIAGNOSTIC SETTINGS

If you want to create a VM as your machine profile, then first set up diagnostic settings on the template VM itself. You can refer to the detailed instructions provided in the Microsoft documentation Diagnostic settings in Azure Monitor.

You can run the following commands to verify that there are now diagnostic settings associated with the VM or NIC:

```
az monitor diagnostic-settings list --resource-group matspo --resource
matspo-tog-cc2659 --resource-type microsoft.network/networkInterfaces
```

```
az monitor diagnostic-settings list --resource-group matspo --resource
matspo-tog-cc2 --resource-type microsoft.compute/virtualMachines
```

CREATE A TEMPLATE SPEC-BASED MACHINE PROFILE WITH DIAGNOSTIC SETTINGS

If you want to use a VM that already has diagnostic settings enabled and export it into an ARM template spec, these settings won't be automatically included within the template. You must manually add or modify diagnostic settings within the ARM template.

However, if you want a VM as your machine profile, MCS ensures that the critical diagnostic settings are accurately captured and applied to the resources within your MCS catalog.

1. Create a standard template spec that defines a VM and NICs.
2. Add additional resources to deploy the diagnostic settings according to the spec: Microsoft.Insights diagnosticSettings. For scope, reference either a VM or NIC that's in the template by name with a partial ID. For example, for creating diagnostic settings attached to a VM named test-VM in the template spec, specify the scope as:

   ```
   "scope": "microsoft.compute/virtualMachines/test-VM",
   ```

3. Use the template spec as a machine profile source.

Create or update a catalog with diagnostic settings

After you create a machine profile source, you can now create a machine catalog using `New-ProvScheme` command, update an existing machine catalog using `Set-ProvScheme` command, and update existing VMs using `Request-ProvVMUpdate` command.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Verify the Windows license

You can verify that the provisioned VM is using the licensing benefit by running the following PowerShell command: `Get-AzVM -ResourceGroup MyResourceGroup -Name MyVM`.

- For the Windows Server license type, verify that the license type is **Windows_Server**. More instructions are available at `<https://docs.microsoft.com/en-us/azure/virtual-machines/windows/hybrid-use-benefit-licensing/>`.
- For the Windows Client license type, verify that the license type is **Windows_Client**. More instructions are available at `<https://docs.microsoft.com/en-us/azure/virtual-machines/windows/windows-desktop-multitenant-hosting-deployment/>`.

Alternatively, you can use the `Get-Provscheme` PowerShell SDK to do the verification. For example: `Get-Provscheme -ProvisioningSchemeName "My Azure Catalog"`. For more information about this cmdlet, see `<https://developer-docs.citrix.com/projects/citrix-virtual-apps-desktops-sdk/en/latest/MachineCreation/Get-ProvScheme/>`.

Configure the Linux license

With bring-your-own-subscription (BYOS) Linux licenses, you do not have to pay for the software. The BYOS charge only includes the compute hardware fee. There are two types of licenses:

- **RHEL_BYOS**: To use RHEL_BYOS type successfully, enable Red Hat Cloud Access on your Azure subscription.
- **SLES_BYOS**: The BYOS versions of SLES include support from SUSE.

You can set the LicenseType value to Linux options at `New-ProvScheme` and `Set-ProvScheme`.

Example of setting LicenseType to RHEL_BYOS at `New-ProvScheme`:

```
New-ProvScheme -CleanOnBoot -ProvisioningSchemeName "azureCatalog"
-RunAsynchronously -Scope @() -SecurityGroup @() -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"><Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" /><Property xsi:type="StringProperty"
Name="StorageAccountType" Value="StandardSSD_LRS" /><Property
xsi:type="StringProperty" Name="ResourceGroups" Value="hu-dev-mcs" /
><Property xsi:type="StringProperty" Name="OsType" Value="Linux" /
><Property xsi:type="StringProperty" Name="LicenseType"
Value="RHEL_BYOS" /></CustomProperties>'
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example of setting LicenseType to SLES_BYOS at `Set-ProvScheme`:

```
Set-ProvScheme -ProvisioningSchemeName "azureCatalog" -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"><Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" /><Property xsi:type="StringProperty"
Name="StorageAccountType" Value="StandardSSD_LRS" /><Property
xsi:type="StringProperty" Name="ResourceGroups" Value="hu-dev-mcs" /
><Property xsi:type="StringProperty" Name="OsType" Value="Linux" /
><Property xsi:type="StringProperty" Name="LicenseType"
Value="SLES_BYOS" /></CustomProperties>'
```

NOTE:

If `LicenseType` value is empty, then the default values are Azure Windows Server License or Azure Linux License, depending on OsType value.

Example of setting LicenseType to empty:

```
Set-ProvScheme -ProvisioningSchemeName "azureCatalog" -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"><Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" /><Property xsi:type="StringProperty"
Name="StorageAccountType" Value="StandardSSD_LRS" /><Property
xsi:type="StringProperty" Name="ResourceGroups" Value="hu-dev-mcs" /
><Property xsi:type="StringProperty" Name="OsType" Value="Linux" /></
CustomProperties>'
```

Create a machine catalog with an Azure ephemeral disk

To provision ephemeral OS disks using `New-ProvScheme`, consider the following constraints:

- The VM size used for the catalog must support ephemeral OS disks.
- The size of the cache or temporary disk associated with the VM size must be greater than or equal to the size of the OS disk.
- The temporary disk size must be greater than the cache disk size.

Also consider these constraints when:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Creating the provisioning scheme
- Modifying the provisioning scheme
- Updating the image

To use ephemeral disks, you must set the custom property `UseEphemeralOsDisk` to **true** when running `New-ProvScheme`.

NOTE:

If the custom property `UseEphemeralOsDisk` is set to **false** or a value is not specified all provisioned VDAs continue to use a provisioned OS disk.

The following is an example set of custom properties to use in the provisioning scheme:

```
"CustomProperties": [

            {

                "Name": "UseManagedDisks",

                "Value": "true"

            },

            {

                "Name": "StorageType",

                "Value": "Standard_LRS"

            },

            {

                "Name": "UseSharedImageGallery",

                "Value": "true"

            },

            {
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                "Name": "SharedImageGalleryReplicaRatio",
                "Value": "40"
            },
            {
                "Name": "SharedImageGalleryReplicaMaximum",
                "Value": "10"
            },
            {
                "Name": "LicenseType",
                "Value": "Windows_Server"
            },
            {
                "Name": "UseEphemeralOsDisk",
                "Value": "true"
            }
        ],
```

Configure an ephemeral disk for an existing catalog

To configure an Azure ephemeral OS disk for an existing catalog, use the `UseEphemeralOsDisk` parameter in `Set-ProvScheme`. Set the value of the `UseEphemeralOsDisk` parameter to **true**.

NOTE:

To use this feature, you must also enable the parameters `UseManagedDisks` and `UseSharedImageGallery`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example:

```
Set-ProvScheme -ProvisioningSchemeName catalog-name -CustomProperties
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="UseSharedImageGallery"
Value="true" />

<Property xsi:type="StringProperty" Name="UseEphemeralOsDisk"
Value="true" />

</CustomProperties>'
```

Configure storage type used by ephemeral disks

By default, `Standard_LRS` is the storage type used by the ephemeral OS disk feature. You can set the storage type to use SSDs instead for increased disk IOPS on read operations by specifying the `StorageType` custom property. Current supported values are `Standard_LRS`, `StandardSSD_LRS`, and `Premium_LRS`.

`StorageType` can also be updated on existing ephemeral machines with `Set-ProvScheme` and `Set-ProvVMUpdateTimeWindow`.

Configure Azure Compute Gallery

Use the `New-ProvScheme` command to create a provisioning scheme with Azure Compute Gallery support. Use the `Set-ProvScheme` command to enable or disable this feature for a provisioning scheme and to change the replica ratio and replica maximum values.

Three custom properties were added to provisioning schemes to support the Azure Compute Gallery feature:

`UseSharedImageGallery`

- Defines whether to use the Azure Compute Gallery to store the published images. If set to **True**, the image is stored as an Azure Compute Gallery image, otherwise the image is stored as a snapshot.
- Valid values are **True** and **False**.
- If the property is not defined, the default value is **False**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`SharedImageGalleryReplicaRatio`

- Defines the ratio of machines to gallery image version replicas.
- Valid values are integer numbers greater than 0.
- If the property is not defined, default values are used. The default value for persistent OS disks is 1000 and the default value for non-persistent OS disks is 40.

`SharedImageGalleryReplicaMaximum`

- Defines the maximum number of replicas for each gallery image version.
- Valid values are integer numbers greater than 0 and up to 100. MCS generates an error if you provide a value other than the valid range.
- If the property is not defined, the default value is 10.
- If the property is not defined, the default value is 100.

TIP:

When using Azure Compute Gallery to store a published image for MCS provisioned catalogs, MCS sets the gallery image version replica count based on the number of machines in the catalog, the replica ratio, and the replica maximum. The replica count is calculated by dividing the number of machines in the catalog by the replica ratio (rounding up to the nearest integer value) and then capping the value at the maximum replica count. For example, with a replica ratio of 20 and a maximum of 5, 0–20 machines have one replica created, 21–40 have 2 replicas, 41–60 have 3 replicas, 61–80 have 4 replicas, 81+ have 5 replicas.

Use case: Updating the Azure Compute Gallery replica ratio and replica max

The existing machine catalog uses Azure Compute Gallery. Use the `Set-ProvScheme` command to update the custom properties for all existing machines in the catalog and any future machines:

```
Set-ProvScheme -ProvisioningSchemeName catalog-name -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<Property xsi:type="StringProperty" Name="StorageType"
Value="Standard_LRS"/> <Property xsi:type="StringProperty"
Name="UseManagedDisks" Value="True"/> <Property xsi:type="StringProperty"
Name="UseSharedImageGallery" Value="True"/> <Property
xsi:type="IntProperty" Name="SharedImageGalleryReplicaRatio" Value="30"/>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="IntProperty" Name="SharedImageGalleryReplicaMaximum"
Value="20"/></CustomProperties>'
```

Use Case: Converting a snapshot catalog to an Azure Compute Gallery catalog

For this use case:

1. Run `Set-ProvScheme` with the `UseSharedImageGallery` flag set to **True**. Optionally include the `SharedImageGalleryReplicaRatio` and `SharedImageGalleryReplicaMaximum` properties.
2. Update the catalog.
3. Power cycle the machines to force an update.

For example:

```
Set-ProvScheme -ProvisioningSchemeName catalog-name -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<Property xsi:type="StringProperty" Name="StorageType"
Value="Standard_LRS"/> <Property xsi:type="StringProperty"
Name="UseManagedDisks" Value="True"/> <Property xsi:type="StringProperty"
Name="UseSharedImageGallery" Value="True"/> <Property
xsi:type="IntProperty" Name="SharedImageGalleryReplicaRatio" Value="30"/>
<Property xsi:type="IntProperty" Name="SharedImageGalleryReplicaMaximum"
Value="20"/></CustomProperties>'
```

TIP:

The parameters `SharedImageGalleryReplicaRatio` and `SharedImageGalleryReplicaMaximum` are not required. After the `Set-ProvScheme` command completes the Azure Compute Gallery image has not yet been created. Once the catalog is configured to use the gallery, the next catalog update operation stores the published image in the gallery. The catalog update command creates the gallery, the gallery image, and the image version. Power cycling the machines updates them, at which point the replica count is updated, if appropriate. From that time, all existing non-persistent machines are reset using the Azure Compute Gallery image and all newly provisioned machines are created using the image. The old snapshot is cleaned up automatically within a few hours.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use Case: Converting an Azure Compute Gallery catalog to a snapshot catalog

For this use case:

1. Run `Set-ProvScheme` with the `UseSharedImageGallery` flag set to **False** or not defined.
2. Update the catalog.
3. Power cycle the machines to force an update.

For example:

```
Set-ProvScheme -ProvisioningSchemeName catalog-name -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<Property xsi:type="StringProperty" Name="StorageType"
Value="Standard_LRS"/> <Property xsi:type="StringProperty"
Name="UseManagedDisks" Value="True"/> <Property xsi:type="StringProperty"
Name="UseSharedImageGallery" Value="False"/></CustomProperties>'
```

TIP:

Unlike updating from a snapshot to an Azure Compute Gallery catalog, the custom data for each machine is not yet updated to reflect the new custom properties. Run the following command to see the original Azure Compute Gallery custom properties: `Get-ProvVm -ProvisioningSchemeName catalog-name`. After the `Set-ProvScheme` command completes the image snapshot has not yet been created. Once the catalog is configured to not use the gallery, the next catalog update operation stores the published image as a snapshot. From that time, all existing non-persistent machines are reset using the snapshot and all newly provisioned machines are created from the snapshot. Power cycling the machines updates them, at which point the custom machine data is updated to reflect that `UseSharedImageGallery` is set to **False**. The old Azure Compute Gallery assets (gallery, image, and version) are automatically cleaned up within a few hours.

Create or update a catalog with multiple NICs per VM

MCS supports multiple NICs per VM. You can associate multiple NICs on a VM to multiple subnets, however, those subnets must be in the same virtual network (VNet). You can use PowerShell command to:

- Create a catalog with multiple NICs on a VM

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Update an existing catalog configuration to have multiple NICs on a VM so that newly created VMs have multiple NICs
- Update an existing VM to have multiple NICs

You can create or update a non-machine profile-based machine catalog and machine profile-based machine catalog to have multiple NICs on a VM. Currently, for a machine profile-based machine catalog, you can only have the same number of NICs as specified in the machine profile source.

Property such as accelerated networking is derived from the machine profile source.

NOTE:

The VM size must support the same number of NICs and corresponding accelerated networking, otherwise you get an error.

You can retrieve the maximum number of NICs associated with a selected VM size. A PowerShell property called `MaxNetworkInterfaces` displays the maximum NIC count when you run the PowerShell `get-item` command with the `AdditionalData` parameter.

Retrieve the maximum NIC count

To retrieve the maximum NIC count:

1. Open a **PowerShell** window from the Delivery Controller™ host.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run `Get-ChildItem -Path "XDHyp:\Connections\abc-connection\East US.region\serviceoffering.folder"` to list all available VM sizes.
4. Run `get-item -Path "XDHyp:\Connections\abc-connection\East US.region\serviceoffering.folder\Standard_M416ms_v2.serviceoffering").AdditionalData`
5. Check `MaxNetworkInterfaces` to know the maximum NIC count.

Create a catalog with multiple NICs on a VM

To create a catalog with multiple NICs on a VM, do the following:

1. Open a PowerShell window from the Delivery Controller host.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create an identity pool if not already created.
4. Create the provisioning scheme:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If creating a non-machine profile-based machine catalog, run `New-ProvScheme` command with `NetworkMappings` parameter. You can add multiple subnets to the parameter `NetworkMappings`. For example:

```
New-Provscheme -NetworkMappings
@{"0"="subnetpath1";"1"="subnetpath1"}
```

- If creating a machine profile-based machine catalog:

  a. Create a VM in Azure to have multiple NICs. For information, see Create and manage a Windows virtual machine that has multiple NICs. You can also create a new VM, and then attach a network interface in the Networking page of Azure portal.

  b. Run `New-ProvScheme` command with the VM as a machine profile input.

NOTE:

When creating a machine profile-based machine catalog, the count of `NetworkMappings` must be the same as the `NetworkInterfaceCount` of the machine profile. The `NetworkInterfaceCount` can be retrieved from `AdditionalData` of `Get-item -Path "machine profile path"`.

5. Finish creating the catalog.

Update a catalog to have multiple NICs on a VM

To update a catalog to have multiple NICs on a VM, do the following:

1. Open a **PowerShell** window from the Delivery Controller host.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Update the provisioning scheme:

   - If creating a non-machine profile-based machine catalog, run the `Set-ProvScheme` command with `NetworkMappings` parameter. You can add multiple subnets to parameter `NetworkMappings`. For example:

```
Set-Provscheme -NetworkMappings
@{"0"="subnetpath1";"1"="subnetpath1"}
```

   - If creating a machine catalog based on a machine profile:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Create a VM in Azure to have multiple NICs. For information, see Create and manage a Windows virtual machine that has multiple NICs.

b. Run `Set-ProvScheme` command with the VM as a machine profile input.

Update an existing VM to have multiple NICs on a VM

You can also update an existing VM using `Set-ProvVMUpdateTimeWindow` and also perform power cycle on existing VM during the update time window. For more information on updating an existing VM, see Update provisioned machines to current provisioning scheme state.

Create a machine catalog with non-persistent write-back cache disk

To configure a catalog with non-persistent write-back cache disk, use the PowerShell parameter `New-ProvScheme CustomProperties`. The custom properties are:

- `UseTempDiskForWBC`. This property indicates whether you are accepting to use the Azure temporary storage to store the write-back cache file. This must be configured to true when running `New-ProvScheme` if you want to use the temporary disk as write-back cache disk. If this property is not specified, the parameter is set to False by default.

For example, using the `CustomProperties` parameter to set `UseTempDiskForWBC` to true:

```
-CustomProperties '<CustomProperties xmlns=" http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi=" http://www.w3.org/2001/XMLSchema-
instance"> `

<Property xsi:type="StringProperty" Name="PersistWBC" Value="false"/> `

<Property xsi:type="StringProperty" Name="PersistOsDisk" Value="false"/> `

<Property xsi:type="StringProperty" Name="PersistVm" Value="false"/> `

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS"/> `

<Property xsi:type="StringProperty" Name="WBCDiskStorageType"
Value="Premium_LRS"/> `

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client"/> `

<Property xsi:type="StringProperty" Name="UseTempDiskForWBC" Value="true"/
> `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>'
```

NOTE:

After you commit the machine catalog to use Azure local temporary storage for write-back cache file, it cannot be changed to use VHD later.

Create a machine catalog with persistent write-back cache disk

To configure a catalog with persistent write-back cache disk, use the PowerShell parameter `New-ProvScheme CustomProperties`.

TIP:

Use the PowerShell parameter `New-ProvScheme CustomProperties` only for cloud-based hosting connections. If you want to provision machines using a persistent write-back cache disk for an on-premises solution (for example, XenServer®) PowerShell is not needed because the disk persists automatically.

This parameter supports an extra property, `PersistWBC`, used to determine how the write-back cache disk persists for MCS provisioned machines. The `PersistWBC` property is only used when the `UseWriteBackCache` parameter is specified, and when the `WriteBackCacheDiskSize` parameter is set to indicate that a disk is created.

NOTE:

This behavior applies to both Azure and GCP where the default MCSIO write-back cache disk is deleted and re-created when power cycling. You can choose to persist the disk to avoid the deletion and recreation of MCSIO write-back cache disk.

Examples of properties found in the `CustomProperties` parameter before supporting `PersistWBC` include:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />

</CustomProperties>
```

NOTE:

This example only applies to Azure. The properties are different in the GCP environment.

When using these properties, consider that they contain default values if the properties are omitted from the `CustomProperties` parameter. The `PersistWBC` property has two possible values: **true** or **false**.

Setting the `PersistWBC` property to **true** does not delete the write-back cache disk when the Citrix DaaS administrator shuts down the machine from the management interface.

Setting the `PersistWBC` property to **false** deletes the write-back cache disk when the Citrix DaaS administrator shuts down the machine from the management interface.

NOTE:

If the `PersistWBC` property is omitted, the property defaults to **false** and the write-back cache is deleted when the machine is shut down from the management interface.

For example, using the `CustomProperties` parameter to set `PersistWBC` to true:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="PersistWBC" Value="true" />

</CustomProperties>
```

IMPORTANT:

The `PersistWBC` property can only be set using the `New-ProvScheme` PowerShell cmdlet. Attempting to alter the `CustomProperties` of a provisioning scheme after creation has no impact on the machine catalog and the persistence of the write-back cache disk when a machine is shut down.

For example, set `New-ProvScheme` to use the write-back cache while setting the `PersistWBC` property to true:

```
New-ProvScheme

-CleanOnBoot

-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`">

<Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" />

<Property xsi:type=`"StringProperty`" Name=`"StorageAccountType`"
Value=`"Premium_LRS`" />

<Property xsi:type=`"StringProperty`" Name=`"ResourceGroups`"
Value=`"benvaldev5RG3`" />

<Property xsi:type=`"StringProperty`" Name=`"PersistWBC`" Value=`"true`" /
>

</CustomProperties>"

-HostingUnitName "adSubnetScale1"

-IdentityPoolName "BV-WBC1-CAT1"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-MasterImageVM "XDHyp:
\HostingUnits\adSubnetScale1\image.folder\GoldImages.resourcegroup\W10MCSI
O-01_OsDisk_1_a940e6f5bab349019d57ccef65d2c7e3.manageddisk"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\adSubnetScale1\
\virtualprivatecloud.folder\CloudScale02.resourcegroup\adVNET.virtualpriva
tecloud\adSubnetScale1.network"}

-ProvisioningSchemeName "BV-WBC1-CAT1"

-ServiceOffering "XDHyp:
\HostingUnits\adSubnetScale1\serviceoffering.folder\Standard_D2s_v3.servic
eoffering"

-UseWriteBackCache

-WriteBackCacheDiskSize 127

-WriteBackCacheMemorySize 256
```

Improve boot performance with MCSIO

You can improve boot performance for Azure and GCP managed disks when MCSIO is enabled. Use the PowerShell `PersistOSDisk` custom property in the `New-ProvScheme` command to configure this feature. Options associated with `New-ProvScheme` include:

```
<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="ResourceGroups"
Value="benvaldev5RG3" />

<Property xsi:type="StringProperty" Name="PersistOsDisk" Value="true" />

</CustomProperties>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable this feature, set the `PersistOSDisk` custom property to **true**. For example:

```
New-ProvScheme

-CleanOnBoot

-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" /><Property xsi:type=`"StringProperty`"
Name=`"StorageAccountType`" Value=`"Premium_LRS`" /><Property
xsi:type=`"StringProperty`" Name=`"ResourceGroups`"
Value=`"benvaldev5RG3`" /><Property xsi:type=`"StringProperty`"
Name=`"PersistOsDisk`" Value=`"true`" /></CustomProperties>"

-HostingUnitName "adSubnetScale1"

-IdentityPoolName "BV-WBC1-CAT1"

-MasterImageVM "XDHyp:
\HostingUnits\adSubnetScale1\image.folder\GoldImages.resourcegroup\W10MCSI
O-01_OsDisk_1_a940e6f5bab349019d57ccef65d2c7e3.manageddisk"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\adSubnetScale1\
\virtualprivatecloud.folder\CloudScale02.resourcegroup\adVNET.virtualpriva
tecloud\adSubnetScale1.network"}

-ProvisioningSchemeName "BV-WBC1-CAT1"

-ServiceOffering "XDHyp:
\HostingUnits\adSubnetScale1\serviceoffering.folder\Standard_D2s_v3.servic
eoffering"

-UseWriteBackCache

-WriteBackCacheDiskSize 127

-WriteBackCacheMemorySize 256
```

Create a machine catalog with customer-managed encryption key

If you want to create a machine catalog using PowerShell commands, where the encryption key is a customer-managed key, do the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Enter `cd xdhyp:/`.
4. Enter `cd .\HostingUnits\(your hosting unit)`.
5. Enter cd diskencryptionset.folder.
6. Enter dir to get the list of the Disk Encryption Sets.
7. Copy the Id of a Disk Encryption Set.
8. Create a custom property string to include the Id of the Disk Encryption Set. For example:

```
$customProperties = "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`">

<Property xsi:type=`"StringProperty`" Name=`"persistWBC`"
Value=`"False`" />

<Property xsi:type=`"StringProperty`" Name=`"PersistOsDisk`"
Value=`"false`" />

<Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" />

<Property xsi:type=`"StringProperty`" Name=`"DiskEncryptionSetId`"
Value=`"/subscriptions/0xxx4xxx-xxb-4bxx-xxxx-xxxxxxxx/resourceGroups/
abc/providers/Microsoft.Compute/diskEncryptionSets/abc-des`"/>

</CustomProperties>
```

9. Create an identity pool if not already created. For example:

```
New-AcctIdentityPool -IdentityPoolName idPool -NamingScheme ms##
-Domain def.local -NamingSchemeType Numeric
```

10. Run the New-ProvScheme command: For example:

```
New-ProvScheme -CleanOnBoot -HostingUnitName "name" -IdentityPoolName
"name" -InitialBatchSizeHint 1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-MasterImageVM "XDHyp:\HostingUnits\azure-
res2\image.folder\def.resourcegroup\def.snapshot"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\azure-res2\
\virtualprivatecloud.folder\def.resourcegroup\def-
vnet.virtualprivatecloud\subnet1.network"}

-ProvisioningSchemeName "name"

-ServiceOffering "XDHyp:\HostingUnits\azure-
res2\serviceoffering.folder\Standard_DS2_v2.serviceoffering"

-MachineProfile "XDHyp:
\HostingUnits\<adnet>\machineprofile.folder\<def.resourcegroup>\<machin
e profile vm.vm>"

-CustomProperties $customProperties
```

11. Finish creating the machine catalog.

Create a machine catalog with encryption at host capability

To create a machine catalog with encryption at host capability

1. Check if the subscription has the encryption at host feature enabled or not. To do this, see `<https://learn.microsoft.com/en-us/rest/api/resources/features/get?tabs=HTTP/>`. If not enabled, you must enable the feature for the subscription. For information on enabling the feature for your subscription, see `<https://learn.microsoft.com/en-us/azure/virtual-machines/disks-enable-host-based-encryption-portal?tabs=azure-powershell#prerequisites/>`.
2. Check if a particular Azure VM size supports encryption at host or not. To do this, in a PowerShell window, run one of the following:

```
PS XDHyp:\Connections\<your connection>\east
us.region\serviceoffering.folder>
```

```
PS XDHyp:\HostingUnits\<your hosting unit>\serviceoffering.folder>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Create a VM or a template spec, as an input for machine profile, in the Azure portal with encryption at host enabled.

   - If you want to create a VM, select a VM size that supports encryption at host. After you create the VM, the VM property **Encryption at host** is enabled.
   - If you want to use a template spec, assign the parameter `Encryption at Host` as **true** inside `securityProfile`.

4. Create an MCS machine catalog with machine profile workflow by either selecting a VM or a template spec.

   - OS disk / Data Disk: Gets encrypted through Customer-managed key and Platform-managed key
   - Ephemeral OS Disk: Gets encrypted only through Platform-managed key
   - Cache Disk: Gets encrypted through Customer-managed key and Platform-managed key

   You can create the machine catalog using Studio or running PowerShell commands.

Retrieve encryption at host information from a machine profile

You can retrieve the encryption at host information from a machine profile when you run the PowerShell command with the `AdditionalData` parameter. If `EncryptionAtHost` parameter is **True**, it indicates that the encryption at host is enabled for the machine profile.

For example: When the machine profile input is a VM, run the following command:

```
(get-item XDHyp:
\HostingUnits\myAzureNetwork\machineprofile.folder\abc.resourcegroup\def.v
m).AdditionalData
```

For example: When the machine profile input is a template spec, run the following command:

```
(get-item XDHyp:
\HostingUnits\myAzureNetwork\machineprofile.folder\abc.resourcegroup\def_t
emplatespec.templatespec\EncryptionAtHost.templatespecversion).AdditionalD
ata
```

Create a machine catalog with double encryption

You can create and update a machine catalog with double encryption using Studio and PowerShell commands.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The detailed steps on how to create a machine catalog with double encryption are:

1. Create an Azure Key Vault and DES with Platform-managed and customer-managed keys. For information on how to create an Azure Key Vault and a DES, see Use the Azure portal to enable double encryption at rest for managed disks.
2. To browse available Disk Encryption Sets in your hosting connection:

   a. Open a **PowerShell** window.

   b. Run the following PowerShell commands:

      i. `asnp citrix*`

      ii. `cd xdhyp:`

      iii. `cd HostingUnits`

      iv. `cd YourHostingUnitName (ex. azure-east)`

      v. `cd diskencryptionset.folder`

      vi. `dir`

   You can use an Id of the `DiskEncryptionSet` to create or update a catalog using custom properties.
3. If you want to use machine profile workflow, create a VM or template spec as a machine profile input.

   - If you want to use a VM as a machine profile input:

     a. Create a VM in Azure Portal.

     b. Navigate to **Disks>Key management** to encrypt the VM directly with any `DiskEncryptionSetID`.

   - If you want to use a template spec as a machine profile input:

     a. In the template, under `properties>storageProfile>osDisk>managedDisk`, add `diskEncryptionSet` parameter and add the id of the double encryption DES.
4. Create the machine catalog.

   - If using Studio, do one of the following in addition to the steps in Create machine catalogs.

     - If you do not use a machine-profile based workflow, on the **Disk Settings** page, select **Use the following key to encrypt data on each machine**. Then, select your double encryption DES from the drop-down list. Continue creating the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If using the machine profile workflow, on the **Image** page, select a master image (or prepared image) and a machine profile. Make sure that the machine profile has a disk encryption set id in its properties.

All machines created in the catalog are double encrypted by the key associated with the DES that you selected.

- If using PowerShell commands, do one of the following:
  - If not using machine profile-based workflow, add the custom property `DiskEncryptionSetId` in the `New-ProvScheme` command. For example:

```
New-ProvScheme -CleanOnBoot -CustomProperties '<CustomProperties
xmlns="http://schemas.citrix.com/2014/xd/machinecreation"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" />

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS" />

<Property xsi:type="StringProperty" Name="DiskEncryptionSetId"
Value="/subscriptions/12345678-xxxx-1234-1234-123456789012/
resourceGroups/Sample-RG/providers/Microsoft.Compute/
diskEncryptionSets/SampleEncryptionSet" />

</CustomProperties>'

-HostingUnitName "Redacted"

-IdentityPoolName "Redacted"

-InitialBatchSizeHint 1

-MasterImageVM "Redacted"

-NetworkMapping @{"0"="Redacted"}

-ProvisioningSchemeName "Redacted"

-ServiceOffering "Redacted"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If using machine profile-based workflow, use a machine profile input in the `New-ProvScheme` command. For example:

```
New-ProvScheme -CleanOnBoot

-HostingUnitName azure-east

-IdentityPoolName aio-ip

-InitialBatchSizeHint 1

-MasterImageVM XDHyp:\HostingUnits\azure-
east\image.folder\abc.resourcegroup\fgb-vda-snapshot.snapshot

-NetworkMapping @{"0"="XDHyp:\HostingUnits\azure-
east\virtualprivatecloud.folder\apa-
resourceGroup.resourcegroup\apa-resourceGroup-
vnet.virtualprivatecloud\default.network"}

-ProvisioningSchemeName aio-test

-MachineProfile XDHyp:\HostingUnits\azure-
east\machineprofile.folder\abc.resourcegroup\abx-
mp.templatespec\1.0.0.templatespecversion
```

Finish creating a catalog using the remote PowerShell SDK. All machines created in the catalog are double encrypted by the key associated with the DES you selected.

Convert an unencrypted catalog to use double encryption

You can update a machine catalog's encryption type (using custom properties or machine profile).

- If not using machine profile-based workflow, add the custom property DiskEncryptionSetId in the `Set-ProvScheme` command. For example:

```
Set-ProvScheme -ProvisioningSchemeName "SampleProvSchemeName"

-CustomProperties '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="DiskEncryptionSetId" Value="/
subscriptions/12345678-xxxx-1234-1234-123456789012/resourceGroups/
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Sample-RG/providers/Microsoft.Compute/diskEncryptionSets/
SampleEncryptionSet" />

</CustomProperties>'
```

- If using machine profile-based workflow, use a machine profile input in the `Set-ProvScheme` command. For example:

```
Set-ProvScheme -ProvisioningSchemeName mxiao-test -MachineProfile
XDHyp:\HostingUnits\azure-
east\machineprofile.folder\aelx.resourcegroup\elx-
mp.templatespec\1.0.0.templatespecversion
```

Once successful, all new VMs that you add in your catalog are double encrypted by the key associated with the DES you selected.

Verify the catalog is double encrypted

- In Studio:
  a. Navigate to **Machine Catalogs**.
  b. Select the catalog that you want to verify. Click the **Template Properties** tab located near the bottom of the screen.
  c. Under **Azure Details**, verify the Disk Encryption Set ID in **Disk Encryption Set**. If the catalog's DES Id is blank, the catalog is not encrypted.
  d. In the Azure Portal, verify that the encryption type of the DES associated with the DES Id is platform-managed and customer-managed keys.
- Using the PowerShell command:
  a. Open the **PowerShell** window.
  b. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
  c. Use `Get-ProvScheme` to get the information of your machine catalog. For example:

```
Get-ProvScheme -ProvisioningSchemeName "SampleProvSchemeName"
```

  d. Retrieve the DES Id custom property of the machine catalog. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="DiskEncryptionSetId"
Value="/subscriptions/12345678-1234-1234-1234-123456789012/
resourceGroups/Sample-RG/providers/Microsoft.Compute/
diskEncryptionSets/SampleEncryptionSet" />
```

e. In the Azure Portal, verify that the encryption type of the DES associated with the DES Id is platform-managed and customer-managed keys.

Page file location determination

The page file location is determined according to the following scenario:

NOTE:

The default page file location is OS disk.

SCENARIO	LOCATION
Page file setting is specified in the custom properties	As specified in the custom properties
Ephemeral OS disk or hibernation is enabled	OS disk
VM has a temporary disk	Temporary disk
MCS IO is enabled	WBC disk

Page file setting scenarios

The following table describes some of the possible scenarios of page file setting during image preparation and provisioning scheme update:

DURING	SCENARIO	OUTCOME
Image preparation	You set the source image page file on the temporary disk, while the VM size that you specify in the provisioning scheme has no temporary disk	The page file is placed on the OS

© 1997–2026 Citrix Systems, Inc. All rights reserved.

DURING	SCENARIO	OUTCOME
Image preparation	You set the source image page file on the OS disk, while the VM size that you specify in the provisioning scheme has a temporary disk	The page file is placed on the temporary disk
Image preparation	You set the source image page file on the temporary disk and enable the ephemeral OS disk in the provisioning scheme	The page file is placed on the OS disk
Provisioning scheme update	You attempt to update the provisioning scheme when the VDA version is earlier than 2311	Modifies the page file setting with a warning
Provisioning scheme update	You attempt to update the provisioning scheme when the VDA version is 2311 or later	Determines the page file location as per Page file location determination

Specify page file setting

Using PowerShell commands, you can specify page file settings, including the location and size. This overrides the page file settings determined by MCS as per Page file location determination. You can do this by running the following `New-ProvScheme` command during machine catalog creation.

Important considerations

Consider the following before proceeding with the catalog creation:

- You must provide all the custom properties ('PageFileDiskDriveLetterOverride', 'InitialPageFileSizeInMB', and 'MaxPageFileSizeInMB') in the `New-ProvScheme` command or none of them.
- This feature is not supported through Citrix Studio.
- The initial page file size must be between 16 MB and 16777216 MB.
- The maximum page file size must be greater than or equal to the initial page file size and less than 16777216 MB.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You can set both the initial page file size and maximum page file size to zero at the same time.

NOTE:

You can modify the page file settings of the newly added VMs of an existing catalog, without updating the master image. To modify the page file settings, you need VDA version 2311 or later. You can modify the page file settings using the PowerShell commands. For more information, see Modify page file settings.

```
New-ProvScheme -CleanOnBoot `

-HostingUnitName "zijinnet" `

-IdentityPoolName "PageFileSettingExample" `

-ProvisioningSchemeName "PageFileSettingExample" `

-InitialBatchSizeHint 1 `

-MasterImageVM "XDHyp:\HostingUnits\zijinnet\image.folder\neal-zijincloud-
resources.resourcegroup\CustomWin10VDA_OsDisk_1_9473d7c8a6174b2c8284c7d3ef
eea88f.manageddisk" `

-NetworkMapping @{"0"="XDHyp:\\HostingUnits\\zijinnet\
\virtualprivatecloud.folder\\East US.region\\virtualprivatecloud.folder\
\neal-zijincloud-resources.resourcegroup\\neal-zijincloud-resources-
vnet.virtualprivatecloud\\default.network"} `

-ServiceOffering "XDHyp:\\HostingUnits\\zijinnet\\serviceoffering.folder\
\Standard_B2ms.serviceoffering" `

-CustomProperties '<CustomProperties xmlns=" http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi=" http://www.w3.org/2001/XMLSchema-
instance"> `

<Property xsi:type="StringProperty" Name="PersistOsDisk" Value="false"/> `

<Property xsi:type="StringProperty" Name="PersistVm" Value="false"/> `

<Property xsi:type="StringProperty" Name="PageFileDiskDriveLetterOverride"
Value="d"/> `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="InitialPageFileSizeInMB"
Value="2048"/> `

<Property xsi:type="StringProperty" Name="MaxPageFileSizeInMB"
Value="8196"/> `

<Property xsi:type="StringProperty" Name="StorageAccountType"
Value="Premium_LRS"/> `

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client"/> `

</CustomProperties>'
```

Modify page file settings

You can modify the page file settings of the newly added VMs to an existing catalog without updating the master image. Currently, this feature is applicable to only Azure environments.

To modify the page file settings, you need VDA version 2311 or later. You can modify the page file settings using the PowerShell commands.

Following are the various page file settings that you can modify in the Azure environment:

- `PageFileDiskDriveLetterOverride`
- `InitialPageFileSizeInMB`
- `MaxPageFileSizeInMB`

Modify the page file settings of an existing catalog

To modify the page file settings of an existing machine catalog, run the `Set-ProvScheme` command. In this case, the updates are applied only to the new VMs added to the catalog. For example:

```
Set-ProvScheme -ProvisioningSchemeName $schemeName -CustomProperties
'<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks" Value="true" />

<Property xsi:type="StringProperty" Name="OsType" Value="Windows" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Property xsi:type="StringProperty" Name="StorageType"
Value="StandardSSD_LRS" />

<Property xsi:type="StringProperty" Name="PageFileDiskDriveLetterOverride"
Value="D" />

<Property xsi:type="StringProperty" Name="InitialPageFileSizeInMB"
Value="2048" />

<Property xsi:type="StringProperty" Name="MaxPageFileSizeInMB"
Value="8196" />

<Property xsi:type="StringProperty" Name="LicenseType"
Value="Windows_Client" />

<Property  xsi:type="StringProperty" Name="Zones" Value="1" />

<Property xsi:type="StringProperty" Name="ResourceGroups" Value="neal-
test-group1" />

<Property xsi:type="StringProperty" Name="SchemaVersion" Value="2" />

</CustomProperties>'
```

NOTE:

If you enable the write-back cache and try to set the `PageFileDiskDriveLetterOverride` to `C:` using the PowerShell command, MCS I/O driver automatically redirects the page file to a correct disk drive and not `C:`.

Provision catalog VMs with AMA enabled

1. Set up a machine profile template.
    - If you want to use a VM as a machine profile template:
        a. Create a VM on the Azure portal.
        b. Power on the VM.
        c. Add the VM to the data collection rule under **Resources**. This invokes agent installation on the template VM.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If you must create a Linux catalog, set up a Linux machine.

- If you want to use template spec as a machine profile template:

  a. Set up a template spec.

  b. Add the following extension and data collection rule association to the generated template spec:

```
{

"type": "Microsoft.Compute/virtualMachines/extensions",

"apiVersion": "2022-03-01",

"name": "<vm-name>/AzureMonitorWindowsAgent",

"dependsOn": [

    "Microsoft.Compute/virtualMachines/<vm-name>"

],

"location": "<azure-region>",

"properties": {

    "publisher": "Microsoft.Azure.Monitor",

    "type": "AzureMonitorWindowsAgent",

    "typeHandlerVersion": "1.0",

    "autoUpgradeMinorVersion": true,

    "enableAutomaticUpgrade": true

}

},
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
 {

    "type": "Microsoft.Insights/dataCollectionRuleAssociations",

    "apiVersion": "2021-11-01",

    "name": "<associatio-name>",

    "scope": "Microsoft.Compute/virtualMachines/<vm-name>",

    "dependsOn": [

     "Microsoft.Compute/virtualMachines/<vm-name>",

    "Microsoft.Compute/virtualMachines/<vm-name>/extensions/
AzureMonitorWindowsAgent"

    ],

    "properties": {

       "description": "Association of data collection rule.
Deleting this association will break the data collection for this
Arc server.",

     "dataCollectionRuleId": "/subscriptions/<azure-
subscription>/resourcegroups/<azure-resource-group>/providers/
microsoft.insights/datacollectionrules/<azure-data-collection-
rule>"

     }

    }
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If you have a data collection rule setup with a Microsoft Sentinel data connector, you can simply add `dataCollectionRuleAssociation` in the template spec in the same manner as a regular DCR association. The catalog VMs can then show up in the Sentinel DCR and the AMA would be installed on those VMs. For information on the best practices for data collection rule creation, see Best practices for data collection rule creation and management in Azure Monitor.

2. Create or update an existing MCS machine catalog.

   - To create a new MCS catalog:

     a. Select that VM or template spec as a machine profile in Studio.

     b. Proceed with the next steps to create the catalog.

   - To update an existing MCS catalog, use the following PowerShell commands. In this case, only the new VMs get the updated machine profile template.

     ```
     Set-ProvScheme -ProvisioningSchemeName "name"

     -MachineProfile "XDHyp:
     \HostingUnits\Unit1\machineprofile.folder\abc.resourcegroup\ab-
     machine-profile.vm"
     ```

   - To update existing VMs with the updated machine profile template, run `Set-ProvScheme`, and then run `Set-ProvVMUpdateTimeWindow`:

     ```
     Set-ProvScheme -ProvisioningSchemeName "name" -MachineProfile
     "XDHyp:
     \HostingUnits\Unit1\machineprofile.folder\abc.resourcegroup\ab-
     machine-profile.vm"

     Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName my-catalog
     -StartsNow -DurationInMinutes -1
     ```

3. Power on catalog VMs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Go to the Azure portal and check if the monitor extension is installed on the VM and the VM is showing up under DCR's Resources. After a few minutes monitoring data is displayed on the Azure Monitor.

Troubleshooting

For information in troubleshooting guidance for Azure Monitor Agent, see the following:

- `<https://learn.microsoft.com/en-us/azure/azure-monitor/agents/azure-monitor-agent-troubleshoot-windows-vm/>`
- `<https://learn.microsoft.com/en-us/azure/azure-resource-manager/troubleshooting/create-troubleshooting-template/>`

Create a catalog using Azure Spot VMs

Azure Spot VMs allow you to take advantage of Azure's unused computing capacity at a significant cost savings. However, the ability to allocate an Azure Spot VM depends on the current capacity and pricing. Therefore, Azure might evict your running VM, fail to create the VM, or fail to power on the VM as per the Eviction policy. Therefore, Azure Spot VMs are good for some non-critical applications and desktops. For more information, see Use Azure Spot Virtual Machines.

Limitations

- All VM sizes aren't supported for Azure Spot VMs. For more information, see Limitations.

  You can run the following PowerShell command to check whether a VM size supports Spot VMs or not. If a VM size supports Spot VM, then `SupportsSpotVM` is **True**.

  ```
  (Get-Item "XDHyp:\HostingUnits\azure-res-conn2\serviceoffering.folder\Standard_D2ds_v4.serviceoffering").AdditionalData
  ```

- Currently, Azure Spot VMs do not support hibernation.

Requirement

While creating the machine profile source (VM or template spec) for Azure Spot VMs catalog, you must select Azure Spot Instance (if using VM) or set `priority` as `Spot` (if using template spec).

Steps to create a catalog using Azure Spot VMs

1. Create a machine profile source (VM or launch template).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For creating a VM using the Azure portal, see Deploy Azure Spot Virtual Machines using the Azure portal.
- For creating a template spec, add the following properties under **resources > type: Microsoft.Compute/virtualMachines > properties** in the template spec. For example:

```
"priority": "Spot",

"evictionPolicy": "Deallocate",

"billingProfile": {

"maxPrice": 0.01

}
```

NOTE:

- Eviction policy can be **Deallocate** or **Delete**.
- For non-persistent VMs, MCS always sets the eviction policy as **Delete**. If the VM is evicted, it is deleted along with any non-persistent disks (For example, OS disk). Any persistent disks (for example, Identity disk) are not deleted. However, an OS disk is persistent if the catalog type is persistent or the `PersistOsDisk` custom property is set to True. Similarly, a WBC disk is persistent if the `PersistWbc` custom property is set to **True**.
- For persistent VMs, MCS always sets the eviction policy as Deallocate. If the VM is evicted, it is deallocated. No changes are made to the disks.
- The maximum price is the price that you are willing to pay per hour. If you are using **Capacity Only**, then this is **-1**. The maximum price can only be null, -1, or a decimal greater than zero. For more information, see Pricing.

2. You can run the following PowerShell command to check if a machine profile is Azure Spot VM enabled or not. If the `SpotEnabled` parameter is **True** and `SpotEvictionPolicy` is set to **Deallocate** or **Delete**, then the machine profile is Azure Spot VM enabled. For example,

   - If the machine profile source is a VM, run the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
(Get-Item "XDHyp:\HostingUnits\azure-res-
conn2\machineprofile.folder\fifthcolumn.resourcegroup\kb-spot-
delete.vm"). AdditionalData
```

- If the machine profile source is a template spec, run the following command:

```
(Get-Item "XDHyp:\HostingUnits\azure-res-
conn2\machineprofile.folder\fifthcolumn.resourcegroup\fc-aeh-
templatespec.templatespec\14.0.0-spot-
delete.templatespecversion").AdditionalData
```

3. Create a machine catalog using a machine profile with `New-ProvScheme` PowerShell command.

You can update a catalog using the `Set-ProvScheme` command. You can also update existing VMs using the PowerShell command `Set-ProvVmUpdateTimeWindow`. The machine profile is updated on the next power on.

Evictions on a running Azure Spot VM

If the computing capacity is unavailable or the price per hour is higher than the maximum price as configured, Azure evicts a running Spot VM. By default, you are not notified of an eviction. The VM simply freezes and the VM is evicted. Microsoft recommends using Scheduled Events to monitor evictions. See Continuously monitor for eviction. You can also run scripts from within a VM to get a notification before the eviction. For example, Microsoft has a polling script in Python ScheduledEvents.cs.

Troubleshooting

- You can see Spot VM properties in the provisioned VM's customMachineData using the `Get-ProvVM` command. If the priority field is set to **Spot**, then Spot is in use.
- You can check if a VM is using Spot in Azure Portal:

  a. Find the VM in the Azure Portal.

  b. Go to the **Overview** page.

  c. Scroll down to the bottom and locate the **Azure Spot** section.

    - If Spot is not in use, then this field is empty.
    - If Spot is in use, the **Azure Spot** and **Azure Spot eviction policy** fields are set.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. You can check the billing profile or maximum price per hour for the VM on the Configuration page.

Configure backup VM sizes

Public clouds can run out of capacity for a specific VM size. When Azure lacks capacity, MCS falls back to a preconfigured list of backup VM sizes. This curated list, tailored by the customer to their workload requirements, increases the likelihood that one of these sizes has sufficient capacity to boot on Power On or Resume if the VM was previously hibernated.

When a power action is initiated, MCS implements an automated fallback sequence to ensure high availability. The workflow is as follows:

1. Initiation: A user or administrator issues a **PowerOn** or **Resume** command via Web Studio.
2. Exception Monitoring: MCS attempts to start the VM using the primary configuration. It monitors for specific Azure capacity exceptions likeQuota Exceeded, Allocation Failed orZonal Allocation Failed and SKU Not Available(Can just go general on this and say we monitor Azure for any capacity or allocation failures)
3. Sequential Fallback: If one of the above errors occurs, MCS automatically iterates through the BackupVmConfiguration list sequentially until the VM successfully starts. If all sizes in the BackupVmConfiguration fail, the power action is marked as failed.
4. Update vs. Re-creation Logic:
    - Direct Update: In most cases, MCS performs a simple VM size update to the backup SKU and then powers the VM on.
    - Delete and Re-create: To maintain environment integrity, certain transitions require the existing VM to be deleted and a new one created in its place. This occurs when:
        - Switching between Spot and Regular VM types.
        - Switching between VM sizes with Resource Disk (Temporary Storage) support and those without.
5. Data Persistence & Recovery: During a "Delete and Re-create" operation, if all backup sizes also fail due to extreme Azure capacity shortages, the VM may temporarily disappear from the Azure Portal. However, no data loss occurs. Upon the next PowerOn attempt, MCS will recreate the VM using the original settings and reattach the existing OS, Identity, and Data disks.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Spot VM Billing & MaxPrice Behavior If your primary configuration utilizes a Machine Profile (VM Template) with Spot priority and a specific Billing Profile (MaxPrice), the following logic applies during fallback:
    - Primary Size: Uses the MaxPrice defined in your Machine Profile. Eviction is based on Price or Capacity.
    - Backup Spot Sizes: The BackupVmConfiguration property does not currently support a unique `MaxPrice` input for each SKU, MCS handles the transition as follows:
    - MaxPrice Reset: MCS sets the MaxPrice to -1.
    - Eviction Policy Shift: This changes the Azure eviction behavior from Price-based to Capacity-based.
    - Pricing: You will be charged the current Spot price, capped at the standard Pay-As-You-Go (PAYG) rate for that backup SKU. This ensures the VM is only evicted if Azure truly runs out of physical capacity, rather than because of a price fluctuation.
7. Persistence of Backup State: Once started, the VM remains on the backup size for the duration of the session until a Shutdown or Hibernate request is processed.
8. Restoration of Primary Size: Upon the next PowerOn or Resume, MCS always attempts to "home" the VM back to its Primary Service Offering (as defined in the Catalog or Machine Profile). If the primary size remains unavailable, the fallback sequence repeats.

Challenges with hibernation

Azure does not allow size changes on a hibernated VM, as explained General limitations. The VM must be in a Stopped state. Therefore, before changing the size, MCS issues a Deallocate request to clear the hibernated state, which causes the VM's hibernation state to be lost. MCS then loops over the backup sizes, updates the VM size, and powers it on.

Backup VM size unsupported scenarios

The following configurations are unsupported:

- For persistent VMs, the following scenarios are unsupported:
    - VM uses DiskControllerType SCSI, but Backup VM size supports only DiskControllerType NVMe.
    - VM uses DiskControllerType NVMe, but Backup VM size supports only DiskControllerType SCSI.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For non-persistent VMs with MCSIO enabled, switching to a size without temporary storage is unsupported if the write-back cache disk uses Resource Disk temporary storage.

Prerequisites to configure Backup VM sizes

If any of the following are unmet, an error is thrown.

- Supported only when the Machine Profile is in use on the Machine Catalog.
- Type is optional and can be either Spot or Regular. Defaults to Regular if unspecified.
- Each combination of ServiceOffering must be unique to avoid repeated configurations.
- Regional Quota must have enough cores for the ServiceOffering.
- Network interface count must not exceed the maximum allowed for a ServiceOffering.
- ServiceOfferings in this BackupVmConfiguration list must be compatible with current Custom Properties, capabilities of the Master Image and the MachineProfile. Some failure scenarios are:
  - Azure Dedicated Hosts: Hosts in the Host Group must support the ServiceOffering if dedicated hosts are used.
  - Ephemeral OS Disk: ServiceOffering must support Ephemeral OS Disks if enabled in custom properties.
  - Premium Storage: ServiceOffering must support Premium storage if specified in custom properties.
  - Accelerated Networking: ServiceOffering must support Accelerated Networking if it is enabled in MachineProfile.
  - DiskEncryptionAtHost: ServiceOffering must support Encryption at Host if enabled in MachineProfile.
  - Temporary Storage: If MCSIO is in use and Write Back Cache is on the Temporary disk, use of a VM size that does not have Temporary Storage is not allowed.
  - HyperVGeneration: ServiceOffering must be compatible with the VM generation (1 or 2) specified in MasterImageVM.
  - TrustedLaunch: ServiceOffering must support TrustedLaunch if enabled in MachineProfile.
  - Confidential VMs: ServiceOffering must support Confidential VM if enabled in MachineProfile.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog with backup VM sizes

NOTE:

To address the issue of the Studio UI freezing, replace all the single quotes with `"` while running the PowerShell commands.

1. Open a PowerShell window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Create a Broker catalog. This catalog is populated with machines which are about to be created.
4. Create an identity pool. This becomes a container for AD accounts created for the machines that are to be created.
5. Create a provisioning scheme with the machine profile. See How to configure backup configuration.
6. Update the `BrokerCatalog` with the unique Id of the provisioning scheme.
7. Create and add VMs to the catalog.

Update an existing catalog

You can update a provisioning scheme using the `Set-ProvScheme` command. See How to configure backup configuration.

Update existing VMs

You can update existing VMs in a catalog using `Set-ProvVMUpdateTimeWindow` PowerShell command. The command updates the VMs created from the provisioning scheme associated with the catalog on the next power on within the given time window. For example:

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName azure-catalog
-StartTimeInUTC "3/12/2022 3am" -DurationInMinutes 60`
```

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName azure-catalog
-StartsNow -DurationInMinutes 60
```

You can configure the backup VM size list for a selected number of existing MCS VMs using the `Set-ProvVM` command. However, to apply the updates, set an update time window for the VMs using `Set-ProvVMUpdateTimeWindow` and start the VMs within the window. For example,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Run the `Set-ProvVM` command to configure the backup VM size list for a selected existing MCS VM. For example:

```
Set-ProvVM -ProvisioningSchemeName "name" -VMName "Vm-001"

-CustomProperties

"<CustomProperties xmlns=`"http://schemas.citrix.com/2014/xd/
machinecreation`"xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`">

<Property xsi:type=`"StringProperty`" Name=`"UseManagedDisks`"
Value=`"true`" />

<Property xsi:type=`"StringProperty`" Name=`"StorageAccountType`"
Value=`"Premium_LRS`" />

<Property xsi:type=`"StringProperty`" Name=`"LicenseType`"
Value=`"Windows_Server`"/>

<Property xsi:type=`"StringProperty`" Name=`"PersistWBC`"
Value=`"true`"/>  <Property xsi:type=`"StringProperty`"
Name=`"BackupVmConfiguration`" Value=`"[{&quot;ServiceOffering&quot;:
&quot;Standard_D2as_v4&quot;, &quot;Type&quot;: &quot;Spot&quot;},
{&quot;ServiceOffering&quot;: &quot;Standard_D2s_v3&quot;,
&quot;Type&quot;: &quot;Regular&quot;}, {&quot;ServiceOffering&quot;:
&quot;Standard_D2s_v3&quot;, &quot;Type&quot;: &quot;Spot&quot;}]`"/>
</CustomProperties>"
```

2. Run the `Set-ProvVMUpdateTimeWindow` command to apply the updates. For example:

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName azure-catalog
-StartsNow -DurationInMinutes 60
```

Copy tags on all resources

You can copy tags specified in a machine profile to all the resources such as, multiple NICs and disks (OS disk, Identity disk, and write-back cache disk) of a new VM or an existing VM in a machine catalog. The machine profile source can be a VM or an ARM template spec.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

You must add the policy on the tags (See Assign policy definitions for tag compliance) or add the tags in a machine profile source to retain the tags on the resources.

Prerequisites

Create the machine profile source (VM or ARM template spec) to have tags on VM, disks, and NICs of that VM.

- If you want to have a VM as a machine profile input, then apply tags on the VM and all the resources in the Azure portal. See Apply tags with Azure portal.
- If you want to have ARM template spec as a machine profile input, then add the following tag block under each resource.

```
 "tags": {

"TagC": "Value3"

},
```

NOTE:

You can have a maximum of one disk and at least one NIC in the template spec.

Copy tags to the resources of a VM in a new machine catalog

1. Create a non-persistent or persistent catalog with a VM or ARM template spec as a machine profile input.
2. Add a VM to the catalog and power it on. You must see the tags specified in the machine profile copied to the corresponding resources of that VM.

NOTE:

You get an error if there is a mismatch in the number of NICs provided in the machine profile and the number of NICs you want the VMs to use.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Modify tags on the resources of an existing VM

1. Create a machine profile with the tags on all the resources.
2. Update the existing machine catalog with the updated machine profile. For example:

```
Set-ProvScheme -ProvisioningSchemeName <YourCatalogName>
-MachineProfile <PathToYourMachineProfile>
```

3. Turn off the VM on which you want to apply the updates.
4. Request a scheduled update for the VM. For example:

```
Set-ProvVMUpdateTimeWindow -ProvisioningSchemeName <YourCatalogName>  -
VMName machine1 -StartsNow -DurationInMinutes -1
```

5. Turn on the VM.
6. You must see the tags specified in the machine profile copied to the corresponding resources.

NOTE:

You get an error if there is a mismatch in the number of NICs provided in the machine profile and the number of NICs provided in the `Set-ProvScheme`.

Create a preformatted WBC disk catalog

You can create a preformatted WBC disk catalog to improve startup performance of provisioned machines. To implement this functionality, create an Azure catalog with WBC enabled and include an additional custom property `PreformatWriteBackCache` as `True`.

You can update an existing catalog using the `Set-ProvScheme` command to update the WBC disk size.

This feature is compatible with the Image management workflow where MCS separates the mastering phase from the overall provisioning workflow. For information on Image management, see Image management.

Example of creating an Azure catalog with WBC enabled and `PreformatWriteBackCache` as `True`:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$customProperties = @'

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="PreformatWriteBackCache"
Value="true" />

</CustomProperties>

'@

New-ProvScheme -CleanOnBoot `

-ProvisioningSchemeName "provisioningschemename" `

-HostingUnitName "hostingunitname" `

-IdentityPoolName "identitypoolnamename" `

-MasterImageVM "XDHyp:
\HostingUnits\AzureHostingUnit\image.folder\rg.resourcegroup\masterImage.m
anageddisk" `

-CustomProperties $customProperties `

-NetworkMapping $networkMapping `

-UseWriteBackCache `

-WriteBackCacheDiskSize 30
```

Example of updating the WBC disk cache size of an existing catalog:

```
Set-ProvScheme -ProvisioningSchemeName provisioningschemename
-WriteBackCacheDiskSize 127
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Delete WBC disk at shutdown for MCS provisioned Citrix Provisioning™ catalogs

While creating an MCS provisioned Citrix Provisioning catalogs in Azure, you can provision the WBC disk to be non-persistent (`PersistWBC` as False). This configuration helps to delete the write-back cache (WBC) disk after you shut down the VM for MCS provisioned Citrix Provisioning catalogs in Azure.

Condition:

You must set the custom property `PreformatWriteBackCache` as `True` for this feature to work.

Example of creating an Azure catalog with `PersistWBC` as `False` and `PreformatWriteBackCache` as `True`:

```
$customProperties = @'

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

<Property xsi:type="StringProperty" Name="PersistWBC" Value="false" />

<Property xsi:type="StringProperty" Name="PreformatWriteBackCache"
Value="true" />

</CustomProperties>

'@

New-ProvScheme -CleanOnBoot `

-ProvisioningSchemeName "provisioningschemename" `

-HostingUnitName "hostingunitname" `

-IdentityPoolName "identitypoolnamename" `

-MasterImageVM "XDHyp:
\HostingUnits\AzureHostingUnit\image.folder\rg.resourcegroup\masterImage.m
anageddisk" `

-CustomProperties $customProperties `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-NetworkMapping $networkMapping `

-UseWriteBackCache `

-WriteBackCacheDiskSize 30
```

You can also update an existing catalog using the `Set-ProvScheme` command to update the `PersistWBC` custom property.

Provision data disk

You can create and assign a persistent data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in Azure.

The data disk must be provisioned from a managed disk as an image source.

Data disk properties

The data disk derives properties from custom properties or OS disk template if the properties are not specified in the custom properties.

- Properties derived from custom properties
  - `DiskEncryptionSetId`
  - `Zones`
  - `StorageType`
- Properties derived from OS disk template if not specified in custom properties
  - `DiskEncryptionSetId`
  - `Zones`
  - `StorageType`

NOTE:

- If Zone Redundant Storage (ZRS) is not specified in custom properties or OS disk template, then the data disk is placed in the same zone as the OS disk and Identity disk.
- Tags are derived only from the OS disk template.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations

The following operations are currently not supported:

- Provisioning of more than one data disk.
- Provisioning of non-persistent data disks.
- Creating a data disk with a template.
- Modifying existing catalogs and VMs to use data disks.
- Resetting the data disk.
- Image update of the data disk.
- Using a source other than a managed disk.
- Storing data disk in Azure Compute Gallery (ACG).
- Using `StorageTypeAtShutdown` for the data disk

Create a catalog with data disk

Include the following parameters in the `New-ProvScheme` PowerShell command to provision an MCS machine catalog with data disk.

- `DataDisk`: Path to a valid ManagedDisk type of inventory item.
- `DataDiskPersistence`: To indicate whether the `DataDisk` is persistent or non-persistent. However, currently, only persistent data disks are supported.

For example:

```
New-ProvScheme  -CleanOnBoot -HostingUnitName "<HostingUnitName >"
-IdentityPoolName "<IdentityPoolName >" -InitialBatchSizeHint 1
-MasterImageVM disk.manageddisk -NetworkMapping <NetworkMapping >
-ProvisioningSchemeName "<ProvisioningSchemeName >" -DataDisk "XDHyp:
\HostingUnits\Azure-Resources-1\image.folder\<resourcegroupname>\xxxx-
datadisk.manageddisk"  -DataDiskPersistence "Persistent"  -Scope @()
-VMCpuCount 4  -VMMemoryMB 6144  -TenancyType Shared  -FunctionalLevel
"L7_20"
```

Determine if a data disk is in use

Do the following to verify if the data disk is assigned to a VM:

- Run `Get-ProvVm` and check the VM's `CustomVmData`. If the VM is using the data disk, there is a disk record with role `DiskRole.DataDisk`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Check if a data disk is present under the VM in the Azure portal.

Delete a data disk

If you delete the catalog, the data disk is deleted unless you use `forgetVM` or `purgeDBOnly` option. If you delete the VM, the data disk is deleted unless you use the `forgetVM` or `purgeDBOnly` option.

Migrate from unmanaged to managed disks

On September 30, 2025, Azure will officially retire unmanaged disks (that is, VHDs). Any existing VMs using unmanaged disks will be stopped and deallocated after the deadline.

However, you can migrate your MCS provisioned VMs from unmanaged to managed disks, which helps to avoid service outages due to Azure's unmanaged disk retirement plans.

All unmanaged disks attached to the VM are converted. This includes the Identity Disk, OS Disk, and WBC Disk (if used).

For more information on Azure's unmanaged disk retirement plan, see Migrate your Azure unmanaged disks by September 30, 2025.

Use cases

This feature applies to persistent and non-persistent MCS-provisioned catalogs.

It also supports migration for both on-demand and non-on-demand (legacy) VMs:

- On-Demand VMs: Transition your existing disks from unmanaged to managed disks to align with Azure's updated support.
- Non-On-Demand (Legacy) VMs: Legacy or non-on-demand VMs only support unmanaged disks. Use this feature to convert your legacy VMs to on-demand while also migrating to managed disks.

For more information on on-demand provisioning, see Azure on-demand provisioning.

Limitations

- Once a machine catalog or VM is converted to managed disks, it cannot be converted back to unmanaged disks
- For non-on-demand (legacy) VMs, the migration process includes converting them to on-demand provisioning. You cannot convert the disks only and continue to use non-on-demand VMs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Important considerations

- Conversion does not occur automatically. It happens as part of a power-on operation.
- If multiple updates are requested for a VM, the disk conversion takes precedence. Additional updates are deferred until a subsequent power on.
- Once the VM is successfully converted and powered on, VHDs for the VM are cleaned up to save costs. The storage account itself are not cleaned up.
  - A base disk might still exist in the storage account. You can run a catalog update, and a new snapshot (or ACG) basedisk is created.
  - Once all the VMs in the catalog are converted and the new basedisk is created, the empty storage account can be deleted.

Required permissions

You need the following permission on your Azure Service Principal to allow conversion from unmanaged to managed disks:

```
Microsoft.Compute/virtualMachines/convertToManagedDisks/write
```

Configuration steps

For On-Demand Catalogs:

1. Run `Set-ProvScheme` (or `Set-ProvVM` for persistent VMs)to update `UseManagedDisks` to `True`. For example:

```
Set-ProvScheme -ProvisioningSchemeName "<provscheme-name>"
-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`"
Name=`"UseManagedDisks`" Value=`"true`" /></CustomProperties>"
```

```
Set-ProvVM -ProvisioningSchemeName "<provscheme-name>" -VMName "<vm-
name>" -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property
xsi:type=`"StringProperty`" Name=`"UseManagedDisks`" Value=`"true`" /
></CustomProperties>"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Run `Set-ProvVMUpdateTimeWindo`w` to apply the updates. In this example, the update is applied on the next power on for the VM.

```
Set-ProvVmUpdateTimeWindow -ProvisioningSchemeName "<provscheme-name>"
-VMName "<vm-name>"
```

3. Power on the VMs.

For Non-On-Demand (Legacy) Catalogs:

1. Run `Set-ProvScheme` (or `Set-ProvVM` for persistent VMs) to configure `Set DeploymentSchema` to `1.1`. For example:

```
Set-ProvScheme -ProvisioningSchemeName "<provscheme-name>"
-CustomProperties "<CustomProperties xmlns=`"http://schemas.citrix.com/
2014/xd/machinecreation`" xmlns:xsi=`"http://www.w3.org/2001/XMLSchema-
instance`"><Property xsi:type=`"StringProperty`"
Name=`"DeploymentSchema`" Value=`"1.1`" /></CustomProperties>"
```

```
Set-ProvVM -ProvisioningSchemeName "<provscheme-name>" -VMName "<vm-
name>" -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property
xsi:type=`"StringProperty`" Name=`"DeploymentSchema`" Value=`"1.1`" /
></CustomProperties>
```

2. Run `Set-ProvVMUpdateTimeWindow` to apply the updates. In this example, the update is applied on the next power on for the VM.

```
Set-ProvVmUpdateTimeWindow -ProvisioningSchemeName "<provscheme-name>"
-VMName "<vm-name>"
```

3. Power on the VMs.

Troubleshooting

If a VM fails to convert from unmanaged to managed disks:

- Verify that the `UseManagedDisks` or `DeploymentSchema` custom properties are set correctly:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - If using `Set-ProvScheme`, verify the ProvScheme custom properties by running `Get-ProvScheme`. For more information, see Get-ProvScheme.
  - If using `Set-ProvVM`, verify the VM has a new configuration with the updated custom property by running `Get-ProvVMConfiguration`. For more information, see Set-ProvVM.

- Verify that the following permission is present in your Azure Service Principal:
  - `Microsoft.Compute/virtualMachines/convertToManagedDisks/write`
- Run `Get-ProvOperationEvent` to view any warnings for the Provisioning Scheme. For more information, see Get-ProvOperationEvent. For example:

```
Get-ProvOperationEvent -LinkedObjectType ProvisioningScheme
-LinkedObjectUid <your-provscheme-id>
```

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage a Microsoft Azure catalog.

More information

- Create and manage connections and resources
- Connection to Microsoft Azure Resource Manager
- Create machine catalogs

Create a Microsoft SCVMM catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Microsoft System Center Virtual Machine Manager (VMM) virtualization environments.

NOTE:

Before creating a VMM catalog, you need to finish creating a connection to VMM. See Connection to Microsoft System Center Virtual Machine Manager.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a master VM

- Install a VDA on the master VM, and select the option to optimize the desktop. This improves performance.
- Take a snapshot of the master VM to use as a backup.
- Create virtual desktops.

MCS on SMB 3 file shares

For machine catalogs created with MCS on SMB 3 file shares for VM storage, credentials must meet the following requirements to ensure that calls from the XenServer® Communications Library (HCL) connect successfully to SMB storage.

- VMM user credentials must include full read write access to the SMB storage.
- Storage-virtual disk operations during VM lifecycle events are performed through the Hyper-V server using the VMM user credentials.

For more information on SMB 3, see Overview of file sharing using the SMB 3 protocol in Windows Server.

When using VMM 2012 SP1 with Hyper-V on Windows Server 2012: When using SMB as storage, enable the Authentication Credential Security Support Provider (CredSSP) from the Cloud Connector to individual Hyper-V machines. For more information, see CTX137465.

Using a standard PowerShell V3 remote session, the HCL in the Cloud Connector uses CredSSP to open a connection to the Hyper-V machine. This feature passes Kerberos-encrypted user credentials to the Hyper-V machine, and the PowerShell commands in the session on the remote Hyper-V machine run with the credentials provided (in this case, those of the VMM user), so that communication commands to storage work correctly.

The following tasks use PowerShell scripts that originate in the HCL. The scripts are then sent to the Hyper-V machine to act on the SMB 3.0 storage.

Consolidate Master Image: An image creates a new MCS provisioning scheme (machine catalog). It clones and flattens the master VM ready for creating new VMs from the new disk created (and removes dependency on the original master VM).

ConvertVirtualHardDisk on the root\\virtualization\\v2 namespace

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
$ims = Get-WmiObject -class $class -namespace "root\\virtualization\\v2";

$result = $ims.ConvertVirtualHardDisk($diskName, $vhdastext)

$result
```

Create differencing disk: Creates a differencing disk from the image generated by consolidating the image. The differencing disk is then attached to a new VM.

CreateVirtualHardDisk on the root\\virtualization\\v2 namespace

Example:

```
$ims = Get-WmiObject -class $class -namespace "root\\virtualization\\v2";

$result = $ims.CreateVirtualHardDisk($vhdastext);

$result
```

Upload identity disks: The HCL cannot directly upload the identity disk to SMB storage. Therefore, the Hyper-V machine must upload and copy the identity disk to the storage. Because the Hyper-V machine cannot read the disk from the Cloud Connector, the HCL must first copy the identity disk through the Hyper-V machine as follows.

1. The HCL uploads the Identity to the Hyper-V machine through the administrator share.
2. The Hyper-V machine copies the disk to the SMB storage through a PowerShell script running in the PowerShell remote session.

   A folder is created on the Hyper-V machine and the permissions on that folder are locked for the VMM user only (through the remote PowerShell connection).
3. The HCL deletes the file from the administrator share.
4. When the HCL completes the identity disk upload to the Hyper-V machine, the remote PowerShell session copies the identity disks to SMB storage, and then deletes it from the Hyper-V machine.

The identity disk folder is recreated if deleted to make it available for reuse.

Download identity disks: As with uploads, the identity disks pass through the Hyper-V machine to the HCL. The following process creates a folder that has only VMM user permissions on the Hyper-V server if it does not exist.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. The HyperV machine copies the disk from the SMB storage to local Hyper-V storage using a PowerShell script running in the PowerShell V3 remote session.
2. HCL reads the disk from the Hyper-V machine's administrator share into memory.
3. HCL deletes the file from the administrator share.

Create catalog with a machine profile

You can use a machine profile to create and update an MCS machine catalog in System Center Virtual Machine Manager (SCVMM) environments. You can enable vTPM. You can also add custom tags of a machine profile VM to the provisioned VMs.

Important considerations

- Master image can only be a snapshot and not a VM.
- You can only use VM as the machine profile source.
- In System Center Virtual Machine Manager (SCVMM) environments, you can use a machine profile to create and update an MCS machine catalog. You can enable vTPM and/or Secure Boot. You can also add custom tags from a machine profile VM to provisioned VMs.
- If the master image has vTPM enabled, then you must enable the vTPM on the machine profile source.
- vTPM is only supported on Generation 2 machines.
- The following parameters overwrite the values captured in a machine profile if provided separately:
  - VMCpuCount
  - VMMemoryMB
  - Disk storage
- The custom tags are inherited only from the machine profile and not from the master image. The `CitrixProvisioningSchemeId` tag is added by default to the VM. If you do not want to include the `CitrixProvisioningSchemeId` tag, then add the `-NoVmTagging` parameter while creating a hosting unit. Example:

```
New-Item -HypervisorConnectionName  $ConnectionName `

-NetworkPath @($NetworkPath) `

-Path @($HostingUnitPath) `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-PersonalvDiskStoragePath @() `
-RootPath $RootPath `
-StoragePath @($StoragePath) `
-NoVmTagging
```

- You can update an existing catalog using the `Set-ProvScheme` command.

SUPPORT MATRIX

MASTER IMAGE	MACHINE PROFILE	RESULT
No vTPM	vTPM	Cloned machines get vTPM enabled
vTPM	vTPM	Cloned machines get vTPM enabled
vTPM	No vTPM	Preflight error - operation blocked
No vTPM	No vTPM	Cloned machines have no vTPM

Create a machine catalog using a machine profile

1. Create a VM to be a machine profile source. For more information, see Provision virtual machines in the VMM fabric. You cannot change the **Generation** once selected. You can do the following in SCVMM:
    - To enable vTPM:
        a. After you create the VM, log in to the Hyper-V host and find your VM under the **Hyper-V Manager**.
        b. Right-click the VM, then go to **Settings**.
        c. Under **Security**, select the **Enable Trusted Platform Module** checkbox.
2. Open a **PowerShell** window.
3. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Create a Broker catalog. This catalog is populated with machines which are about to be created.
5. Create an identity pool. This becomes a container for AD accounts created for the machines that are to be created.
6. Create a provisioning scheme with the machine profile. For example:

```
New-ProvScheme -HostingUnitName "<hostingunit name>"

-IdentityPoolName "ID1" -MasterImageVM "XDHyp:\HostingUnits\HU1\<path
to the checkpoint/snapshot>"

-ProvisioningSchemeName "<catalogname>"  -MachineProfile "XDHyp:\<path
to the machine profile VM>"
```

7. Updates the Broker catalog with the unique Id of the provisioning scheme.
8. Create and add VMs to the catalog.

Update an existing catalog

You can update an existing catalog using the Set-ProvScheme command. For example:

```
Set-ProvScheme -ProvisioningSchemeName "<catalogname>" -MachineProfile
"XDHyp:\<path to the machine profile VM>"
```

Remove a VM

You can choose to remove a VM from a catalog but not delete the VM from the SCVMM. In this case, the `CitrixProvisioningSchemeId` tag is only removed from the VM. The custom tags are not deleted from the VM. You can remove a VM using Studio or PowerShell commands.

REMOVE A VM USING STUDIO

1. Select and right-click the VM.
2. Click **Delete**.
3. Select **Remove the virtual machines from the catalog but do not delete the virtual machines**.

USING POWERSHELL COMMANDS

`Remove-ProvVM` with `ForgetVM` parameter. For more information, see:

- Remove tags

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Delete machines without hypervisor access

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage a Microsoft System Center Virtual Machine Manager catalog.

More information

- Create and manage connections and resources
- Connection to Microsoft System Center Virtual Machine Manager
- Create machine catalogs

Create a Nutanix catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Nutanix virtualization environments.

NOTE:

Before creating a Nutanix catalog, you need to finish creating a connection to Nutanix. See Connection to Nutanix.

Create a machine catalog using Nutanix machine template version

When creating an MCS-provisioned machine catalog with a Citrix-managed Nutanix AHV Prism Central host connection, the base image is created from a Nutanix VM template version. A key advantage is that Nutanix Prism Central allows a VM template to be used across multiple clusters. As a result, Citrix administrators can use a single Nutanix VM template version as the master VM for multiple MCS machine catalogs, even if those catalogs are on different Nutanix clusters.

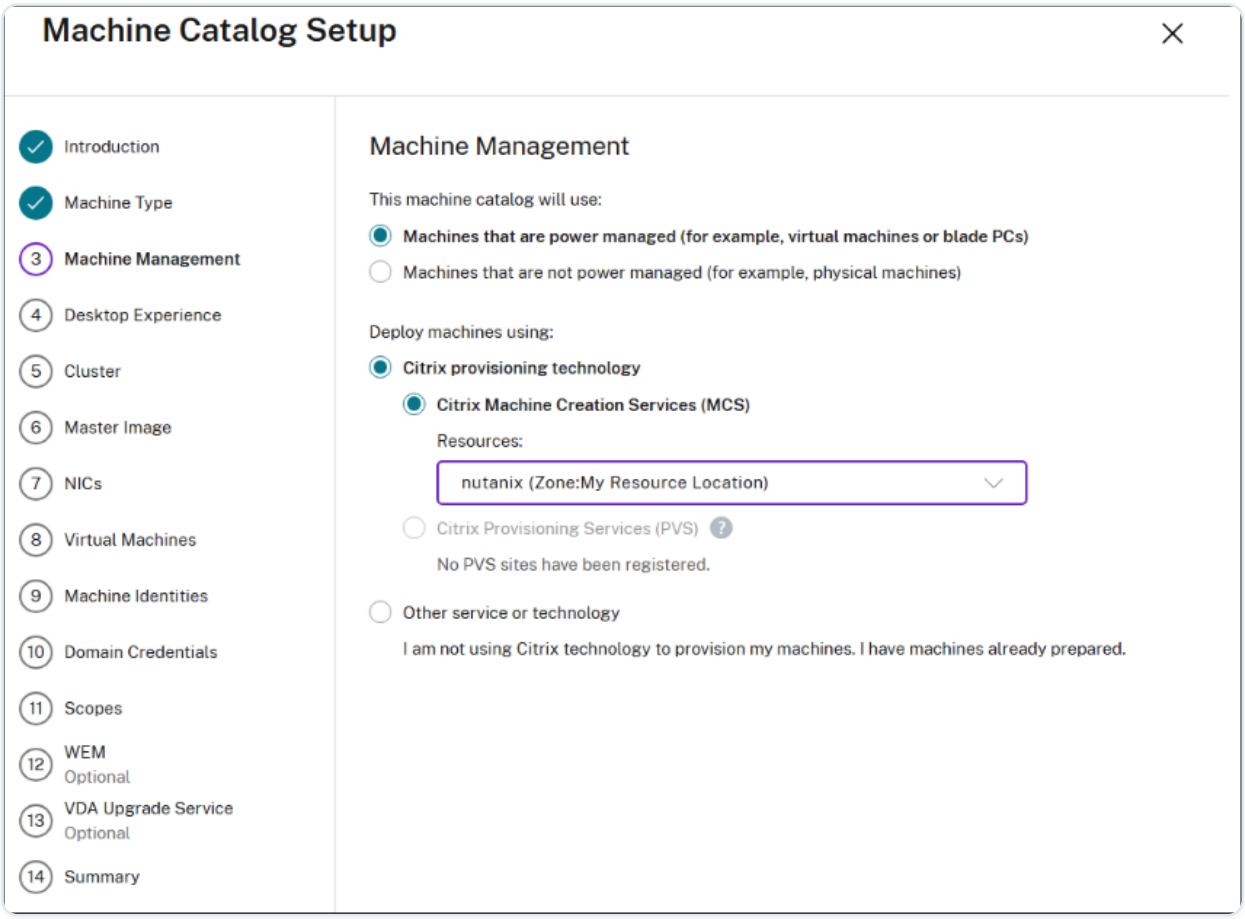
Before creating the catalog, create a master VM, and convert it to a VM template version in Nutanix Prism Central. See Nutanix documentation for the steps.

You can create a catalog using:

- Studio. You can also create a catalog using existing VMs. See Create a machine catalog using existing machines (power managed)
- PowerShell commands

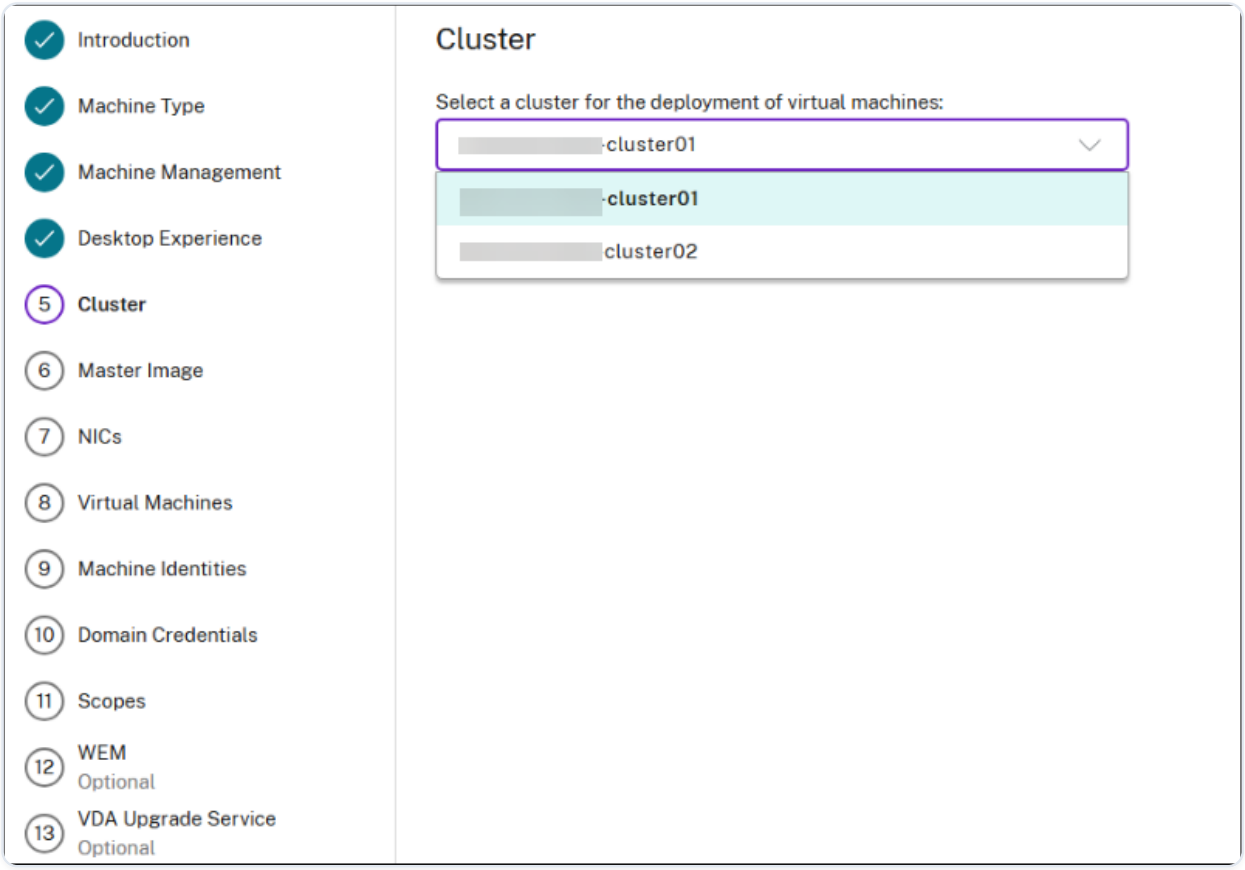
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations



- Attaching multiple NICs to the same subnet is not supported.
- Due to Nutanix limitation, each MCS provisioned machine catalog can only be assigned with NICs in a single type of network among Overlay networks, VLAN Basic Subnets, and VLAN Subnets.
- In some scenarios, updating MCS master image for a non-persistent machine catalog might cause potential issues. See Secure Boot and vTPM in Nutanix Prism Central.
- When creating a machine catalog on Nutanix, cluster name containing a period (.) is not supported.
- When selecting a Nutanix VM template as the master image, the template name or template version name must not contain any characters like # or **&**.

Create a machine catalog using Studio

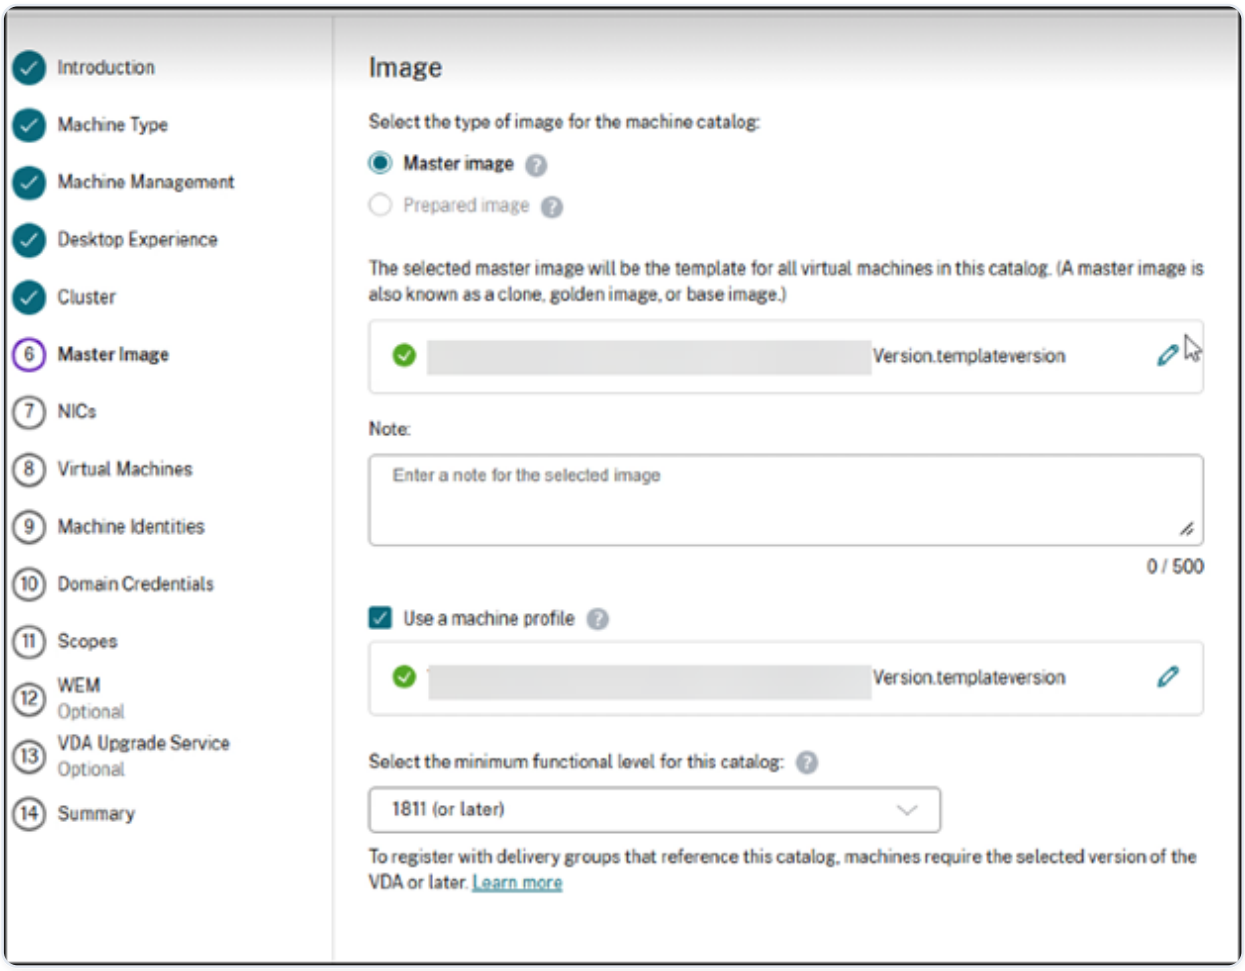


In the Machine Catalog Setup wizard:

1. On the **Machine Type** page, select **Multi-session OS**, **Single-session OS**, or **Remote PC Access**.
2. On the **Machine Management** page, select **Machines that are power managed** and **Citrix Machine Creation Services™** as the deployment method. Select the **Resources**.

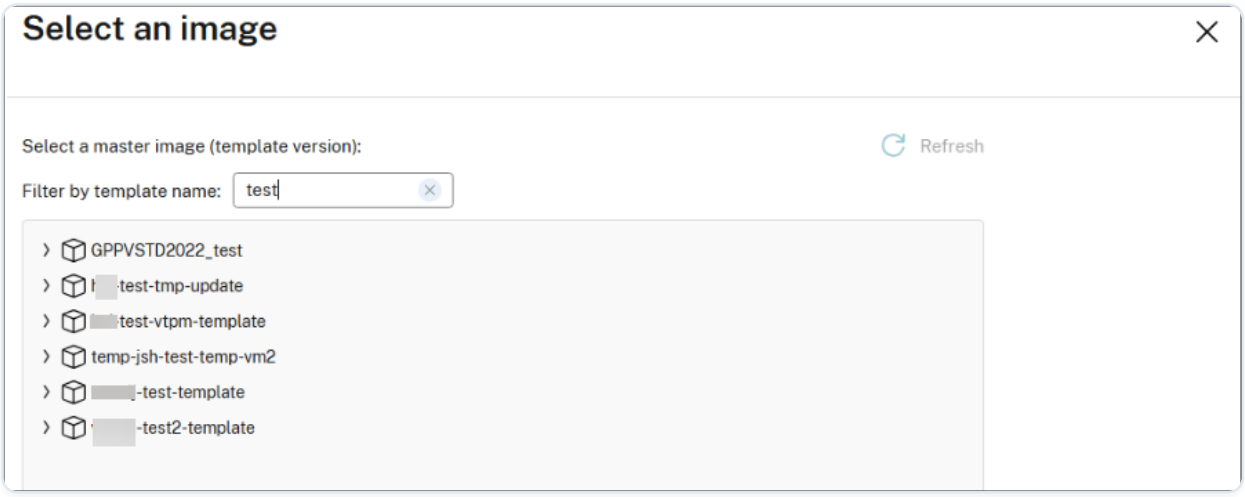
© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Desktop Experience** page, select one of the two options.
4. On the **Cluster** page, select a cluster for the deployment of the VMs.



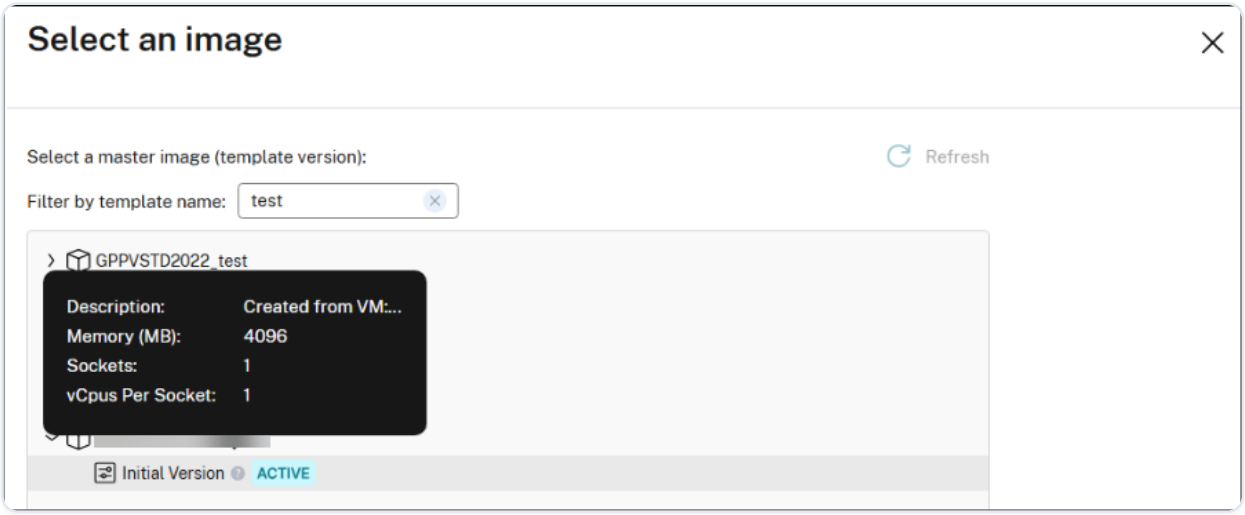
© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. On the **Master Image** page, click **Master Image** and select a master image (template version). You can filter machine templates by name. The master image's template version defaults as the machine profile for new catalogs. However, you can change the template version for the machine profile.



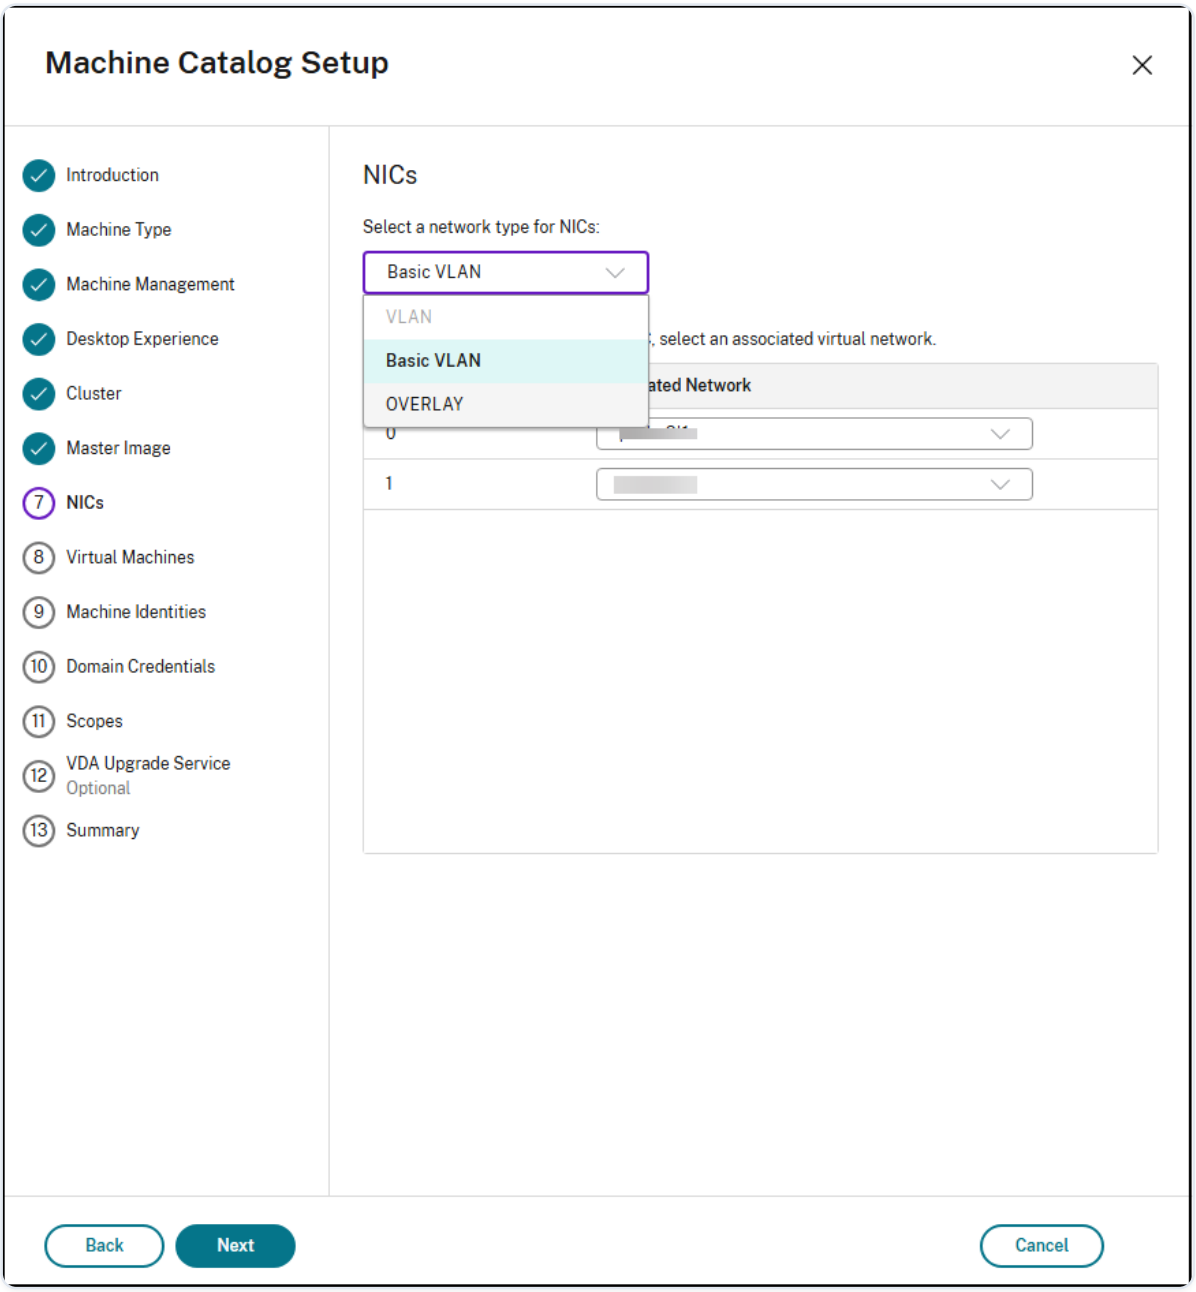
NOTE:

You can use a single Nutanix VM template version as the master VM for multiple MCS machine catalogs, even if those catalogs are on different Nutanix clusters.



Filter machine templates by name:

© 1997–2026 Citrix Systems, Inc. All rights reserved.



See description of a template:

6. On the **NICs** page:

   - Select a NIC type from the drop-down to filter associated networks. The network types of NICs available are: **VLAN** (Advanced VLAN), **Basic VLAN**, and **OVERLAY**.
   - If you create a catalog with a machine profile, then the NIC number is consistent with the NIC number of the machine profile and can't be changed. Select an associated virtual network for each NIC.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If you create a catalog without a machine profile, click **Add NIC** to increase NIC count or click **Remove** to delete selected NICs. Select one or more NICs and then select an associated virtual network for each NIC.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. On the **Virtual Machines** page, indicate the number of virtual machines you want to create and configure your machines for Total memory (MB) on each machine, Virtual CPUs, and Cores per CPU. These values are automatically populated from the machine profile.
8. On the **Summary** page, check the details of the machine catalog. Enter a name and description for the machine catalog. Click **Finish**.

EXPORT THE MACHINE PROFILE

You can export the machine profile used by the machine catalog to a JSON file.

1. Select the machine catalog and navigate to the **Templates Properties** tab.
2. Under **Machine Profile** details, click **Export** next to the **Last version**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a machine catalog using PowerShell commands

1. Open the PowerShell window.
2. Run `asnp citrix*`.
3. Create an identity pool if not already created. For example:

```
New-AcctIdentityPool    -Domain "<string>" -IdentityPoolName "<string>"
-IdentityType "ActiveDirectory"  -NamingScheme "DemoVM-##"
-NamingSchemeType "Numeric" -ZoneUid "GUID" -Scope @()
```

4. Create a provisioning scheme.

   For example: Without a machine profile

```
New-ProvScheme -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property
xsi:type=`"StringProperty`" Name=`"ClusterId`"
Value=`"00062c63-1fb0-58c9-4fc8-5c2573352378`" /><Property
xsi:type=`"StringProperty`" Name=`"CPUCores`" Value=`"1`" /></
CustomProperties>" -HostingUnitName "<Hosting unit name>"
-IdentityPoolName "<string>" -InitialBatchSizeHint 1  -MasterImageVM
"XDHyp:\HostingUnits\<Hosting Unit Name>\Templates.folder\<template
name>.template\<template version name>.templateversion" -NetworkMapping
@{"5"="XDHyp:\HostingUnits\<Hosting unit name>\Clusters.folder\<Cluster
Name>.cluster\<Network name>.network"} -ProvisioningSchemeName
"<Catalog name>" -ProvisioningSchemeType "MCS" -RunAsynchronously
-Scope @() -VMCpuCount 2 -VMMemoryMB 10240
```

   For example: With a machine profile

   Use a machine profile to capture hardware properties from a template version and apply them to provisioned VMs. If you don’t specify machine profile, hardware properties are captured from the master image template version.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The OS Disk, vTPM, and Secure Boot properties are always captured from the master image, even when a machine profile is used.
- Since OS Disk is not read from the machine profile, you can create a diskless VM and convert it to a template version that can be used for the machine profile.
- As the complete JSON spec of the machine profile template version is stored, you can create the VMs even if you delete the template version from the Prism Central.

Properties captured from the machine profile are:

PROPERTY	PROPERTY NAME IN API (GETTEMPLATEVERSIONBYID)	COMMENTS/REFERENCES
CPU	**numSockets**	
RAM	**memorySizeBytes**	
Core	**numCoresPerSocket**	
Categories	**categories**	Category Management
GPU	**gpus**	GPUs Summary View
Threads Per Core	**numThreadsPerCore**	aCLI-VM
Numa Nodes	**numNumaNodes**	
Enable VCPU Hard Pinning	**isVcpuHardPinningEnabled**	
Enable CPU Passthrough	**isCpuPassthroughEnabled**	
Enable Memory Overcommit	**isMemoryOvercommitEnabled**	Creating a VM through Prism Central (AHV)
Enable GPU Console Access	**isGpuConsoleEnabled**	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PROPERTY	PROPERTY NAME IN API (GETTEMPLATEVERSIONBYID)	COMMENTS/REFERENCES
Enable CPU Hot Plug	**isCpuHotplugEnabled**	
Enable SCSI Controller	**isScsiControllerEnabled**	
Timezone	**hardwareClockTimezone**	Creating a VM through Prism Central (AHV)
Enable AHV branding	**isBrandingEnabled**	
Enable VGA Console	**isVgaConsoleEnabled**	
VM	**isAgentVm**	Creating a VM through Prism Central (AHV)

NOTE:

Using the same master image template version, you can create different catalogs with various machine profiles, each featuring a distinct set of properties mentioned above. For example, you might assign different Categories that can be linked to Nutanix Policies, adjust CPU/Memory, modify Memory Overcommit settings, or add and remove multiple GPUs.

The command-line parameters, such as `VMCpuCount`, `VMMemoryMB`, and `CPUCores` in the `CustomProperties`, can be provided and takes precedence over the values for these parameters from the machine profile template version. If not provided, these are read from the given machine profile.

```
$customProperties = @"

<CustomProperties xmlns="http://schemas.citrix.com/2014/xd/
machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

    <StringProperty Name="ClusterId"
Value="00062c63-1fb0-58c9-4fc8-5c2573352378" />

    <StringProperty Name="CPUCores" Value="2" />
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
</CustomProperties>

"@

New-ProvScheme -HostingUnitName "<Hosting unit name>" `

           -IdentityPoolName "<string>" `

           -InitialBatchSizeHint 1 `

           -MasterImageVM "XDHyp:\HostingUnits\<Hosting Unit
Name>\Templates.folder\<template name>.template\<template version
name>.templateversion" `

           -MachineProfile "XDHyp:\HostingUnits\<Hosting Unit
Name>\Templates.folder\<template name for machine
profile>.template\<template version name>.templateversion" `

           -NetworkMapping @{"0"="XDHyp:\HostingUnits\<Hosting unit
name>\Clusters.folder\<Cluster Name>.cluster\<Network name>.network"} `

           -ProvisioningSchemeName "<Catalog name>" `

           -ProvisioningSchemeType "MCS" `

           -CustomProperties $customProperties `

           -RunAsynchronously `

           -VMCpuCount 2 `

           -Scope @()
```

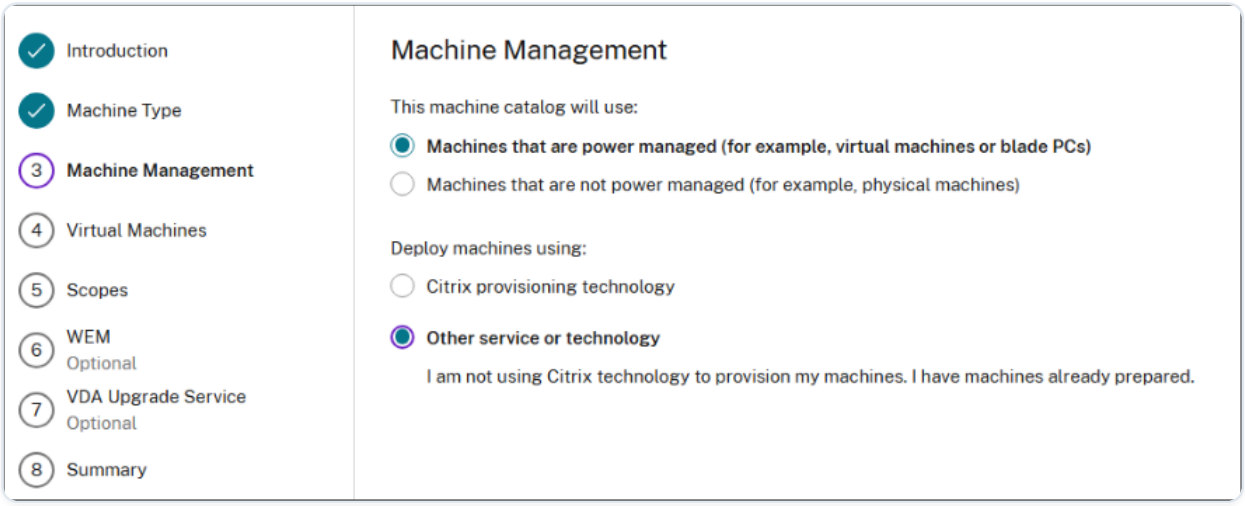
5. Register a provisioning scheme as a broker catalog. For example:

```
New-BrokerCatalog -AllocationType "Random" -IsRemotePC $False  -
MinimumFunctionalLevel "L7_20" -Name "<Catalog Name>"
-PersistUserChanges "Discard" -ProvisioningType "MCS"    -
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
SessionSupport "MultiSession" -ZoneUid "GUID"  -ProvisioningSchemeId
fe7df345-244e-4xxxx-xxxxxxxxx `  -Scope @()
```

Create a machine catalog with existing machines (power managed)

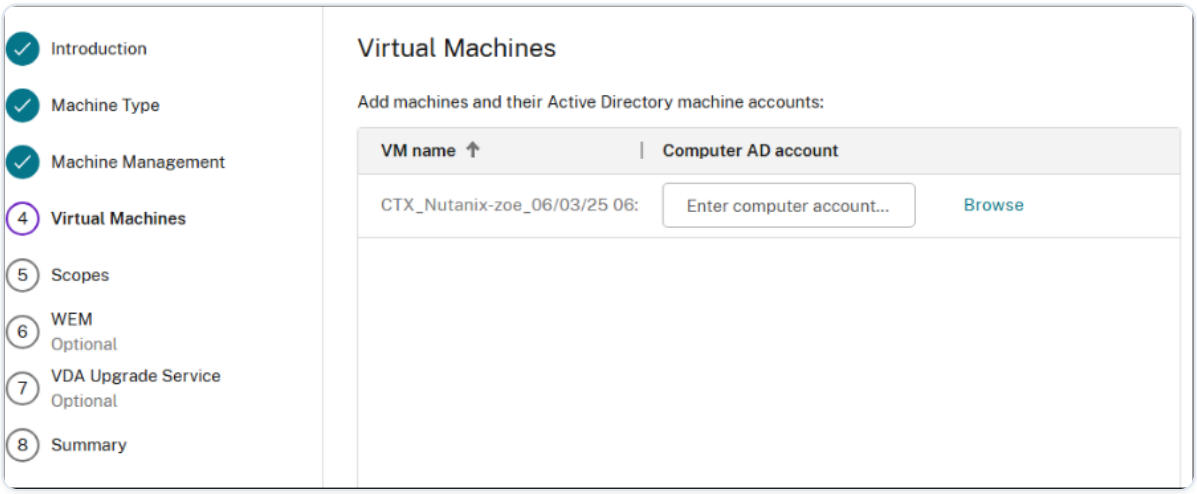


You can create a machine catalog with existing machines (power managed) using:

- Studio
- PowerShell

Create a machine catalog with existing machines (power managed) using Studio

In the Machine Catalog Setup wizard:



1. On the **Operating System** page, select **Multi-session OS** or **Single-session OS**.
2. On the **Machine Management** page, select **Machines that are power managed** and **Other service or technology**.

3. On the **Virtual Machines** page, add machines and their Active Directory machine accounts. You can do one of the following:

   - Click **Import from CSV file** to bulk add machines. For information about using CSV files to add machines, see Use CSV files to bulk add machines to a catalog.
   - Click **Add Machines** to add machines manually. The **Select VMs** window appears. Expand the Nutanix AHV Prism Central connection that you created earlier and select the VMs you want to add. Then add the associated machine account names.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. The **Scopes** and **Summary** pages do not contain information specific to Nutanix AHV Prism Central.

Create a machine catalog with existing machines (power managed) using PowerShell

1. Open the PowerShell window.
2. Run `asnp citrix*`.
3. Create a catalog to have power-managed VMs that are assigned to the user. For example:

```
New-BrokerCatalog -AllocationType "Permanent"  -IsRemotePC $False
-MachinesArePhysical $False  -Name "<Catalog Name>" -PersistUserChanges
"OnLocal" -ProvisioningType "Manual" -Scope @() -SessionSupport
"SingleSession" -ZoneUid "fb202053-8c35-4db2-a299-a8d9538ec6be"
```

4. Add VMs to the catalog. For example:

```
New-BrokerMachine  -CatalogUid 6 -HostedMachineId "d859caf3-4bf0-447b-
b012-8af0594c7d88" -HypervisorConnectionUid 1 -IsReserved $False  -
MachineName "S-1-5-21-1334627847-1250330507-3910179295-100245"
```

Create a machine catalog using a Nutanix snapshot

This section describes how to create an MCS provisioned machine catalog with Nutanix Acropolis (Prism Element) host connection. Before creating the catalog, create master images and snapshots in Nutanix. For more information, see the Nutanix documentation.

In the Machine Catalog Setup wizard:

- The **Container** or **Cluster and Container** page is unique to Nutanix.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - If you deploy machines by using Nutanix AHV XI as the resources, on the **Container** page, select a container where the VMs' identity disks will be placed.
    - If you deploy machines by using Nutanix AHV PC as the resources, you see the **Cluster and Container** page. Select which cluster to use for the deployment of VMs and then a container.

- On the **Image** page, select the image snapshot. Use the Acropolis console to rename your snapshots if needed. If you rename snapshots, restart the catalog creation wizard to see a refreshed list.
- On the **Virtual Machines** page, indicate the number of virtual CPUs and the number of cores per vCPU.
- On the **NICs** page, select the NIC type to filter associated networks. This option is available only for Nutanix AHV PC connections.
- The **Machine Identities**, **Domain Credentials**, **Scopes**, and **Summary** pages do not contain Nutanix-specific information.

Limitations

When creating an MCS catalog with Nutanix host connection (specifically, Nutanix AHV plug-in 2.7.1 and Nutanix AHV plug-in 2.5.1), the hard disk size of provisioned VMs are incorrectly displayed on Studio.

- Nutanix AHV plug-in 2.7.1: The size displayed is smaller (1 GB) than the real storage size.
- Nutanix AHV plug-in 2.5.1: The size displayed is smaller (32 GB) than the real storage size.

However, this works as designed if the master image VM is a snapshot in VM.

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage a Nutanix catalog.

More information

- Create and manage connections and resources
- Connection to Nutanix
- Connection to Nutanix cloud and partner solutions
- Create machine catalogs

Create a Red Hat OpenShift catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to Red Hat OpenShift virtualization environments.

NOTE:

Before creating a Red Hat OpenShift catalog, finish creating a connection and hosting unit to Red Hat OpenShift. See Connection to Red Hat OpenShift.

Create a master image VM

A master image VM is required to create a machine catalog.

1. Access the OpenShift Console using your login ID.
2. Navigate to **Virtualization > VirtualMachines** to see the list of VMs, including master image VMs.
3. Create a master image. When creating a master image, make sure that the master image VM has only one storage device.

NOTE:

- Ensure that a routable NAD is added to the master image VM according to the customer's requirements for the cluster environment.
- When the master image is joined to a domain, it might lose domain trust after being used for catalog creation. This issue affects Citrix Virtual Apps and Desktops™ 2503 due to a limitation in the OpenShift environment. The workaround is not to join domain in master images. Citrix is working with Red Hat to enhance network isolation capabilities.
- When creating an MCS machine catalog in a Red Hat OpenShift virtualization environment, you can’t use a master image and a machine profile that have different operating system types. This is due to how Red Hat OpenShift manages each OS type. Therefore, using a Windows VM as the master image with a non-Windows (example, Linux) VM as the machine profile, or the other way around, is not supported.
- Currently, the VMs created using `InstanceType` are not supported as a master image.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a catalog

You can create OpenShift catalogs to create, deliver, and power manage machines in your OpenShift environments.

- Create a catalog using Studio
- Create a catalog using PowerShell commands

Create a catalog using Studio

You can create an MCS machine catalog in the Red Hat OpenShift environment with or without a machine profile using Web Studio. A VM is used as a machine profile input.

In the Machine Catalog Setup wizard:

1. On the **Operating System** page, select **Multi-session OS** or **Single-session OS**.
2. On the Machine Management page:
    - Select **Machines that are power managed (for example, virtual machines or blade PCs)**.
    - Select to deploy machines using **Citrix provisioning technology Citrix Machine Creation Services™ (MCS)**.
    - Select the Openshift hosting unit under Citrix Machine Creation Services (MCS)
3. On the **Desktop Experience** page, select the option according to the machine type you select on the **Machine Type** page.
4. On the **Image** page:
    a. Select a master image. Currently, Openshift doesn’t support Prepared image.
    b. You can add a note for the selected image.
    c. You can select the **Use a machine profile** checkbox and select a machine profile.
    d. To enable use of the latest product features, ensure that the master image has the latest VDA version installed. Do not change the default minimum VDA selection. However, if you must use an earlier VDA version, see VDA versions and functional levels.
5. On the **NICs** page, select one or more NICs, associate a virtual network with each card.
6. On the **Virtual Machines** page:
    a. Specify how many virtual machines to create. Enter 0 (zero) if you do not want to create any. Later, you can create VMs for an empty catalog by adding machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. Choose the amount of memory (in MB) each VM has.

c. If you are creating a random non-persistent catalog, you can enable Write-Back Cache for machines to improve I/O performance. See Configure cache for temporary data.

7. Follow the on-screen instructions to complete the remaining steps, which don't include OpenShift-specific information.

You can also use Studio to create Openshift catalogs to deliver and manage the power of existing machines in your OpenShift environments. Do the following:

In the Machine Catalog Setup wizard:

1. On the **Operating System** page, select **Multi-session OS** or Single-session OS.
2. On the **Machine Management** page, select **Machines that are power managed and Another service or technology**.
3. On the **Virtual Machines** page, add machines and their Active Directory machine accounts. You can:

   - *Add machines manually*: Click **Add Machines to add machines manually**. The **Select VMs** window appears. Expand the OpenShift connection you created earlier and select the nodes (VMs) you want to add. Then add the associated machine account names.
   - *Add machines using a CSV file*: Click **Add CSV File to bulk add machines**. For information about using CSV files to add machines, see Use CSV files to bulk add machines to a catalog.

4. Follow the on-screen instructions to complete the remaining steps, which don't include OpenShift-specific information.

Create a catalog using PowerShell commands

Currently, you can create an MCS machine catalog in the Red Hat OpenShift environment using only PowerShell commands. You can create the machine catalog with or without using a machine profile. A VM is used as a machine profile input.

1. Open a PowerShell window.
2. Run `asnp citrix*`.
3. Run PowerShell commands to

   a. Create an identity pool

   b. Create AD accounts

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. Create an MCS machine catalog with persistent VMs with or without a machine profile.
d. Add VMs to the catalog
e. Create a broker catalog
f. Add broker machines to the new VMs

Following is a sample script:

CREATE AN IDENTITY POOL

```
New-AcctIdentityPool `

    -IdentityPoolName "IdentityPoolName" `

    -ZoneUid "00000000-0000-0000-0000-000000000000" `

    -NamingScheme "vm###" `

    -NamingSchemeType "Numeric" `

    -AllowUnicode `

    -Domain "MyDomain.local" `

    -AdminAddress "MyDDC.MyDomain.Local"
```

CREATE AD ACCOUNTS

```
New-AcctADAccount `

    -IdentityPoolUid "11111111-1111-1111-1111-111111111111" `

    -ADUserName "MyDomain\MyUserName" `

    -ADPassword SecurePassword `

    -Count 1 `

    -AdminAddress "MyDDC.MyDomain.Local"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE A PROVISIONING SCHEME WITH PERSISTENT MACHINES (WITHOUT MACHINE PROFILE)

```
New-ProvScheme `

    -ProvisioningSchemeName "ProvisioningSchemeName" `

    -HostingUnitName "HostingUnitName" `

    -IdentityPoolName "IdentityPoolName" `

    -ProvisioningSchemeType "MCS" `

    -MasterImageVM "XDHyp:
\HostingUnits\HostingUnitName\TargetNamespace.namespace\MasterImageVM.vm"
`

    -NetworkMapping @{"0" = "XDHyp:
\HostingUnits\HostingUnitName\TargetNamespace.namespace\MyNetwork.network"
 } `

    -VMCpuCount 1 `

    -VMMemoryMB 4096 `

    -InitialBatchSizeHint 1 `

    -AdminAddress "MyDDC.MyDomain.Local"
```

CREATE A PROVISIONING SCHEME WITH PERSISTENT MACHINES (WITH MACHINE PROFILE)

```
New-ProvScheme `

    -ProvisioningSchemeName "ProvisioningSchemeName" `

    -HostingUnitName "HostingUnitName" `

    -IdentityPoolName "IdentityPoolName" `

    -ProvisioningSchemeType "MCS" `

    -MasterImageVM "XDHyp:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
\HostingUnits\HostingUnitName\TargetNamespace.namespace\MasterImageVM.vm"
`

    -NetworkMapping @{"0" = "XDHyp:
\HostingUnits\HostingUnitName\TargetNamespace.namespace\MyNetwork.network"
 } `

    -VMCpuCount 1 `

    -VMMemoryMB 4096 `

    -InitialBatchSizeHint 1 `

    -AdminAddress "MyDDC.MyDomain.Local" `

    -MachineProfile "XDHyp:
\HostingUnits\HostingUnitName\TargetNamespace.namespace\MachineProfileVM.v
m"
```

CREATE NEW PROVVMS

```
New-ProvVM `

    ProvisioningSchemeName "ProvisioningSchemeName" `

    ADAccountName "MyDomain\vm001" `

    AdminAddress "MyDDC.MyDomain.Local"

Lock-ProvVM `

    -ProvisioningSchemeName "ProvisioningSchemeName" `

    -Tag "Brokered" `

    -VMID "TargetNamespace:vm001"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CREATE NEW BROKER CATALOG

```
New-BrokerCatalog `

    -Name "ProvisioningSchemeName" `

    -ProvisioningType "MCS" `

    -SessionSupport "MultiSession" `

    -AllocationType "Random" `

    -PersistUserChanges "OnLocal" `

    -ZoneUid "00000000-0000-0000-0000-000000000000" `

    -AdminAddress "MyDDC.MyDomain.Local"
```

SET BROKER CATALOG METADATA

```
Set-BrokerCatalogMetadata `

    -CatalogId "1" `

    -Name "Citrix_DesktopStudio_IdentityPoolUid" `

    -Value "11111111-1111-1111-1111-111111111111"

Set-BrokerCatalog `

    -Name "ProvisioningSchemeName " `

    -ProvisioningSchemeId "22222222-2222-2222-2222-222222222222"
```

CREATE BROKER MACHINES FOR THE NEW PROVVMS

```
New-BrokerMachine `

    -CatalogUid "33333333-3333-3333-3333-333333333333" `

    -AdminAddress "MyDDC.MyDomain.Local" `
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    -MachineName "S-0-0-00-0000000000-0000000000-000000000-000000"
```

Where to go next

- If this is the first catalog created, Studio guides you to Create a delivery group

More information

- Create and manage connections and resources
- Connection to Red Hat OpenShift
- Create machine catalogs

Create a VMware catalog

Create machine catalogs describes the wizards that create a machine catalog.

NOTE:

Before creating a VMware catalog, you need to finish creating a connection to VMware. See Connection to VMware.

Create a machine catalog using a machine profile

You can create an MCS machine catalog using a machine profile. The source of the machine profile input is a VMware template. The machine profile captures the hardware properties from a VMware template and applies them to the newly provisioned VMs in the catalog.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Master image input (snapshot) and machine profile input (VMware template) must either be both vTPM enabled or both vTPM disabled. This rule applies to both `New-ProvScheme` and `Set-ProvScheme`.
- If the master image is vTPM enabled, then the VMware template can only come from the same VM source as the master image.
- Encrypted storage policy only supports full clone.
- The machine profile-based catalogs utilize the provided VMware template to gather storage controller information, relying on the attached virtual disks. The template must include a virtual disk which is required to retrieve the storage controller information that is used to configure virtual disks for the virtual machines.

The VMware template in the machine profile must exist during the catalog life cycle to allow provisioning of VMs to the catalog. Without a VMware template, you cannot provision new VMs. When a VMware template gets deleted, you must supply a new template using the `Set-ProvScheme` command.

- MCS captures the properties of a VMware template. You can create a new VMware template referencing stored properties of the VMware template using the `Get-Provscheme` command.
- Alternatively, if the machine catalog and provisioned VMs exist, then an MCS provisioned machine can also be used to create a new VMware template.
- When MCSIO is enabled, you can update the memory and disk cache sizes after creating the MCS catalogs.

Based on different OS, you can create a machine catalog with different configurations:

- If Windows 11 is installed on the master image, then it is a requirement to have vTPM enabled for the master image. Therefore, the VMware template, which is a source of machine profile, must have vTPM attached to it.
- If Windows 10 is installed on the master image with no vTPM attached, then you can create a machine catalog with non-vTPM VMware template as source for machine profile.

There is another configuration where you can create a machine catalog using full copy disk mode with machine profile template applied with encrypted storage policy.

To create a machine catalog using PowerShell commands with machine profile as input:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Open a **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific PowerShell modules.
3. Run the following commands:

   - To create a machine catalog with vTPM attached VMware template as a source for machine profile input and windows11 installed master image:

```
$identityPool = New-AcctIdentityPool

-IdentityPoolName "<string>"

-NamingScheme "<string>-###"

-NamingSchemeType Numeric

-Domain "<domain name"

-ZoneUid "<Uid>"  -Scope @()
```

```
$provScheme =New-ProvScheme  -CleanOnBoot

-HostingUnitName "vSanRg"

-IdentityPoolName "<string>"

-InitialBatchSizeHint 1

-MasterImageVM "XDHyp:\HostingUnits\<hosting unit name>\<snapshot
name>.snapshot"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\<hosting unit name>\
\<network name>.network"}

-ProvisioningSchemeName "<string>"

-Scope @() -VMCpuCount 4  -VMMemoryMB 6144

-MachineProfile "XDHyp:\HostingUnits\<hosting unit name>\<template
name>.template"

-TenancyType Shared
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-FunctionalLevel "L7_20"
```

```
$catalog = New-BrokerCatalog

-AllocationType "Static"

-PersistUserChanges  "OnLocal"

-Description "<string>"  -IsRemotePC $False

-MinimumFunctionalLevel 'L7_9' -Name "<catalog name>"
-ProvisioningType 'MCS'

-Scope @()  -SessionSupport "SingleSession"

-ZoneUid "<Uid>"
```

```
Set-BrokerCatalog -Name "<string>"

-ProvisioningSchemeId $provScheme.ProvisioningSchemeUid.Guid
```

- To create a machine catalog with non-vTPM VMware template as source for machine profile and Windows10 installed master image:

```
$identityPool = New-AcctIdentityPool

-IdentityPoolName "<string>"

-NamingScheme "<string>-###"

-NamingSchemeType Numeric

-Domain "<domain name>"

-ZoneUid "<Uid>"  -Scope @()
```

```
$provScheme =New-ProvScheme  -CleanOnBoot

-HostingUnitName "<string>"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-IdentityPoolName "<string>"

-InitialBatchSizeHint 1

-MasterImageVM "XDHyp:\HostingUnits\<hosting unit name>\<snapshot
name>.snapshot"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\<hosting unit name>\
\<string>.network"}

-ProvisioningSchemeName "<string>"  -Scope @() -VMCpuCount 4  -
VMMemoryMB 8192

-MachineProfile "XDHyp:\HostingUnits\<hosting unit name>\<template
name>.template"

-TenancyType Shared  -FunctionalLevel "L7_20"
```

```
$catalog = New-BrokerCatalog

-AllocationType "Static"

-PersistUserChanges  "OnLocal"  -Description "<string>"  -IsRemotePC
$False

-MinimumFunctionalLevel 'L7_9' -Name "<string>" -ProvisioningType
'MCS' -Scope @()  -SessionSupport "SingleSession" -ZoneUid "<Uid"
```

```
Set-BrokerCatalog -Name "<string>"

-ProvisioningSchemeId $provScheme.ProvisioningSchemeUid.Guid
```

- To create a machine catalog using Full copy disk mode with machine profile template applied with encrypted storage policy:

```
$identityPool = New-AcctIdentityPool

-IdentityPoolName "<string>"

-NamingScheme "<string>-###"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-NamingSchemeType Numeric

-Domain "<domain name>"

-ZoneUid "<Uid>"  -Scope @()
```

```
$provScheme =New-ProvScheme

-HostingUnitName "<string>"

-IdentityPoolName "<string>" -InitialBatchSizeHint 1

-MasterImageVM "XDHyp:\HostingUnits\<hosting unit name>\<snapshot
name>.snapshot"

-NetworkMapping @{"0"="XDHyp:\HostingUnits\<hosting unit name>\
\<string>.network"}

-ProvisioningSchemeName "<string>"  -Scope @() -VMCpuCount 4  -
VMMemoryMB 8192

-MachineProfile "XDHyp:\HostingUnits\<hosting unit name>\<template
name>.template"

-TenancyType Shared  -FunctionalLevel "L7_20"

-UseFullDiskCloneProvisioning
```

```
$catalog = New-BrokerCatalog

-AllocationType "Static"

-PersistUserChanges  "OnLocal"

-Description "<string>"

-IsRemotePC $False

-MinimumFunctionalLevel 'L7_9' -Name "<string>" -ProvisioningType
'MCS' -Scope @()
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-SessionSupport "SingleSession" -ZoneUid "<Uid>"
```

```
Set-BrokerCatalog -Name "<string>"

-ProvisioningSchemeId $provScheme.ProvisioningSchemeUid.Guid
```

- To update a machine profile, use the `Set-ProvScheme` command. For example:

```
Set-ProvScheme -ProvisioningSchemeName 'name' -IdentityPoolName
'name' -MachineProfile 'XDHyp:\HostingUnits\<hosting unit
name>\<template name>.template
```

Check for multiple NICs

You get various error messages during the pre-flight checks for multiple NICs when using a machine profile and the `NetworkMapping` parameter in the `New-ProvScheme` and `Set-ProvScheme` commands.

The pre-flight checklist for multiple NICs is as follows:

- Only NIC count from the machine profile template is used and validated. The network to which these NICs point towards, is not used or validated against the hosting unit networks.
- If the NIC count in the machine profile template is greater than the number of networks in the hosting unit, you get an error message.
- If the NIC count in the machine profile template is zero, you get an error message. When the NIC count in the machine profile template is one, then:
  - If no network mapping is specified in the `New-ProvScheme` or `Set-ProvScheme` command, and the hosting unit network is one, then the hosting unit network is used.
  - If a network mapping is specified, then the specified network mapping is used if it is valid.
- When the NIC count in the machine profile template is greater than 1, or the hosting unit network count is greater than 1, then:
  - Valid network mapping is required in the command, and it should provide mapping for each NIC (that is, the NetworkMapping count must be the same as the machine profile NIC count).
  - Multiple NICs cannot be mapped to the same network in the hosting unit.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `NetworkMapping` count and machine profile NIC count must be less than or equal to the hosting unit network count.
- `NetworkMapping` must be provided for each id from 0 to n-1, where n is the number of network adapters in the machine profile template.

Provision a Data disk on MCS created VM

A Data disk allows storage of persistent data like event logs, security traces, and application data. You can create and assign a persistent or non-persistent Data disk to an MCS created persistent or non-persistent VM of an MCS machine catalog in VMware.

Provision the Data disk from the master image. The prepared master image Data disk is stored in `<Prov Scheme Name>-dataDisk-<datastoreId>` folder.

You can create both machine profile and non-machine profile-based MCS catalog. For machine profile-based MCS catalog, you can use the same master image VM as the Data disk source for the machine profile.

The provisioned VM's Data disk derives properties like storage policy and size from the master image. For machine profile based catalog, it can optionally use the VM template's Data disk for deriving the properties. If the VM template doesn't have a data disk, then Storage's default policy is used.

The Data disk of the provisioned VM is created in the same directory as the OS and Identity disk.

Supported Data disk scenarios

Following are the supported OS disk and Data disk scenarios:

- Persistent OS disk with persistent Data disk
- Non-persistent OS Disk with persistent Data disk
- Non-persistent OS Disk with non-persistent Data disk

NOTE:

A persistent machine catalog cannot have a non-persistent Data disk.

Limitations

The following operations are currently not supported:

- Provisioning of more than one Data disk.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Resetting the Data disk.
- Updating an MCS catalog with a Data disk to a non-Data disk MCS catalog. Similarly, updating an MCS catalog without a Data disk to a Data disk MCS catalog.

Key steps

1. Create a master image VM with a Data disk in VMware. For a machine profile-based MCS catalog, you can use the same master image VM as the Data disk source for the machine profile.
2. Create an MCS machine catalog with Data disk provisioned VMs using the `New-ProvScheme` PowerShell command. See Create a catalog with Data disk provisioned VMs.
3. Add VMs to the catalog using the `New-ProvVM` PowerShell command.
4. Log in to the VM to see if the Data disk is formatted correctly. If there is content on the Data disk referenced in the master image VM, then that content is also on the Data disk.

Create a master image VM with Data disk in VMware

1. Create a VM with two hard disks. One is the OS disk and second is the Data disk. Follow this guide to add a New Hard Disk (Data disk) to an existing VM.
2. Log in to the VM to initialize the disk, set the desired drive letter, and add the content.

Create a catalog with Data disk provisioned VMs

Include the following parameters in the `New-ProvScheme` PowerShell command to provision an MCS machine catalog with Data disk.

- `DataDisk`: To Specify the path of the Data disk specified.
- `DataDiskPersistence`: To indicate whether the DataDisk is persistent or non-persistent.

  The Data disk cannot be non-persistent if `CleanOnBoot` is false. You cannot change the value of `DataDiskPersistence` for a machine catalog once configured.

After you create the catalog, add VMs using the `New-ProvVM` command.

Image update

Run `Publish-ProvMasterVMImage` command to update the source of the OS and Data disk. After running the `Publish-ProvMasterVMImage` command:

- The new VMs are created with the updated OS and Data disks.
- The existing VMs' non-persistent disks are updated on the next power cycle.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The existing VMs' persistent disks are not updated on the next power cycle.

Delete the Data disk

If you delete the catalog, the Data disk is deleted unless you use `forgetVM` or `purgeDBOnly` option. If you delete the VM, the Data disk is deleted unless you use the `forgetVM` or `purgeDBOnly` option. These conditions are applicable to only persistent MCS machine catalogs.

Troubleshooting

If the catalog fails to create, see CTX294978.

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage a VMware catalog.

More information

- Create and manage connections and resources
- Connection to VMware
- Connection to VMware cloud and partner solutions
- Create machine catalogs

Create a XenServer® catalog

Create machine catalogs describes the wizards that create a machine catalog. The following information covers details specific to XenServer (formerly Citrix Hypervisor) virtualization environments.

NOTE:

Before creating a XenServer catalog, you need to finish creating a connection to XenServer. See Connection to XenServer.

Create a machine catalog using a GPU-capable XenServer

GPU-capable machines require a dedicated master image. Those VMs require video card drivers that support GPUs. Configure GPU-capable machines to allow the VM to operate with software that uses the GPU for operations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. In XenCenter®, create a VM with standard VGA, networks, and vCPU.
2. Update the VM configuration to enable GPU use (either Passthrough or vGPU).
3. Install a supported operating system and enable RDP.
4. Install Citrix VM Tools and NVIDIA drivers.
5. Turn off the Virtual Network Computing (VNC) Admin Console to optimize performance, and then restart the VM.
6. You are prompted to use RDP. Using RDP, install the VDA and then restart the VM.
7. Optionally, create a snapshot for the VM as a baseline template for other GPU master images.
8. Using RDP, install customer-specific applications that are configured in XenCenter and use GPU capabilities.

Create a machine profile-based machine catalog using PowerShell

When you create a catalog to provision machines using MCS, you can use a machine profile to capture the hardware properties from a virtual machine and apply them to newly provisioned VMs in the catalog. If the `MachineProfile` parameter is not used, the hardware properties are captured from the master image VM or snapshot.

You can also create an MCS machine catalog using a machine profile that is enabled with vTPM. This helps to create machine catalogs of Windows 11 VMs with vTPM enabled.

NOTE:

- Currently, you can use only a snapshot as a machine profile input.
- If master image input is vTPM enabled, then the machine profile input must also be vTPM enabled. This rule applies to both `New-ProvScheme` and `Set-ProvScheme`.
- If the master image is vTPM enabled, then the machine profile can only come from the same VM source as the master image.
- On catalog creation, the vTPM of the VM should be the same vTPM that is in use for the master image snapshot.

You can update the memory and disk cache sizes after creating the MCS catalogs when MCSIO is enabled. You can explicitly configure the following parameters to overwrite the values of the parameters in the machine profile input:

- `VMCpuCount`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `VMMemory`
- `NetworkMapping`

Create a catalog with a machine profile

1. Open the PowerShell window.
2. Run `asnp citrix*`.
3. Create an identity pool. The identity pool is a container for the Active Directory (AD) accounts for the VMs to be created. For example:

```
New-AcctIdentityPool -Domain "citrix-xxxxxx.local" -IdentityPoolName
"ExampleIdentityPool" -NamingScheme "abc1-##" -NamingSchemeType
"Numeric" -Scope @() -ZoneUid "xxxxxxxx"
```

4. Create the required AD computer accounts in Active Directory.

```
$password = "password123" | ConvertTo-SecureString -AsPlainText -Force

New-AcctADAccount -IdentityPoolName "ExampleIdentityPool" -Count 10
-ADUserName "citrix-xxxxxx\admin1" -ADPassword $password

Set-AcctAdAccountUserCert -IdentityPoolName "ExampleIdentityPool"
-ADUserName "citrix-xxxxxx\admin1" -ADPassword $password
```

5. Run the `New-ProvScheme` command to create a catalog. For example:

```
New-ProvScheme -CleanOnBoot -HostingUnitName "ExampleHostingUnit"
-IdentityPoolName "ExampleIdentityPool" -InitialBatchSizeHint 2
-CustomProperties '<CustomProperties xmlns="http://schemas.citrix.com/
2014/xd/machinecreation" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">

<Property xsi:type="StringProperty" Name="UseManagedDisks"
Value="true" />

</CustomProperties>'

-MasterImageVM "XDHyp:
\HostingUnits\ExampleHostingUnit\ExampleVDA.vm\ExampleVDA.snapshot"
-ProvisioningSchemeName "ExampleCatalog" -Scope @() -SecurityGroup @()
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-MachineProfile "XDHyp:
\HostingUnits\ExampleHostingUnit\ExampleMachineProfile.vm\ExampleSnapsh
ot.snapshot"
```

6. Register provisioning scheme as a broker catalog. For example:

```
$ConfigZone = Get-ConfigZone | Where-Object { $_.Name -eq "xxxxxx" }

New-BrokerCatalog -Name "MPLT1" -AllocationType Random -Description
"Machine profile catalog" -ProvisioningSchemeId fe7df345-244e-4xxxx-
xxxxxxxxx -ProvisioningType Mcs -SessionSupport MultiSession
-PersistUserChanges Discard -ZoneUid ($ConfigZone.Uid)
```

7. Add VMs to the catalog.

Update a catalog with a new machine profile

NOTE:

- The `Set-ProvScheme` command in this case does not change the machine profile of the existing VMs in the catalog. Only the newly created VMs added to the catalog have the new machine profile.
- You cannot convert a machine profile-based machine catalog to non-machine profile-based machine catalog.

To update a catalog with a new machine profile:

1. Run the `Set-ProvScheme` command. For example:

```
Set-ProvScheme -ProvisioningSchemeName "ExampleCatalog" -MachineProfile
"XDHyp:
\HostingUnits\ExampleHostingUnit\ExampleMachineProfileVm.vm\ExampleMach
ineProfileSnapshot.snapshot"
```

   For more information on the Set-ProvScheme command, see Set-ProvScheme.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Where to go next

- If this is the first catalog created, you are guided to create a delivery group.
- To review the entire configuration process, see Plan and build a deployment.
- To manage catalogs, see Manage machine catalogs and Manage a XenServer catalog.

More information

- Create and manage connections and resources
- Connection to XenServer
- Create machine catalogs

Identity pools of different machine identity join types

Using MCS, you can provision machines as non-domain-joined, on-premises AD joined, Microsoft Entra joined, or Microsoft Entra hybrid joined.

For information about how to configure machine identities in Studio, see Create machine catalogs.

For specific information on how to create identity pools of different machine identity join types, see the following:

- Identity pool of on-premises Active Directory joined machine identity
- Identity pool of Microsoft Entra joined machine identity
- Identity pool of Microsoft Entra hybrid joined machine identity
- Identity pool of Microsoft Intune enabled machine identity
- Identity pool of non-domain-joined machine identity

Identity pool of on-premises Active Directory joined machine identity

This article describes how to create identity pool of on-premises Active Directory joined machine identity using Citrix DaaS.

Use Studio

The following information is a supplement to the guidance in Create machine catalogs.

In the catalog creation wizard:

1. On the **Machine Identities** page:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Select identity type as **On-premises Active Directory**.

b. Select an Active Directory account option:

- **Create new Active Directory accounts**:
  - If you select **Create new Active Directory accounts** and do use an existing identity pool to create new accounts, then select a domain for those accounts and specify an account naming scheme.

    To find a specific domain quickly, type the domain name in the search box at the top of the **Location (domain)** dropdown and click **Enter**. **Web Studio** shows a progress indicator while it retrieves the matching domain.
  - If you select **Create new Active Directory accounts** and use an existing identity pool to create new accounts, then select an identity pool from the list.
- **Use existing Active Directory accounts**: You can browse or import from CSV file, and reset password or specify the same password for all accounts.

c. Click **Next**.

2. On the **Domain credentials** page, select a service account or enter credentials manually. For information on service accounts, see On-premises Active Directory service accounts.

Modify the service account association

To change the associated service account or add an association to an existing MCS machine catalog, use the **Edit Machine Catalog** page.

- To add a service account, click **Select service account** on the **Service Account** page.
- To change the service account association, click the edit icon on the **Service Account** page.

Use PowerShell

You can associate an on-premises service account with an MCS created machine catalog by associating an on-premises service account with the identity pool. You can create an identity pool or update an existing identity pool to associate it with a service account.

For example: To create a new identity pool and associate it with a service account, run the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-AcctIdentityPool -IdentityType ActiveDirectory -IdentityPoolName
MyPool -NamingScheme Acc#### -Domain MyDomain.com -NamingSchemeType
Numeric -OU "CN=MyOU,DC=MyDomain,DC=com" -ServiceAccountUid
$serviceAccountUid
```

For example: To update an existing identity pool to associate it with a service account, run the following:

```
$identityPoolUid = (Get-ProvScheme -ProvisioningSchemeName
"MyProvScheme").IdentityPoolUid

Set-AcctIdentityPool -IdentityPoolUid $identityPoolUid -ServiceAccountUid
$serviceAccountUid
```

NOTE:

The `$serviceAccountUid` must be a valid UID of an on-premises Active Directory service account.

More information

- Service accounts for machine identity management
- On-premises Active Directory service accounts

Identity pool of Microsoft Entra joined machine identity

This article describes how to create identity pool of Microsoft Entra joined machine identity using Citrix DaaS.

For information on requirements, limitations, and considerations, see Microsoft Entra joined.

Before you create the machine catalog, you need the following:

1. New resource location
    - Navigate to the Citrix Cloud™ admin UI > upper left hamburger menu > **Resource Locations**.
    - Click **+ Resource Location**.
    - Enter a name for the new resource location and click **Save**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Create a hosting connection. See Create and manage connections section for details. When deploying machines on Azure, see Connection to Azure Resource Manager.

You can create Microsoft Entra joined catalogs by using Studio or PowerShell.

Use Studio

The following information is a supplement to the guidance in Create machine catalogs. To create Microsoft Entra joined catalogs, follow the general guidance in that article, minding the details specific to Microsoft Entra joined catalogs.

In the catalog creation wizard:

1. On the **Image** page:
   - Select 2106 or later as the functional level.
   - Select **Use a machine profile** and select the appropriate machine from the list.
2. On the **Machine Identities** page:
   a. Select **Microsoft Entra joined**. The created machines are owned by an organization and are signed into with a Microsoft Entra account that belongs to that organization. They exist only in the cloud.

   NOTE:

   - The **Microsoft Entra joined** identity type requires version 2106 or later as the minimum functional level for the catalog.
   - The machines are joined to the Microsoft Entra domain associated with the tenant to which the hosting connection is bound.

   b. Click **Select service account** and select an available service account from the list. If a suitable service account is not available for the Microsoft Entra tenant that the machine identities will join to, you can create a service account. For information on service account, see Microsoft Entra service accounts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The service account that you selected might be in an unhealthy status due to various reasons. You can go to **Administrators > Service Accounts** to view details and fix the issues according to the recommendations. Alternatively, you can proceed with the machine catalog operation and fix the issues later. If you do not fix the issue, stale Microsoft Entra joined or Microsoft Intune enrolled devices are generated that can block Microsoft Entra join of the machines.

c. Click **Add Extension Attributes** to store unique, custom data directly on your Entra ID device objects. On the **Add Extension Attributes** page, add **Extension attributes** and **Value**.

NOTE:

- You can add a maximum of 15 extension attributes.
- The name must be unique and the value can't be empty.

d. Select an Active Directory account option:

- **Create new Active Directory accounts**:
  - If you select **Create new Active Directory accounts** and do use an existing identity pool to create new accounts, then select a domain for those accounts and specify an account naming scheme.
  - If you select **Create new Active Directory accounts** and use an existing identity pool to create new accounts, then select an identity pool from the list.
- **Use existing Active Directory accounts**: You can browse or import from a CSV file, and reset the password or specify the same password for all accounts.

- Specify an account naming scheme.

Users must be granted explicit access in Azure to log into the machines using their Microsoft Entra credentials. See Microsoft Entra joined section for more details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add or modify extension attributes

To change or add additional extension attributes to an existing MCS machine catalog, or add extension attributes to an MCS catalog without a service account, use the **Edit Machine Catalog** wizard.

- To change or add additional extension attributes, navigate to the **Microsoft Entra Device Extension Attributes** page. Click the pencil icon, and add or update extension attributes.
- To add extension attributes to an MCS catalog without a Microsoft Entra service account:

  a. Navigate to the **Service Account** page. Select a Microsoft Entra service account for the Microsoft Intra ID.

  b. Go to the Microsoft Entra Device Extension Attributes page, click **Add Extension Attributes**.

Modify the service account association

To change the associated service account or add an association to an existing MCS machine catalog, use the **Edit Machine Catalog** page.

- To add a service account, click **Select service account** on the **Service Account** page.
- To change the service account association, click the edit icon on the **Service Account** page.

Use PowerShell

The following are **PowerShell** steps equivalent to operations in Studio.

The difference between on-premises AD joined catalogs and Microsoft Entra joined ones lies in the creation of the identity pool and the provisioning scheme.

You must associate a Microsoft Entra service account with the identity pool, and then create the machine catalog. You can either create a new identity pool or update an existing identity pool to associate it with a service account.

Create new identity pool

For example: To create a new identity pool and associate it with a service account, run the following:

```
New-AcctIdentityPool -IdentityType AzureAD -IdentityPoolName MyPool
-NamingScheme Acc#### -NamingSchemeType Numeric -ServiceAccountUid
$serviceAccountUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example: To create a new identity pool with specified extension attributes and associate it with a service account, run the following:

```
New-AcctIdentityPool -IdentityPoolName MyPool -NamingScheme ACC####
-NamingSchemeType Numeric -Domain "abc.local" -IdentityType AzureAD
-ServiceAccountUid $serviceAccountUid -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

When a VM is powered on for the first time, after joining Microsoft Entra ID, the VM reports its Entra ID deviceId to MCS.

For example: To check the `EntraIDDeviceID`, run `Get-AcctADAccount` or `Get-AcctIdentity`.

```
Get-AcctADAccount -IdentityPoolName MyPool
```

After reboot, for persistent VMs, the `EntraIDDeviceID` remains the same. For non-persistent VMs, there is a new `EntraIDDeviceID` after every reboot.

NOTE:

MCS automatically removes associated extension attributes when you delete a VM from the catalog but don't delete from Azure.

Update existing identity pool

For example: To update an existing identity pool to associate it with a service account, run the following:

```
$identityPoolUid = (Get-ProvScheme -ProvisioningSchemeName
"MyProvScheme").IdentityPoolUid

Set-AcctIdentityPool -IdentityPoolUid $identityPoolUid -ServiceAccountUid
$serviceAccountUid
```

NOTE:

The `$serviceAccountUid` must be a must be a valid UID of a Microsoft Entra service account.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example: To edit extension attributes for the existing catalog, run the following:

NOTE:

- After upgrading existing catalog VMs to VDA version 2511 or later, a reboot is necessary. This reboot allows the VM to report its Entra ID deviceId to MCS, enabling MCS to then configure the VM's extension attributes.
- The existing catalog should have an AzureAD type of service account with permission "Device.ReadWrite.All".

To add some new attributes:

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

To remove some existing attributes

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{}
```

OR

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{extensionAttribute1 = ""; extensionAttribute2 = ""}
```

`Set-AcctIdentityPool` also updates the Entra ID device's extension attributes for VMs that are already joined to Entra ID and possess an `EntraIDDeviceID` value within their identities.

Create Microsoft Entra joined catalogs

To create a provisioning scheme for Microsoft Entra joined catalogs, the **MachineProfile** parameter is required in `New-ProvScheme`. For example:

```
New-ProvScheme -CustomProperties "<CustomProperties xmlns=`"http://
schemas.citrix.com/2014/xd/machinecreation`" xmlns:xsi=`"http://
www.w3.org/2001/XMLSchema-instance`"><Property xsi:type=`"StringProperty`"
Name=`"UseManagedDisks`" Value=`"true`" /><Property
xsi:type=`"StringProperty`" Name=`"StorageType`"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Value=`"StandardSSD_LRS`" /><Property xsi:type=`"StringProperty`"
Name=`"LicenseType`" Value=`"Windows_Server`" /></CustomProperties>"
-HostingUnitName "AzureResource" -IdentityPoolName "AzureADJoinedCatalog"
-InitialBatchSizeHint 1 -MachineProfile "XDHyp:
\HostingUnits\AzureResource\image.folder\azuread-
rg.resourcegroup\MasterVDA.vm" -MasterImageVM "XDHyp:
\HostingUnits\AzureResource\image.folder\azuread-rg.resourcegroup\azuread-
small_OsDisk_1_5fb42fadf7ff460bb301ee0d56ea30da.manageddisk"
-NetworkMapping @{"0"="XDHyp:
\HostingUnits\AzureResource\virtualprivatecloud.folder\East
US.region\virtualprivatecloud.folder\azuread-rg.resourcegroup\azuread-
vnet.virtualprivatecloud\Test_VNET.network"} -ProvisioningSchemeName
"AzureADJoinedCatalog" -RunAsynchronously -Scope @() -SecurityGroup @()
-ServiceOffering "XDHyp:
\HostingUnits\AzureResource\serviceoffering.folder\Standard_DS1_v2.service
offering"
```

To create a Microsoft Entra catalog using a prepared image. For Example:

```
New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
<preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid> -IdentityPoolUid
<IdentityPoolUid> [-CleanOnBoot] -NetworkMapping @{"0"="XDHyp:
\HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.folder
\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<sunNetN
ame>.network"} -ServiceOffering <serviceofferingPath> [-MachineProfile
<machineProfilePath>] [-CustomProperties <>]
```

View the status of the Microsoft Entra join process

In Studio, the status of the Microsoft Entra join process is visible when Microsoft Entra joined machines in a delivery group are in a powered-on state. To view the status, use Search to identify those machines and then for each check **Machine Identity** on the **Details** tab in the lower pane. The following information can appear in **Machine Identity**:

- Microsoft Entra joined
- Not yet joined to Microsoft Entra ID

NOTE:

If the machines fail to be in Microsoft Entra joined state, they do not register with the Delivery Controller. Their registration status appears as **Initialization.**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Also, using Studio, you can learn why machines are unavailable. To do that, click a machine on the **Search** node, check **Registration** on the **Details** tab in the lower pane, and then read the tooltip for additional information.

Delivery Group

See Create delivery groups section for details.

Enable Rendezvous

Once the delivery group has been created, you can enable Rendezvous. See Rendezvous V2 for details.

Troubleshoot

If machines fail to be Microsoft Entra joined, do the following:

- Check if the system assigned managed identity is enabled for the machines. MCS-provisioned machines must have this enabled automatically. The Microsoft Entra join process fails without a system-assigned managed identity. If the system assigned managed identity is not enabled for MCS-provisioned machines, then the possible reason is:
  - `IdentityType` of the identity pool associated with the provisioning scheme is not set to `AzureAD`. You can verify this by running `Get-AcctIdentityPool`.
- For catalogs that use master images with VDA version 2206 or earlier, check the provisioning status of the **AADLoginForWindows** extension for the machines. If the **AADLoginForWindows** extension does not exist, possible reasons are:
  - `IdentityType` of the identity pool associated with the provisioning scheme is not set to `AzureAD`. You can verify this by running `Get-AcctIdentityPool`.
  - The **AADLoginForWindows** extension installation is blocked by Azure policy.
- To troubleshoot **AADLoginForWindows** extension provisioning failures, you can check logs under `C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.ActiveDirectory.AADLoginForWindows` on the MCS-provisioned machine.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

MCS does not rely on the `AADLoginForWindows` extension to join a VM to Microsoft Entra ID when using a master image with VDA version 2209 or later. In this case, the `AADLoginForWindows` extension will not be installed on the MCS-provisioned machine. Therefore, `AADLoginForWindows` extension provisioning logs can't be collected.

- Check the Microsoft Entra join status and debug logs by running `dsregcmd /status` command on the MCS-provisioned machine.
- Check Windows event logs under **Application and Services Logs > Microsoft > Windows > User Device Registration**.
- Check if Microsoft Entra device management is correctly configured by running `Get-Item -LiteralPath XDHyp:\Connections\${HostingConnectionName}`.

  Ensure that the value of:

  - `AzureAdDeviceManagement` property in `CustomProperties` is **true**
  - `Citrix_MCS_AzureAdDeviceManagement_PermissionGranted` property in metadata is **true**

  If `Citrix_MCS_AzureAdDeviceManagement_PermissionGranted` is **false**, it indicates that the `ServicePrincipal` of the application used by the hosting connection is not granted with sufficient permissions to perform Microsoft Entra device management. To resolve this, assign the `ServicePrincipal` with the **Cloud Device Administrator** role.

Microsoft Entra dynamic security groups

Dynamic group rules place the VMs in the catalog to a dynamic security group based on the naming scheme of the machine catalog.

If the naming scheme of the machine catalog is Test### (where, # means number), Citrix® creates the dynamic membership rule \^*Test{3}$* in the dynamic security group. Now, if the name of the VM created by Citrix is anything from Test001 to Test999, then the VM is included in the dynamic security group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If the name of the VM created by you manually is anything from Test001 to Test999, then also the VM is included in the dynamic security group. This is one of the limitations of the dynamic security group.

The dynamic security group feature is useful when you want to manage the VMs by Microsoft Entra ID. This is also useful when you want to apply Conditional Access policies or distribute apps from Intune by filtering the VMs with Microsoft Entra dynamic security group.

You can use **PowerShell** commands to:

- Create a machine catalog with Microsoft Entra dynamic security group
- Enable security group feature for a Microsoft Entra catalog
- Delete a machine catalog with Microsoft Entra joined device security group

IMPORTANT:

- To create a machine catalog with Microsoft Entra dynamic security group, add machines to the catalog, and delete the machine catalog, you must have a Microsoft Entra access token. For information on getting the Microsoft Entra access token, see `<https://docs.microsoft.com/en-us/graph/graph-explorer/graph-explorer-features#consent-to-permissions/>`.
- To request an access token in Microsoft Entra ID, Citrix requests the **Group.ReadWrite.All** permission for the Microsoft Graph API. An Microsoft Entra user who has tenant-wide admin consent permission can grant **Group.ReadWrite.All** permission for the Microsoft Graph API. For information on how to grant tenant-wide admin consent to an application in Microsoft Entra ID, see the Microsoft document `<https://learn.microsoft.com/en-us/entra/identity/enterprise-apps/grant-admin-consent>`.
- You don't need a Microsoft Entra access token if you use a Microsoft Entra service account. For information on service accounts, see Service accounts for machine identity management.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a machine catalog with Microsoft Entra dynamic security group

1. In the machine catalog setup the user interface of the web-based console, on the **Machine Identities** page, select **Microsoft Entra joined**.
2. Log in to Microsoft Entra ID.
3. Get the access token to the MS Graph API. Use this access token as a value of `$AzureADAccessToken` parameter when you run the **PowerShell** commands. You don't need a Microsoft Entra access token if you use a Microsoft Entra service account.
4. Run the following command to verify if the dynamic security group name exists in the tenant.

   ```
   Get-AcctAzureADSecurityGroup

   –AccessToken  $AzureADAccessToken

   –Name "SecurityGroupName"
   ```

   Or, run the following if you are using a Microsoft Entra service account:

   ```
   Get-AcctAzureADSecurityGroup -ServiceAccountUid <service account uid> –
   Name "SecurityGroupName"
   ```

5. Create a machine catalog using the Tenant ID, access token, and dynamic security group. Run the following command to create an IdentityPool with `IdentityType=AzureAD` and create a dynamic security group in Azure.

   ```
   New-AcctIdentityPool

   -AllowUnicode

   -IdentityPoolName "SecurityGroupCatalog"

   -NamingScheme "SG-VM-###"

   -NamingSchemeType "Numeric" -Scope @()

   -ZoneUid "81291221-d2f2-49d2-ab12-bae5bbd0df05"

   -WorkgroupMachine

   -IdentityType "AzureAD"
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-DeviceManagementType "None"

-AzureADTenantId  620387bb-9167-4bdd-8435-e3dccc58369e

-AzureADSecurityGroupName "SecurityGroupName"

-AzureADAccessToken $AzureADAccessToken
```

Or, run the following if you are using a Microsoft Entra service account:

```
New-AcctIdentityPool  -AllowUnicode -AzureADSecurityGroupName
"<security group name>" -AzureADTenantId "<Azure tenant id>"
-DeviceManagementType "Intune" -IdentityPoolName "dynamic security
group test" -IdentityType "AzureAD"  -NamingScheme "<naming scheme>"
-NamingSchemeType "Numeric" -Scope @() -ServiceAccountUid @("<service
account uid>") -StartCount 1 -WorkgroupMachine -ZoneUid "<Zone UID>"
```

Enable security group feature for a Microsoft Entra catalog

You can enable the dynamic security feature for a Microsoft Entra catalog that was created without the dynamic security group feature enabled. To do this:

1. Manually create a new dynamic security group. You can also reuse an existing dynamic security group.
2. Log in to Microsoft Entra ID, and get the access token to the MS Graph API. Use this access token as a value of `$AzureADAccessToken` parameter when you run the **PowerShell** commands.

   NOTE:

   - For information on the permissions required by the Microsoft Entra user, see `<https://learn.microsoft.com/en-us/entra/identity/enterprise-apps/grant-admin-consent?pivots=portal#prerequisites/>`.
   - You don’t need a Microsoft Entra access token if you use a Microsoft Entra service account.

3. Run the following command to connect the identity pool to the created Microsoft Entra dynamic security group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-AcctIdentityPool

-IdentityPoolName "SecurityGroupCatalog"

-AzureADTenantId 620387bb-9167-4bdd-8435-e3dccc58369e

-AzureADSecurityGroupNam "ExistingSecurityGroupName"

-AzureADAccessToken $AzureADAccessToken
```

Or, run the following if you are using a Microsoft Entra service account:

```
Set-AcctIdentityPool

-IdentityPoolName "SecurityGroupCatalog"

-AzureADTenantId 620387bb-9167-4bdd-8435-e3dccc58369e

-AzureADSecurityGroupNam "ExistingSecurityGroupName"

-ServiceAccountUid @("<service account uid>") -StartCount 1
-WorkgroupMachine -ZoneUid "<Zone UID>"
```

If you update the naming scheme, Citrix updates the naming scheme to a new membership rule. If you delete the catalog, the membership rule gets deleted, and not the security group.

Delete a machine catalog with Microsoft Entra joined device security group

When you delete a machine catalog, the Microsoft Entra joined device security group is also deleted.

To delete the Microsoft Entra dynamic security group, do the following:

1. Log in to Microsoft Entra ID.
2. Get the access token to the MS Graph API. Use this access token as value of `$AzureADAccessToken` parameter when you run the **PowerShell** commands. You don't need a Microsoft Entra access token if you use a Microsoft Entra service account.
3. Run the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Remove-AcctIdentityPool

-IdentityPoolName "SecurityGroupCatalog"

-AzureADAccessToken $AzureADAccessToken
```

Or, run the following if you are using a Microsoft Entra service account:

```
Remove-AcctIdentityPool

-IdentityPoolName "SecurityGroupCatalog"

-ServiceAccountUid @("<service account uid>") -StartCount 1
-WorkgroupMachine -ZoneUid "<Zone UID>"
```

Create a Microsoft Entra dynamic security group under an existing Microsoft Entra ID assigned security group

You can create a Microsoft Entra dynamic security group under an existing Microsoft Entra ID assigned security group. You can do the following:

- Get security group information.
- Get all Microsoft Entra ID assigned security groups that are synced from on-premises AD server or the assigned security groups to which Microsoft Entra roles can be assigned.
- Get all Microsoft Entra dynamic security groups.
- Add the Microsoft Entra dynamic security group as a member of the Microsoft Entra ID assigned group.
- Remove the membership between Microsoft Entra dynamic security group and Microsoft Entra ID assigned security group when Microsoft Entra dynamic security group is deleted along with the machine catalog.

You can also see explicit error messages when any of the operations fail.

Requirement:

You must have the access token to the MS Graph API when you run the **PowerShell** commands. You don't need a Microsoft Entra access token if you use a Microsoft Entra service account. Therefore, instead of `-AccessToken <token>`, use ServiceAccountUid `<service account uid>`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To get the access token:

1. Open Microsoft graph explorer and log in to Microsoft Entra ID.
2. Make sure that you have consent to **Group.ReadWrite.All** and **GroupMember.ReadWrite.All** permissions.
3. Get access token from Microsoft graph explorer. Use this access token when you run the **PowerShell** commands.

To get security group information by group id:

1. Get the access token.
2. Find group object id from the Azure portal.
3. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token> -GroupId <GroupUid>
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup -ServiceAccountUid <guid> -GroupId
<GroupUid>
```

To get security groups by group display the name:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token>

-Name <TargetGroupDisplayName>
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup

-ServiceAccountUid <guid>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-Name <TargetGroupDisplayName>
```

To get security groups whose display the name contains a substring:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token>

-SearchString <displayNameSubString>
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup

-ServiceAccountUid <guid>

-SearchString <displayNameSubString>
```

To get all Microsoft Entra ID assigned security groups that are synced from on-premises AD server or the assigned security groups to which Microsoft Entra roles can be assigned:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token>

-Assigned true
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup

-ServiceAccountUid <guid>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-Assigned true
```

To get all Microsoft Entra dynamic security groups:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token>

-Dynamic true
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup

-ServiceAccountUid <guid>

-Dynamic true
```

To get Microsoft Entra ID assigned security groups with maximum record count:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroup

-AccessToken <token>

-Assigned true

-MaxRecordCount 10
```

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroup

-ServiceAccountUid <guid>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-Assigned true

-MaxRecordCount 10
```

To add Microsoft Entra dynamic security group as a member of Microsoft Entra ID assigned security group:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Add-AcctAzureADSecurityGroupMember

-AccessToken <token>

-GroupId <ASG-Id>

-RefGroupId <DSG-Id>
```

Or, run the following if you are using a Microsoft Entra service account:

```
Add-AcctAzureADSecurityGroupMember

-ServiceAccountUid <guid>

-GroupId <ASG-Id>

-RefGroupId <DSG-Id>
```

To get Microsoft Entra ID assigned security group members:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Get-AcctAzureADSecurityGroupMember

-AccessToken <token>

-GroupId <ASG-Id>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Or, run the following if you are using a Microsoft Entra service account:

```
Get-AcctAzureADSecurityGroupMember

-ServiceAccountUid <guid>

-GroupId <ASG-Id>
```

NOTE:

`Get-AcctAzureADSecurityGroupMember` provides you only the direct members of the security group type under Microsoft Entra ID assigned security group.

To remove the membership between Microsoft Entra dynamic security group and Microsoft Entra ID assigned security group when Microsoft Entra dynamic security group is deleted along with machine catalog:

1. Get the access token.
2. Run the following **PowerShell** command in the **PowerShell** console:

```
Remove-AcctIdentityPool

-IdentityPoolName "SecurityGroupCatalog"

-AzureADAccessToken $AzureADAccessToken
```

Or, run the following if you are using a Microsoft Entra service account:

```
Remove-AcctIdentityPool

-ServiceAccountUid <guid>

-IdentityPoolName "SecurityGroupCatalog"
```

Modify Microsoft Entra dynamic security group name

You can modify the Microsoft Entra dynamic security group name associated with a machine catalog. This modification makes the security group information stored in the Microsoft Entra identity pool object to be consistent with the information stored in the Azure portal.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The Microsoft Entra dynamic security groups do not include security groups synced from on-premises AD and other group types like Office 365 group.

You can modify the Microsoft Entra dynamic security group name using Studio and PowerShell commands.

To modify the Microsoft Entra dynamic security group name using **PowerShell**:

1. Open the **PowerShell** window.
2. Run `asnp citrix*` to load the Citrix-specific **PowerShell** modules.
3. Run the command `Set-AcctIdentityPool -AzureAdSeurityGroupName [DSG-Name]`.

You get appropriate error messages if the Microsoft Entra dynamic security group name cannot be modified.

More information

- Service accounts for machine identity management
- Microsoft Entra service accounts

Identity pool of Microsoft Entra hybrid joined machine identity

This article describes how to create identity pool of Microsoft Entra hybrid joined machine identity using Citrix DaaS.

For information on requirements, limitations, and considerations, see Microsoft Entra hybrid joined.

Use Studio

The following information is a supplement to the guidance in Create machine catalogs. To create Microsoft Entra hybrid joined catalogs, follow the general guidance in that article, minding the details specific to Microsoft Entra hybrid joined catalogs.

In the catalog creation wizard:

1. On the **Machine Identities** page:
    a. Select the identity type as **Microsoft Entra hybrid joined**.
    b. Under Advanced configurations, click **Select service account** and select an available service account from the list. If a suitable service account is not available that the machine

© 1997–2026 Citrix Systems, Inc. All rights reserved.

identities will join to, you can create a service account. For information on service account, see Microsoft Entra service accounts.

c. Click **Add Extension Attributes** to store unique, custom data directly on your Entra ID device objects. On the **Add Extension Attributes** page, add **Extension attributes** and **Value**.

> **NOTE:**
>
> - You can add a maximum of 15 extension attributes.
> - The name and value must be unique and can't be empty.

d. Select an Active Directory account option:

- **Create new Active Directory accounts**:
  - If you select **Create new Active Directory accounts** and do use an existing identity pool to create new accounts, then select a domain for those accounts and specify an account naming scheme.
  - If you select **Create new Active Directory accounts** and use an existing identity pool to create new accounts, then select an identity pool from the list.
- **Use existing Active Directory accounts**: You can browse or import from a CSV file, and reset the password or specify the same password for all accounts.

e. Click **Next**.

2. On the **Domain credentials** page, select a service account or enter credentials manually. Microsoft Entra hybrid joined identity pool can also be associated with an on-premises AD service account. For information on service accounts, see On-premises Active Directory service accounts.

Add or modify extension attributes

To change or add additional extension attributes to an existing MCS machine catalog, or add extension attributes to an MCS catalog without a service account, use the **Edit Machine Catalog** wizard.

- To change or add additional extension attributes, navigate to the **Microsoft Entra Device Extension Attributes** page. Click the pencil icon, and add or update extension attributes.
- To add extension attributes to an MCS catalog without a Microsoft Entra service account:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Navigate to the **Service Account** page. Select a Microsoft Entra service account for the Microsoft Intra ID.

b. Go to the Microsoft Entra Device Extension Attributes page, click **Add Extension Attributes**.

Use PowerShell

The following PowerShell steps are equivalent to operations in Studio.

The difference between on-premises AD joined catalogs and Microsoft Entra hybrid joined ones lies in the creation of the identity pool and the machine accounts.

Create new identity pool

For example: To create an identity pool along with the accounts for Microsoft Entra hybrid joined catalogs:

```
New-AcctIdentityPool -AllowUnicode -IdentityType "HybridAzureAD" -Domain
"corp.local" -IdentityPoolName "HybridAADJoinedCatalog" -NamingScheme
"HybridAAD-VM-##" -NamingSchemeType "Numeric" -OU
"CN=AADComputers,DC=corp,DC=local" -Scope @() -ZoneUid "81291221-
d2f2-49d2-ab12-bae5bbd0df05"

New-AcctADAccount -IdentityPoolName "HybridAADJoinedCatalog" -Count 10
-ADUserName "corp\admin1" -ADPassword $password

Set-AcctAdAccountUserCert -IdentityPoolName "HybridAADJoinedCatalog" -All
-ADUserName "corp\admin1" -ADPassword $password
```

NOTE:

The `$password` is the matching password for an AD user account with Write Permissions.

All other commands used to create Microsoft Entra hybrid joined catalogs are the same as for traditional on-premises AD joined catalogs.

You can also associate an on-premises service account with an MCS created machine catalog by associating an on-premises service account with the identity pool. You can create an identity pool or update an existing identity pool to associate it with a service account.

For example: To create a new identity pool and associate it with a service account, run the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-AcctIdentityPool -AllowUnicode -IdentityType "HybridAzureAD" -Domain
"corp.local" -IdentityPoolName "HybridAADJoinedCatalog" -NamingScheme
"HybridAAD-VM-##" -NamingSchemeType "Numeric" -OU
"CN=AADComputers,DC=corp,DC=local" -Scope @() -ZoneUid "81291221-
d2f2-49d2-ab12-bae5bbd0df05" -ServiceAccountUid $serviceAccountUid
```

For example: To create a new identity pool with specified extension attributes and associate it with a service account, run the following:

```
New-AcctIdentityPool -IdentityPoolName HybridAzureAD -NamingScheme ACC####
-NamingSchemeType Numeric -Domain "abc.local" -IdentityType HybridAzureAD
-ServiceAccountUid $serviceAccountUid -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

When a VM is powered on for the first time, after joining Microsoft Entra ID, the VM reports its Entra ID deviceId to MCS.

For example: To check the `EntraIDDeviceID`, run `Get-AcctADAccount` or `Get-AcctIdentity`.

```
Get-AcctADAccount -IdentityPoolName MyPool
```

After reboot, for persistent and non-persistent VMs, the `EntraIDDeviceID` remains the same.

NOTE:

MCS automatically removes associated device IDs and extension attributes when you delete a VM from the catalog but don't delete from Azure.

Update existing identity pool

For example: To update an existing identity pool to associate it with a service account, run the following:

```
$identityPoolUid = (Get-ProvScheme -ProvisioningSchemeName
"MyProvScheme").IdentityPoolUid
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-AcctIdentityPool -IdentityPoolUid $identityPoolUid -ServiceAccountUid
$serviceAccountUid
```

NOTE:

The `$serviceAccountUid` must be a valid UID of an on-premises Active Directory service account.

For example: To edit extension attributes for the existing catalog, run the following:

NOTE:

- After upgrading existing catalog VMs to VDA version 2511 or later, a reboot is necessary. This reboot allows the VM to report its Entra ID deviceId to MCS, enabling MCS to then configure the VM's extension attributes.
- The existing catalog should have an AzureAD type of service account with permission "Device.ReadWrite.All".

To add some new attributes:

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

To remove some existing attributes

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{}
```

OR

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{extensionAttribute1 = ""; extensionAttribute2 = ""}
```

`Set-AcctIdentityPool` also updates the Entra ID device's extension attributes for VMs that are already joined to Entra ID and possess an `EntraIDDeviceID` value within their identities.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a Hybrid Microsoft Entra catalog

You can also create a Hybrid Microsoft Entra catalog using a prepared image. For the complete set of PowerShell commands to create image definition, image version, and prepared image version spec, see:

- Azure virtualization environment: Use PowerShell.
- VMware virtualization environment: Use PowerShell

After creating the prepared image version spec, create the identity pool and machine catalog. For example:

```
New-AcctIdentityPool -IdentityPoolName "mypool" -NamingScheme ACC##  -
NamingSchemeType "Numeric"  -ZoneUid $zoneuid -Domain $domainName -OU
"OU=HAAD Computers,DC=haad,DC=link" -IdentityType "HybridAzureAD"

New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
<preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid> -IdentityPoolUid
<IdentityPoolUid> [-CleanOnBoot] -NetworkMapping @{"0"="XDHyp:
\HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.folder
\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<sunNetN
ame>.network"} -ServiceOffering <serviceofferingPath> [-MachineProfile
<machineProfilePath>] [-CustomProperties <>]
```

View the status of the hybrid Microsoft Entra join process

In Studio, the status of the hybrid Microsoft Entra join process is visible when Microsoft Entra hybrid joined machines in a delivery group are in a powered-on state. To view the status, use Search to identify those machines and then for each check **Machine Identity** on the **Details** tab in the lower pane. The following information can appear in **Machine Identity**:

- Microsoft Entra hybrid joined
- Not yet joined to Microsoft Entra ID

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- You might experience delayed hybrid Microsoft Entra join when the machine initially powers on. This is caused by the default machine identity sync interval (30 minutes of Microsoft Entra Connect). The machine is in Microsoft Entra hybrid joined state only after the machine identities are synced to Microsoft Entra ID through Microsoft Entra Connect.
- If machines fail to be in Microsoft Entra hybrid joined state, they are not registered with the Delivery Controller. Their registration status appears as **Initialization**.

Also, using Studio, you can learn why machines are unavailable. To do that, click a machine on the **Search** node, check **Registration** on the **Details** tab in the lower pane, and then read the tooltip for additional information.

Troubleshoot

If machines fail to be Microsoft Entra hybrid joined, do the following:

- Check if the machine account has been synced to Microsoft Entra ID through the Microsoft Microsoft Entra portal. If synced, **Not yet joined to Microsoft Entra ID** appears, indicating pending registration status.

  To sync machine accounts to Microsoft Entra ID, make sure:

  - The machine account is in the OU that is configured to be synced with Microsoft Entra ID. Machine accounts without the **userCertificate** attribute are not synced to Microsoft Entra ID even they are in the OU that is configured to be synced.
  - The attribute **userCertificate** populates in the machine account. Use Active Directory Explorer to view the attribute.
  - Microsoft Entra Connect must have been synced at least once after the machine account is created. If not, manually run the `Start-ADSyncSyncCycle -PolicyType Delta` command in the PowerShell console of the Microsoft Entra Connect machine to trigger an immediate sync.

- Check if the Citrix managed device key pair for hybrid Microsoft Entra join is correctly pushed to the machine by querying the value of **DeviceKeyPairRestored** under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Citrix**.

  Verify that the value is 1. If not, then possible reasons are:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

  - `IdentityType` of the identity pool associated with the provisioning scheme is not set to `HybridAzureAD`. You can verify this by running `Get-AcctIdentityPool`.
  - The machine is not provisioned using the same provisioning scheme of the machine catalog.
  - The machine is not joined to the local domain. Local domain joined is a prerequisite of the hybrid Microsoft Entra join.

- Check diagnostic messages by running the `dsregcmd /status /debug` command on the MCS-provisioned machine.
  - If hybrid Microsoft Entra join is successful, **AzureAdJoined** and **DomainJoined** are **YES** in the output of the command line.
  - If not, refer to the Microsoft documentation to troubleshoot the issues: `<https://docs.microsoft.com/en-us/azure/active-directory/devices/troubleshoot-hybrid-join-windows-current>`.
  - If you get the error message **Server Message: The user certificate is not found on the device with id: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx**, then run the following PowerShell command to repair the user certificate:

    ```
    Repair-AcctIdentity -IdentityAccountName TEST\VM1 -Target
    UserCertificate
    ```

For more information about the user certificate issue, see CTX566696.

Identity pool of Microsoft Intune enabled machine identity

This article describes how to create identity pool of Microsoft Intune enabled machine identity using Citrix DaaS.

You can create:

- Microsoft Entra joined catalogs enrolled in Microsoft Intune for persistent and non-persistent, single and multi-session VMs. For creating catalogs, see Create Microsoft Entra catalogs enrolled in Microsoft Intune.
- Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune for persistent single and multi-session VMs using device credential with co-management capability. For creating catalogs, see Create Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune. You can also create Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune for non-

© 1997–2026 Citrix Systems, Inc. All rights reserved.

persistent single and multi-session VMs. However, this is currently under Preview. See Enrollment of Hybrid Entra ID joined non-persistent VMs into Microsoft Intune.

For information on requirements, limitations, and considerations, see Microsoft Intune.

Create Microsoft Entra catalogs enrolled in Microsoft Intune

You can create Microsoft Entra catalogs enrolled in Microsoft Intune for persistent and non-persistent VMs using both Studio and PowerShell.

For information on requirements, limitations, and considerations, see:

- Requirements for Microsoft Entra joined catalogs enrolled in Microsoft Intune
- Limitations for Microsoft Entra joined catalogs enrolled in Microsoft Intune

Use Studio

The following information is a supplement to the guidance in Create machine catalogs.

In the catalog creation wizard:

- On the **Machine Identities** page:
  - Select **Microsoft Entra joined** and then **Enroll the machines in Microsoft Intune**. If enabled, enroll the machines in Microsoft Intune for management. You can create Microsoft Entra joined catalogs enrolled in Microsoft Intune for both persistent and non-persistent single-session and multi-session VMs. However, for non-persistent VMs, you must have the VDA version as 2407 or later.
  - Click **Select service account** and select an available service account from the list. If a suitable service account is not available for the Microsoft Entra tenant that the machine identities will join to, you can create a service account. For information on service account, see Microsoft Entra service accounts.

    NOTE:

    The service account that you selected might be in an unhealthy status due to various reasons. You can go to **Administrators > Service Accounts** to view details and fix the issues according to the recommendations. Alternatively, you can proceed with the machine catalog operation and fix the issues later. If you do not fix the issue, stale Microsoft Entra joined or Microsoft Intune enrolled devices are generated that can block Microsoft Entra join of the machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Click **Add Extension Attributes** to store unique, custom data directly on your Entra ID device objects. On the **Add Extension Attributes** page, add **Extension attributes** and **Value**.

  NOTE:

  - You can add a maximum of 15 extension attributes.
  - The name and value must be unique and can’t be empty.

Add or modify extension attributes

To change or add additional extension attributes to an existing MCS machine catalog, or add extension attributes to an MCS catalog without a service account, use the **Edit Machine Catalog** wizard.

- To change or add additional extension attributes, navigate to the **Microsoft Entra Device Extension Attributes** page. Click the pencil icon, and add or update extension attributes.
- To add extension attributes to an MCS catalog without a Microsoft Entra service account:

  a. Navigate to the **Service Account** page. Select a Microsoft Entra service account for the Microsoft Intra ID.

  b. Go to the Microsoft Entra Device Extension Attributes page, click **Add Extension Attributes**.

Use PowerShell

The following are the PowerShell steps that are equivalent to operations in Studio.

To enroll machines in Microsoft Intune using the Remote PowerShell SDK, use the `DeviceManagementType` parameter in `New-AcctIdentityPool`. This feature requires that the catalog is Microsoft Entra joined and that Microsoft Entra ID possesses the correct Microsoft Intune license. For example:

```
New-AcctIdentityPool -AllowUnicode -DeviceManagementType "Intune"
IdentityType="AzureAD" -WorkgroupMachine -IdentityPoolName
"AzureADJoinedCatalog" -NamingScheme "AzureAD-VM-##" -NamingSchemeType
"Numeric" -ServiceAccountUid $serviceAccountUid -Scope @() -ZoneUid
"81291221-d2f2-49d2-ab12-bae5bbd0df05"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example: To create a new identity pool with specified extension attributes and associate it with a service account, run the following:

```
New-AcctIdentityPool -IdentityPoolName MyPool -NamingScheme ACC####
-NamingSchemeType Numeric -Domain "abc.local" -IdentityType AzureAD
-ServiceAccountUid $serviceAccountUid -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

When a VM is powered on for the first time, after joining Microsoft Entra ID, the VM reports its Entra ID deviceId to MCS.

For example: To check the `EntraIDDeviceID`, run `Get-AcctADAccount` or `Get-AcctIdentity`.

```
Get-AcctADAccount -IdentityPoolName MyPool
```

After reboot, for persistent VMs, the `EntraIDDeviceID` remains the same. For non-persistent VMs, there is a new `EntraIDDeviceID` after every reboot.

NOTE:

MCS automatically removes associated extension attributes when you delete a VM from the catalog but don’t delete from Azure.

For example: To edit extension attributes for the existing catalog, run the following:

NOTE:

- After upgrading existing catalog VMs to VDA version 2511 or later, a reboot is necessary. This reboot allows the VM to report its Entra ID deviceId to MCS, enabling MCS to then configure the VM's extension attributes.
- The existing catalog should have an AzureAD type of service account with permission "Device.ReadWrite.All".

To add some new attributes:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

To remove some existing attributes

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{}
```

OR

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{extensionAttribute1 = ""; extensionAttribute2 = ""}
```

`Set-AcctIdentityPool` also updates the Entra ID device's extension attributes for VMs that are already joined to Entra ID and possess an `EntraIDDeviceID` value within their identities.

For example: To create a Microsoft Entra catalog enrolled in Microsoft Intune using a prepared image:

```
New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
<preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid> -IdentityPoolUid
<IdentityPoolUid> [-CleanOnBoot] -NetworkMapping @{"0"="XDHyp:
\HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.folder
\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<sunNetN
ame>.network"} -ServiceOffering <serviceofferingPath> [-MachineProfile
<machineProfilePath>] [-CustomProperties <>]
```

Troubleshoot

If machines fail to enroll in Microsoft Intune, do the following:

- Check if the MCS-provisioned machines are Microsoft Entra joined. The machines fail to enroll in Microsoft Intune if they are not Microsoft Entra joined. See Troubleshoot to troubleshoot Microsoft Entra join issues.
- Check if your Microsoft Entra tenant is assigned with the appropriate Intune license. See `<https://learn.microsoft.com/en-us/mem/intune/fundamentals/licenses>` for license requirements of Microsoft Intune.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- For catalogs that use master images with VDA version 2206 or earlier, check the provisioning status of the **AADLoginForWindows** extension for the machines. If the **AADLoginForWindows** extension does not exist, possible reasons are:
  - `IdentityType` of the identity pool associated with the provisioning scheme is not set to `AzureAD` or `DeviceManagementType` is not set to `Intune`. You can verify this by running `Get-AcctIdentityPool`.
  - Azure policy has blocked the **AADLoginForWindows** extension installation.
- To troubleshoot **AADLoginForWindows** extension provisioning failures, you can check logs under `C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.ActiveDirectory.AADLoginForWindows` on the MCS provisioned machine.

  NOTE:

  MCS does not rely on the `AADLoginForWindows` extension to join a VM to Microsoft Entra ID and enroll to Microsoft Intune when using a master image with VDA version 2209 or later. In this case, the `AADLoginForWindows` extension is not installed on the MCS-provisioned machine. Therefore, `AADLoginForWindows` extension provisioning logs can't be collected.

- Check Windows event logs under **Application and Services Logs > Microsoft > Windows > DeviceManagement-Enterprise-Diagnostics-Provider**.
- The service account that you selected might be in an unhealthy status due to various reasons. You can go to **Administrators > Service Accounts** to view details and fix the issues according to the recommendations. If you do not fix the issue, stale Microsoft Entra joined or Microsoft Intune enrolled devices are generated that can block Microsoft Entra join of the machines.

Create Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

You can create co-management enabled catalogs for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune for persistent single and multi-session VMs. You can create co-management enabled catalogs using both Studio and PowerShell.

For information on requirements, limitations, and considerations, see:

- Requirements for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune
- Limitations for Microsoft Entra hybrid joined catalogs enrolled in Microsoft Intune

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use Studio

The following information is a supplement to the guidance in Create machine catalogs.

In the **Machine Catalog Setup** wizard:

- On the **Machine Identities** page, select **Microsoft Entra hybrid joined** and then **Enroll the machines in Microsoft Intune with Configuration Manager**. Using this action, Configuration Manager and Microsoft Intune (that is, co-managed) manages the VMs.
- Click **Add Extension Attributes** to store unique, custom data directly on your Entra ID device objects. On the **Add Extension Attributes** page, add **Extension attributes** and **Value**.

  NOTE:

  - You can add a maximum of 15 extension attributes.
  - The name and value must be unique and can’t be empty.

Add or modify extension attributes

To change or add additional extension attributes to an existing MCS machine catalog, or add extension attributes to an MCS catalog without a service account, use the **Edit Machine Catalog** wizard.

- To change or add additional extension attributes, navigate to the **Microsoft Entra Device Extension Attributes** page. Click the pencil icon, and add or update extension attributes.
- To add extension attributes to an MCS catalog without a Microsoft Entra service account:

  a. Navigate to the **Service Account** page. Select a Microsoft Entra service account for the Microsoft Intra ID.

  b. Go to the Microsoft Entra Device Extension Attributes page, click **Add Extension Attributes**.

Use PowerShell

The following are the PowerShell steps equivalent to steps in Studio.

To enroll machines in Microsoft Intune with Configuration Manager using the Remote PowerShell SDK, use the `DeviceManagementType` parameter in `New-AcctIdentityPool`. This feature requires that the catalog is Microsoft Entra hybrid joined and that Microsoft Entra ID possesses the correct Microsoft Intune license.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The difference between Microsoft Entra hybrid joined catalogs and co-management enabled ones lies in the creation of the identity pool. For example:

```
New-AcctIdentityPool -AllowUnicode -DeviceManagementType "IntuneWithSCCM"
IdentityType="HybridAzureAD" -IdentityPoolName "CoManagedCatalog"
-NamingScheme "CoManaged-VM-##" -NamingSchemeType "Numeric" -Scope @()
-ZoneUid "81291221-d2f2-49d2-ab12-bae5bbd0df05"
```

For example: To create a new identity pool with specified extension attributes and associate it with a service account, run the following:

```
New-AcctIdentityPool -IdentityPoolName HybridAzureAD -NamingScheme ACC####
-NamingSchemeType Numeric -Domain "abc.local" -IdentityType HybridAzureAD
-ServiceAccountUid $serviceAccountUid -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

When a VM is powered on for the first time, after joining Microsoft Entra ID, the VM reports its Entra ID deviceId to MCS.

For example: To check the `EntraIDDeviceID`, run `Get-AcctADAccount` or `Get-AcctIdentity`.

```
Get-AcctADAccount -IdentityPoolName MyPool
```

After reboot, for persistent and non-persistent VMs, the `EntraIDDeviceID` remains the same.

NOTE:

MCS automatically removes associated device IDs and extension attributes when you delete a VM from the catalog but don’t delete from Azure.

For example: To edit extension attributes for the existing catalog, run the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- After upgrading existing catalog VMs to VDA version 2511 or later, a reboot is necessary. This reboot allows the VM to report its Entra ID deviceId to MCS, enabling MCS to then configure the VM's extension attributes.
- The existing catalog should have an AzureAD type of service account with permission "Device.ReadWrite.All".

To add some new attributes:

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{"extensionAttribute1" = "val1"; "extensionAttribute2" = "val2"}
```

To remove some existing attributes

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{}
```

OR

```
Set-AcctIdentityPool -IdentityPoolName MyPool -EntraIDExtensionAttributes
@{extensionAttribute1 = ""; extensionAttribute2 = ""}
```

`Set-AcctIdentityPool` also updates the Entra ID device's extension attributes for VMs that are already joined to Entra ID and possess an `EntraIDDeviceID` value within their identities.

You can also create a persistent Hybrid Microsoft Entra catalog enrolled in Microsoft Intune using a prepared image. For the complete set of PowerShell commands to create image definition, image version, and prepared image version spec, see:

- Azure virtualization environment: Use PowerShell.
- VMware virtualization environment: Use PowerShell

After creating the prepared image version spec, create the identity pool and machine catalog. For example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
New-AcctIdentityPool -IdentityPoolName "mypool" -NamingScheme ACC##  -
NamingSchemeType "Numeric"  -ZoneUid $zoneuid -Domain $domainName -OU
"OU=HAAD Computers,DC=haad,DC=link" -IdentityType "HybridAzureAD"
-DeviceManagement IntuneWithSCCM

New-ProvScheme -ProvisioningSchemeName <name> -ImageVersionSpecUid
<preparedVersionSpecUid> -HostingUnitUid <hostingUnitUid> -IdentityPoolUid
<IdentityPoolUid> [-CleanOnBoot] -NetworkMapping @{"0"="XDHyp:
\HostingUnits\<hostingunitName>\<region>.region\virtualprivatecloud.folder
\<resourcegroupName>.resourcegroup\<vnetName>.virtualprivatecloud\<sunNetN
ame>.network"} -ServiceOffering <serviceofferingPath> [-MachineProfile
<machineProfilePath>] [-CustomProperties <>]
```

NOTE:

Enrollment of Microsoft Entra hybrid joined non-persistent VMs into Microsoft Intune is currently under preview.

Troubleshoot

If machines fail to enroll in Microsoft Intune or fail to reach co-management state, do the following:

- Check Intune license

  Check if your Microsoft Entra tenant is assigned with the appropriate Intune license. See Microsoft Intune licensing for license requirements of Microsoft Intune.

- Check Hybrid Microsoft Entra join status

  Check if the MCS-provisioned machines are Microsoft Entra hybrid joined. The machines are not eligible for co-management if not Microsoft Entra hybrid joined. See Troubleshoot to troubleshoot Hybrid Microsoft Entra join issues.

- Check co-management eligibility

  - Check if the MCS-provisioned machines are correctly assigned with the expected Configuration Manager site. To get the assigned site, run the following PowerShell command on the affected machines.

    ```
    (New-Object -ComObject "Microsoft.SMS.Client").GetAssignedSite()
    ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If no site is assigned to the VM, use the following command to check if the Configuration Manager site can be automatically discovered.

  ```
  (New-Object -ComObject "Microsoft.SMS.Client").AutoDiscoverSite()
  ```

- Ensure that boundaries and boundary groups are well configured in your Configuration Manager environment if no site code can be discovered. See Considerations for details.
- Check `C:\Windows\CCM\Logs\ClientLocation.log` for any Configuration Manager client site assignment issues.
- Check the co-management states of the machines. Open the **Configuration Manager control panel** on the affected machines and go to the **General** tab. The value of Co-management property must be **Enabled**. If not, check logs under `C:\Windows\CCM\Logs\CoManagementHandler.log`.

- Check Intune enrollment

  Machines might fail to enroll in Microsoft Intune even if all prerequisites are satisfied. Check Windows event logs under **Application and Services Logs > Microsoft > Windows > DeviceManagement-Enterprise-Diagnostics-Provider** for Intune enrollment issues.

More information

- Service accounts for machine identity management
- Microsoft Entra service accounts

Identity pool of non-domain-joined machine identity

This article describes how to create identity pool of non-domain-joined machine identity using Citrix DaaS.

For information on requirements, limitations, and considerations, see Non-domain-joined.

Before you create the machine catalog, you need the following:

1. New resource location

   - Navigate to the Citrix Cloud™ admin UI > upper left hamburger menu > **Resource Locations**.
   - Click **+ Resource Location**.
   - Enter a name for the new resource location and click **Save**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Create a hosting connection. See Create and manage connections section for details.

Using Citrix DaaS, you can create catalogs based on workgroups for non-domain-joined machines. Creating non-domain-joined machines depends on how the account identity pool is created. The account identity pool is the mechanism used by MCS to create and track machine names during catalog provisioning.

You can create non-domain-joined catalogs by using Studio or PowerShell.

Use Studio

The following information is a supplement to the guidance in Create machine catalogs. To create non-domain-joined catalogs, follow the general guidance in that article, minding the details specific to non-domain-joined catalogs.

In the catalog creation wizard:

- On the **Machine Identities** page, select **Non-domain-joined**. The created machines are not joined to any domain.

NOTE:

The **Non-domain-joined** identity type requires version 1811 or later of the VDA as the minimum functional level for the catalog. To make it available, update the minimum functional level if necessary.

Use PowerShell

The following are PowerShell steps equivalent to operations in Studio.

You can create an identity pool for non-domain-joined catalogs using the Remote PowerShell SDK.

Use the PowerShell parameters, **WorkgroupMachine** and **IdentityType** to create an identity pool for non-domain-joined catalogs. The parameters eliminate the need to specify all AD-specific parameters including domain administrator credentials:

```
New-AcctIdentityPool -AllowUnicode -IdentityType "Workgroup"
-WorkgroupMachine -IdentityPoolName "NonDomainJoinedCatalog" -NamingScheme
"NDJ-VM-##" -NamingSchemeType "Numeric" -Scope @() -ZoneUid "81291221-
d2f2-49d2-ab12-bae5bbd0df05"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

All other commands used to create non-domain-joined catalogs are the same as for the traditional on-premises Active Directory joined catalogs.

Manage machine catalogs

NOTE:

This article describes how to manage catalogs using Studio and PowerShell commands. If you created the catalog using the Quick Deploy node, and continue using that node to manage the catalog, then follow Manage catalogs in Quick Deploy.

Introduction

You can add or remove machines from a machine catalog, and rename, change the description, or manage a catalog's Active Directory computer accounts.

Catalog maintenance can also include the tasks of making sure that each machine has the latest OS updates, antivirus software updates, operating system upgrades, or configuration changes.

- Catalogs containing pooled random machines created using Machine Creation Services™ (MCS) maintain machines by updating the image used in the catalog and then updating the machines. This method lets you update large numbers of user machines efficiently.
- For catalogs containing static, permanently assigned machines, you can manage the image or template that those catalogs currently use but only the machines you add to the catalogs later are created using the new image or template.
- For Remote PC Access catalogs, you manage updates to users' machines outside of Studio. Perform this task individually or collectively using third-party software distribution tools.

For information about creating and managing connections to host hypervisors and cloud services, see Create and manage connections and resources.

NOTE:

MCS does not support Windows 10 IoT Core and Windows 10 IoT Enterprise. Refer to the Microsoft site for more information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

About persistent instances

When updating the master image for an MCS catalog containing persistent machines, any new machines added to the catalog use the updated image. Existing machines continue to use the original master image. The process of updating an image is done the same way for any other type of catalog. Consider the following:

- With persistent disk catalogs, the pre-existing machines are not updated to the new image, but any new machines added to the catalog use the new image.
- For non-persistent disk catalogs, the machine image is updated the next time only if the machine is restarted within Studio or PowerShell. If the machine is restarted from the hypervisor outside of Studio, the disk is not reset.
- For catalogs that do not persist, if you want different images for different machines, the images must reside in separate catalogs.

Manage Machine Catalogs

You can manage a machine catalog in two ways:

- Using Studio
- Using PowerShell

Use Studio

This section details how you can manage catalogs using Studio:

- View catalog details
- Add machines to a catalog
- Delete machines from a catalog
- Edit a catalog
- Rename a catalog
- Delete a catalog
- Manage Active Directory computer accounts in a catalog
- Change the master image for a catalog
- Convert MCS-provisioned catalogs from using master images to using prepared images.
- Change the functional level or undo the change
- Clone a catalog

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Organize catalogs using folders
- Upgrade VDAs
- Manage experience optimization settings for a catalog
- Retry catalog creation
- (Non-Citrix® provisioned VDAs only) Generate and manage enrollment tokens

View catalog details

1. Use the search function to locate a specific machine catalog. Refer to Search for instances for instructions.
2. From the search results, select a catalog as necessary.
3. Refer to the following table for descriptions of the catalog columns.

COLUMN	DESCRIPTION
Machine Catalog	The name and the allocation type of the catalog. Allocation types include
	• Random: Machines in the catalog are allocated to a user randomly.
	• Permanent: Machines in the catalog are allocated to a user permanently.
Machine Type	The supported session type of the machines in the catalog. Possible values include
	• OS type: Multi-session OS (Virtual); User data: Discard.
	• OS type: Multi-session OS (Virtual); User data: On local disk
	• OS type: Single-session OS (Remote PC Access)
	• OS type: Single-session OS (Virtual); User data: Discard
	• OS type: Single-session OS (Virtual); User data: On local disk

© 1997–2026 Citrix Systems, Inc. All rights reserved.

COLUMN	DESCRIPTION
Machine Count	The machine count in the catalog and the provisioning method. Possible provisioning methods include: Machine Creation Services (MCS machine), Manual, and Citrix Provisioning™ Services.
Allocated Count	The number of machines in the catalog assigned to a delivery group.
Folder	The location of the catalog within the **Machine Catalogs** tree. It displays the name of the folder that the catalog is in (including the trailing backslash), or `-` if the catalog is at the root level.
VDA Upgrade	VDA Upgrade State. Possible values include: Not configured, Scheduled, Available, and Up to date.
Image Status	The status of the image update of the catalog. Applicable only to non-persistent machine catalogs. Possible values include: Fully updated, Partially updated, Pending updates, Preparing

4. Click a tab in the bottom details pane for more information about a selected catalog.

TAB	DESCRIPTION
Details	Summarizes key machine catalog settings, such as machine type, provisioning method, service account, OS, and VDA version, enabling you to quickly view and manage your resources.
Template Properties	Available for MCS provisioned catalogs only.
	Displays detailed provisioning information for the selected catalog, including

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TAB	DESCRIPTION
	• Machine Template Properties
	• Hypervisor-Specific Details
	• Machine Profile Properties
Machines	Displays a paginated list of machine names in the selected catalog.
Delivery Groups	Available for Remote PC catalogs.
	Displays delivery groups associated with the selected catalog. It displays delivery group name and catalog association.
Tags	Not available in multi-tenant environments.
	Displays tag name and description of the tags assigned to the selected machine catalog.
Workspace Environment Management	Only visible when WEM service is provisioned and accessible.
	Displays Workspace Environment Management System optimization settings.
Cost Insights	Applicable to only Azure MCS catalogs, this displays
	• Total cost incurred over the past 30 days.
	• A comparison between the current 30-day total cost and the previous 30-day period.
	Access requires the Citrix **Cost Management > Manage > Read cost** permission (default for Cloud Administrators) to view the tab, and the `Microsoft.CostManagement/query/read` Azure permission to view cost details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TAB	DESCRIPTION
Troubleshoot	Displays catalog errors or warnings with recommended actions.

Add machines to a catalog

Before you start:

- Make sure the virtualization host (hypervisor or cloud service provider) has sufficient processors, memory, and storage to accommodate the additional machines.
- Make sure that you have enough unused Active Directory computer accounts. If you are using existing accounts, the number of machines you can add is limited by the number of accounts available.
- If you use Studio to create Active Directory computer accounts for the additional machines, you must have appropriate domain administrator permission.

TIP:

If the Citrix DaaS account used to add machines to the machine catalog has restricted AD permissions, add all Cloud Connectors you intend to use in the **Log on to..** screen.

To add machines to a catalog:

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select a machine catalog and then select **Add machines** in the action bar.
3. On the **Virtual Machines** page, select the number of virtual machines to add.
4. On the **Machine Identities** page, configure the settings as follows:

    - Select an identity from the list.
    - If applicable, indicate whether to create accounts or use existing ones, and the location (domain) for those accounts.

      If there are insufficient existing Active Directory accounts for the number of VMs you are adding, select the domain and location where the accounts are created.

      If you use existing Active Directory accounts, browse to the accounts or select **Import** and specify a `.csv` file containing account names. Make sure that there are enough accounts for all the machines you are adding. Studio manages these accounts. Allow that interface to

© 1997–2026 Citrix Systems, Inc. All rights reserved.

reset the passwords for all the accounts, or specify the account password, which must be the same for all accounts.

- If this identity pool is used by other catalogs, you can't change it to a different pool using Studio. Instead, use the **Set-ProvScheme** PowerShell cmdlet. For more information, see the Citrix Virtual Apps and Desktops SDK Documentation.
- Specify an account naming scheme, using hash marks to indicate where sequential numbers or letters appear. For example, a naming scheme of PC-Sales-## (with 0-9 selected) results in computer accounts named PC-Sales-01, PC-Sales-02, PC-Sales-03, and so on.
- Optionally, you can specify what the account names start with.

  When specifying what the account names start with, be aware of the following scenario: If the starting numbers or letters are already in use, the first account created is named using the nearest unused numbers or letters thereafter.

  See Manage the sequence number of the machine name to customize the sequence number of machines, which are deployed using MCS, through PowerShell commands.

5. On the **Domain Credentials** page, select **Enter credentials** and enter user credentials with sufficient permissions to create machine accounts.

The machines are created as a background process, and can take much time when creating many machines. Machine creation continues even if you close the Studio.

Use CSV files to bulk add machines to a catalog

You can bulk add machines by using CSV files. The feature is available for all catalogs except catalogs provisioned through MCS.

To bulk add machines to a catalog, complete the following steps:

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select a machine catalog and then select **Add Machines** in the action bar. The **Add Machines** window appears.
3. Select **Add CSV File**. The **Add Machines in Bulk** window appears.
4. Select **Download CSV Template**.
5. Fill out the template file.
6. Drag or browse to the file to upload it.
7. Select **Validate** to perform validation checks on your import.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

8. Select **Import** to complete the process.

Considerations when using CSV files to add machines

NOTE:

- For non-Active Directory users, you must type their names in this format: `<identity provider>:<user name>`. Example: `AzureAD:username`.
- VM names are case sensitive. When entering VM paths, make sure that you enter the VM names correctly.

When editing the CSV template file, keep the following in mind:

- The feature gives you more flexibility to bulk add machines through a CSV file. In the file, you can add only machines (for use with user auto-assignments) or add machines along with user assignments. Type your data in the following format:
  - For machine account and user name (samName) pairs:
  - Domain\ComputerName1, Domain\Username1
  - Domain\ComputerName2, Domain\Username1;Domain\Username2
  - Domain\ComputerName3, AzureAD:username
  - For machine accounts only:
  - Domain\ComputerName1
  - Domain\ComputerName2
  - For VM and user name pairs:
  - XDHyp: \Connections\ConnectionName\RegionName\vm.folder\VMName1.vm,Domain\ComputerName1,Domai
  - XDHyp: \Connections\ConnectionName\RegionName\vm.folder\VMName2.vm,Domain\ComputerName2,Domai
  - For VMs only:
  - XDHyp: \Connections\ConnectionName\RegionName\vm.folder\VMName1.vm,Domain\ComputerName1
  - XDHyp: \Connections\ConnectionName\RegionName\vm.folder\VMName2.vm,Domain\ComputerName2

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example: `XDHyp:\Connections\xpace-scale\East US.region\vm.folder\wsvdaV3-2.vm`

where,

- `xpace-scale` is the ConnectionName: The name of the connection that you entered in **Hosting > Add Connections and Resources**. For more information, see Create a connection and resources.
- `East US.region` is the RegionName: The name of the region with `.region` as extension.
- `wsvdaV3-2.vm` is the VMName: The name of the virtual machine with `.vm` as extension.

- The maximum number of machines that a file can contain is 1,000. To import more than 1,000 machines, spread them across different files and then import those files one by one. We recommend that you import no more than 1,000 machines. Otherwise, catalog creation can take a long time to complete.

You can also export machines from a catalog on the same **Add Machines** page. The exported CSV of machines can then be used as a template when adding machines in bulk. To export machines:

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select a machine catalog and then select **Add Machines** in the action bar. The **Add Machines** window appears.
3. Select **Export to CSV file**. A CSV file containing a list of the machines is downloaded.
4. Open the CSV file to add or edit machines as needed. To add machines in bulk using the saved CSV file, see the previous section, Use CSV files to bulk add machines to a catalog.

NOTE:

- This feature is not available for Remote PC Access and MCS-provisioned catalogs.
- Export and import of machines in CSV files is only supported between catalogs of the same type.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enroll machines to catalogs using the WebSocket VDA enrollment tool

The WebSocket VDA enrollment tool facilitates token-based enrollment for VDA machines. This tool helps you convert a connection to a WebSocket connection by adding the VDA to the machine catalog using the enrollment token.

NOTE:

This tool is designed to enroll VDA machines that haven't been enrolled in any machine catalog.

Follow the instructions to run the enrollment tool:

1. Log in to the VDA.
2. Locate the tool `EnrollMachine.exe`, in `C:\Program Files\Citrix\Virtual Desktop Agent\Web Socket Vda Enrollment Tool`.
3. Run the tool with the appropriate input parameters. For example, `EnrollMachine.exe -websocket_token_string:xxxxxxxxx`

The following table describes the input parameters of the enrollment tool:

PARAMETER NAME	REQUIRED	DESCRIPTION	EXAMPLE
`-websocket_token_stdin`	Yes	Reads the enrollment token.	`.\EnrollMachine.exe -websocket_token_stdin`
`-websocket_token_string`		Reads the enrollment token directly from the command line parameter.	`.\EnrollMachine.exe -websocket_token_string:<token>`
`-websocket_token_file:[token-file-path]`		Reads the enrollment token from the path provided.	`.\EnrollMachine.exe -websocket_token_file:C:\token\test2.txt`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PARAMETER NAME	REQUIRED	DESCRIPTION	EXAMPLE
`log:[log-file-path]`	No	Shows the Enrollment tool logs.	`.\EnrollMachine.exe log:[C:\ProgramData\Citrix\EnrollMachine\EnrollMachine.txt]`
`-help`	No	Shows a brief help text.	`.\EnrollMachine.exe -help`

After successful enrollment, you will receive a success message on the tool and in the logs. Ensure to sign in to Studio to verify that the VDA machine is added to the catalog and that the status of the machine is registered.

Troubleshooting

By default, you can find the logs of the enrollment tool at:

`C:\ProgramData\Citrix\EnrollMachine\EnrollMachine.txt`

If you have specified a different path for the logs, you can use `log:[log-file-path]` to retrieve your logs.

The following table lists the codes returned by the enrollment tool:

CODE	STRING	DESCRIPTION
0	Success	VDA is successfully added to the machine catalog.
-1	InvalidArgument	The input parameter in the enrollment token is invalid.
-2	BrokerAgentNotFound	The broker agent service is not found.
-3	TokenInvalid	The token entered is invalid.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CODE	STRING	DESCRIPTION
-4	TokenMissingRequiredClaims	The required claims for the token are missing, for example, CustomerId, or Enrollment URIs.
-5	InternalError	A general error has occurred.
-6	TimedOut	The task has timed out.
-7	FailedToDetermineMachineADJoinedStatus	The service that returns the machine AD joined status failed.
-8	ADMachineFailedToFindSid	The service that returns the AD machine Sid failed.
-9	EnrollRequestFailed	The request failed due to an HTTP error.
-10	EnrollResponseMissingRequiredFields	The enrollment tool response is missing the parameter `VirtualSiteId`.
-11	InsufficientPermission	You do not have the required permission to run the task.
-12	FailedToDetermineMachineAadJoinedStatus	The service that checks the machine AD join status throws an error.
-13	AadMachineFailedToFindDeviceId	The additional parameter `AAD device id` added by the system is empty.
-14	AadDeviceIdNotValid	The additional parameter `AAD device id` added by the system is not a valid GUID.
-15	NoValidMacAddress	Invalid MAC address.

CODE	STRING	DESCRIPTION
-16	FailedToGetComputerHostNameForVdaInstanceName	Failed to get the computer host name to set the additional parameter `VdaInstanceName`.
-17	VirtualDesktopAgentRegistryKeyFailedToOpen	Failed to open the VDA registry key to write the list of Delivery controllers.
-18	Failed Token reached the max count	Failed Token reached the max count.

Delete machines from a catalog

After you delete a machine from a machine catalog, users can no longer access it, so before deleting a machine, ensure that:

- User data is backed up or no longer required.
- All users are logged off. Turning on maintenance mode stops new connections from being made to a machine.
- Machines are powered off.

To delete machines from a catalog:

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select a catalog and then select **View Machines** in the action bar.
3. Select one or more machines and then select **Delete** in the action bar.
4. If you are deleting persistent machines from the catalog, choose whether to delete them from the hypervisor or cloud service as well. If you choose to delete them, indicate whether to retain, disable, or delete their Active Directory accounts.

When you delete persistent machines from an Azure Resource Manager catalog, the machines and associated resource groups are deleted from Azure, even if you choose to retain them.

When you delete non-persistent machines from a catalog, they are automatically deleted from the hypervisor or cloud service.

Edit a catalog

1. From Studio, select **Machine Catalogs** in the left pane.
2. Select a catalog and then select **Edit Machine Catalog** in the action bar.
3. On the **Scopes** page, change the scopes.
4. On the **NIC** page, perform the following actions:

   - To change the subnet mapping of an NIC, select a network from the **Associated Network** field.
   - To add a subnet mapping, select **Add NIC**, select a network from the **Associated Network** field, and click **Save**.

   Only those subnets present in the host associated with the catalog appear in the **Associated Network** field.

   You can only add NIC to Azure machine catalogs without machine profiles.

   NOTE:

   - For AWS machine catalogs, you cannot map the same subnet to more than one NIC.
   - For machine catalogs with machine profiles, the number of NICs on the catalog must be equal to the number of NICs on the machine profile.
   - This feature is not supported for IBM Cloud hypervisors.
   - This feature is supported only for Nutanix Prism Element in Nutanix hypervisors.

5. On the **VDA Upgrade** page, change or select the VDA version to upgrade to. For more information, see VDA upgrade.
6. You might see additional pages depending on the catalog type.

   For catalogs created using an Azure Resource Manager image, the following pages are visible. Keep in mind that the changes you make apply only to machines you add to the catalog later. Existing machines remain unchanged.

   - On the **Virtual Machines** page, change the machine size and availability zones where you want to create machines.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Only the machine sizes that the catalog supports are shown.
- If necessary, select **Show only machine sizes used in other machine catalogs** to filter the machine size list.
- For Azure catalogs, if **ZRS** is the Storage redundancy on the Storage and License Types page, then you get a warning suggesting to clear the zone selection and let Azure manage the VM availability zones.

- On the **Machine Profile** page, choose whether to use or change a machine profile.

NOTE:

For Azure catalogs, when you modify a machine profile that includes availability zones and choose ZRS for storage redundancy, a warning suggests you to clear the zone selection.

- (Only when the catalog is configured with a dedicated group host) On the **Dedicated host group** page, choose whether to change a host group.
