• To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially
  with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites.

GSLB Services

A GSLB service is usually a representation of a load balancing or content switching virtual server, al-
though it can represent any type of virtual server. The GSLB service identifies the virtual server’s IP
address, port number, and service type. GSLB services are bound to GSLB virtual servers on the Cit-
rix ADC appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the
same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in
a different data center is remote from that GSLB virtual server.

Note
Sites and services are inherently linked to indicate proximity between the two. That is, all ser-
vices must belong to a site, and are assumed to be in the same location as the GSLB site for
proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked
to the resources that are available.

GSLB Virtual Servers

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those
services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to
which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a Citrix ADC appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

**Load Balancing or Content Switching Virtual Servers**

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server’s virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server’s VIP address.

For more information about load balancing or content switching virtual servers and services, see Load Balancing or Content Switching.

**ADNS Services**

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the Citrix ADC appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

**DNS VIPs**

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the Citrix ADC appliance. DNS requests for domains for which the Citrix ADC appliance is authoritative can be sent to a DNS VIP.

GSLB methods

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a Citrix ADC appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the appliance responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The Citrix ADC appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

**Specifying a GSLB method other than static proximity or dynamic RTT**

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see “Load Balancing.”
To change the GSLB method by using the CLI

At the command prompt, type:

```
set gslb vserver <name> -lbMethod GSLBMethod
```

Example:

```
set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
```

To change the GSLB method by using the GUI

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In the details pane, select a GSLB virtual server and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click OK, and verify that the method you selected appears under Details at the bottom of the screen.

GSLB algorithms

April 12, 2019

Contributed by:

C

The following algorithm are supported for GSLB.

- **Round Robin**: When a GSLB virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

- **Least Response Time**: When the GSLB virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between
sends a request packet to a service and receiving the first response packet from the service. The Citrix ADC appliance uses response code 200 to calculate TTFB.

- **Least Connections**: When a GSLB virtual server is configured to use the least connection GSLB algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.
- **Least Bandwidth**: A GSLB virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps).
- **Least Packets**: A GSLB virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.
- **Source IP Hash**: A GSLB virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.
- **Custom Load**: Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all of the services in the GSLB setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the GSLB decision when those services are not UP.

For more details, see [Load Balancing](#).

**Static proximity**

January 25, 2019

Contributed by: C

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client’s local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC
appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

For details about configuring static proximity, see Configuring Static Proximity.

Dynamic round trip time method

January 23, 2019

Contributed by: C

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client’s local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client’s DNS request for a domain comes to the Citrix ADC appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Citrix ADC appliance as Load Balancing Monitors and are easily identified due to their use of the “ldns” prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp
These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
set gslb parameter -ldnsprobeOrder DNS PING TCP
```

Unless they have been customized, the Citrix ADC appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the appliance uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric.”

If RTT information is not available (for example, when a client’s local DNS server accesses the site for the first time), the Citrix ADC appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site’s GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

**Configure a GSLB virtual server for dynamic RTT**

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The Citrix ADC appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all Citrix ADC appliances deployed in the GSLB domain.

**To configure a GSLB virtual server for dynamic RTT by using the command line interface**

At the command prompt, type:

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
```

**Example:**

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
```
To configure a GSLB virtual server for dynamic RTT by using the configuration utility

Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.

Set the probing interval of local DNS servers

The Citrix ADC appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

To modify the probing interval by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <integer> <units> -resptimeout <integer> <units>
```

Example:

```
set lb monitor monitor-HTTP-1 HTTP -interval 10 sec -resptimeout 5 sec
```

To modify the probing interval by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and double-click the monitor that you want to modify (for example, ping).

Add a location file to create a static proximity database

February 25, 2019
Contributed by: C

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a Citrix ADC appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the Citrix ADC appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as www.maxmind.com and www.ip2location.com).

The Citrix ADC appliance includes the following two IP geolocation database files. These are GeoLite2 files, published by MaxMind.
• Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4
• Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6

These database files are available in a format supported by the Citrix ADC appliance in the directory /var/netscaler/inbuilt_db.

You can use these IP geolocation databases as the location file for the static proximity based GSLB method, or in location based policies.

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the Citrix ADC appliance. Specifying an incorrect value for the format option can corrupt the internal data.

Note

• After an upgrade, if the /var/netscaler/inbuilt_db/ directory contains the database file (Citrix_Netscaler_InBuilt_GeoIP_DB.csv) from the earlier Citrix ADC software versions, the file is retained.
• The default location of the database file is /var/netscaler/locdb, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both Citrix ADC appliances.

The following abbreviations are used in this section:

CshN. Short name of a country based on the country code standard of ISO-3166.

Lcn. Long name of the country.

Rc. Region code based on ISO-3166-2 (for US and Canada). The region code “FIPS-10-4” is used for the other regions.

• Some databases provide short country names according to ISO-3166 and long country names as well. The Citrix ADC uses short names when storing and matching qualifiers.
• To create a static proximity database, log on to the UNIX shell of the Citrix ADC appliance and use an editor to create a file with the location details in one of the Citrix ADC supported formats.

To add a static location file by using the CLI

At the command prompt, type:

```bash
1 add locationFile <locationFile> [-format <format>]
2 - show locationFile
```
Example:

```
1 add locationFile /var/nmap/locdb/nsgeo1.0 -format netscaler
2 Done
3
4 show locationFile
5 Location File: /var/nmap/locdb/nsgeo1.0
6 Format: netscaler
7 Done
8 >
```

To add a static location file by using the GUI:

1. Navigate to AppExpert > Location, click the Static Database tab.
2. Click Add to add a static location file.

You can view an imported location file database by using the View Database dialog box in the configuration utility. There is no CLI equivalent.

To view a static location file by using the GUI:

1. Navigate to AppExpert > Location, click the Static Database tab.
2. Select a static location file, and from the Action list, click View Database.

To convert a location file into the Citrix ADC format:

By default, when you add a location file, it is saved in the Citrix ADC format. You can convert a location file of other formats into the Citrix ADC format.

**Note:** The nmap option can be accessed only from the command line interface. The conversion is possible only into the Citrix ADC format.

To convert the static database format, at the CLI prompt, type the following command:

```
1 nmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
```

Example:

```
1 nmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.csv
```

Script to convert Maxmind GeoLite2 database format to Citrix ADC database format

MaxMind GeoIP database cannot be used directly in Citrix ADC. The MaxMind GeoIP database must be converted into Citrix ADC format and then loaded for IP location detection in GSLB static proximity.
You can use a script to convert the GeoLite2 database format to Citrix ADC database format. This script can be used to convert both IPv4 and IPv6 files. The script is available in the location: https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format

**Steps to convert GeoIP2 database to Citrix ADC format**

1. Download the GeoLite2 City or GeoLite2 Country database in .csv format from https://dev.maxmind.com/geoip/geoip2/geolite2/.

2. Copy the file in a Citrix ADC directory (say /var). Unzip the file using the following shell command, which would create a directory with the same name.

   ```
   tar -xf <filename>
   ```

4. To check the acceptable options for the script execution, run the following command:

   ```
   perl Convert_GeoIPDB_To_Netscaler_Format.pl -help
   ```

   Various options available are:

   - `<filename>`
     IPv4 output file.
     Default output file name: Netscaler_Maxmind_GeoIP_DB_IPv4.csv
   
   - `-p <filename>`
     IPv6 output file.
     Default output file name: Netscaler_Maxmind_GeoIP_DB_IPv6.csv
   
   - `-logfile <filename>`
     File containing list of events/messages
   
   - `-debug`
     Prints all the messages to STDOUT

4. Execute the following command to convert the GeoLite2 database format to Citrix ADC database format.

   ```
   perl Convert_GeoIPDB_To_Netscaler_Format.pl
   ```
Note: The operation can take up to 5 minutes.

The default file names used in the script are that of the Maxmind GeoLite2 City based database. If you have downloaded GeoLite2 Country database, you must provide the input file names accordingly as listed.

- **-b <filename>** name of IPv4 block file to be converted.
  Default file name: GeoLite2-City-Blocks-IPv4.csv
- **-i <filename>** name of IPv6 block file to be converted.
  Default file name: GeoLite2-City-Blocks-IPv6.csv
- **-l <filename>** name of location file to be converted.
  Default file name: GeoLite2-City-Locations-en.csv

**Example:**

```
```

The following are the output files generated after running the script.

- Netscaler_Maxmind_GeoIP_DB_IPv4.csv
- Netscaler_Maxmind_GeoIP_DB_IPv6.csv

5. Once the conversion of the database into Citrix ADC format is complete, use the following command to start using it.

```
add locationFile <locationFile>
```

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

**Add custom entries to a static proximity database**

January 23, 2019

Contributed by:
C

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The
first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of
the geographical location of the IP address-range for selecting a service with the static proximity GSLB
method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity
database and verify the configuration:

```
1 add location < IPfrom> < IPto> <preferredLocation> [-longitude <integer>
    >[-latitude <integer>]]
2 show location
```

Example:

```
1 >add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
2 >show location
```

Parameters for adding custom entries

- **IPfrom**
  First IP address in the range, in dotted decimal notation. This is a mandatory argument.

- **IPto**
  Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

- **preferredLocation**
  String of qualifiers, in dotted notation, describing the geographical location of the IP
  address range. Each qualifier is more specific than the one that precedes it, as in contin-
  nent.country.region.city.isp.organization. For example,"NA.US.CA.San Jose.ATT.citrix".
  Note: A qualifier that includes a dot (.) or space () must be enclosed in double quotation marks.
  This is a mandatory argument. Maximum Length: 197

- **longitude**
  Numerical value, in degrees, specifying the longitude of the geographical location of the IP
  address-range.
  Note: Longitude and latitude parameters are used for selecting a service with the static proxim-
  ity GSLB method. If they are not specified, selection is based on the qualifiers specified for the
  location.
  Maximum value: 180
• latitude

Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.
Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.
Maximum value: 180

To add custom entries by using the configuration utility

Navigate to AppExpert > Location, click the Custom Entries tab, and add the custom entries.

2. Citrix ADC
3. Citrix ADC 12.1

Set location qualifiers

January 23, 2019
Contributed by:
C

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. Citrix ADC has two built-in contexts:

Geographic context, which has the following qualifier labels:

• Qualifier 1 – “Continent”
• Qualifier 2 – “Country”
• Qualifier 3 – “State”
• Qualifier 4 – “City”
• Qualifier 5 – “ISP”
• Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

• Qualifier 1 – “Qualifier 1”
• Qualifier 2 – “Qualifier 2”
• Qualifier 3 – “Qualifier 3”
• Qualifier 4 – “Qualifier 4”
• Qualifier 5 – “Qualifier 5”
• Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the Citrix ADC appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

To set the location qualifiers by using the command line interface

At the command prompt, type:

```
set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
```

Example:

```
set locationparameter -context custom -q1label asia
```

To set the location qualifiers by using the configuration utility

1. Navigate to AppExpert > Location.
2. From the Action list, click Location Parameters and set the location qualifiers.

Specify proximity method

January 23, 2019
When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set gslb vserver <name> -lbMethod STATICPROXIMITY
2 show gslb vserver <name>
```

Example:

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
2 show gslb vserver
```

To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.
2. Click the Method section and from the Choose Method drop-down list, select STATICPROXIMITY.
3. Citrix ADC
4. Citrix ADC 12.1

Synchronize GSLB static proximity database

January 23, 2019

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.
Synchronizing GSLB static proximity databases synchronizes the files in the /var/netscaler/locdb directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the rsync program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the rsync program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the \texttt{sync gslb config} command on Site1:

```
1 sync gslb config -nowarn
2 Sync Time: Feb 24 2014 14:56:16
3 Retrieving local site info: ok
4 Retrieving all participating gslb sites info:
5 0 bytes in 0 blocks
6 ok
7 site1[Master]:
8   Getting Config: ok
9 site2[Slave]:
10   Syncing gslb static proximity database: ok
11   Getting Config: ok
12   Comparing config: ok
13   Applying changes: ok
14 Done
```

2. Citrix ADC
3. Citrix ADC 12.1

**Configure site-to-site communication**

May 9, 2019

Contributed by:
C

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The Citrix ADC appliance uses this user name and password to au-
authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a Citrix ADC owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use a subnet IP (SNIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the Citrix ADC appliance:

**Changing the password of an RPC node**

You can secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the show rpcNode command to compare the encrypted form of the password before and after the change.

**To change the password of an RPC node by using the command line interface**

At the command line, type the following commands to change the password of an RPC node:

```bash
1     set ns rpcNode <IPAddress> {
2       -password }
3     show ns rpcNode
```

**Example:**

```bash
1     > set rpcNode 192.0.2.4 -password mypassword
2       Done
3     > show rpcNode
4       .
5       .
6       .
7     2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e
8       SrcIP: *        Secure: OFF
9       Done
10     >
```
To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the password parameter, without a value.

To change the password of an RPC node by using the configuration utility

Navigate to System > Network > RPC, select the RPC node, and change the password.

Encrypt the exchange of site metrics

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the Citrix ADC appliance encrypts all communication sent from the node to other RPC nodes.

To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

```
1  set ns rpcNode <IPAddress> [-secure ( YES | NO )]
2  show rpcNode
```

Example:

```
1  > set rpcNode 192.0.2.4 -secure YES
2   Done
3  >
4  > show rpcNode
5   .
6   .
7   3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: ON
8   Done
9  >
```

To unset the secure parameter by using the command line interface

To unset the secure parameter by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the secure parameter, without a value.
To encrypt the exchange of site metrics by using the Citrix ADC configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. Select the Secure option, and click OK.

Configure source IP address for an RPC node

By default, the Citrix ADC appliance uses a Citrix ADC owned subnet IP (SNIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address. If a SNIP address is not available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NSIP address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address.

Note

From NetScaler 11.0.64.x release onwards, you can configure the appliance to use GSLB Site IP address as the source IP address for an RPC node.

To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

1. set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr>*]
2. show ns rpcNode

Example:

1. set rpcNode 192.0.2.4 -srcIP 192.0.2.3
2. Done
3. show rpcNode

1. IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: OFF
2. Done

To unset the source IP address parameter by using the command line interface

To unset the source IP address parameter by using the CLI, type the unset rpcNodecommand, the IP address of the RPC node, and the srcIP parameter, without a value.
To specify a source IP address for an RPC node by using the Citrix ADC configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. In the Source IP Address field, enter the IP address that you want the RPC node to use as the source IP address and click OK.

**Important**
The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the sync gslb config –forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances.

Configure metrics exchange protocol

January 25, 2019

Contributed by: C

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for Citrix ADC appliance. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metric (round-trip time) can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, virtual IP (VIP) address, or the NSIP address, as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the Citrix ADC appliances.

Note: You cannot configure a GSLB site IP address as the source IP address for site metrics exchange.

If the source and target sites (the site that initiates a MEP connection and the site that receives the
connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in “Monitoring GSLB Services.” When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the Citrix ADC appliance to interact with a non Citrix ADC load balancing device. The Citrix ADC appliance can monitor non Citrix ADC devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

With NetScaler release 11.1.51.x or later, to avoid unnecessary disruption of services, you can set a time delay for marking GSLB services as DOWN when a MEP connection goes DOWN.

**Enable site metrics exchange**

Site metrics exchanged between the GSLB sites include the status of each load balancing, or content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The Citrix ADC appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

**To enable or disable site metrics exchange by using the command line interface**

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

```
1 set gslb site <siteName> -metricExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
```

**To enable or disable site metric exchange by using the GUI**

1. Navigate to **Traffic Management > GSL > Sites**, and select the site.
2. In the **Configure GSLB Site** dialog box, select the **Metric Exchange** option.

### Enable network metric exchange

If your GSLB sites use the round-trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see “**GSLB Methods**.”

### To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

```plaintext
1. set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)
2. show gslb site <<siteName>
```

**Example:**

```plaintext
1. set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
2. set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
3. show gslb site Site-GSLB-East-Coast
```

### To enable or disable network metric information exchange by using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**.
2. In the **Configure GSLB Site** dialog box, select the **Network Metric Exchange** option.

### Configuring a time delay for the GSLB services to be marked as DOWN when a MEP connection goes DOWN

If the status of a MEP connection to a remote site changes to DOWN, the status of every GSLB service on that remote site is marked as DOWN, although the site might not actually be DOWN.

You can now set a delay to allow some time for reestablishment of the MEP connection before the site is marked as DOWN. If the MEP connection is back UP before the delay expires, the services are not affected.

For example, if you set the delay 10, the GSLB services are marked as DOWN until the MEP connection has been DOWN for 10 seconds. If the MEP connection is back UP within 10 seconds, the GSLB services remain in the UP state.
**Note:** This delay is applicable only to services not bound to a monitor. The delay does not affect the trigger monitors.

**To set a time delay by using the command line interface**

At the command prompt, type the following command:

```
set gslb parameter -- GSLBSvcStateDelayTime <sec>
```

**Example:**

```
set gslb parameter - GSLBSvcStateDelayTime 10
```

**To set a time delay by using the GUI**

1. Navigate to **Configuration > Traffic Management > GSLB > Change GSLB Settings.**
2. In the **GSLB Service State Delay Time (secs)** box, type the time delay in seconds.

**Enable persistence information exchange**

You can configure Citrix ADC appliance to provide persistent connections, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged once every 5 seconds between Citrix ADC appliances participating in GSLB.

For details about configuring persistence, see [Configuring Persistent Connections](#).

**To enable or disable persistence information exchange by using the command line interface**

At the command prompt, type the following commands to enable or disable persistence-information exchange and verify the configuration:

```
1 set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -sessionExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -sessionExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
```
To enable or disable persistence information exchange by using the GUI

1. Navigate to Traffic Management > GSLB > Sites, and double-click the site.
2. In the Configure GSLB Site dialog box, select or clear the Persistence Session Entry Exchange check box.

Configure GSLB by using a wizard

January 25, 2019
Contributed by: C

You can now use a wizard to configure the GSLB deployment types: active-active, active-passive, and parent-child.

This wizard is available in the GUI. To access the wizard, navigate to Configuration > Traffic Management > GSLB and click Get Started.

You can also access this wizard from the GSLB dashboard. Navigate to Configuration > Traffic Management > GSLB > Dashboard and click Configure GSLB.

Note: You can also configure the GSLB entities individually.

- Active-Active Site Configuration
- Active-Passive Site Configuration
- Parent-Child Topology Configuration

Important

This feature is supported in High Availability deployment and not in Admin Partition and Cluster deployments.
Configure active-active site

January 25, 2019
Contributed by: C

The following figure shows the workflow involved in a GSLB active-active site configuration.

Before you begin configuring an active-active site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure an active-active site by using the wizard

On the Configuration tab, do the following:

1. Navigate to Traffic Management > GSLB, and then click Get Started.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click View and then click Add.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select Active-Active Site.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:

- **ALWAYS.** Monitor the GSLB service at all times.
- **MEP Fails.** Monitor the GSLB service only when the exchange of metrics through MEP fails.
- **MMEP Fails and Service ID Down.** Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

6. Configure the GSLB services. To create an active-active site you must add at least two GSLB services.

   a) Enter the service details, such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
   d) To associate an existing server, select the server name. The service IP address is automatically populated.
      - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
      - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      - To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB virtual servers.

   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      - If you choose the Algorithm based method, select the primary and backup methods and also specify the dynamic weight option.
      - If you choose the Static Proximity method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      - If you choose the Dynamic Proximity (RTT) method, select the backup method and
specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.

8. Click **Done** if the configuration is complete. The GSLB dashboard appears.

9. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
   - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.
   - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
     a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
     b) Select the **Automatic Config Sync** check box.

10. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

---

**Configure active-passive site**

January 25, 2019

Contributed by: C

The following figure shows the workflow involved in the active-passive site configuration.

Before you begin configuring an active-passive site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave Citrix ADC appliances are running the same Citrix ADC software versions.
- All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
• The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure an active-passive site by using the wizard

On the Configuration tab, do the following:

1. Navigate to Traffic Management > GSLB, and then click Get Started.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click View and then click Add.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select Active-Passive Site.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site’s configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
   d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      • ALWAYS. Monitor the GSLB service at all times.
      • MEP Fails. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      • MEP Fails and Service ID Down. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services.
   a) Enter the service details, such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
   d) To associate an existing server, select the server name. The service IP address is automatically populated.
      • If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
      • To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
• To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB backup virtual servers. The GSLB backup virtual servers become operational only when the primary GSLB virtual servers is inaccessible or it is marked DOWN for any reason.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in Service Binding, and choose the GSLB services that must be bound to the GSLB virtual server.
   c) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods.
      • If you choose the Static Proximity method, select the backup method and provide the location of the database file.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.

8. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods and also specify the dynamic weight option.
      • If you choose the Static Proximity method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.

9. Click Done if the configuration is complete. The GSLB dashboard appears.

10. If you have modified the GSLB site configuration, click Auto Synchronize GSLB in the dashboard to synchronize the configuration to other sites in the GSLB setup.
   • Before synchronization, make sure that the local site’s configuration includes information
about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other Citrix ADC appliances.

- If real-time synchronization is enabled, you do not have to click Auto Synchronize GSLB. The synchronization happens automatically. To enable real time synchronization, do the following:
  a) Navigate to Traffic Management > GSLB > Dashboard and click Change GSLB Settings.
  b) Select the Automatic Config Sync check box.

11. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Note
For details about configuring GSLB entities of an active-passive GSLB setup for disaster recovery, see Configuring GSLB for Disaster Recovery.

Configure parent-child topology

January 25, 2019
Contributed by: C

In a parent-child topology, at the top level are parent sites, which have peer relationships with other parents. Each parent can have multiple child sites, and each parent site exchanges health information with its child sites and with other parent sites. However, a child site communicates only with its parent site.

The following figure shows the workflow involved in a GSLB parent-child topology configuration.

Before you begin configuring the parent-child topology deployment, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
• All the Citrix ADC appliances participating as sites should have the same Citrix ADC software version (the sites are not in a master-slave relationship).
• The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure a parent-child deployment by using the wizard

On the Configuration tab, do the following:

1. Navigate to Traffic Management > GSLB, and then click Get Started.
2. If you have not configured an ADNS server or a DNS virtual server for the site, you can do it now.
   a) Click View and then click Add.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
4. In the Select the site type field, choose;
   • Parent – When configuring the parent site, you must configure its associated child sites and also configure the other parent sites in the GSLB setup.
   • Child – When configuring the child site, you must configure only the child site and its parent site.

To configure a parent site

1. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
2. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site’s configuration must include all the other sites as remote GSLB sites. There can be only one local site. All other sites are remote sites. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.
3. Enter the site details, such as the site name and site IP address.
   a) Select the site type.
   b) Optionally, change the RPC password and, if necessary, secure it.
   c) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      • Always. Monitor the GSLB service at all times.
      • MEP Fails. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      • MEP Fails and Service is DOWN. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
4. Configure the GSLB services.
   a) Enter the service details such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site to which the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
      • To associate an existing server, select the server name. The service IP address is auto-populated.
      • To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      • To associate a virtual server, select an already existing virtual server or click + and add a new virtual server. This vserver is the load balancing vserver to which this GSLB service will be associated. If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the public port number.

5. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to view the domain name that is bound to the GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are automatically populated by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods and also specify the dynamic weight option.
      • If you choose the Static Proximity method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.

6. Click Done if the configuration is complete. The GSLB dashboard appears.

7. If you have modified the GSLB parent-site configuration, click Auto Synchronize GSLB to synchronize the configuration to the other parent sites in the GSLB setup. In a parent-child topology, synchronization for the child sites is skipped.
   • Before synchronization, make sure that the local site’s configuration includes information about the remote sites.
   • If real-time synchronization is enabled, you do not have to click Auto Synchronize GSLB.
The synchronization happens automatically. To enable real time synchronization, do the following:

a) Navigate to Traffic Management > GSLB > Dashboard and click Change GSLB Settings.

b) Select the Automatic Config Sync check box.

8. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

To configure a child site

1. Configure the GSLB sites.

   a) Enter the site details, such as the site name and site IP address.
   
   b) Select the site type.
   
   c) Optionally, change the RPC password and, if necessary, secure it.

4. If a monitor is bound to the GSLB service, select the condition under which the monitor is to monitor the service. The possible conditions are:

   • Always. Monitor the GSLB service at all times.
   
   • MEP Fails. Monitor the GSLB service only when the exchange of metrics through MEP fails.
   
   • MEP Fails and Service is DOWN. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

2. Click Done if the configuration is complete. The GSLB dashboard appears.

3. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Configure GSLB entities individually

January 25, 2019

Contributed by:

C

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, www.mycompany.com, which is hosted on two geographically separated server farms or data centers. Both server farms use Citrix ADC appliances. The Citrix ADC appliances in these server farms
are set up in one-arm mode and function as authoritative DNS servers for the www.mycompany.com domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology

To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both Citrix ADC appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a Citrix ADC cluster setup, see Setting Up GSLB in a Cluster.

Configuring a Standard Load Balancing Setup

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the Citrix ADC appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see Load Balancing.

Configure an authoritative DNS service

January 25, 2019

Contributed by: C

When you configure the Citrix ADC appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the Citrix ADC appliance to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see Domain Name System.
To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

1. `add service <name> <IP>@ADNS <port>`
2. `show service <name>`

Example:

1. `add service Service-ADNS-1 10.14.39.21 ADNS 53`
2. `show service Service-ADNS-1`

To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

1. `set service <name> <IPAddress> ADNS <port>`

Example:

1. `set service Service-ADNS-1 10.14.39.21 ADNS 53`

To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

1. `rm service <name>`

Example:

1. `rm service Service-ADNS-1`

To configure an ADNS service by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Add a new ADNS service, or select an existing service and edit its settings.
   1. **Citrix ADC**
   2. **Citrix ADC 12.1**
Configure a basic GSLB site

January 23, 2019
Contributed by: C

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every Citrix ADC appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the Citrix ADC appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

To create a GSLB site by using the command line interface

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

1. `add gslb site <siteName> <siteIPAddress>
2. `show gslb site <siteName>

Example:

1. `add gslb site Site-GSLB-East-Coast 10.14.39.21
2. `show gslb site Site-GSLB-East-Coast

To modify or remove a GSLB Site by using the command line interface

- To modify a GSLB site, use the `set gslb site` command, which is just like using the `add gslb site` command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the `unset gslb site` command, followed by the `siteName` value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the `rm gslb site` command, which accepts only the `<name>` argument.

To configure a basic GSLB site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

**To view the statistics of a GSLB site by using the command line interface**

At the command prompt, type:

```
stat gslb site <siteName>
```

**Example:**

```
stat gslb site Site-GSLB-East-Coast
```

**To view the statistics of a GSLB site by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Sites.
2. Select the GSLB site and click Statistics.

**Configure a GSLB service**

January 23, 2019

Contributed by:

C

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

**Important**

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

The GSLB service IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.
To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

1. `add gslb service <serviceName> <serverName | IP> <serviceType> <port> -siteName <string>
2. `show gslb service <serviceName>

Example:

1. `add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 -siteName Site-GSLB-East-Coast
2. `show gslb service Service-GSLB-1

To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the `set gslb service <serviceName>` command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the `add gslb service` command for details about the parameters. Example

  1. `> set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -maxClient 8
   2. Done
   3. `> sh gslb service SKP_GSLB_NOTCNAME_SVC2
   4. SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80) - HTTP
   5. ...
   6. Max Conn: 8  Max Bandwidth: 25 kbits

- To reset a parameter to its default value, you can use the `unset gslb service <serviceName>` command and the parameters to be unset. Example

  1. `> unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandWidth
   2. Done
   3. `> sh gslb service SKP_GSLB_NOTCNAME_SVC2
   4. SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80) - HTTP
   5. ...
   6. Max Conn: 8  Max Bandwidth: 0 kbits

- To remove a GSLB service, use the `rm gslb service <serviceName>` command.
To create a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Add a new GSLB service, or select an existing service and edit its settings.

To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```bash
stat gslb service <serviceName>
```

Example:

```
stat gslb service Service-GSLB-1
```

To view the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB Service and click Statistics.

Configure a GSLB service group

Service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable an option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled or disabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to the service groups.

**Important**

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-
The GLSB service group IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

The Citrix ADC supports the following types of GSLB service groups.

- IP address based service groups
- Domain name based service groups
- Domain name based autoscale service groups

GSLB domain name based autoscale service groups

The Citrix ADC hybrid and multi-cloud global server load balancing (GSLB) solution enables customers to distribute application traffic across multiple data centers in hybrid clouds, multiple clouds, and on premises. The Citrix ADC GSLB solution supports various load balancing solutions, such as the Citrix ADC load balancer, Elastic Load Balancing (ELB) for Amazon Web Services (AWS), and other third-party load balancers. Also, the GSLB solution performs global load balancing even if the GSLB and load balancing layers are independently managed.

In cloud deployments, users are given a domain name as a reference when accessing the load balancing solution for management purposes. It is recommended that external entities do not use the IP addresses that these domain names resolve to. Also, the load balancing layers scale up or down based on the load, and the IP addresses are not guaranteed to be static. Therefore, it is recommended to use the domain name to refer to the load balancing endpoints instead of IP addresses. This requires the GSLB services to be referred using the domain name instead of IP addresses and it must consume all the IP addresses returned for the load balancing layer domain name and have a representation for the same in GSLB.

To use domain names instead of IP addresses when referring to the load balancing endpoints, you can use the domain name based service groups for GSLB.

Monitor GSLB domain name based service groups

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications; tcp-default and ping-default. The tcp-default monitor is bound to all TCP services and the ping-default monitor is bound to all non-TCP services. The built-in monitors are bound by default to the GSLB service groups. However, it is recommended to bind an application specific monitor to the GSLB service groups.

Recommendation for setting the trigger monitors option to MEPDOWN
The Trigger Monitors option can be used to indicate if the GSLB site must use the monitors always, or use monitors when metrics exchange protocol (MEP) is DOWN.

The Trigger Monitors option is set to ALWAYS by default.

When the Trigger Monitors option is set to ALWAYS, each GSLB node triggers the monitors independently. If each GSLB node triggers the monitors independently, then each GSLB node might operate on different set of GSLB services. This might result in discrepancies in the DNS responses for the DNS requests landing on these GSLB nodes. Also, if each GSLB node is monitoring independently, then the number of monitor probes reaching the load balancer entity increases. The persistence entries also become incompatible across the GSLB nodes.

Therefore, it is recommended that the Trigger Monitors option on GSLB site entity is set to MEPDOWN. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and monitoring ownership lies with the local GSLB node. When Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and subsequent monitoring is done by the local GSLB node of a GSLB service group. The results are then propagated to all other nodes participating in GSLB by using the metrics exchange protocol (MEP).

Also, whenever the set of IP addresses associated with a load balancing domain are updated, it is notified through MEP.

Limitations of GSLB service groups

- For a load balancing domain, the IP address that is returned in the DNS response is generally the public IP address. The private IP address cannot be applied dynamically when the load balancing domain is resolved. Therefore, public IP port and private IP port for the GSLB domain name based autoscale service groups IP port bindings are the same. These parameters cannot be set explicitly for the domain name based autoscale service groups.

- Site persistence, DNS views, and clustering are not supported for GSLB service groups.

Configure and manage GSLB service groups by using the CLI

<table>

### Operation CLI Command

**To bind a GSLB service group to a virtual server**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bind gslb serviceGroup &lt;serviceGroupName&gt; ((&lt;IP&gt;@&lt;port&gt;)</td>
<td>&lt;serverName&gt;@</td>
</tr>
</tbody>
</table>

**Example:**

```
binding gslb serviceGroup
Service-Group-1 203.0.113.2;
binding gslb serviceGroup Service-Group-1 S1 80;
binding gslb serviceGroup Service-Group-1 -monitorName Mon1
```

**To unbind a GSLB service group to a virtual server**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unbind gslb serviceGroup &lt;serviceGroupName&gt; ((&lt;IP&gt;@&lt;port&gt;)</td>
<td>&lt;serverName&gt;@</td>
</tr>
</tbody>
</table>

**Example:**

```
unbind gslb serviceGroup
Service-Group-1 -monitorName Mon1
```

**To set parameters for a GSLB service group**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>set gslb serviceGroup &lt;serviceGroupName&gt;@ [(&lt;serverName&gt;@&lt;port&gt; [-weight &lt;positive_integer&gt;] [-hashId &lt;positive_integer&gt;] [-publicIP &lt;ip_addr</td>
<td>ipv6_addr</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operation</th>
<th>CLI Command</th>
</tr>
</thead>
</table>
| To enable a GSLB service group | `enable gslb serviceGroup <serviceGroupName>@ [::<serverName>@ <port>]`  
**Example:** `enable gslb serviceGroup SG1 S1 80` |
| To disable a GSLB service group | `disable gslb serviceGroup <serviceGroupName>@ [::<serverName>@ <port>] [-delay <secs>] [-graceful (YES / NO)]`  
**Example:** `disable gslb serviceGroup SRG2 S1 80`  
**Note:** The service group that has to be disabled must be a DBS service group and not an autoscale service group. |
| To remove a GSLB service group | `rm gslb serviceGroup <serviceGroupName>`  
**Example:** `rm gslb serviceGroup Service-Group-1` |
| To view the statistics of a GSLB service group | `stat gslb serviceGroup [<serviceGroupName>]`  
**Example:** `stat gslb serviceGroup Service-Group-1` |
| To view the properties of a GSLB service group | `show gslb serviceGroup [<serviceGroupName> -includeMembers]` |
Changes to the existing GSLB CLI commands

The following table lists some of the changes that are done to the existing GSLBs commands after the introduction of the GSLB service groups.

<table>
<thead>
<tr>
<th>CLI Command</th>
<th>Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>bind gslb vserver</td>
<td>The service group name is added to the bind command.</td>
</tr>
<tr>
<td>Example: bind gslb vserver &lt;name&gt;((-serviceName &lt;string&gt; [-weight &lt;positive_integer&gt;] )</td>
<td>&lt;serviceGroupName&gt;@</td>
</tr>
<tr>
<td>unbind gslb vserver</td>
<td>The service group is added to the unbind command.</td>
</tr>
<tr>
<td>Example: unbind gslb vserver &lt;name&gt; (-serviceName &lt;string&gt; &lt;serviceGroupName&gt; @ /(-domainName &lt;string&gt; [-backupIP] [-cookieDomain ])</td>
<td>-policyName &lt;string&gt;@)</td>
</tr>
<tr>
<td>show gslb site</td>
<td>When this command is executed, the GSLB service groups are also displayed.</td>
</tr>
<tr>
<td>show gslb vs</td>
<td>When this command is executed, the GSLB service groups be displayed.</td>
</tr>
</tbody>
</table>
**Configure GSLB service groups by using the GUI**

1. Navigate to **Traffic Management > GSLB > Service Groups**.
2. Create a service group and set the AutoScale Mode to DNS.

**Configure site persistence for the GSLB service groups**

You can configure site persistence for the IP address based and domain name based service groups. Site persistence is not supported for domain name based autoscale service groups.

**To set site persistence based on HTTP cookies by using the CLI**

- For connection proxy persistence, you do not have to set the site prefix.

At the command prompt, type:

```plaintext
1 set gslb service group <serviceGroupName> [-sitePersistence <sitePersistence>]
```

- For HTTP redirect persistence, you must first set the site prefix for a member of the service group and then set the HTTPRedirect persistence parameter for the service group.

At the command prompt, type:

```plaintext
2 set gslb servicegroup <serviceGroupName> <serviceGroup member name|Ip> <port> [-sitePrefix <string>]
3 set gslb servicegroup <serviceGroupName> [-sitePersistence <sitePersistence>]
```

**Examples:**

- Connection proxy persistence

  ```plaintext
  set gslbservicegroup sg1 -sitePersistence connectionProxy
  ```
• HTTPRedirect persistence

    set gslb servicegroup sg2 test1 80 -sitePrefix vserver-GSLB-1

    set gslb servicegroup sg2 -sitePersistence hTTPRedirect

To set site persistence based on cookies by using the GUI

1. Navigate to Traffic Management > GSLB > Services Groups and select the service group that you want to configure for site persistence (for example, servicegroup-GSLB-1).
2. Click the Site Persistence section and set the persistence that meets your requirement.

Tip
For deployment scenario and example configuration of GSLB service groups, see the following topics:

• Use Case: Deployment of Domain Name Based Autoscale Service Group
• Use Case: Deployment of IP Address Based Autoscale Service Group

Configure a GSLB virtual server

March 5, 2019
Contributed by: C

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

Note
A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent with respect to other types of virtual servers. The Service Type parameter on a service or a virtual server is not leveraged while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for doing lookups via MEP.
To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

1. `add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)`
2. `show gslb vserver <name>`

Example:

```
1 add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
2 add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
3 show gslb vserver Vserver-GSLB-1
4 show gslb vserver Vserver-GSLB-2
```

To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the `set gslb vserver` command, which is just like using the `add gslb vserver` command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the `unset gslb vserver` command followed by the `vserverName` value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the `rm gslb vserver` command, which accepts only the name argument.

To configure a GSLB virtual server by using the configuration utility

1. Navigate to `Traffic Management > GSLB > Virtual Servers`.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 stat gslb vserver <name>
```

Example:

```
1 stat gslb vserver Vserver-GSLB-1
```
To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to Traffic Management > GSLB > Virtual Servers, select the virtual server and click Statistics.

GSLB virtual server statistics

Starting from Citrix ADC version 12.1 build 51.xx and later, the GSLB virtual server statistics also display the following information in addition to details such as; vserver hits, current persistence session, request bytes, response bytes, spillover threshold, spillover hits, current client established connections, and vserver down backup hits.

- **Primary LB method failures**: Number of times the primary GSLB method has failed.
- **Backup LB method failures**: Number of times the backup GSLB method has failed.
- **Vserver persistence hits**: The number of times the request is served through the persistence sessions.

**Note:**
The primary or the backup method can fail when primary method is static proximity and backup method is RTT. In this scenario, if there is no location corresponding to LDNS IP, the static proximity fails and backup method is attempted. The statistics are updated based on the following:

- If the backup method is successful, only primary method failure statistics are incremented.
- If RTT calculation is not successful, then backup method also fails. In this case, both primary and backup method failure statistics are incremented.

When the backup method fails, the last resort method of round robin is used.

The following image is a sample of GSLB virtual server statistics from CLI.
The following image is a sample of GSLB virtual server statistics from GUI.

GSLB service statistics

When you run the stat gslb service command from the command line or click on the Statistics link from the configuration utility, the following details of the service will be displayed:

- **Request bytes**: Total number of request bytes received on this service or virtual server.
- **Response bytes**: Number of response bytes received by this service or virtual server.
- **Current client established connections**: Number of client connections in ESTABLISHED state.
- **Current load on the service**: Load on the service (Calculated from the load monitor bound to the service).
The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

**Clearing the GSLB virtual server or service statistics**

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. Citrix ADC provides the following two options to clear the statistics:

- **Basic**: Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GSLB service.
- **Full**: Clears both the virtual server and the bound GSLB service statistics.

**To clear the statistics of a GSLB virtual server by using the command line interface**

At the command prompt, type:

```
stat gslb vserver <name> -clearstats <basic | full>
```

**Example:**

```
stat gslb vserver Vserver-GSLB-1 -clearstats basic
```

**To clear the statistics of a GSLB service by using the command line interface**

At the command prompt, type:

```
stat gslb service <name> -clearstats <basic | full>
```

**Example:**

```
stat gslb service service-GSLB-1 -clearstats basic
```

**To clear the statistics of a GSLB virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.
To clear the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB service and, click Statistics, and then click Clear.
3. From the Clear drop-down list, select Basic or Full, and then click OK.

Enabling and Disabling GSLB Virtual Servers

When you create a GSLB virtual server, it is enabled by default. If you disable it, it cannot process traffic. A disabled GSLB virtual server is not included in GSLB configuration but is not removed from the Citrix ADC appliance.

To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

```
1  enable gslb vserver <name＠
2  disable gslb vserver <name＠
```

Example:

```
1  enable gslb vserver Vserver-GSLB-1
2  disable gslb vserver Vserver-GSLB-1
```

To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select a virtual server and, from the Action list, select enable or disable.

1.
2. Citrix ADC
3. Citrix ADC 12.1

Bind GSLB services to a GSLB virtual server

January 23, 2019
Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

**To bind a GSLB service to a GSLB virtual server by using the command line interface**

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

```
1 bind gslb vserver <name> -serviceName <string>
2 show gslb vserver <name>
```

**Example:**

```
1 bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
2 show gslb vserver Vserver-GSLB-1
```

**To unbind a GSLB service from a GSLB virtual server by using the command line interface**

At the command prompt, type:

```
1 unbind gslb vserver <name> -serviceName <string>
```

**To bind GSLB services by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click in the **Domains** section, and configure a domain and bind the domain.

**Bind a domain to a GSLB virtual server**

January 25, 2019
To make a Citrix ADC appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the Citrix ADC appliance adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see Domain Name System.

**To bind a domain to a GSLB virtual server by using the command line interface**

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

```
1  bind gslb vserver <name> -domainName <string>
2  show gslb vserver <name>
```

**Example:**

```
1  bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
2  show gslb vserver Vserver-GSLB-1
```

**To unbind a GSLB domain from a GSLB virtual server by using the command line interface**

At the command prompt, type:

```
1  unbind gslb vserver <name> -domainName <string>
```

**To bind a domain to a GSLB virtual server by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
   - To create a new Domain, click Add.
   - To modify an existing Domain, select the domain, and then click Open.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:

   - Domain Name*—domainName (for example, www.mycompany.com)

/* A required parameter

5. Click Create.

6. Click OK.

**To view the statistics of a domain by using the command line interface**

At the command prompt, type:

```
stat gslb domain <name>
```

**Example:**

```
stat gslb domain www.mycompany.com
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the Citrix ADC appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

**To view the statistics of a domain by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click **Statistics**.

**To view the configuration details of the entities bound to a GSLB domain using the command line**

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```
show gslb domain <name>
```

**Example:**
```
show gslb domain gslb1.com
  gslb1.com
  gvs1 - HTTP  state: DOWN
  DNS Record Type: A
  Configured Method: LEASTCONNECTION
  Backup Method: ROUNDROBIN
  Persistence Type: NONE
  Empty Down Response: DISABLED
  Multi IP Response: DISABLED
  Dynamic Weights: DISABLED

gsvc1 (10.102.239.165: 80) - HTTP State: DOWN  Weight: 1
  Dynamic Weight: 0  Cumulative Weight: 1
  Effective State: DOWN
  Threshold : BELOW

  Monitor Name : http
    State: DOWN  Weight: 1
    Probes: 144  Failed [Total: 144 Current: 144]
    Last response: Failure - TCP syn sent, reset received.
    Response Time: 2000 millisec

gsvc2 (10.102.239.179: 80) - HTTP State: DOWN  Weight: 1
  Dynamic Weight: 0  Cumulative Weight: 1
  Effective State: DOWN
  Threshold : BELOW

  Monitor Name : http-ecv
    State: DOWN  Weight: 1
    Probes: 141  Failed [Total: 141 Current: 141]
    Last response: Failure - TCP syn sent, reset received.
    Response Time: 2000 millisec
```

To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

**Note:** This feature is available in NetScaler release 10.5.e.

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click the field below the **Domains** pane.
3. In the **GSLB Virtual Server Domain Binding** dialog box, select a domain, and then click **Show Bindings**.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

**Example of a GSLB setup and configuration**

January 23, 2019
Contributed by: C

An organization has a geographically dispersed network and has three data centers located in the United States, Mexico, and Colombia. In the configuration related to these locations, these are referred to as US, MX, and CO respectively. At each location, the company has a server farm, which provides the same content and the setup is working as expected. The Citrix ADC appliance at each location is configured through a virtual server with the HTTP protocol on port 80.

The organization has implemented the GSLB setup by adding a site identifier at each site. The site identifier includes a site name and an IP address that is owned by the Citrix ADC appliance and is used for the GSLB communications. Each site has a site local to the appliance. Also, each site has two sites remote to the local appliance. On each site, a GSLB virtual server is created with the same name. This virtual server identifies the website of the organization globally and does not have any IP address associated with it. The setup also has GSLB services configured that point to the load balancing virtual servers configured on each GSLB site by specifying the IP address, protocol, and port number of the respective virtual server. These services are bound to the GSLB virtual server.

**Note:** In the procedure below, the commands use private IP addresses for the GSLB sites. For public sites and GSLB services, ensure that you use public IP addresses for these sites.

The following table lists the IP addresses and locations used in the example:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3.1.101</td>
<td>Site IP of local Citrix ADC.</td>
</tr>
<tr>
<td>172.16.1.101</td>
<td>Site IP of remote location site-MX.</td>
</tr>
<tr>
<td>192.168.1.101</td>
<td>Site IP of remote location site-CO.</td>
</tr>
<tr>
<td>172.16.1.100</td>
<td>Service IP of remote location site-MX.</td>
</tr>
</tbody>
</table>
When adding a GSLB site, if the site communicates over the internet only then use the “Public IP” field. For example, when there is no site to site VPN connectivity between the GSLB sites.

To configure the GSLB setup with Citrix ADC appliances by using the CLI commands

1. Enable the GSLB feature, if not already done.

   ```bash
   enable ns feature gslb
   ```

2. Identify a SNIP that for adding local GSLB site.

3. Add the GSLB site for the local Citrix ADC appliance.

   ```bash
   add gslb site site-US 10.3.1.101
   ```

4. Add the GSLB sites for the remote Citrix ADC appliances.

   ```bash
   add gslb site site-MX 172.16.1.101
   add gslb site site-CO 192.168.1.101
   ```

5. Add the GSLB virtual server that references a service being used in the GSLB setup:

   ```bash
   add gslb vserver gslb-lb HTTP
   ```

6. Add the GSLB services for each site participating in the GSLB setup:

   ```bash
   add gslb service gslb_SVC30 172.16.1.100 HTTP 80 -siteName site-MX
   add gslb service gslb_SVC10 10.3.1.100 HTTP 80 -siteName site-US
   add gslb service gslb_SVC20 192.168.1.100 HTTP 80 -siteName site-CO
   ```

7. Bind the GSLB services to the GSLB virtual server:

   ```bash
   bind gslb vserver gslb-lb -serviceName gslb_SVC10
   bind gslb vserver gslb-lb -serviceName gslb_SVC20
   bind gslb vserver gslb-lb -serviceName gslb_SVC30
   ```

8. Bind the domain to the GSLB virtual server.
bind gslb vserver gslb-lb -domainName www.mycompany.com -TTL 30

9. Add an ADNS service that listens to the DNS queries.

set service Service-ADNS-1 10.14.39.21 ADNS 53

Synchronize the configuration in a GSLB setup

January 25, 2019

Contributed by: C

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each Citrix ADC, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point, you must ensure that the configuration across all GSLB sites is identical. You can use the Citrix ADC’s GSLB configuration synchronization option to synchronize the configuration across the GSLB sites.

The Citrix ADC appliance from which you use the synchronization option is referred to as the ‘master node’ and the GSLB sites on which the configuration is copied as ‘slave nodes’. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the master node.

Synchronization (may also be referred to as ‘auto sync’) is carried out in the following manner:

- The master node finds the differences between the configuration of the master node and slave node, and changes the configuration of the slave node to make it similar to the master node. If you force a synchronization (use the ‘force sync’ option), the appliance deletes the GSLB configuration from the slave node and then configures the slave to make it similar to the master node.
- During synchronization, if a command fails, synchronization is not aborted and the error message are logged into a .err file in the /var/netscaler/gslb directory.
- Synchronization is done only on the parent sites. GSLB child sites’ configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site’s details. Also, GSLB services are not always required to be configured in the child sites.
• If you disable the internal user login, the GSLB auto sync uses the SSH keys to synchronize the configuration. But, to use GSLB auto sync in partition environment, you need to enable the internal user login and make sure that the partition username in the local and remote GSLB sites is same.

Note

• On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in management subnet, as in most cases, then NSIP is used as the source IP address.

To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through GSLB site IP subnet.

• The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for an RPC node is specific to each Citrix ADC appliance. Therefore, after you force a synchronization (using the sync gslb config-forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other Citrix ADC appliances.

• Port 22 is also required for synchronizing the database files to the remote site.

If you use the saveconfig option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The master node saves its configuration immediately before it initiates the process of synchronization.
2. After the process of synchronization is complete, the slave nodes save their configuration. A slave node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave node, you must manually investigate the cause of the failure and take corrective action.

Limitations of synchronization

• On the master node, the names of the remote GSLB sites must be identical to the names of sites configured on the Citrix ADC appliances hosting those sites.
• During the synchronization, traffic disruptions may occur.
• Citrix ADC can synchronize only up to 80,000 lines of the configuration.
• Synchronization may fail:
  – If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
  – If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the master node and then try to synchronize.
If the RPC node passwords are different for NSIP and loopback IP address.

- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes should be same.
- If you rename any GSLB entity that is part of your GSLB configuration (use “show gslb running-config” command to display the GSLB configuration). You need to use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and readded to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

Points to note before start the synchronization of a GSLB setup

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the master node, management access and SSH should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the Citrix ADC appliance. For more information about adding the GSLB site IP addresses and enabling Management Access, see “Configuring a Basic GSLB Site”.
- The GSLB configuration on the Citrix ADC appliance that is considered as the master node is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB need to have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.
- The master node and the slave nodes run the same Citrix ADC versions. Starting from release 12.1, build 50.x, the appliance checks for the firmware version on master and slave nodes before initiating synchronization. If the master and the slave nodes run different versions, the synchronization is aborted for that remote site to avoid pushing any incompatible changes across the versions. Also, an error message displaying the site details on which the synchronization aborted appears.

The following figures display sample error messages from the CLI and the GUI.

Important

The following directories are synchronized as part of the GSLB configuration synchronization.

- /var/netscaler/locdb/
- /var/netscaler/ssl/
- /var/netscaler/inbuilt_db/
Manual synchronization between sites participating in GSLB

January 23, 2019

Contributed by: C

**Important:** After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Perform the synchronization only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.

**To synchronize a GSLB configuration by using the CLI:**

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

```
1. sync gslb config [-preview | -forceSync <string> | -nowarn | -saveconfig] [-debug]
2. show gslb syncStatus
```

**Example:**

```
1. sync gslb config
2. [WARNING]: Syncing config may cause configuration loss on other site.
3. Please confirm whether you want to sync-config (Y/N)? [N]:y
5. Retrieving local site info: ok
6. Retrieving all participating gslb sites info: ok
7. Gslb_site1[Master]:
8. Getting Config: ok
```
To synchronize a GSLB configuration by using the GUI:

1. Navigate to Traffic Management > GSLB > Dashboard.
2. Click Auto Synchronization GSLB and select ForceSyn.
3. In GSLB Site Name, select the GSLB sites that are to be synchronized with the master node configuration.

Previewing GSLB synchronization

By previewing the GSLB synchronization operation, you can see the differences between the master node and each slave node. If there are any discrepancies, you can troubleshoot before synchronizing the GSLB configuration.

To preview the GSLB synchronization output by using the CLI:

At the command prompt, type the following command:

```
sync gslb config -preview
```

To preview the GSLB synchronization output by using the GUI:

1. Navigate to Configuration > Traffic Management > GSLB > Dashboard.
2. Click Auto Synchronization GSLB and select Preview.
3. Click Run.
   A progress window displays any discrepancies in the configuration.

Debugging the commands triggered during synchronization process

You can view the status (success or failure) of each command triggered during the synchronization process and troubleshoot accordingly.

To debug the GSLB synchronization commands by using the CLI:

At the command prompt, type the following command:
To debug the GSLB synchronization commands by using the GUI:

1. Navigate to Configuration > Traffic Management > GSLB > Dashboard.
2. Click Auto Synchronization GSLB and select Debug.
3. Click Run.
   A progress window displays the status of each command triggered during synchronization.

Real-time synchronization between sites participating in GSLB

January 25, 2019
Contributed by: C

If you want to synchronize GSLB configuration across slave sites automatically when the commands are executed on master sites, you can now use the AutomaticConfigSync option to automatically synchronize the real-time GSLB configuration. You do not have to manually trigger the AutoSync option to synchronize the configuration.

If you attempt to manually synchronize (with the sync gslb config command) a site while it is being autosynchronized, a “Sync in progress” error message appears. Autosynchronization cannot be triggered for a site that is in the process of being synchronized manually.

Attention:
Starting with Citrix ADC 12.1 build xx.xx, SNMP traps are generated when you synchronize the GSLB configuration. Note that in real-time synchronization, the synchronization status in the first SNMP trap is captured as failure. You can ignore this status because a second SNMP trap is automatically generated immediately after the first trap with the actual synchronization status. However, if the synchronization failed in the second attempt also, SNMP trap is not generated because the synchronization status has not changed from the previous synchronization status.

For details on configuring Citrix ADC appliance to generate traps, see Configuring the Citrix ADC to generate SNMP traps.

Notes:
All logs related to real-time sync are stored in the /var/netscaler/gslb/periodic_sync.log file.

The sync status file and default configuration file are stored in the location /var/netscaler/gslb_sync.

Enabling AutomaticConfigSync from default partition of a partitioned appliance is not supported. However, it can be enabled from all other partitions. The sync status file and default configuration file are stored in the location /var/partitions/<partition name>/netscaler/gslb_sync.

Best practices for using the real-time synchronization feature

- It is recommended that all the Citrix ADC appliances participating as sites have the same Citrix ADC software version.
- To change the RPC node password, first change the password on the slave site and then on the master site.
- Configure local GSLB sites on each site participating in GSLB.
- Enable automaticConfigSync on one of the sites where the configuration is performed. This site eventually gets synchronized to other GSLB sites.
- If there is a new configuration or changes are made to the existing configuration, make sure to check the status using the “show gslb syncStatus” command to confirm if the changes are synchronized across all sites or if there was any error.

To enable real-time synchronization by using the CLI

At the command prompt, type:

```
set gslb parameter -automaticConfigSync (ENABLED | DISABLED)
```

Example:

```
set gslb parameter -automaticConfigSync ENABLED
```

To enable real-time synchronization by using the GUI

1. Navigate to Configuration > Traffic Management > GSLB > Change GSLB Settings.
2. Select Automatic ConfigSync.

   **Note**: This option must be enabled only in the site where the configuration is performed.

   **Tip**
   For information on the following topics, see Manual synchronization between sites participating in GSLB.
After the GSLB configuration is synchronized across the GSLB sites, you can view the detailed status and the summary of the last GSLB sync operation. This is applicable to both manual and real-time GSLB synchronization.

**To view the GSLB synchronization status or summary by using the CLI**

At the command prompt, type:

```
1 show gslb sync status
```

or

```
1 show gslb syncStatus -summary
```

The following figure displays a sample GSLB configuration synchronization status.

The following figure displays a sample GSLB configuration synchronization summary.

**To view the GSLB synchronization status or summary by using the GUI**

1. Navigate to `Configuration > Traffic Management > GSLB > Dashboard`.
2. Click `View Synchronization Summary` or `View Synchronization Status`, as required.

SNMP traps for GSLB configuration synchronization

January 25, 2019
Contributed by: C

Starting with Citrix ADC 12.1 build 49.xx, the Citrix ADC appliance generates SNMP traps for both local and remote sites when you synchronize the GSLB configuration. SNMP traps are generated for both manual synchronization and real-time synchronization.

When you synchronize the GSLB configuration for the first time, SNMP traps are generated. In the subsequent synchronization attempts, the SNMP traps are generated only if there is a change in the synchronization status from the previous synchronization status. Also, the SNMP traps are generated only for sites for which the synchronization status changed from the previous state.

For example, consider that the first GSLB configuration synchronization is successful. When you synchronize the configuration for the second time and if the synchronization is successful again, then SNMP traps are not generated because the status is not changed. However, in the third attempt, if the synchronization fails for one of the sites, then SNMP trap is generated for that site alone.

In a high availability and a cluster setup, the appliance generates the SNMP traps when you synchronize the GSLB configuration from the new node irrespective of the previous synchronization status. Also, if SNMP trap option was previously disabled and then enabled, SNMP traps are generated from that point onwards irrespective of previous synchronization status.

The following figure displays sample SNMP traps of GSLB configuration synchronization.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

GSLB dashboard

January 23, 2019
Contributed by: C

You can view the overall status of the GSLB sites participating in GSLB on the GSLB dashboard. You can access the GSLB settings from the dashboard. You can also start the GSLB configuration wizard from the dashboard. Additionally, you can perform the synchronization and test the GSLB setup from the dashboard.
To access the GSLB dashboard, navigate to Configuration > Traffic Management > GSLB > Dashboard.

2. Citrix ADC
3. Citrix ADC 12.1

Monitor GSLB services

January 23, 2019
Contributed by: C

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence Information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The Citrix ADC appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the Citrix ADC appliance uses the state of the service reported by the monitor. However, you can configure the Citrix ADC appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the appliance to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.
To use monitors, first create them, and then bind them to GSLB services.

**Configure monitor trigger**

You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the Citrix ADC appliance stops monitoring when MEP returns to the UP state.

**To configure monitor triggering by using the command line interface**

At the command prompt, type:

```
set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN | MEPDOWN_SVCDOWN)
```

**Example:**

```
set gslb site Site-GSLB-North-America -triggerMonitor Always
```

**To configure monitor triggering by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Trigger Monitors** drop-down list, select an option for when to trigger monitoring.

**Add or remove monitors**

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

**To add a monitor by using the command line interface**

At the command prompt, type the following commands to create a monitor and verify the configuration:

```
add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>
show lb monitor <monitorName>
```

**Example:**

```
add lb monitor Monitor1 -type HTTP -destPort 80
show lb monitor Monitor1
```
To remove a monitor by using the command line interface

At the command prompt, type:

```
1 rm lb monitor <monitorName>
```

To add a monitor by using the configuration utility

Navigate to
Traffic Management > Load Balancing > Monitors, and add or delete a monitor.

Bind monitors to a GSLB service

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service's monitoring threshold.

To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
1 bind monitor <name> <serviceName> [ -state (Enabled | Disabled) ] -weight <positiveInteger>
```

Example:

```
1 bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
```
**To set the monitoring threshold for a GSLB service by using the command line interface**

At the command prompt, type:

```
set gslb service <ServiceName> -monThreshold <PositiveInteger>
```

**Example:**

```
set gslb service service-GSLB-1 -monThreshold 9
```

**To bind the monitor to the GSLB service by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor** section and bind the monitor to the GSLB service.

**To set the monitoring threshold for a GSLB service by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor Threshold** section and enter a threshold value.

**Use case: Deployment of domain name based autoscale service group**

January 25, 2019

Contributed by:

C

Tip

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#)

**Deployment scenario**

Two datacenters are deployed in two AWS regions, one in Sydney and one in North Virginia. Another datacenter is deployed in Azure. An AWS ELB in each AWS region is used to load balance the application servers. ALB is used for Azure to load balancing the application server. The Citrix ADC appliances are configured for GSLB for the ELBs and ALB using GSLB domain name based autoscale service group.
Important
You must configure the required security groups in AWS and attach it to the GSLB instance. Port 53 must be allowed in the security group inbound and outbound rules. Also, ports (3009 or 3011 depending on secure MEP configuration) for MEP communication must be open. For application monitoring, the corresponding ports must be allowed in the security group outbound rules.

The configuration steps for the above deployment scenario and the corresponding CLI commands are as follows:

1. Create datacenters (represented by GSLB sites).

   1. `add gslb site aws-sydney 192.0.2.2`
   2. `add gslb site aws-nvirginia 198.51.100.111`
   3. `add gslb site alb-southindia 203.0.113.6`

2. Add a name server with the DNS gateway IP address where the GSLB node is added. This must be done in all datacenters.

   `add dns nameServer 8.8.8.8`

3. Add servers for ELB and ALB.

   1. `add server aws-sydney_server lb-sydney-1052691850.ap-southeast-2.elb.amazonaws.com`
   2. `add server aws-nvirginia_server LB-nvirginia-860559595.us-east-1.elb.amazonaws.com`
   3. `add server alb-southindia_server alb.southindia.cloudapp.azure.com`

4. Add GSLB autoscale service groups for each ELB and ALB and bind each server to the respective service group.

   1. `add gslb serviceGroup aws-nvirginia_sg HTTP -autoScale DNS -siteName aws-nvirginia`
   2. `add gslb serviceGroup aws-sydney_sg HTTP -autoScale DNS -siteName aws-sydney`
   3. `add gslb serviceGroup alb-southindia_sg HTTP -autoScale DNS -siteName alb-southindia`
   4. `bind gslb serviceGroup aws-nvirginia_sg aws-nvirginia_server 80`
5. Add a GSLB virtual server and bind the application domain and the service groups to this virtual server.

```bash
bind gslb serviceGroup aws-sydney_sg aws-sydney_server 80ind gslb serviceGroup alb-southindia_sg alb-southindia_server 80
```

**Use case: Deployment of IP address based autoscale service group**

January 25, 2019

Contributed by: C

Tip

For information about the GSLB service groups, see Configuring a GSLB Service Group.

**Deployment scenario**

If there are multiple applications hosted on the same application server, the GSLB should probe these applications to see if the applications are responding or not. If an application is not responding, the user must be directed to the server on which the application is UP. Also, if one of the applications is DOWN, then the server should not be marked DOWN, because the other applications are UP.

In the following example, multiple applications (HTTPS) are hosted on one server in each GSLB site and hence all these applications resolve to one IP address of the respective site.

Using the GSLB service groups, you can have the same server with an IP address and port bound to multiple service groups where each service group represents a different application.
An application specific monitor is bound to the service groups that marks the service group as DOWN if the application is DOWN. Thus, whenever an application is DOWN, only that application is taken out from the setup and not the server.

```
1  add gslb serviceGroup app1_site1 HTTP -maxClient 0 -cip DISABLED -cltTimeout 180 -svrTimeout 360 -siteName s1
2
3  add gslb serviceGroup app2_site1 HTTP -maxClient 0 -cip DISABLED -cltTimeout 180 -svrTimeout 360 -siteName s1
4
5  add gslb serviceGroup app1_site2 HTTP -maxClient 0 -cip DISABLED -cltTimeout 180 -svrTimeout 360 -siteName s2
6
7  add gslb serviceGroup app2_site2 HTTP -maxClient 0 -cip DISABLED -cltTimeout 180 -svrTimeout 360 -siteName s2
8
9  add lb monitor http_app2 HTTP -respCode 200 -httpRequest "GET /testsitesite/app2.html"
10
11 add lb monitor http_app1 HTTP -respCode 200 -httpRequest "GET /testsitesite/app1.html"
12
13  bind gslb serviceGroup app1_site1 192.0.2.140 80
14
15  bind gslb serviceGroup app1_site1 -monitorName http_app1
16
17  bind gslb serviceGroup app2_site1 192.0.2.140 80
18
19  bind gslb serviceGroup app2_site1 -monitorName http_app2
20
21  bind gslb serviceGroup app1_site2 192.0.2.142 80
22
23  bind gslb serviceGroup app1_site2 -monitorName http_app1
24
25  bind gslb serviceGroup app2_site2 192.0.2.142 80
26
27  bind gslb serviceGroup app2_site2 -monitorName http_app2
```

How-to articles

January 25, 2019
Contributed by: C

The GSLB how-to articles contain information about some of the important GSLB configurations such as customizing GSLB configuration, configuring persistent connections, disaster recovery, and so on.

Customizing Your GSLB Configuration
Configuring Persistent Connections
Managing Client Connections
Configuring GSLB for Proximity
Protecting the GSLB Setup Against Failure
Configuring GSLB for Disaster Recovery
Overriding Static Proximity Behavior by Configuring Preferred Locations
Configuring GSLB Service Selection Using Content Switching
Configuring Global Server Load Balancing for DNS Queries with NAPTR records
Using the EDNS0 Client Subnet Option for Global Server Load Balancing
Example of a Complete Parent-Child Configuration Using the Metrics Exchange Protocol

Customize your GSLB configuration

January 25, 2019
Contributed by: C

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.
These settings depend on your network deployment and the types of clients you expect to connect to your servers.

**Modify maximum connections or maximum bandwidth for a GSLB service**

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

**To modify the maximum clients or bandwidth of a GSLB service by using the command line interface**

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

```
1 set gslb service <serviceName> [-maxClients <positive_integer>] [-maxBandwidth <positive_integer>]
2 show gslb service <serviceName>
```

**Example:**

```
1 set glsbl service Service-GSLB-1 -maxBandwidth 100 -maxClients 100
2 show gslb service Service-GSLB-1
```

**To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**, and double-click a service.
2. Click in the **Other Settings** section and set the following parameters:
   - Max Clients—maxClients
   - Max Bandwidth—maxBandwidth

**Create CNAME-based GSLB services**

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMEs) for the services.
For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the Citrix ADC appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the Citrix ADC appliance provides the CNAME with the corresponding A record (IP address). The Citrix ADC appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different Citrix ADC appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a Citrix ADC appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.
To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

```
1 add gslb service <serviceName> -cnameEntry <string> -siteName <string>
```

Example:

```
1 add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -siteName Site-GSLB-East-Coast
2 add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -siteName Site-GSLB-West-Coast
```

To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Create a service, and set the Type to Canonical Name Based.

Configure transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

Configure dynamic weights for services

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.
When dynamic weights are configured on the GSLB virtual server, requests are distributed according
to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of
the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore,
when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis
of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that
the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual
servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services
that can serve the client. If a service at either site goes down, the other server in that site has to handle
twice as much traffic as a service at the other site. If dynamic weight is based on the number of active
services, the site with both services active has twice the weight of the site with one service down and
therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are
twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to
the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see “
Assigning Weights to Services”.

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB
service bound to it. The GSLB service represents a load balancing virtual server that in turn has two
services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two
services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled**: The cumulative weight of the GSLB virtual server is the product of the dynamic weight
  (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT**: The count is the sum of the number of services bound to the load balancing
  virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product
  of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWIGHT**: The dynamic weight is the sum of the number of services bound to the GSLB
  service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight
  of the GSLB service (3), which is 6.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

**To configure a GSLB virtual server to use dynamic weights by using the command line interface**

At the command prompt, type:
set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT

Example:

set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT

To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the Method section and, from the Dynamic Weight drop-down list, select SERVICECOUNT or SERVICEWEIGHT.

Configure persistent connections

January 25, 2019
Contributed by:
C

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. Persistence is useful for deployments that deal with e-commerce, such as shopping card usage, where the server needs to maintain the state of the connection to track the transaction. To maintain the state of connection, you must configure persistence on a virtual server. With persistence configured, the Citrix ADC appliance selects a data center to process a client request and forwards the IP address of the selected data center for all subsequent DNS requests. If the configured persistence applies to a site that is down, the Citrix ADC appliance uses a GSLB method to select a new site, and the new site becomes persistent for subsequent requests from the client.

The GSLB virtual server is responsible for DNS-based site persistence, and it controls the site persistence for a remote GSLB service. The Citrix ADC appliance supports persistence based on the source IP address or on HTTP cookies.
When you bring a physical service DOWN with a delay time, the physical service goes into the transition out of service (TROFS) state. Site persistence is supported as long as the service is in the TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

Note: If connection proxy is specified as the site persistence method and if you also want to configure persistence of the physical servers, do not configure SOURCEIP persistence. When the connection is proxied, an IP address owned by the appliance is used, and not the actual IP address of the client. Configure methods such as cookie persistence or rule-based persistence on the load balancing virtual server.

**Configure persistence based on source IP address**

With source-IP persistence, when a DNS request is received at a data center, the Citrix ADC appliance first looks for an entry in the persistence table and, if an entry for the local DNS server exists and the server mentioned in the entry is configured, the IP address of that server is sent as the DNS response.

For the first request from a particular client, the Citrix ADC appliance selects the best GSLB site for the request and sends its IP address to the client. Since persistence is configured for the source IP address of the client, all subsequent requests by that client or another local DNS server in the same IP subnet are sent the IP address of the GSLB site that was selected for the first request.

For source-IP address based persistence, the same set of persistence identifiers must be configured on the GSLB virtual servers in all data centers. A persistence identifier is a number used by the data centers to identify a particular GSLB virtual server. A cookie transmits the persistence identifier, enabling the Citrix ADC appliance to identify the domain so that it can forward all appropriate requests to the same domain. When persistence is enabled, the persistence information is also exchanged as part of metrics exchange.

For the Citrix ADC appliance to support persistence across sites, persistence must be enabled on the GSLB virtual servers of all participating sites. When you use source IP address persistence on the network identifier, you must configure a subnet mask. For any domain, persistence takes precedence over any other configured GSLB method.

**To configure persistence based on source IP address by using the command line interface**

At the command prompt, type:

```
set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId <positive_integer> [-persistMask <netmask>] - [timeout <mins>]
```

**Example:**
To configure persistence based on source IP address by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the Persistence section and, from the Persistence drop-down list, select SOURCEIP and set the following parameters:
   - Persistence Id—persistenceId
   - Time-out—timeout
   - IPv4 Netmask or IPv6 Mask length—persistMask

Configure persistence based on HTTP cookies

The Citrix ADC appliance provides persistence at the HTTP-request level by using connection proxy and HTTP redirect. With these persistence methods, the appliance uses an HTTP cookie (known as a “site cookie”) to reconnect the client to the same server. The appliance inserts the site cookie in the first HTTP response.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. The cookie expiration is based on the cookie timeout configured on the Citrix ADC appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

When the Citrix ADC appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. The physical server in that GSLB site adds a site cookie to the HTTP header, and connection persistence is in effect.

If the DNS entry in the client cache expires, and then the client sends another DNS query and is directed to a different GSLB site, the new GSLB site uses the site cookie present in the client request header to implement persistence. If the GSLB configuration at the new site uses connection-proxy persistence, the new site creates a connection to the GSLB site that inserted the site cookie, proxies the client request to the original site, receives a response from the original GSLB site, relays that response back to the client, and closes the connection. If the GSLB configuration uses HTTP redirect persistence, the new site redirections the request to the site that originally inserted the cookie.

Note: Connection proxy persistence can be configured only for local services. However, connection proxy persistence must be enabled on both local and remote GSLB services that are configured for the GSLB virtual server.

Connection proxy occurs when the following conditions are satisfied:
Requests are sent from a domain participating in GSLB. The domain is obtained from the URL/Host header.

Requests are sent from a local GSLB service whose public IP address matches the public IP address of an active service bound to the GSLB virtual server.

The local GSLB service has connection proxy enabled.

The request includes a valid cookie that contains the IP address of an active remote GSLB service.

If one of the conditions is not met, connection proxy does not occur, but a site cookie is added if the local GSLB service has connection proxy enabled AND:

- No site cookie is supplied; OR,
- The site cookie refers to an IP address that is not an active GSLB remote service; OR,
- The cookie refers to the IP address of the virtual server on which the request is received.

The following are the limitations of using connection proxy site cookies:

- Site cookies do not work for non-HTTP(S) protocols.
- If an HTTP request is sent to a back-up virtual server, the virtual server does not add a cookie.
- Site cookies do not work if SSL client authentication is required.
- At the local site, the statistics for a GSLB service on a remote site are not the same as the statistics recorded for that service at the remote site. At the local site, the statistics for a remote GSLB service are slightly higher than the statistics that the remote site records for that same service.

Redirect persistence can be used only:

- For HTTP or HTTPS protocols.
- If the domain name is present in the request (either in the URL or in the HOST header), and the domain is a GSLB domain.
- When the request is received on a backup VIP or a GSLB local service that is in the down state.

Note

In a GSLB parent-child configuration, connection proxy works as intended even when a GSLB service is not configured on a child site. However, if you have additional configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the site and configure it accordingly.

For more information about parent-child topology, see Parent-Child Topology Deployment Using the MEP Protocol.

To set persistence based on HTTP cookies by using the command line interface

At the command prompt, type:
To set persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the Site Persistence section and set persistence based on cookies.

Manage client connections

January 25, 2019
Contributed by: C

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

Enable delayed cleanup of virtual server connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the Citrix ADC appliance performs a delayed cleanup of connections to a GSLB service that is down.
To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

```
1 set gslb service <name> -downStateFlush (ENABLED | DISABLED)
2 show gslb service <name>
```

Example:

```
1 set gslb service Service-GSLB-1 -downStateFlush ENABLED
2 Done
3
4 show gslb service Service-GSLB-1
5 Done
```

To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the service.
2. Click the Other Settings section and select the Down State Flush option.

Manage local DNS traffic by using DNS policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the Citrix ADC appliance.

DNS expressions

The Citrix ADC appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called rules) are combined to create DNS policies that are then bound globally on the Citrix ADC appliance.

Following is the list of predefined DNS qualifiers available on the Citrix ADC appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS_AREC
- CLIENT.UDP.DNS.IS_AAAAREC
- CLIENT.UDP.DNS.IS_SRVREC
• CLIENT.UDP.DNS.IS_MXREC
• CLIENT.UDP.DNS.IS_SOAREC
• CLIENT.UDP.DNS.IS_PTRREC
• CLIENT.UDP.DNS.IS_CNAME
• CLIENT.UDP.DNS.IS_NSREC
• CLIENT.UDP.DNS.IS_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (\.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")

To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan...).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

Configure DNS actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

• Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.
• Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see Overriding Static Proximity Behavior by Configuring Preferred Locations.
• Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
• Forward a request to the name server without performing a lookup in the appliance’s DNS cache.
• Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, dns_default_act_Drop. If you want to bypass the DNS cache, use the built-in action, dns_default_act_Cachebypass. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.
To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

```
1 add dns action <actionName> <actionType> (-IPAddress <ip_addr | ipv6_addr> ... | -viewName <string> | -preferredLocList <string>) ... [-TTL <secs>]
2 show dns action [<actionName>]
```

Examples

**Example 1: Configuring DNS Response Rewrite.** The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

```
1 add dns action dns_act_response_rewrite Rewrite_Response -IPAddress 192.0.2.20 192.0.2.56 198.51.100.10
2 Done
3 show dns action dns_act_response_rewrite
4 1) ActionName: dns_act_response_rewrite ActionType: Rewrite_Response TTL: 3600 IPAddress: 192.0.2.20 192.0.2.56 198.51.100.10
5 Done
```

**Example 2: Configuring a DNS-View Based Response.** The following DNS action sends the client an IP address for which you have configured a DNS view:

```
1 add dns action send_ip_from_view_internal_ip ViewName -viewName view_internal_ip
2 Done
3 show dns action send_ip_from_view_internal_ip
4 1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName(ViewName: view_internal_ip)
5 Done
```

**Example 3: Configuring a Response Based on a Preferred Location List.** The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
1 add dns action send_preferred_location GslbPrefLoc -preferredLocList NA tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
2 Done
```
To configure a DNS action by using the Citrix ADC configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
   • Action Name (cannot be changed for an existing DNS action)
   • Type (cannot be changed for an existing DNS action)
     To set the
     Type parameter, do one of the following:
     - To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
     - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
     - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
   • TTL (applicable only to the Rewrite Response action type)

Configure DNS policies

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (""") as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

• When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
• If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the Citrix ADC appliance:

- A maximum of 64 policies are supported.
- DNS policies are global to the Citrix ADC appliance and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see “Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol” in “Policy Configuration and Reference”.

To add a DNS policy by using the command line interface
At the command prompt, type the following commands to create a DNS policy and verify the configuration:

```sh
1 add dns policy <name> <rule> <actionName>
2 show dns policy <name>
```

**Example:**

```sh
1 > add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")' my_dns_action
2   Done
3 > show dns policy policy-GSLB-1
4   Name: policy-GSLB-1
5   Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
6   Action Name: my_dns_action
7   Hits: 0
8   Undef Hits: 0
9
10 Done
```

To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```sh
1 rm dns policy <name>
```

**To configure a DNS policy by using the Citrix ADC configuration utility**

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.
2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
   - Policy Name (cannot be changed for an existing policy)
   - Action
   - Expression

   To specify an expression, do the following:
   a) Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
   b) In the second list, select the expression element that you want, and then enter a period.
c) After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.

3. Click Create or OK, and then click Close.

**Bind DNS policies**

DNS policies are bound globally on the Citrix ADC appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts REQ_OVERRIDE and RES_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the REQ_DEFAULT and RES_DEFAULT bind points.

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

```
1 bind dns global <policyName> <priority> [-gotoPriorityExpression <string>] [-type <type>]
2 show dns global -type <type>
```

**Example:**

```
1 bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
2 Done
3 show dns global -type REQ_DEFAULT
4 1) Policy Name: policy-GSLB-1
5   Priority: 10
6   GotoPriorityExpression: END
7 Done
```

To bind a DNS policy globally by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.

5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.

6. To unbind a policy, click the name of the policy, and then click Unbind Policy.

7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.

8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.

9. Click OK.

To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

show dns global

To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings. The global bindings of all DNS policies appear in this dialog box.

Adding DNS Views

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company’s domain and have the server hosted in your company’s network, clients querying for the domain from within your company’s internal network can be provided with the server’s internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain’s public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see Managing Local DNS Traffic by Using DNS Policies.
To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

```
1  add dns view <viewName>
2  show dns view <viewName>
```

Example:

```
1  add dns view PrivateSubnet
2  show dns view PrivateSubnet
```

To remove a DNS view by using the command line interface

At the command prompt, type:

```
1  rm dns view <viewName>
```

To add a DNS view by using the configuration utility

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy and how to bind DNS policies globally, see Managing Local DNS Traffic by Using DNS Policies.

Configure GSLB for proximity

January 25, 2019

Contributed by: C

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.
You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

**Configure dynamic round trip time (RTT) method**

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the Citrix ADC appliance probes the client’s local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB setup and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see *Configuring GSLB Entities Individually*.

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see *Configuring Dynamic RTT*.

**Configure static proximity**

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client’s local DNS server and the GSLB sites. The Citrix ADC appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the Citrix ADC appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB setup and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see *Configuring GSLB Entities Individually*.
Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see Configuring Static Proximity.

**Configure static proximity and dynamic RTT**

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see Configuring Static Proximity and for details on how to configure dynamic RTT, see Configuring Dynamic RTT.

**Protect the GSLB setup against failure**

January 23, 2019

Contributed by:

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the Citrix ADC appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.
Configure a backup GSLB virtual server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the disablePrimaryOnDown option), or you can configure a timeout period after which the primary takes over.

Note: You can configure a single backup entity as a backup for multiple GSLB virtual server.

If you configure both the timeout and the disablePrimaryOnDown option for the backup entity, the backup session time-out takes precedence over the disablePrimaryOnDown setting.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

```
1 set gslb vserver <name> -backupVServer <name> [-backupSessionTimeout <timeoutValue>] [-disablePrimaryOnDown (ENABLED | DISABLED)]
2 show gslb vserver <name>
```

Example:

```
1 set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -backupSessionTimeout 3 -disablePrimaryOnDown ENABLED
2 show gslb vserver vserver-GSLB-1
```

To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, and double-click the GSLB virtual server.
2. Click the Backup Virtual Server section and select the backup virtual server.

Configure a GSLB setup to respond with multiple IP addresses

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the Citrix ADC appliance sends the best GSLB service as the first
record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the Citrix ADC appliance sends the best service as the only record in the response.

To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

```bash
1 set gslb vserver <name> -MIR (ENABLED | DISABLED)
2 - show gslb vserver <name>
```

Example:

```bash
1 set gslb vserver vserver-GSLB-1 -MIR ENABLED
2 show gslb vserver <vserverName>
```

To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “UP,” select the Send all “active” service IP in response (MIR) check box, and click OK.

Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.
To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -EDR (ENABLED | DISABLED)
```

Example:

```
> set gslb vserver vserver-GSLB-1 -EDR ENABLED
Done
```

To set a GSLB virtual server for empty down responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
3. Click OK.

Configure a backup IP address for a GSLB domain

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site’s IP address.

Note: When a backup IP address is sent, persistence is not honored.

To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

```
set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
show gslb vserver <name>
```

Example:
To set a backup IP address for a domain by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the Domains section, configure the GSLB domain and specify the IP address of the backup domain in the Backup IP field.

Divert excess traffic to a backup virtual server

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured either by the number of connections or by the bandwidth.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is
set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:

```
1 set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -soPersistence ( **ENABLED** | **DISABLED** ) -soPersistenceTimeout <timeout>
2 show gslb vserver <name>
```

Example:

```
1 set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000
   -soPersistence ENABLED -soPersistenceTimeout 2
2 show gslb vserver Vserver-GSLB-1
```

To configure a backup GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server that you want to configure as a backup (for example, Vserver-LB-1).
2. Click the SpillOver section and set the following parameters:
   • Method— soMethod
   • Threshold— soThreshold
   • Persistence Time-out (min) — soPersistenceTimeout
3. Select the Persistence option and click OK.

Configure GSLB for disaster recovery

January 25, 2019
Contributed by: C

Disaster recovery capability is critical, because downtime is costly. A Citrix ADC appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

Configure GSLB for disaster recovery in an active-standby data center setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

• Create the active data center.
  – Add a local GSLB site.
  – Add a GSLB vserver, which represents the active data center.
  – Bind the domain to the GSLB virtual server.
  – Add gslb services and bind the services to active GSLB virtual server.
• Create the standby data center.
  – Add a remote gslb site.
  – Add a gslb vserver, which represents standby data center.
  – Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

**To designate the standby GSLB site by using the command line interface**

At both the active site and the remote site, at the command prompt, type:

```
set gslb vserver <name> -backupVserver <string>
```

Example:

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
```

**To configure the standby site by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for the primary site.
2. Click the **Backup Virtual Server** section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the ‘disable primary on down’ option.

**Configure for disaster recovery in an active-active data center setup**

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain
for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site,
create a load balancing virtual server with the same virtual server IP address as the GSLB service.
Once you have configured the first data center, replicate the configuration for other data centers part
of the setup.
For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

**Configuring for Disaster Recovery with Weighted Round Robin**

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB
services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you
can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the
traffic to another. After you do this, the Citrix ADC appliance will send four requests to the first site for
each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the
local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server.
Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which
you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with
the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore
the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to
it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the
particular service to the total weight. You can also configure individual weights for each GSLB service
instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to
use the number of services bound to it to calculate the weight dynamically.
For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.
Once you configure a basic GSLB setup, you must configure the weighted round robin method such
that the traffic is split between the configured GSLB sites according to the weights configured for the
individual services.

**To configure a virtual server to assign weights to services by using the command line interface**

At the command prompt, type one of the following commands, depending upon whether you want to
create a new load balancing virtual server or configure an existing one:

```
1 add lb vserver <name>@ -weight <WeightValue> <ServiceName>
2 set lb vserver <name>@ -weight <WeightValue> <ServiceName>
```
Example:

1. `add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1`
2. `set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1`

**To set dynamic weight by using the command line interface**

At the command prompt, type:

`set gslb vserver <name> -dynamicWeight DynamicWeightType`

Example:

1. `set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight`

**To add weights to the GSLB services by using the command line interface**

At the command prompt, type:

`set gslb vserver <name> -serviceName GSLBServiceName -weight WeightValue`

Example:

1. `set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1`

**To configure a virtual server to assign weights to services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and double-click the virtual server (for example, Vserver-LB-1).
2. Click the Services section and set the weight of a service.

**To add weights to the GSLB services by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the Services section and set the weight of the service in the Weight field.
To set dynamic weight by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1).
2. Click the Method section and, from the Dynamic Weight drop-down list select SERVICEWEIGHT.

Configuring for Disaster Recovery with Data Center Persistence

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB setup and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the Citrix ADC appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

```
1 set gslb service <serviceName> -sitePersistence <sitePersistence> -sitePrefix <string>
2 show gslb service <serviceName>
```

Example:

```
1 set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
2 show gslb service Service-GSLB-1
```
To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the GSLB service to be configured.
2. Click the Site Persistence section, select the HTTPRedirect option, and in the Site Prefix text box, enter the site prefix (for example, vserver-GSLB-1).

Note
When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

Override static proximity behavior by configuring preferred locations

January 25, 2019
Contributed by:
C

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a preferred location for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see Configuring a DNS Action.
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see Adding Custom Entries to a Static Proximity Database. When entering the preferred locations, you must enter them in the descending order of priority.
When a policy evaluates to TRUE, the Citrix ADC appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of .UK.* or Europe.UK.. is a perfect match for the preferred location .UK.*.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

   If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

   If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

   In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
Further consider the following DNS action and policy configuration:

```
1  > add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "Europe.UK"
2  Done
3  > add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*.ZMB .*.*")" prefLoc11
4  Done
```

When the appliance receives a request from the location `.*.ZMB.*`, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.

Configure GSLB service selection using content switching

January 25, 2019
Contributed by: C

In a typical GSLB deployment, you can prioritize the selection of a set of GSLB services bound to a GSLB virtual server, but you cannot do the following:

- Restrict the selection of a GSLB service from a subset of GSLB services bound to a GSLB virtual server for the given domain.
- Apply different load balancing methods on the different subsets of GSLB services in the deployment.
- Apply spillover policies on a subset of GSLB services, and you cannot have a backup for a subset of GSLB services.
- Configure a subset of GSLB services to serve different content. That is, you cannot content switch between servers in different GSLB sites. The GSLB configuration assumes that the servers contain the same content.
- Define a subset GSLB services with different priorities and specify an order in which the services in the subset are applied to a request.

You can now configure a content switching (CS) policy to customize the GSLB deployment. First configure a set of GSLB services and bind it to a GSLB virtual server. Then, configure a CS virtual server of target type GSLB, define a CS policy and action with the GSLB virtual server as target virtual server, and bind the CS policy to CS virtual server.

**Important**

- Only CS policies with DNS based expressions can be bound to a CS virtual server of target type GSLB.
- If a GSLB service is bound to a CS virtual server through a GSLB virtual server, you cannot bind another GSLB virtual server bound with the same GSLB service to the CS virtual server.

**Example**

Consider a GSLB deployment that includes two GSLB sites. At each site, four GSLB services (S-1, S-2, S-3, and S-4) are bound to GSLB virtual server VS-1. You can configure a content switching (CS) virtual server of target type GSLB and define a CS policy and action with VS-1 as the target virtual server, so that requests for content in English are served only by S-1 and S-2, and requests for content in the local language are served only by S-3 and S-4.

You could give S-1 priority by configuring a backup virtual server to VS-1 and binding S-2 to the backup virtual server. Client requests would then be served by S-1 unless the server it represents went down,
in which case the requests would be served by S-2. If both S-1 and S-2 were down, clients would receive an empty response.

**To configure GSLB Service Selection using Content Switching:**

1. Configure GSLB. For instructions, see [Configuring Global Server Load Balancing](#).
2. Configure a Content Switching (CS) virtual server of target type GSLB. For more information, see [Creating Content Switching Virtual Servers](#).
3. Configure Content Switching (CS) policies. For more information, see [Configuring Content Switching Policies](#).
4. Configure CS actions that designate a GSLB virtual server as the target virtual server. For more information, see [Configuring a Content Switching Action](#).
5. Bind the CS policies to the CS virtual server. For more information, see [Binding Policies to a Content Switching Virtual Server](#).
6. Bind the domain to the CS virtual server instead of the GSLB virtual server.

**Sample Configuration**

The following sample configuration sends requests from the client with IP address 5.5.5.5 to SERVICE_GSLB1 and SERVICE_GSLB2. SERVICE_GSLB1 has a higher priority than SERVICE_GSLB2, and SERVICE_GSLB2 serves the client requests only when SERVICE_GSLB1 is down. If both SERVICE_GSLB1 and SERVICE_GSLB2 are down, SERVICE_GSLB3 and service-GSLB4 are not considered, and a blank response is sent to the client.

```bash
1 add cs vs CSVSERVER_GSLB http - targettype GSLB
2 Done
3 add gslb vs VSERVER_GSLB1 http
4 Done
5 add gslb vs VSERVER_GSLB2 http
6 Done
7 add gslb vs VSERVER_GSLB_BACKUP1 http
8 Done
9 set gslb vs VSERVER_GSLB1 -backupvserver VSERVER_GSLB_BACKUP1
10 Done
11 add gslb service SERVICE_GSLB1 1.1.1.1 HTTP 80 -sitename site1
12 Done
13 add gslb service SERVICE_GSLB2 1.1.1.2 HTTP 80 -sitename site1
14 Done
15 add gslb service SERVICE_GSLB3 1.1.1.3 HTTP 80 -sitename site2
16 Done
17 add gslb service SERVICE_GSLB4 1.1.1.4 HTTP 80 -sitename site2
18 Done
19 bind gslb vs VSERVER_GSLB1 -servicename SERVICE_GSLB1
```
Configure GSLB for DNS queries with NAPTR records

January 25, 2019

Contributed by: C

In a typical Global Server Load Balancing (GSLB) deployment, the Citrix ADC appliance receives DNS queries for A/AAAA records, selects the most appropriate GSLB service according to the configured load balancing method, and returns the service's IP address as a reply to the DNS query. You can now configure the appliance to receive DNS queries for NAPTR records and respond with the list of services configured for a domain. The appliance also monitors the health of the services, and in the response it provides a list of only the services that are up.

Example:
In Telco deployments, you can configure a Citrix ADC appliance to receive DNS queries with NAPTR records from clients such as mobile management entities (MMEs), which play the role of a DNS resolver to discover all the services that are offered by the domain name. The appliance responds to the query with NAPTR records for all the services that are up. The MME can use this NAPTR response to run the S-NAPTR procedure to select the nodes on the basis of the service offered, colocation, topological closeness, and so on.

If multiple nodes qualify for selection, the MME can use the preference field in the NAPTR record from the Citrix ADC appliance to determine the node.

**NAPTR Record Format**

While responding to a DNS query with NAPTR record, a Citrix ADC appliance constructs a response NAPTR record for each GSLB service.

The following table lists the files in the NAPTR record:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>The GSLB domain</td>
</tr>
<tr>
<td>TTL</td>
<td>The amount of time for which the NAPTR record can be cached.</td>
</tr>
<tr>
<td>Class</td>
<td>The class of the record. By default, this value is set to IN.</td>
</tr>
<tr>
<td>Type</td>
<td>The DNS record type.</td>
</tr>
<tr>
<td>Order</td>
<td>Specifies the order in which the NAPTR record MUST be processed. You can specify the order in the GSLB service. Otherwise, it is set to 1.</td>
</tr>
<tr>
<td>Preference</td>
<td>Specifies the order in which NAPTR records with equal “order” values SHOULD be processed, low numbers being processed before high numbers. If the order is not specified in the GSLB service, it is set to 1.</td>
</tr>
<tr>
<td>Flags</td>
<td>Controls the aspects of the rewriting and interpretation of the fields in the record. The Citrix ADC appliance sets this value to A.</td>
</tr>
<tr>
<td>Service</td>
<td>Specifies the available service(s).</td>
</tr>
<tr>
<td>Regular Expression</td>
<td>Regular expressions are not supported, so this value is set to NULL.</td>
</tr>
</tbody>
</table>
Field

| Replacement | The domain name of the node that hosts the services. |

**Configuration procedure**

For detailed GSLB configuration instructions, see [Configuring Global Server Load Balancing (GSLB)](Configuring%20Global%20Server%20Load%20Balancing%20(GSLB)). Make sure that you do the following:

- Set the following parameters while adding the GSLB virtual server:
  - `serviceType`: ANY
  - `dnsRecordType`: NAPTR
  - `lbMethod`: CUSTOMLOAD

**Example:**

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
```

- While adding a GSLB site, set the `naptrReplacementSuffix` parameter to the domain name that you want to embed in the NAPTR records.

**Example:**

```
add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
```

- Set the following parameters while adding the GSLB service:
  - `naptrreplacement`
  - `naptrOrder`
  - `naptrServices`
  - `naptrDomainTTL`
  - `naptrPreference`

**Sample configuration**

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
Done
add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
Done
```
add gslb service sgw1 3.3.3.13 ANY * -siteName site1 -naptrreplacement sgw1.site1. -naptrOrder 2 -naptrServices x-3gpp-sgw:x-s5-gtp -naptrDomainTTL 20 -naptrPreference 200

Done

add gslb service sgw2 3.3.3.11 ANY * -siteName site1 -naptrreplacement sgw2.site1. -naptrOrder 5 -naptrServices x-3gpp-sgw:x-s5-gtp -naptrDomainTTL 20 naptrPreference 100

Done

add gslb service sgw3 3.3.3.12 ANY * -siteName site2 -naptrreplacement sgw3.site1. -naptrOrder 10 -naptrServices x-3gpp-sgw:x-s5-gtp -naptrDomainTTL 20 naptrPreference 300

bind gslb vserver gslb_vs -serviceName sgw1

Done

bind gslb vserver gslb_vs -serviceName sgw2

Done

bind gslb vserver gslb_vs -serviceName sgw3

Done

bind gslb service sgw1 -monitorName ping

Done

bind gslb service sgw2 -monitorName ping

Done

bind gslb service sgw3 -monitorName ping

Done

bind gslb vserver gslb_vs -domainName gslb.com -TTL 5

Done
Note
DNS queries with NAPTR records are not supported in parent-child configuration.

Use the EDNS0 client subnet option for GSLB

January 25, 2019
Contributed by:
C

EDNS Client Subnet (ECS) is a DNS header extension that provides the client subnet details. You can use these details to improve the accuracy of Citrix ADC Global Server Load Balancing (GSLB) by using the client network location rather than the DNS resolver location to determine the topological closeness of the client.

Note
Citrix ADC supports only EDNS0.

Important:
Make sure that the LDNS in your deployment supports EDNS0 Client Subnet so that the incoming DNS queries contains the EDNS0 Client Subnet option and the Citrix ADC appliance uses the ECS address while processing the DNS query.

In a typical GSLB deployment, when you use proximity-based load balancing methods like static proximity or dynamic round-trip time (RTT), the Citrix ADC appliance uses the local DNS (LDNS) IP address for determining the topological closeness of the client and performs GSLB accordingly. But when a centralized DNS resolver, such as Google DNS or OpenDNS, is involved in the deployment, the Citrix ADC appliance sends the DNS request to a datacenter close to the centralized DNS resolver, which might not be close to the client. For example, in a typical Citrix ADC GSLB deployment using the static proximity load balancing method, an end-user request from Japan is sent to a datacenter in Japan and an end user request from California is sent to a datacenter in California. But if a centralized DNS resolver is involved, the Citrix ADC appliance might send a request from Japan to a datacenter in California.

You can use the ECS option in deployments that include the Citrix ADC appliance configured as Authoritative DNS (ADNS) server for a GSLB domain. If you use static proximity as the load balancing method, you can use the IP subnet in the EDNS header instead of the LDNS IP address to determine
the geographical proximity of the client. In the case of proxy mode deployment, the Citrix ADC appliance forwards an ECS-enabled DNS query as-is to the back-end servers, and the appliance does not cache ECS-enabled DNS responses.

Note

The ECS option is not applicable for all other deployment modes, such as ADNS mode for non-GSLB domains, resolver mode, and forwarder mode. In all these modes, the ECS option is ignored by the Citrix ADC appliance. Also, by default, ECS is disabled for GSLB deployment.

To enable EDNS0 Client Subnet option by using the command line interface:

At the command prompt, type:

```
1 set gslb vserver <vserver_name> **-ECS ENABLED
2 set gslb vserver vserver-GSLB-1 -ECS ENABLED
```

Address validation

You can configure a GSLB virtual server to verify that the address returned by the EDNS0 Client Subnet (ECS) option of the DNS query is not a private or an unroutable IP address. With address validation enabled, the Citrix ADC appliance ignores the ECS address in the DNS query if it is listed in the following table, and instead uses the LDNS IP address for global server load balancing.

Note

By default, address validation is disabled.

<table>
<thead>
<tr>

Example of a complete parent-child configuration using the metrics exchange protocol

January 25, 2019

Contributed by:

C

Consider the following parent-child topology in which the GSLB sites are distributed globally.

- Site1 and Site2 are the parent sites.
- Site1_child1 and Site1_child2 are the child sites of Site1.
- Site2_child1 and Site2_child2 are the child sites of Site2.

The following commands illustrate the complete configuration of the parent-child topology.

```
site1
```

```
1. add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2. add gslb site site2 10.106.24.164 -publicIP 10.106.24.164
3. add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite site1
4. add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite site1
```
```plaintext
add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -nwMetricExchange DISABED -sessionExchange DISABED -parentSite site1
add gslb site site1_child2 10.102.82.132 -publicIP 10.102.82.132 -nwMetricExchange DISABED -sessionExchange DISABED -parentSite site1
add gslb service site1_child1_http_gsvc1 10.102.82.132 HTTP 80 -publicIP 10.102.82.132 -publicPort 80 -maxClient 0 -siteName site1_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
add gslb service site1_child2_http_gsvc1 10.102.82.68 HTTP 80 -publicIP 10.102.82.68 -publicPort 80 -maxClient 0 -siteName site1_child2 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
add gslb service site2_child1_http_gsvc1 10.106.24.134 HTTP 80 -publicIP 10.106.24.134 -publicPort 80 -maxClient 0 -siteName site2_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED

```

**site2_child2**

```
1  add gslb site site2 10.106.24.164 -publicIP 10.106.24.164
2  add gslb site site2_child2 10.106.24.67 -publicIP 10.106.24.67
   -nwMetricExchange DISABLED -sessionExchange DISABLED
   -parentSite site2

You can add the following commands for load balancing configuration:

```
1  add service svc1 10.102.82.25 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
   -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -svrTimeout 360
   -CKA NO -TCPB NO -CMP NO
2  add lb vserver lb1 HTTP 10.106.24.68 80 -persistenceType NONE
   -cltTimeout 180
3  bind lb vserver lb1 svc1
```
Link load balancing

January 23, 2019
Contributed by:

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix ADC appliance appliance to monitor and control traffic so that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the Citrix ADC appliance and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. Configuring a basic setup involves configuring services, virtual servers, monitors, routes, an LLB method, and, optionally, configuring persistence. Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

2. Citrix ADC
3. Citrix ADC 12.1

Configuring a Basic LLB Setup

January 25, 2019
Contributed by:

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing
method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- Configure services
- Configure an LLB virtual server and binding a service
- Configure the LLB method and persistence
- Configure an LLB route
- Create and bind a transparent monitor

**Configure services**

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in “Creating and Binding a Transparent Monitor.”

**To create a service by using the command line interface**

At the command prompt, type:

```plaintext
1 add service <name> <IP> <serviceType> <port>
2 show service <name>
```

**Example:**

```plaintext
1 add service ISP1R_svc_any 10.10.10.254 any *
2 show service ISP1R_svc_any
   ISP1R_svc_any (10.10.10.254:*) - ANY
   State: DOWN
   Last state change was at Tue Aug 31 04:31:13 2010
   Time since last state change: 2 days, 05:34:18.600
   Server Name: 10.10.10.254
   Server ID : 0  Monitor Threshold : 0
   Max Conn: 0  Max Req: 0  Max Bandwidth: 0 kbits
   Use Source IP: NO
   Client Keepalive(CKA): NO
   Access Down Service: NO
   TCP Buffering(TCPB): YES
   HTTP Compression(CMP): NO
   Idle timeout: Client: 120 sec  Server: 120 sec
```
To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name*—name
   - Server—IP
   - Protocol*—serviceType (Select ANY from the drop-down list.)
   - Port*—port

A required parameter

1. Click Create.
2. Repeat Steps 2-4 to create another service.
3. Click Close.
4. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure an LLB virtual server and bind a service

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method,
To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> <serviceType>
2 bind lb vserver <name> <serviceName>
3 show lb vserver <name>
```

Example:

```
1 add lb vserver LLB-vip any
2 bind lb vserver LLB-vip ISP1R_svc_any
3 sh lb vserver LLB-vip
4     LLB-vip (0.0.0.0:0) - ANY     Type: ADDRESS
5     State: DOWN
6     Last state change was at Thu Sep 2 10:51:32 2010
7     Time since last state change: 0 days, 17:51:46.770
8     Effective State: DOWN
9     Client Idle Timeout: 120 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    No. of Bound Services : 1 (Total)     0 (Active)
13    Configured Method: ROUNDROBIN
14    Mode: IP
15    Persistence: NONE
16    Connection Failover: DISABLED
17
18   1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN     Weight: 1
19   Done
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
   
   Note: Make sure that **Directly Addressable** is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

### Configure the LLB method and persistence

By default, the Citrix ADC appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

#### To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name> -lbMethod <lbMethod> -persistenceType <persistenceType>
show lb vserver <name>
```

**Example:**

```
set lb vserver LLB-vip -lbmethod ROUNDROBIN -persistenceType SOURCEIP
show lb vserver LLB-vip
```

```
LLB-vip (0.0.0.0:0) - ANY        Type: ADDRESS
  State: DOWN
  Last state change was at Fri Sep 3 04:46:48 2010
  Time since last state change: 0 days, 00:52:21.200
  Effective State: DOWN
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services : 0 (Total)   0 (Active)
  Configured Method: ROUNDROBIN
  Mode: IP
  Persistence: SOURCEIP
  Persistence Mask: 255.255.255.255  Persistence v6MaskLength: 128
  Persistence Timeout: 2 min
  Connection Failover: DISABLED
```
To configure the link load balancing method and/or persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the load balancing method and/or persistence settings.
2. In the Advanced Settings section, select Method and configure the load balancing method.
3. In the Advanced Settings section, select Persistence and configure the persistence parameters.

Configure an LLB route

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the LLB virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the LLB virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route <network> <netmask> <gatewayName>
2 show lb route [<network> <netmask>]
```

Example:

```
1 add lb route 0.0.0.0 0.0.0.0 LLB-vip
2 show lb route 0.0.0.0 0.0.0.0
3 Network Netmask Gateway/VIP Flags
4 1) 0.0.0.0 0.0.0.0 LLB-vip UP
```

To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route6 <network> <gatewayName>
2 show lb route6
```

Example:
To configure an LLB route by using the configuration utility

Navigate to System > Network > Routes, and select **LLB**, and configure the LLB route.

**Note:** Select LLBV6 to configure an IPV6 route.

To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:
   - Click LLB to configure an IPv4 route.
   - Click LLBV6 to configure an IPv6 route.
3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
   - **Network**
   - **Netmask**—Required for IPV4 routes.
   - **Gateway Name**—gatewayName

A required parameter

1. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup

**Note**

If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

Create and bind a transparent monitor

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the Citrix ADC appliance and the upstream device. The transparent monitor monitors all
the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

To create a transparent monitor by using the command line interface

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent YES
2
3 show lb monitor [<monitorName>]
```

Example:

```
1 add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
2 > show lb monitor monitor-1
3 1) Name.......: monitor-1 Type.......: PING State....: ENABLED
4 Standard parameters:
5 Interval...........: 5 sec Retries..........: 3
6 Response timeout.: 2 sec Down time...........
7 Reverse..........: NO Transparent...........
8 Secure............: NO LRTM...............:
9 Action............: Not applicable Deviation...........:
10 Destination IP...: 10.10.10.11
11 Destination port.: Bound service
12 Iptunnel.........: NO
13 TOS..............: NO TOS ID............:
14 SNMP Alert Retries: 0 Success Retries...
15 Failure Retries..: 0
```
To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
   - Name*
   - Type*
   - Destination IP
   - Transparent

A required parameter

1. Click Create, and then click Close.
2. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <serviceName>
show service <name>
```

Example:

```
bind lb monitor monitor-HTTP-1 ISP1R_svc_any
Done
> show service ISP1R_svc_any
ISP1R_svc_any (10.10.10.254:*) - ANY
State: UP
```

Configuring RNAT with LLB

January 25, 2019
Contributed by: C

To configure RNAT by using the command line interface

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. This ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in “Configuring a Basic LLB Setup”, and then configure RNAT. You must then enable use subnet IP (USNIP) mode.

To add SNIPs for ISP routers by using the command line interface

At the command prompt, type:

```
1  add IP NS <network><subnet of first ISP in the IP router> <subnet mask> -type SNIP
2
3  add IP NS <in the IP subnet of second ISP router> <subnet mask> -type SNIP
```

Example:

```
1  add ns ip 10.140.23.1 255.255.255.0 -type snip
2
3  add ns ip 10.141.23.1 255.255.255.0 -type snip
```

To configure RNAT by using the command line interface

At the command prompt, type:

```
1  set rnat <network> <netmask>
2
3  show rnat
```

Example:
To configure RNAT by using the configuration utility

1. Navigate to System > Network > NATs.
2. On the RNAT tab, click Configure RNAT.
3. Specify the network on which to perform RNAT.

Note

You can also configure RNAT by using Access Control Lists (ACLs). Refer Configuring RNAT for details.

To enable Use Subnet IP mode by using the command line interface

At the command prompt, type:

```
1 enable ns mode USNIP
2
3 show ns mode
```

Example:

```
1 enable ns mode USNIP
2
3 show ns mode
```

<table>
<thead>
<tr>
<th>Mode</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>

### Configuring a Backup Route

January 25, 2019

Contributed by:

C

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the Citrix ADC appliance automatically uses it when the primary route fails. First create a primary virtual server as described in “Configuring an LLB Virtual Server and Binding a Service.” To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup_Router-vip** is the secondary virtual server designated as the backup virtual server.

Figure 1. Backup Route Setup

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Backup Routing in Operation

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

**To set the secondary virtual server as the backup virtual server by using the command line interface**

At the command prompt, type:

```
set lb vserver <name> -backupVserver <string>
```

**Example:**
To set the secondary virtual server as the backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the secondary virtual server for which you want to configure the backup virtual server.
2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.

**Resilient LLB Deployment Scenario**

January 25, 2019

Contributed by:
C
In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways Router1-vip and Router2-vip, respectively. Router1-vip is configured as a backup to Router2-vip and vice versa. All traffic with the destination IP specified as 30.30.30.30 is sent through Router1-vip and traffic with the destination IP specified as 30.30.31.31 is sent through Router2-vip.

Figure 1. Resilient LLB Deployment Setup

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

However, if any one of the gateways (Router1-vip or Router2-vip) is DOWN, traffic is routed through the backup router. In the following diagram, Router1-vip for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

Monitoring an LLB Setup

January 23, 2019

Contributed by:
C

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
• Port
• Protocol
• State of the virtual server
• Rate of requests received
• Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the Citrix ADC, or for a single virtual server, at the command prompt, type:

```bash
stat lb vserver -detail [<name>]
```

Example:

```
stat lb vserver -detail

Virtual Server(s) Summary

<table>

</tr>
</tbody>
</table>
```

To display virtual server statistics by using the configuration utility

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.
Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

Example:

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Load Balancing

January 23, 2019

Contributed by:

C

The load balancing feature distributes user requests for web pages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance; when one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to;
• Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
• Use any of several different algorithms to determine which server should receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the Citrix ADC appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

How load balancing works

January 25, 2019
Contributed by: C

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the Citrix ADC appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. In some cases, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see Global HTTP Ports.

Load balancing basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

The load balancing virtual server can use any of a number of algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the Citrix ADC appliance forwards each incoming
client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical Citrix ADC load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.

- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.

- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server’s IP address when you create a service. Otherwise, you must specify the server’s IP address when you create a service, and the IP address becomes the name of the server.

- **Monitor.** An entity on the Citrix ADC appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The Citrix ADC appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:

- Configuring Load Balancing in Direct Server Return Mode
- Configuring LINUX Servers in DSR Mode
- Configuring DSR Mode When Using TOS
- Configuring Load Balancing in DSR Mode by Using IP Over IP
- Configuring Load Balancing in One-arm Mode
- Configuring Load Balancing in the Inline Mode
- Load Balancing of Intrusion Detection System Servers
- Load balance remote desktop protocol servers

Understanding the topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the Citrix ADC appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The Citrix ADC appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>IPAddress</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>10.102.29.60</td>
<td>80</td>
<td>HTTP</td>
</tr>
<tr>
<td>Services</td>
<td>Service-HTTP-1</td>
<td>10.102.29.5</td>
<td>80</td>
<td>HTTP</td>
</tr>
<tr>
<td></td>
<td>Service-HTTP-2</td>
<td>10.102.29.6</td>
<td>80</td>
<td>HTTP</td>
</tr>
<tr>
<td>Monitors</td>
<td>Default</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model

Use of wildcards instead of IP addresses and ports

In some cases you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases may require using a wildcard:

- If the Citrix ADC appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single Citrix ADC appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.
When a wildcard-configured virtual server or service receives traffic, the Citrix ADC appliance determines the actual IP address or port and creates new records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each should be used.

<table>
<thead>
<tr>
<th>IP</th>
<th>Port</th>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>*</td>
<td>TCP</td>
<td>A general wildcard virtual server that accepts traffic sent to any IP address and port on the Citrix ADC appliance. When using a wildcarded virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.</td>
</tr>
<tr>
<td>*</td>
<td>*</td>
<td>TCP</td>
<td>A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the Citrix ADC appliance passes traffic through the firewall to the destination.</td>
</tr>
</tbody>
</table>
A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It will not dynamically learn them.

**Note:** You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, `ns param -httpPort 80`). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic.
<table>
<thead>
<tr>
<th>IP</th>
<th>Port</th>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>port</td>
<td>SSL, SSL_TCP</td>
<td>A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it should use. If –cleartext is not specified, the Citrix ADC appliance uses end-to-end SSL.</td>
</tr>
<tr>
<td>*</td>
<td>port</td>
<td>Not applicable</td>
<td>All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers; the Citrix ADC appliance learns them dynamically.</td>
</tr>
</tbody>
</table>

Note: If you have configured your Citrix ADC appliance as a transparent pass through that makes use of global (wildcard) ports, you may want to turn on Edge mode. For more information, see “Configuring Edge Mode.”

The Citrix ADC appliance attempts to locate virtual servers and services by first attempting an exact
match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a * (wildcard) port
3. (wildcard) IP address and a specific port
4. (wildcard) IP address and a * (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server on the basis of the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

Configuring global HTTP ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the set ns param command. After configuring this port, the Citrix ADC appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single set ns param command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the show ns param command to view the ports that are currently configured.

To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

```
1 set ns param -httpPort <port>
2
3 show ns param
```

Example 1: Configuring a port as a global HTTP port

In this example, port 80 is configured as a global HTTP port.
Example 2: Adding ports when one or more global HTTP ports are already configured

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
set ns param -httpPort 80
Done
show ns param

Global configuration settings:
  HTTP port(s): 80
  Max connections: 0
Max requests per connection: 0
  Client IP insertion: DISABLED
  Cookie version: 0
Persistence Cookie Secure Flag: ENABLED
...
...
```

```
> show ns param

Global configuration settings:
  HTTP port(s): 80
  Max connections: 0
Max requests per connection: 0
  Client IP insertion: DISABLED
  Cookie version: 0
Persistence Cookie Secure Flag: ENABLED
  Min Path MTU: 576
...
...
Done
> set ns param -httpPort 80 8888
Done
> show ns param

Global configuration settings:
  HTTP port(s): 80,8888
  Max connections: 0
Max requests per connection: 0
  Client IP insertion: DISABLED
  Cookie version: 0
Persistence Cookie Secure Flag: ENABLED
  Min Path MTU: 576
```
To configure a global HTTP port by using the configuration utility

1. Navigate to System > Settings > Change HTTP Parameters, and then add an HTTP port number.

Set up basic load balancing

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature
**Example**

```bash
> enable ns feature LoadBalancing
Done

> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>Load Balancing</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Done
```

**To enable load balancing by using the GUI**

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

**Configuring a Server Object**

Create an entry for your server on the Citrix ADC appliance. The Citrix ADC appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see Domain Name System.
To create a server object by using the CLI

At the command prompt, type:

```
add server <name>@<IPAddress>@<domain>
```

To create a server object by using the GUI

Navigate to Traffic Management > Load Balancing > Servers, and add a server object.

```
add server web_serv 10.102.27.150
```

Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

Creating a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the Citrix ADC appliance.

**HTTP**

Used for load-balanced servers that accept HTTP traffic, such as standard web sites and web applications. The HTTP service type enables the Citrix ADC appliance to provide compression, content
filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the Citrix ADC appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 support described earlier.

**SSL**

Used for servers that accept HTTPS traffic, such as ecommerce web sites and shopping cart applications. The SSL service type enables the Citrix ADC appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL_BRIDGE, SSL_TCP, or TCP service types. If you do so, however, the appliance performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 support described above.

**FTP**

Used for servers that accept FTP traffic. The FTP service type enables the Citrix ADC appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

**TCP**

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

**SSL_TCP**

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the Citrix ADC appliance performs both the Layer 4 load balancing and SSL offloading.
UDP

Used for servers that accept UDP traffic. You can also use the ANY service type.

SSL_BRIDGE

Used for servers that accept SSL traffic when you do not want the Citrix ADC appliance to perform SSL offloading. Alternatively, you can use the SSL_TCP service type.

NNTP

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

DNS

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the Citrix ADC appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

ANY

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

SIP-UDP

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.
DNS-TCP

Used for servers that accept DNS traffic, where the Citrix ADC appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the Citrix ADC appliance validates the packet format of each DNS request and response and can cache DNS responses, just as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

RTSP

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the Citrix ADC appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NATting.

DHCPRA

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

DIAMETER

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

SSL_DIAMETER

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the Citrix ADC appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the Citrix ADC appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.
Note: You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

**QUIC**

Used by load balancing servers that accept UDP based QUIC video traffic. The service enables the Citrix ADC appliance to optimize encrypted ABR video traffic over UDP protocol.

**To create a service by using the CLI**

At the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2
3 add service Service-HTTP-1 192.0.2.5 HTTP 80
```

**To create a service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters:
   - Service Name—name
   - Server—serverName
   - Protocol—serviceType
   - Port—port

4. Click Create, and then click Close. The service you created appears in the Services pane.

**Creating a Virtual Server**

After you create your services, you must create a virtual server to accept traffic for the load balanced Web sites, applications, or servers. Once load balancing is configured, users connect to the load-balanced Web site, application, or server through the virtual server’s IP address or FQDN.

Note: The virtual server is designated as DOWN until you bind the services that you created to it, and until the Citrix ADC appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.
To create a virtual server by using the CLI

At the command prompt, type:

```bash
add lb vserver <name> <serviceType> <ip> <port>
```

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To create a virtual server by using the GUI

Navigate to Traffic Management > Load Balancing > Virtual Servers, and then create a virtual server.

Binding Services to the Virtual Server

Note: A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. In most cases, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

<table>
<thead>
<tr>
<th>Virtual Server Type</th>
<th>Service Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP</td>
<td>SSL</td>
<td>You would normally bind an SSL service to an HTTP virtual server to do encryption.</td>
</tr>
<tr>
<td>SSL</td>
<td>HTTP</td>
<td>You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.</td>
</tr>
<tr>
<td>SSL_TCP</td>
<td>TCP</td>
<td>You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).</td>
</tr>
</tbody>
</table>

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.
To bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```plaintext
bind lb vserver <name> <serviceName>
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind a service to a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Verifying the Configuration

After finishing your basic configuration, you should view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you should view the statistics for each service and load balancing virtual server to check for possible problems.

Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your Citrix ADC appliance configuration.

To view the properties of server objects by using the command line interface

At the command prompt, type:

```plaintext
show server <serverName>
show server server-1
```

To view the properties of server objects by using the configuration utility

Navigate to Traffic Management > Load Balancing > Servers. The parameter values of the available servers appear in the details pane.
Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

To view the properties of a load balancing virtual server by using the CLI

At the command prompt, type:

```
1  show lb vserver <name>
2
3  show lb vserver Vserver=LB-1
```

To view the properties of a load balancing virtual server by using the GUI

2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.
3. To view cache redirection and content switching virtual servers that are bound to this virtual server, click Show CS/CR Bindings.

Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

To view the properties of services by using the CLI

At the command prompt, type:

```
1  show service <name>
2
3  show service Service=HTTP-1
```
To view the properties of services by using the GUI

Navigate to **Traffic Management > Load Balancing > Services.** The details of the available services appear on the Services pane.

**Viewing the Bindings of a Service**

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

To view the bindings of a service by using the CLI

At the command prompt, type:

```
1  show service bindings <name>
2  show service bindings Service-HTTP-1
```

To view the bindings of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services.**
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings.**

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the Citrix ADC appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits
To display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [<name>]
```

**Example:**

```bash
stat lb vserver server-1
```

The following figure displays a sample statistics.

To display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click **Statistics**.

**Viewing the Statistics of a Service**

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the CLI

At the command prompt, type:

```
stat service <name>
```

**Example:**

```bash
stat service Service-HTTP-1
```

To view the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

Load balance virtual server and service states

January 25, 2019
Contributed by: C

A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the service(s) bound to it and whether it is administratively disabled:

- **UP**: At least one of the services bound to the virtual server is UP.
- **DOWN**: All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.
- **Out of Service (OFS)**: If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state, is controlled by the administrator.

The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual server(s). If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.

A service can take the following states:

- **UP**: If probes from all the monitors bound to the service are successful.
- **DOWN**: If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE**: If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service
- **GOING OUT OF SERVICE (TROFS)**: If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more information, see Graceful Shut down of Services.
- **DOWN WHEN GOING OUT OF SERVICE (TROFS_DOWN)**: A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if
a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.

Note
You can configure spillover to a backup virtual server by setting the “healthThreshold” parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.

The following diagrams show the conditions under which a service transitions from one state to another.

2. Citrix ADC
3. Citrix ADC 12.1

Support for load balancing profile

January 23, 2019
Contributed by: C

A load balancing configuration has a large number of parameters, so setting the same parameters on a number of virtual servers can become tedious. From release 11.1, a load balancing (LB) profile makes this task easier. You can now set load balancing parameters in a profile and associate this profile with virtual servers, instead of setting these parameters on each virtual server.

The following parameters are presently supported in an LB profile:

- HTTPonlyflag—Include the HttpOnly attribute in persistence cookies. The HttpOnly attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.
- UseSecuredPersistenceCookie—Encrypt the persistence cookie values by using a SHA2 hash algorithm.
- Cookiepassphrase—Specify the passphrase used to generate a secured persistence cookie value.
- DBS_LB—Enable database specific load balancing for MySQL and MSSQL service types.
- **Cl_process_local**—Packets destined to a virtual server in a cluster are not steered. Enable option for single packet request response mode or when the upstream device is performing a proper RSS for connection based distribution.

**Note**

You can set DBS_LB and Cl_process_local parameters on a virtual server and in the profile. If you enable these parameters on a virtual server and then set a profile to this virtual server, the parameters appear as disabled in the output of the “show lb vserver” command for that virtual server. Check the profile to see the actual status of these parameters. In addition, if you set and then unset a profile to a virtual server, the parameters will be set with default values for that virtual server.

**To create an LB profile by using the CLI**

At the command prompt, type:

```
add lb profile <lbprofilename> -dbsLb (ENABLED | DISABLED) -processLocal (ENABLED | DISABLED) -httpOnlyCookieFlag (ENABLED | DISABLED) -cookiePassphrase -useSecuredPersistenceCookie (ENABLED | DISABLED)
```

**Example:**

```
add lb profile p1
Done
show lb profile p1
LB Profile name: p1
DBS LB : DISABLED Process Local: DISABLED
Persistence Cookie HttpOnly Flag: ENABLED
Use Secured Persistence Cookie Flag: DISABLED
No of vservers bound: 0
Done
```
To create an LB profile by using the GUI

Navigate to System > Profiles > LB Profile, and add a profile.

To associate an LB profile with an LB virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -lbprofilename <string>
```

Example

```
set lbvserver lbvip1 -lbprofile p1
```

To associate an LB profile with an LB virtual server by using the GUI

2. Select a virtual server, and click Edit.
3. In Advanced Settings, click Profiles.
4. In the LB Profile list, select the profile to associate with this virtual server.

Load balancing algorithms

January 23, 2019

The load balancing algorithm defines the criteria that the Citrix ADC appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the Citrix ADC appliance supports, with a brief description of how each operates.

<table>
<thead>
<tr>
<th>Name</th>
<th>Server selection based on</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEASTCONNECTION</td>
<td>Which service currently has the fewest client connections. This is the default load balancing algorithm.</td>
</tr>
<tr>

<tr>
<td>LRTM</td>
<td>Fewest active connections and the lowest average response time.</td>
</tr>
</tbody>
</table>

Depending on the protocol of the service that it is load balancing, the Citrix ADC appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.
## Types of Load Balanced Service Specifies

<table>
<thead>
<tr>
<th>Granularity</th>
<th>Types of Load Balanced Service</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-based</td>
<td>HTTP or HTTPS</td>
<td>A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.</td>
</tr>
<tr>
<td>Connection-based</td>
<td>TCP and TCP-based protocols other than HTTP</td>
<td>A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.</td>
</tr>
<tr>
<td>Time-based</td>
<td>UDP and other IP protocols</td>
<td>A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period of time. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.</td>
</tr>
</tbody>
</table>

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin*, helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the appliance switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, the appliance uses the round robin method for the specified number of requests before switching to the specified load balancing method.
method.

- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the Citrix ADC appliance.

**To set the startup round-robin factor by using the CLI**

At the command prompt, type:

```
set lb parameter -startupRRFactor
```

Example

```
set lb parameter -startupRRFactor 25000
```

**To set the startup round-robin factor by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and set the Startup RR Factor.

**Least connection method**

January 25, 2019

Contributed by: C

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL_TCP services, the Citrix ADC appliance includes the following connection types in its list of existing connections:

- **Active connections to a service**. Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
• **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server’s connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the Citrix ADC appliance creates a session between the source IP address and port and the destination IP address and port.

For Real-Time Streaming Protocol (RTSP) connections, the Citrix ADC appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

  - Service-HTTP-1 is handling 3 active transactions.
  - Service-HTTP-2 is handling 15 active transactions.
  - Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the Citrix ADC appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

  - Service-HTTP-3 receives the first request, because it is not handling any active transactions. Note: The service with no active transaction is selected first.
  - Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
  - Service-HTTP-1 receives the fourth request Because Service-HTTP-1 and Service-HTTP-3 have same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. At that time, the Citrix ADC appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

Note: If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described above.

<table>
<thead>
<tr>
<th>Incoming Connection</th>
<th>Service Selected</th>
<th>Current Number of Active Connections</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N = 0)</td>
<td>1</td>
<td>Service-HTTP-3 has the fewest active connections.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3; (N = 1)</td>
<td>2</td>
<td>Service-HTTP-3 has the fewest active connections.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (N = 2)</td>
<td>3</td>
<td>-</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (N = 3)</td>
<td>4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.</td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3; (N = 3)</td>
<td>4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.</td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1; (N = 4)</td>
<td>5</td>
<td>-</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-3; (N = 4)</td>
<td>5</td>
<td>-</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1; (N = 5)</td>
<td>6</td>
<td>-</td>
</tr>
</tbody>
</table>

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current
connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The Citrix ADC appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

\[
Nw = (\text{Number of active transactions}) \times \frac{10000}{\text{weight}}
\]

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.

  Note: If services are not handling any active transactions, the Citrix ADC appliance uses the round robin method regardless of the weights assigned to each of the services.

- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has lowest Nw value.

- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described above.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw (Number of active transactions) * (10000 / weight) value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (Nw = 0)</td>
<td>Nw = 2500</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3; (Nw = 2500)</td>
<td>Nw = 5000</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (Nw = 5000)</td>
<td>Nw = 7500</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3; (Nw = 7500)</td>
<td>Nw = 10000</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3; (Nw = 10000)</td>
<td>Nw = 12500</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-3; (Nw = 12500)</td>
<td>Nw = 15000</td>
<td></td>
</tr>
<tr>
<td>Request Received</td>
<td>Service Selected</td>
<td>Current Nw (Number of active transactions) * (10000 / weight) value</td>
<td>Remarks</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------</td>
<td>-------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-1; (Nw = 15000)</td>
<td>Nw = 20000</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same Nw values</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-3; (Nw = 15000)</td>
<td>Nw = 17500</td>
<td></td>
</tr>
</tbody>
</table>

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the Citrix ADC appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

To configure the least connection method, see Configuring a Load Balancing Method that Does Not Include a Policy.

### Round robin method

January 25, 2019

Contributed by: C

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the Citrix ADC appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works
If you assign a different weight to each service, the Citrix ADC appliance performs weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

Note: You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method Works with Weighted Services

To configure the round robin method, see Configuring a Load Balancing Method that Does Not Include a Policy.

**Least response time method**

January 25, 2019

Contributed by: C

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) load balancing virtual servers only. The
response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The Citrix ADC appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the Citrix ADC appliance chooses between them by applying the Round Robin method.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the appliance switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described above.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value (Number of Active Transactions * TTFB)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N = 0)</td>
<td>N = 2</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3; (N = 2)</td>
<td>N = 4</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request Received</td>
<td>Service Selected</td>
<td>Current N Value</td>
<td>Remarks</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------</td>
<td>----------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (N = 4)</td>
<td>N = 6</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (N = 6)</td>
<td>N = 8</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values. The appliance uses the round robin method to distribute the requests.</td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3; (N = 6)</td>
<td>N = 8</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-2; (N = 7)</td>
<td>N = 8</td>
<td>Service-HTTP-2 has the lowest N value.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-3; (N = 8)</td>
<td>N = 10</td>
<td>Service-HTTP-1, Service-HTTP-2 and Service-HTTP-3 have the same N values. The Citrix ADC appliance uses the round robin method to distribute the requests.</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1; (N = 8)</td>
<td>N = 10</td>
<td>Service-HTTP-1 and Service-HTTP-2 have the same N values, the appliance uses the round robin method to distribute the requests.</td>
</tr>
</tbody>
</table>

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).
### Selection of services when weights are assigned

The following diagram illustrates how the Citrix ADC appliance uses the least response time method when weights are assigned.

**Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned**

The virtual server selects a service by using the value \(N_w\) in the following expression:

\[
N_w = (N) \times (10000 / \text{weight})
\]

Where \(N = \text{(number of active transactions \times TTFB)}\)

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The Citrix ADC appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
  
  If services are not handling any active transactions, the appliance selects them regardless of the weights assigned to them.

- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest \(N_w\) value.

- Service-HTTP-2 receives the sixth request, because this service has the lowest \(N_w\) value.

- Service-HTTP-3 receives the seventh request, because this service has the lowest \(N_w\) value.

- Service-HTTP-2 receives the eighth request, because this service has the lowest \(N_w\) value.

Service-HTTP-1 has the lowest weight and therefore the highest \(N_w\) value, so the virtual server does not select it for load balancing.

The following table explains how connections are distributed in the three-service load balancing setup described above.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current (N_w) Value = ((N) \times (10000 / \text{Weight}))</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N_w = 0)</td>
<td>(N_w = 5000)</td>
<td>Service-HTTP-3 has the lowest (N_w) value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3; (N_w = 5000)</td>
<td>(N_w = 10000)</td>
<td>Service-HTTP-3 has the lowest (N_w) value.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (N_w = 10000)</td>
<td>(N_w = 15000)</td>
<td>Service-HTTP-3 has the lowest (N_w) value.</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3; (N_w = 15000)</td>
<td>(N_w = 20000)</td>
<td>Service-HTTP-3 has the lowest (N_w) value.</td>
</tr>
<tr>
<td>Request Received</td>
<td>Service Selected</td>
<td>Current Nw Value</td>
<td>Remarks</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------</td>
<td>------------------</td>
<td>----------------------------------------------</td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3; (Nw = 20000)</td>
<td>Nw = 25000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-2; (Nw = 23333.34)</td>
<td>Nw = 26666.67</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-3; (Nw = 25000)</td>
<td>Nw = 30000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-2; (Nw = 26666.67)</td>
<td>Nw = 30000</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

**To configure the least response time load balancing method by using the CLI**

At the command prompt type;

```
set lb vserver <name> -lbMethod LEASTRESPONSETIME
```

**Example:**

```
set lb vserver Vserver-LB-1 -lbMethod LEASTRESPONSETIME
```

**To configure the least response time load balancing method by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select LEASTRESPONSETIME.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

3. Citrix ADC 12.1
LRTM method

January 25, 2019

Contributed by: C

Note: LRTM stands for Least response time method using monitors (LRTM).

When a load balancing virtual server is configured to use the LRTM method, it uses the existing monitoring infrastructure to get the fastest response time. The load balancing virtual server then selects the service with the smallest number of active transactions and lowest response time. Before you use the LRTM method, you must bind application-specific monitors to each service and enable LRTM mode on these monitors. The Citrix ADC appliance then makes load balancing decisions based on the response times it calculates from monitoring probes.

You can use the LRTM method to load balance non-HTTP and non-HTTPS services also. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for various monitors.

<table>
<thead>
<tr>
<th>Monitor</th>
<th>Response time calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PING</td>
<td>Time difference between the ICMP ECHO request and the ICMP ECHO response.</td>
</tr>
<tr>
<td>TCP</td>
<td>Time difference between the SYN request and the SYN+ACK response.</td>
</tr>
<tr>
<td>HTTP</td>
<td>Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.</td>
</tr>
<tr>
<td>TCP-ECV</td>
<td>Time difference between the time the data send string is sent and the data receive string is returned. A tcp-ecv monitor without the send and receive strings is considered to have an incorrect configuration.</td>
</tr>
<tr>
<td>HTTP-ECV</td>
<td>Time difference between the HTTP request and the HTTP response.</td>
</tr>
</tbody>
</table>
Monitor | Response time calculation
--- | ---
UDP-ECV | Time difference between the UDP send string and the UDP receive string. A UDP-ECV monitor without the receive string is considered to have an incorrect configuration.
DNS | Time difference between a DNS query and the DNS response.
TCPS | Time difference between a SYN request and the SSL handshake completion.
FTP | Time difference between the sending of the user name and the completion of user authentication.
HTTPS (monitors HTTPS requests) | Time difference is same as for the HTTP monitor.
HTTPS-ECV (monitors HTTPS requests) | Time difference is same as for the HTTP-ECV monitor
USER | Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.

The following example shows how the Citrix ADC appliance selects a service for load balancing by using the LRTM method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the Citrix ADC appliance follows when it forwards requests.

**Figure 1. How the LRTM Method Works**

The virtual server selects a service by using the value (N) in the following expression:

\[ N = (\text{Number of active transactions} \times \text{Response time that is determined by the monitor}) \]

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third and fourth requests, because this service has the lowest N value.
• Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
• Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the Citrix ADC appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
• Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the Citrix ADC appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value (Number of Active Transactions * TTFB)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N = 0)</td>

<tr>
<td>Request-6</td>
<td>Service-HTTP-3; (N = 8)</td>
<td>N = 10</td>
<td>Service-HTTP-2 and Service-HTTP-3 have the same N values. Citrix ADC appliance switches to the round robin method and selects Service-HTTP-3.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-2; (N = 8)</td>
<td>N = 9</td>
<td>Service-HTTP-2 has the lowest N value.</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-2; (N = 9)</td>
<td>N = 10</td>
<td>Service-HTTP-2 has the lowest N value.</td>
</tr>
</tbody>
</table>
Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

**Selection of services when weights are assigned**

The Citrix ADC appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The Citrix ADC appliance selects the service by using the value (Nw) in the following expression:

\[ Nw = (N) \times \left( \frac{10000}{\text{weight}} \right) \]

Where \( N = \) (Number of active transactions \(*\) Response time that is determined by the monitor)

The following diagram illustrates how the virtual server uses the LRTM method when weights are assigned.

**Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned**

In this example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, fourth and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the Citrix ADC appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw Value (N) (*) (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (Nw = 0)</td>
<td>Nw = 5000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3; (Nw = 5000)</td>
<td>Nw = 10000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (Nw = 10000)</td>
<td>Nw = 15000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3; (Nw = 15000)</td>
<td>Nw = 20000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
</tbody>
</table>
Request Received | Service Selected | Current Nw Value (N) | Remarks
---|---|---|---
Request-5 | Service-HTTP-3; (Nw = 20000) | Nw = 25000 | Service-HTTP-3 has the lowest Nw value.
Request-6 | Service-HTTP-2; (Nw = 23333.34) | Nw = 26666.67 | Service-HTTP-2 has the lowest Nw value.
Request-7 | Service-HTTP-3; (Nw = 25000) | Nw = 30000 | Service-HTTP-3 has the lowest Nw value.
Request-8 | Service-HTTP-2; (Nw = 26666.67) | Nw = 30000 | Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

**To configure the LRTM load balancing method by using the CLI**

At the command prompt type;

```
set lb vserver <name> [-lbMethod <lbMethod>]
```

**Example:**

```
set lb vserver Vserver-LB-1 -lbMethod LRTM
```

**To configure the LRTM load balancing method by using the GUI**

2. In Advanced Settings, select **LRTM**.

**To enable the LRTM option in monitors by using the CLI**

At the command prompt type;

```
set lb monitor <monitorName> <type> [-LRTM ( ENABLED | DISABLED )]
```

**Example:**

```
set lb monitor monitor-HTTP-1 HTTP -LRTM ENABLED
```
To enable the LRTM option in monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor.
2. In Advanced Parameters, select **LRTM (Least Response Time using Monitoring)**.

For more information about configuring monitors, see Configuring Monitors in a Load Balancing Setup.

**Hashing methods**

January 25, 2019

Contributed by:

C

Load balancing methods based on hashes of certain connection information or header information constitute the majority of the Citrix ADC appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used Web sites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The Citrix ADC appliance provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method
- Source IP Source Port hash method
- Call ID hash method
- Token method
These hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup. Most of them calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The Citrix ADC appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with highest hash value. As the appliance computes a hash value for each request and selects the service that will process the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

Figure 1. How the Hashing Methods Distribute Requests

Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the Citrix ADC appliance calculates the hash value for the last log of the number of services. The appliance then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

Note: If the Citrix ADC appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. You should adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

**The URL Hash Method**

When you configure the Citrix ADC appliance to use the URL hash method for load balancing the services, for selecting a service, the appliance generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The appliance caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the appliance cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, the appliance uses a specific algorithm and considers a part of the URL. By default, the appliance considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 to 4096 bytes.
Generally, if long URLs are used where only a small number of characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. The appliance selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the appliance selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, the appliance sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, the appliance sends requests that generate the hash U1 to Service-HTTP-3. If these services are UP, the requests that generate the hash U1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see Configuring a Load Balancing Method that Does Not Include a Policy. Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.

**The Domain Hash Method**

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the appliance gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the Citrix ADC appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the Citrix ADC appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
**The Destination IP Hash Method**

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLength parameter. In the configuration utility, text boxes for setting these parameters appear when you select the Destination IP Hash method.

To configure the destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

**The Source IP Hash Method**

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

**The Source IP Destination IP Hash Method**

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric; the hash-value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).
The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see Connection Failover.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure the call ID hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.

Least bandwidth method

January 25, 2019

Contributed by:
C

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.
Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N = 2)</td>
<td>N = 3</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1; (N = 3)</td>
<td>N = 4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (N = 3)</td>
<td>N = 4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (N = 4)</td>
<td>N = 5</td>
<td>-</td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3; (N = 4)</td>
<td>N = 5</td>
<td>-</td>
</tr>
</tbody>
</table>
Note: If you enable the RTSP NAT option on the virtual server, the Citrix ADC appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about RTSP NAT option, see Managing RTSP Connections.

The Citrix ADC appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

\[ Nw = (N) \times \left( \frac{10000}{\text{weight}} \right) \]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.
The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

</tbody>
</table>
A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in last 14 seconds.
- Service-HTTP-2 has handled five packets in last 14 seconds.
- Service-HTTP-3 has handled two packets in last 14 seconds.

The following diagram illustrates how the Citrix ADC appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

The Citrix ADC appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3; (N = 2)</td>
<td>N = 3</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1; (N = 3)</td>
<td>N = 4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3; (N = 3)</td>
<td>N = 4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (N = 4)</td>
<td>N = 5</td>
<td>-</td>
</tr>
</tbody>

</tr>
</tbody>
</table>

Note: If you enable the RTSP NAT option on the virtual server, the appliance uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about RTSP NAT option, see [Managing RTSP Connections](#).

The Citrix ADC appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value \( Nw \) in the following expression:

\[
Nw = (N) \times \left(\frac{10000}{\text{weight}}\right)
\]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The Citrix ADC appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest \( Nw \) value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest \( Nw \) value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest \( Nw \) value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest \( Nw \) value.

The following table summarizes how \( Nw \) is calculated.
<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>

Custom load method

January 25, 2019
Contributed by: C

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the Citrix ADC appliance usually selects a service that is not handling any active transactions. If all of the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see Understanding Load Monitors. The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate

The load monitor uses Simple Network Management Protocol (SNMP) probes to calculate load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics, described below, to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the Citrix ADC appliance.
- Threshold value set for each metric.
- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 megabytes (MB) of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The Citrix ADC appliance compares the exported metrics, and
then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

<table>
<thead>
<tr>
<th>Request received</th>
<th>Service selected</th>
<th>Current N Value (Number of Active Transactions)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-1; (N = 20)</td>
<td>N = 30</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1; (N = 30)</td>
<td>N = 40</td>
<td>-</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-1; (N = 40)</td>
<td>N = 50</td>
<td>-</td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (N = 50)</td>
<td>N = 60</td>
<td>-</td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-1; (N = 60)</td>
<td>N = 70</td>
<td>-</td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1; (N = 70)</td>
<td>N = 80</td>
<td>Service-HTTP-2 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-2; (N = 70)</td>
<td>N = 80</td>
<td>Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1; (N = 80)</td>
<td>N = 90</td>
<td>Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.</td>
</tr>
</tbody>
</table>
If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

\[
Nw = (N) \times \frac{10000}{\text{weight}}
\]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the Citrix ADC appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated:

<table>
<thead>
<tr>
<th>Request received</th>
<th>Service selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-1; (Nw = 50000)</td>
<td>Nw = 75000</td>
<td>Service-HTTP-1 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1; (Nw = 5000)</td>
<td>Nw = 100000</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-1; (Nw = 15000)</td>
<td>Nw = 125000</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1; (Nw = 20000)</td>
<td>Nw = 150000</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-1; (Nw = 23333.34)</td>
<td>Nw = 175000</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1; (Nw = 25000)</td>
<td>Nw = 200000</td>
<td></td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-1; (Nw = 23333.34)</td>
<td>Nw = 225000</td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1; (Nw = 25000)</td>
<td>Nw = 250000</td>
<td></td>
</tr>
</tbody>
</table>
## Static proximity method

January 25, 2019

Contributed by: C

When a virtual server is configured to use the static proximity method, it selects the service that best matches the proximity criteria.

For the static proximity method to work, you must either configure the Citrix ADC appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the load balancing method.

For more details, see the following topics.

- [Adding a Location File to Create a Static Proximity Database](#)

### Table

<table>
<thead>
<tr>
<th>Request received</th>
<th>Service selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-9</td>
<td>Service-HTTP-2; (Nw = 233333.34)</td>
<td>Nw = 266666.67</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the Citrix ADC appliance uses the custom load method when weights are assigned.

**Figure 3. How the Custom Load Method Works When Weights Are Assigned**

To configure the custom load method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

1. Citrix ADC
2. Citrix ADC 12.1
• Adding Custom Entries to a Static Proximity Database
• Setting the Location Qualifiers
• Specifying the Static Proximity method

Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
set lb vserver <name> -lbMethod STATICPROXIMITY
show lb vserver <name>
```

Example:

```
set lb vserver Vserver-LB-1 -lbMethod STATICPROXIMITY
show lb vserver
```

To specify static proximity by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server.
2. Click Edit and expand the Method section.
3. In the Load Balancing Method list, select STATICPROXIMITY.

1. Citrix ADC
2. Citrix ADC 12.1

Token method

January 25, 2019
A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

This method is content aware; it operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see Policy Configuration and Reference.

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the appliance searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the Citrix ADC appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works

To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

```
1 set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length> -dataoffset <offset>
2
3 show lb vserver <name>
```

Example:
To configure the token load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

Configure a load balancing method that does not include a policy

January 25, 2019
Contributed by: C

After you select a load balancing algorithm for your load balancing setup, you must configure the Citrix ADC appliance to use that algorithm. You can configure it by using the CLI or by using the configuration utility.

Note:
The token method is policy based and requires more configuration than is described here. To configure the token method, see Token method.

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see Hashing methods.

To set the load balancing method by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -lbMethod <method>
```

Example:
To set the load balancing method by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Method, and in the Load Balancing Method list, select a method.

Persistence and persistent connections

January 25, 2019
Contributed by: C

Unless you configure persistence, a load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections. Different transmissions from the same client might be directed to different servers even though all of the transmissions are part of the same session. You must configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the Citrix ADC appliance to provide persistent connections for those Web sites and Web applications that require them.

You can also configure backup persistence, which takes effect in the event that the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see Configuring RADIUS Load Balancing with Persistence.

1. Citrix ADC
2. Citrix ADC 12.1
You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, Web-based email, or other network application. The persistence session remains in effect for a period of time, which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the Citrix ADC appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and be used as the basis for persistence.

The following table summarizes the persistence types available on the Citrix ADC appliance.

<table>
<thead>
<tr>
<th>Persistence Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source IP</td>
<td>SOURCEIP. Connections from the same client IP address are parts of the same persistence session.</td>
</tr>
<tr>
<td>HTTP Cookie</td>
<td>COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.</td>
</tr>
<tr>
<td>SSL Session ID</td>
<td>SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.</td>
</tr>
<tr>
<td>URL Passive</td>
<td>URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.</td>
</tr>
</tbody>
</table>
Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

<table>
<thead>
<tr>
<th>Persistence Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom Server ID</td>
<td>CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>Destination IP</td>
<td>DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>Source and Destination IPs</td>
<td>SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>SIP Call ID</td>
<td>CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>RTSP Session ID</td>
<td>RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>User-Defined Rule</td>
<td>RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.</td>
</tr>
</tbody>
</table>

Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

<table>
<thead>
<tr>
<th>Persistence Type</th>
<th>Number of Simultaneous Persistent Connections Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID</td>
<td>250 K</td>
</tr>
<tr>
<td>Cookie, URL Server ID, Custom Server ID</td>
<td>Memory limit. In case of CookieInsert, if timeout is not 0, the number of connections is limited by memory.</td>
</tr>
</tbody>
</table>
Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

<table>
<thead>
<tr>
<th>Persistence Type</th>
<th>HTTP</th>
<th>HTTPS</th>
<th>TCP</th>
<th>UDP/IP</th>
<th>SSL_Bridge/SSL_TCP</th>

Source IP address persistence

January 25, 2019

Contributed by:
C

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the
time-out value expires, the session is discarded, and the configured load balancing algorithm is used
to select a new server.

**Caution:** In some circumstances, using persistence based on source IP address can overload your
servers. All requests to a single Web site or application are routed through the single gateway to the
Citrix ADC appliance, even though they are then redirected to multiple locations. In multiple proxy
environments, client requests frequently have different source IP addresses even when they are sent
from the same client, resulting in rapid multiplication of persistence sessions where a single session
should be created. This issue is called the “Mega Proxy problem.” You can use HTTP cookie-based
persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see Configuring Persistence Types That Do Not
Require a Rule.

**Note:** If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy,
the traffic appears to the Citrix ADC appliance to come from a single source IP address. This prevents
Source IP persistence from functioning properly. Where this is the case, you must select a different
persistence type.

1. 
2. Citrix ADC
3. Citrix ADC 12.1

**HTTP cookie persistence**

January 25, 2019

Contributed by:
C

When HTTP cookie persistence is configured, the Citrix ADC appliance sets a cookie in the HTTP header
of the initial client request. The cookie contains the IP address and port of the service selected by
the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with
any subsequent requests.

When the Citrix ADC appliance detects the cookie, it forwards the request to the service IP and port in
the cookie, maintaining persistence for the connection. You can use this type of persistence with vir-
tual servers of type HTTP or HTTPS. This persistence type does not consume any appliance resources
and therefore can accommodate an unlimited number of persistent clients.

Note: If the client’s Web browser is configured to refuse cookies, HTTP cookie-based persistence will
not work. It might be advisable to configure a cookie check on the Web site, and warn clients that do
not appear to be storing cookies properly that they will need to enable cookies for the Web site if they want to use it.

The format of the cookie that the Citrix ADC appliance inserts is:

```
NSC_XXXX=<ServiceIP><ServicePort>
```

where:

- NSC_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period of time, the Citrix ADC appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the Citrix ADC appliance does not specify an expiration time, but sets a session cookie that is not saved when the client’s browser is shut down.

By default, the Citrix ADC appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the “Max-Age” attribute of the HTTP cookie. In this case, the client’s browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see Configuring Persistence Types That Do Not Require a Rule.

In the HTTP cookie, the appliance by default sets the httponly flag to indicate that the cookie is non-scriptable and should not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the httponly flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the httponly flag in the persistence cookie.

To change the httponly flag setting by using the command line interface

At the command prompt, type:
set lb parameter -httpOnlyCookieFlag (ENABLED DISABLED)

Example:

```
1 > set lb parameter -httpOnlyCookieFlag disabled
2   Done
3 > show lb parameter
4 Global LB parameters:
5       Persistence Cookie HttpOnly Flag: DISABLED
6       Use port for hash LB: YES
7   Done
```

**To change the httponly flag setting by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters, and select or clear the Persistence Cookie HTTPOnly Flag.

**Encrypting the Cookie**

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

**To encrypt the cookie by using the command line interface, at the command prompt, type**

```
set lb parameter -UseEncryptedPersistenceCookie ENABLED -cookiePassphrase test
```

**To encrypt the cookie by using the configuration utility**

1. Navigate to Traffic Management > Change Load Balancing Parameters, and select **Encode Persistence Cookie Values** and enter a passphrase in **Cookie Passphrase**.

1.
2. Citrix ADC
3. Citrix ADC 12.1
SSL session ID persistence

January 25, 2019
Contributed by: C

When SSL session ID persistence is configured, the Citrix ADC appliance uses the SSL session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

Note:
There are two issues that users should consider before choosing this type of persistence. First, this type of persistence consumes resources on the Citrix ADC appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support a very large number of concurrent persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server should renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client’s next request is received. This may result in the client’s activity on the website being interrupted and the client might be asked to reauthenticate or restart the session. It may also result in large numbers of abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see Configuring Persistence Types That Do Not Require a Rule.

Note
SSL session ID persistence is not supported with session tickets.

Backup Persistence Support for SSL session ID

From NetScaler release 12.0 build 56.20, source IP persistence is supported as a backup persistence type for SSL session ID persistence. If the client and load-balanced server renegotiate the session, and source IP persistence is configured as the backup persistence, client requests are forwarded to the same server.

To support backup persistence for SSL session ID, the Citrix ADC appliance creates session entries for both source IP and SSL session ID when a client request is received for the first time. For the subsequent requests containing the same session ID, the SSL session ID is used. However, when the client and the load-balanced server renegotiate the session, the client request is forwarded to the same server by using the Source IP persistence and a new SSL Session ID persistence entry is created.
You can use persistence based on the Attribute-Value Pair (AVP) number of a Diameter message to create persistent Diameter sessions. When the Citrix ADC appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

To configure Diameter-based persistence on a virtual server by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name> -PersistenceType <type-> persistAVPno <positive_integer>
```

Example:

```
set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
```

1. Citrix ADC
2. Citrix ADC 12.1
Custom server ID persistence

January 25, 2019
Contributed by: C

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The Citrix ADC appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider should make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the Citrix ADC appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

• In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
• Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
• Configure custom server ID persistence.

Note: The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

Example:

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
1  set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
2
3  set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
```

On virtual server Web11, enable Custom Server ID persistence.
Create the following expression so that all URL queries containing the string “sid=” are examined.
HTTP.REQ.URL.AFTER_STR(“sid=“)

Example:
When a client sends a request with the following URL to the IP address of Web11, the appliance directs the request to Service-2 and honors persistence.

**Example:**

```
http://www.example.com/index.asp?&sid=2345-drawing-abb123
```

For more information about default-syntax policy expressions, see the Policy Configuration and Reference.

**To configure custom server ID persistence by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service and set a server ID.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

---

**IP address persistence**

January 25, 2019

Contributed by: C

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

**Persistence Based on Destination IP Addresses**

With destination IP address-based persistence, when the Citrix ADC appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the

```
1  set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.URL.AFTER_STR("sid=")"
2  bind lb vserver Web11 Service-[1-2]
```
virtual server (the destination IP address). Subsequently, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see Link Load Balancing.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on the destination IP address, see Configuring Persistence Types That Do Not Require a Rule.

**Persistence Based on Source and Destination IP Addresses**

With source and destination IP address-based persistence, when the Citrix ADC appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on both source and destination IP addresses, see Configuring Persistence Types That Do Not Require a Rule.

2. Citrix ADC
3. Citrix ADC

**SIP Call ID persistence**

January 25, 2019

Contributed by: C

With SIP Call ID persistence, the Citrix ADC appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure persistence based on SIP Call ID, see Configuring Persistence Types That Do Not Require a Rule.
RTSP session ID persistence

January 25, 2019
Contributed by: C

With RTSP Session ID persistence, when the Citrix ADC appliance receives a request from a new client, it creates a new persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

Note: RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that may issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see Configuring Persistence Types That Do Not Require a Rule.

Important: If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

Configure URL passive persistence

January 25, 2019
With URL Passive persistence, when the Citrix ADC appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see Policies and Expressions.

The following expression configures the appliance to examine requests for URL queries that contain the string “urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

HTTP.REQ.URL.AFTER_STR("urlp=")

If URL passive persistence is enabled and the above expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

http://www.example.com/index.asp?urlp=0A661D0A0050

The persistence time-out value does not affect this persistence type; persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any appliance resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule. You set the persistence type to URLPASSIVE. You then perform the procedures provided below.

**To configure URL passive persistence by using the CLI**

At the command prompt, type:

```
set lb vserver <vserverName> [-persistenceType <persistenceType>] [-rule <expression>]
```

**Example:**

```
set lb vserver LB-VServer-1 -persistenceType URLPASSIVE -rule HTTP.REQ.URL.AFTER_STR("urlp=")
```
To configure persistence on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

Note
Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Configure persistence based on user-defined rules

January 25, 2019
Contributed by: C

When rule based persistence is configured, the Citrix ADC appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Subsequently, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you could use a classic expression to configure persistence based on the contents of the HTTP Host header. You could also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see Policies and Expressions.

The expressions that you can configure depends on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other
than the ANY type. For TCP and SSL_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

Note: For a use case that involves configuring rule based persistence on the basis of Financial Information eXchange ("FIX") Protocol data transmitted over TCP, see Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream.

Rule based persistence can be used for maintaining persistence with entities such as Branch Repeater appliances, Branch Repeater plug-ins, cache servers, and application servers.

**Note:** On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule, and set the persistence type to RULE. You then perform the procedures provided below. You can configure rule based persistence by using the configuration utility or the CLI.

### To configure persistence based on user-defined rules by using the CLI

At the command prompt, type:

```bash
set lb vserver <vserverName> [-rule <expression>] [-resRule <expression>]
```

**Example:**

```bash
set lb vserver vsvr_name -rule http.req.header("cookie").value(0).typecast_nvlist_t(=,;').value("server")
```

```bash
set lb vserver vsvr_name -resrule http.res.header("set-cookie").value(0).typecast_nvlist_t(=,;').value("server")
```

### To configure persistence based on user-defined rules by using the GUI

2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

**Note**
Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

http header User-Agent contains MyBrowser

Example: Default syntax Expression for a Request Header

The following default syntax expression does exactly the same thing as the previous classic expression.

HTTP.REQ.HEADER(“User-Agent”).CONTAINS (“MyBrowser”)

Example: Default syntax Expression for a Response Cookie

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

HTTP.RES.HEADER(“SET-COOKIE”).VALUE(0).TYPECAST_NVLIST_T(‘=’,””).VALUE(“server”)

Configure persistence types that do not require a rule

March 19, 2019

Contributed by:
C

To configure persistence, you must first set up a load balancing virtual server, as described in Setting Up Basic Load Balancing. You then configure persistence on the virtual server.
To configure persistence on a virtual server by using the CLI

At the command prompt, type the following commands to configure persistence and verify the configuration:

```
1 set lb vserver <name> -PersistenceType <type> [-timeout <integer>]
2 show lb vserver
```

Example:

```
1 set lb vserver Vserver-LB-1 -persistenceType SOURCEIP -timeout 60
2 show lb vserver
```

Timeout is the time period for which a persistence session is in effect. The timeout default and minimum values (in minutes) vary based on the persistence type as listed in the following table.

<table>
<thead>
<tr>
<th>persistence type</th>
<th>Default value</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cookie insert/group cookie insert</td>
<td>2</td>
<td>0</td>
<td>1440</td>
</tr>
<tr>
<td>Other persistence types</td>
<td>2</td>
<td>2</td>
<td>1440</td>
</tr>
</tbody>
</table>

**Note:**
- Group cookie insert persistence type can be set on the load balancing group.
- For IP-based persistence, you can also set the persistMask parameter.

To configure persistence on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

**Note:** Prior to Citrix ADC release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.
Configure backup persistence

January 25, 2019

Contributed by:

C

You can configure a virtual server to use source IP persistence type when the primary persistence type fails.

The following table describes the combinations of primary and secondary backup persistence types, and the conditions when the backup persistence is used.

<table>
<thead>
<tr>
<th>Primary persistence</th>
<th>Backup persistence</th>
<th>When the primary persistence lookup fails…</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cookie Insert</td>
<td>Source IP</td>
<td>The appliance falls back to source-IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.</td>
</tr>
<tr>
<td>Rule</td>
<td>Source IP</td>
<td>The appliance uses source-IP based persistence when the parameter specified in the rule is missing in the incoming request.</td>
</tr>
</tbody>
</table>

Note

- If the primary persistence type is HTTP-Cookie based persistence, and the backup persistence type is Source IP-based, you can set a timeout value for backup persistence. For in-
Instructions, see Setting a Timeout Value for Idle Client Connections.

• You cannot set a timeout value for backup persistence when the primary persistence is rule based, because in that case the timeout value for secondary persistence must be the same as for the primary persistence. Therefore, the primary and secondary expire at the same time.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType <PersistenceType> -persistenceBackup <BackupPersistenceType>
```

Example:

```
set lb vserver Vserver-LB-1 -persistenceType CookieInsert -persistenceBackup SourceIP
set lb vserver Vserver-LB-1 -persistenceType sslsession -persistenceBackup SourceIP
set lb vserver Vserver-LB-1 -persistenceType RULE -rule http.req.header("User-Agent").value(0).contains("MyBrowser") -persistenceBackup SOURCEIP
set lb vserver Vserver-LB-1 -persistenceType sslsession -persistenceBackup SourceIP
```

To set backup persistence for a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, select Persistence, and specify a backup persistence type.

Note: The primary persistence must be set to COOKIEINSERT, RULE, or SSLSESSION.

2. Citrix ADC
3. Citrix ADC 12.1
Configure persistence groups

January 25, 2019

Contributed by: C

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see Persistence Based on HTTP Cookies.

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
bind lb group <vServerGroupName> <vServerName> -persistenceType <PersistenceType>
```

Example:

```
bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType CookieInsert
```
To modify a virtual server group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Persistency Groups, create a persistency
group, and specify the virtual servers that must be part of this group.

To modify a virtual server group by using the command line interface

At the command prompt, type:

```
set lb group <vServerGroupName> -PersistenceBackup <BackupPersistenceType> -persistMask <SubnetMaskAddress>
```

Example:

```
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask 255.255.255.255
```

Share persistent sessions between virtual servers

January 25, 2019

Contributed by: C

In some customer environments (telecom and ISP), a single server handles both control and data traf-
fic. For a given client IP address, both control and data traffic have to be directed to the same back-end
server. For this, one virtual server is required for handling client authentication traffic, and usually
rule based persistency is configured on it. For example, Radius.req.avp(8).value.typecast_text_t. The
second virtual server for handling data traffic. Usually, SourceIP persistence is configured on it.

Previously, persistence entries were local to the vserver. If you had to apply persistence across mul-
tiple vservers, you had to add the vservers to a load balancing group and then apply a common per-
sistence type to the group. The above requirement could not be achieved, because all the vservers
bound to a load balancing group inherited the persistency configured on the group.

With the persistency sharing between vservers feature, you can set the new useVserverPersistency
parameter for a load balancing group to allow the vservers in the group to use their own persistency
parameters instead of inheriting them from the group settings. You can configure separate rule-based persistency on each vserver.

Optionally, you can also designate one of the vservers in the group as a master vserver. When a vserver is designated as a master vserver, only that vserver creates the persistence entries, which are used by all the vservers in the group. If the master vserver is down, the Citrix ADC appliance does not create any new persistence entries.

**Note:** Persistence sharing across vservers is supported only for rule based persistency methods. You must configure compatible rule based persistence parameters on the member virtual servers.

**Example:**
Assume v1 and v2 are bound to a load balancing group, v1 is a RADIUS type vserver and v2 is an HTTP type vserver. ‘Radius.req.avp(8).value.typecast_text_t’ persistency is configured on v1 and ‘client.ip.src’ is configured on v2.

When traffic flows through the RADIUS vserver v1, it creates a persistent entry based on the evaluated rule string. Later, when traffic reaches the HTTP type vserver v2, v2 checks for the persistence entries on the load balancing group and uses the same persistence session to direct traffic to the same backend server.

### Configuring Sharing of Persistent Sessions

To share persistency parameters across vservers in a load balancing group, you must first enable the useVserverPersistency parameter and then designate one of the vservers in the group as a master server.

**To enable the useVserverPersistency parameter by using the command line interface**

At the command prompt, type:

```
set lb group <name> -useVserverPersistency (ENABLED)
```

**Example:**
```
set lb group lb_grp1 -useVserverPersistency ENABLED
```

**To enable the useVserverPersistency parameter by using the GUI**

1. Navigate to **Configuration > Traffic Management > Load Balancing > Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.
To designate a vserver as a master vserver by using the command line interface

At the command prompt, type:

```
set lb group <name> -useVserverPersistency ( ENABLED ) -masterVserver < string>
```

Example:

```
set lb group lb_grp1 -useVserverPersistency ENABLED -masterVserver vs1
```

To designate a vserver as a master vserver by using the GUI

2. Click Add to add a new group or select an existing group and click Edit.
3. Select Use Vserver Persistence.
4. In the Virtual Server Name box, click + to add the vservers to the group. You can select the available vservers or create new vservers.
5. Click Create if you are adding a new group or Close if you are modifying an existing group.
6. Select the group for which you have enabled the useVserverPersistency parameter and click Edit to set a vserver as a master to create persistence entries.
7. From the Master vServer list, select the vserver that has to be designated as a master vserver.

Arguments

useVserverPersistency

Allow the virtual servers in a group to use their own persistency parameters to create persistent sessions, instead of inheriting the persistency settings from the group settings. When this parameter is enabled, persistence cannot be set on the load balancing group.

When this parameter is disabled, the group’s virtual servers inherit the persistency parameters from the group settings.

When this parameter is toggled on the load balancing group, the Citrix ADC appliance flushes all the corresponding persistence entries of the group and the member virtual servers.

Possible values: ENABLED, DISABLED

Default: DISABLED

Example:

```
set lb group lb_grpl -useVserverPersistency ENABLED
```
**masterVserver**

Designate a virtual server as a master virtual server in its load balancing group. Once designated, only the master virtual server can create the persistent entries used by the group.

**Note**: This parameter can be set only if the useVserverPersistency parameter is enabled.

**Example:**

```
set lb group lb_grp1 -masterVserver vs1
```

**Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface**

The virtual servers are created

```
add lb vs vs1 http 10.1.10.11 80 -persistence rule -rule 'client.ip. src'
add lb vs vs2 radius 10.2.2.2 1812 -persistenceType rule -rule 'Radius.req.avp(8).value.typecast_text_t'
```

The groups are created.

```
add lb group lb_grp1 -persistenceType NONE -useVserverPersistency ENABLED
```

A virtual server in a group is designated as master vserver.

```
set lb group lb_grp1 -masterVserver vs1
```

The virtual servers are bound to the group.

```
bind lb group lb_grp1 vs1
bind lb group lb_grp1 vs2
```

For more details, see Setting Up Basic Load Balancing and Configuring Persistence Groups.

Configure RADIUS load balancing with persistence

January 25, 2019
Contributed by:
C

Today’s complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users may connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the Citrix ADC appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in AAA Application Traffic. You must also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

To configure RADIUS load balancing with persistence, see the following sections:
- Enabling the Load Balancing or Content Switching Feature
- Configuring Virtual Servers
- Configuring Services
- Binding Virtual Servers to Services
- Configuring a Persistency Group for Radius
Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new Citrix ADC appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a Citrix ADC appliance with a previous configuration on it, and you are not certain that the feature you will use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see Enabling Load Balancing.
- For instructions on enabling the content switching feature, see Enabling Content Switching.

Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service will handle authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service will handle accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user’s activities on your protected application or VPN.

**Important:** You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a new load balancing virtual server and verify the configuration:

```
1 add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
2
3 show lb vserver <name>
```

To configure an existing load balancing virtual server, replace the above add lb virtual server command with the set lb vserver command, which takes the same arguments.
To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a new content switching virtual server and verify the configuration:

```
1 add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
2
3 show cs vserver <name>
```

To configure an existing content switching virtual server, replace the above add cs vserver command with the set cs vserver command, which takes the same arguments.

Example:

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
6
7 set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
```

To configure a load balancing or content switching virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers or navigate to Traffic Management > Content Switching > Virtual Servers», and configure a virtual server.

Configuring Services

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created.

Note: Once configured, these services are in the DISABLED state until the Citrix ADC appliance can connect to your RADIUS server’s authentication and accounting IPs and monitor their status. For instructions, see Configuring Services.
**Binding Virtual Servers to Services**

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see [Binding Services to the Virtual Server](#).

**Configuring a Persistence Group for Radius**

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. A persistency group is required because the authentication and accounting virtual servers are different, and both the authentication & accounting message for a single user should reach the same RADIUS server. By configuring a persistency group, the same session is used for both virtual servers. For instructions, see [Configuring Persistence Groups](#).

**Configuring RADIUS Shared Secret**

From release 12.0, a Citrix ADC appliance supports RADIUS shared secret. A RADIUS client and server communicate with each other by using a shared secret that is configured on the client and on the server. Transactions between a RADIUS client and server are authenticated through the use of a shared secret. This secret is also used to encrypt some of the information in the RADIUS packet.

**RADIUS shared secret key validation scenarios**

The validation of the RADIUS shared secret key happens in the following scenarios:

- **RADIUS shared secret key is configured for both the radius client and the radius server**: The Citrix ADC appliance uses the RADIUS secret key for both the client side and the server side. If the verification succeeds, the appliance allows the RADIUS message to go through. Otherwise, it drops the RADIUS message.

- **RADIUS shared secret key is not configured for either the radius client or the radius server**: The Citrix ADC appliance drops the RADIUS message, because shared-secret-key validation cannot be performed on a node that has no radkey configured.

- **RADIUS shared secret key is not configured for both the RADIUS client and the RADIUS server**: The Citrix ADC appliance bypasses the RADIUS secret key validation and allows the RADIUS messages to go through.

You can configure a default RADIUS shared secret or configure on a per client or a subnet basis. It is recommended to add a RADIUS shared secret key for all deployments with RADIUS policy config-
ured. The appliance uses the source IP address of the RADIUS packet to decide which shared secret to use. You may configure a RADIUS client and server and the corresponding shared secret as follows:

At the CLI prompt, type:

```
1 add radiusNode <clientPrefix/Subnet> -radKey <Shared_secret_key>
```

**Arguments**

**IPaddress**

IP address or subnet of the RADIUS client in CIDR format. The appliance uses the source IP address of an incoming request packet to match the client IP address. Instead of configuring a client IP address, you can configure the client network address. Longest prefix is matched to identify the shared secret for an incoming client request.

**Radkey**

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
3 add service radius_auth_service1 192.168.41.68 RADIUS 1812
4 add service radius_acct_service1 192.168.41.70 RADIUS 1813
5 bind lb vserver radius_auth_vs1 radius_auth_service1
6 bind lb vserver radius_acct_vs1 radius_acct_service[1-3]
7 add radiusNode 192.168.41.0/24 -radKey serverkey123
8 add radiusNode 203.0.113.0/24 -radkey clientkey123
```

A shared secret must be configured both for a RADIUS client and server. The command is the same. The subnet determines whether the shared secret is for a client or for a server.

For example, if the subnet specified is a client subnet, the shared secret is for the client. If the subnet specified is a server subnet (192.168.41.0/24 in the above example), the shared secret is for the server. A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients and servers.
Note

Only the PAP and CHAP authentication methods are supported with RADIUS shared secret.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

View persistence sessions

January 23, 2019
Contributed by: C

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

Note: A Citrix ADC nCore appliance uses multiple CPU cores for packet handling. Every session on the appliance is owned by a CPU core. If the appliance receives a request for which a session does not already exist, a session is created, and one of the cores is designated as the owner of that session. Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current. However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session. Consequently, in the output of successively executed show lb persistentSessions commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session continues to be active.

To view a persistence session by using the command line interface

At the command prompt, to view all persistence sessions type:

```
show lb persistentSessions [vServer]
```

Example:

```
show lb persistentSessions myVserver
```
To view persistence sessions by using the configuration utility

Navigate to Traffic Management > Virtual server persistent sessions.

Clear persistence sessions

January 23, 2019
Contributed by: C

You might need to clear persistence sessions from the Citrix ADC appliance if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

To clear a persistence session by using the command line interface

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```plaintext
1  clear lb persistentSessions [<vServer> [-persistenceParam <string>]]
2
3  show persistentSessions <vServer>
```

Examples:

Example 1 clears all persistence sessions for load balancing virtual server lbvip1.

Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

Example 1:

```plaintext
1  > clear persistentSessions lbvip1
2    Done
3  > show persistentSessions
```
Example 2:

```
> show persistentSessions lbvip1
Type SRC-IP ... PERSISTENCE-PARAMETER
RULE 0.0.0.0 ... xls
RULE 0.0.0.0 ... txt
RULE 0.0.0.0 ... html
Done
> clear persistentSessions lbvip1 -persistenceParam xls
Done
> show persistentSessions lbvip1
Type SRC-IP ... PERSISTENCE-PARAMETER
RULE 0.0.0.0 ... txt
RULE 0.0.0.0 ... html
Done
> 
```

To clear persistence sessions by using the configuration utility

1. Navigate to Traffic Management > Clear Persistent Sessions.

1. 
2. Citrix ADC
3. Citrix ADC 12.1

Override persistence settings for overloaded services

January 25, 2019

Contributed by:
C

When a service is loaded or is otherwise unavailable, service to clients is degraded. To work around this situation, you might have to configure the Citrix ADC appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skip-persistency parameter. With the parameter set, when the virtual server receives new connections for
an overloaded service, the virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests. Persistence sessions associated with other services are not affected. The functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see Understanding Load Monitors.

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services on the basis of the configured load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

  Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server on the basis of the destination IP address in the request.

  Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a : IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the Citrix ADC appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. If you configure the virtual server to bypass the virtual server–service configuration for overloaded services, if a Branch Repeater appliance or firewall gets overloaded, the virtual server bridges requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

**To override persistence settings for overloaded services by using the command line interface**

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

```
1 set lb vserver <name> -skippersistency <skippersistency>
2
```
Example

```bash
1 > set lb vserver mylbvserver -skippersistency ReLb
2   Done
3 > show lb vserver mylbvserver
4   mylbvserver (**:*) - ANY Type: ADDRESS
5     ...
6     ...
7   Skip Persistency: ReLb
8     ...
9   Done
10  >
```

To override persistence settings for overloaded services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistency.

Troubleshooting

January 30, 2019

Contributed by: C

- The statistics from the Citrix ADC VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?

  **Cause:** The Citrix ADC appliance has the system limit of 250,000 persistence session for a core.

  **Resolution:** To resolve this issue, you can perform any of the following tasks:
• After configuring Cookie Insert persistence on the Citrix ADC appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?

**Cause:** By default, the time-out value for Cookie Insert persistence is 120 seconds.

**Resolution:** When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

• After configuring an HTTP virtual server on the Citrix ADC appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?

**Resolution:** Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

• After configuring Cookie Insert persistence on the Citrix ADC appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.

**Cause:** Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and Citrix ADC appliance are in different time zones, the cookie is not valid. For example, when a client in EST time zone sends a cookie at 11:00 AM EST to a Citrix ADC appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

**Resolution:** Set the time-out value for Cookie Insert persistence to 0.

• A Citrix ADC appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?

**Cause:** The Citrix ADC appliance receives requests from the terminal server and the source IP
address of the request remains the same. As a result, the appliance cannot distinguish among
the requests received from the thin clients and provide persistence according to the requests
from thin clients.

Resolution: To avoid this problem, you can configure Rule persistence based on some unique
parameter value for each thin client.

- The Citrix ADC appliance is used to load balance Web Interface servers. When accessing
the servers, the user receives the “State Error” error message. Additionally, when one of
the Web Interface servers is shut down or not available, some of the users receive an error
message.

Cause: Lack of persistence to the Web Interface servers can result in error messages when a
user attempts to connect to the server.

Resolution: Citrix recommends that you specify the Cookie Insert persistence method on the
Citrix ADC appliance when load balancing Web Interface servers.

Customize a load balancing configuration

January 25, 2019

Contributed by:

C

After you configure a basic load balancing setup, you can make a number of modifications to it so
that it distributes load exactly as you need. The load balancing feature is complex. You can modify
the basic elements by changing the load balancing algorithm, configuring load balancing groups and
using them to create your load balancing configuration, configuring persistent client-server connec-
tions, configuring the redirection mode, and assigning different weights to different services that have
different capacities.

The default load balancing algorithm on the Citrix ADC appliance is the least connection method,
which configures the appliance to send each incoming connection to the service that is currently han-
dling the fewest connections. You can specify different load balancing algorithms, each of which is
suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same
user be directed to the same server, you can configure the appliance to maintain persistent connec-
tions between clients and servers. You can also specify persistence for a group of virtual servers, causing the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can assign weights to different services, specifying what percentage of incoming load should be directed to each service, so that you can include servers with different capacities in the same load balancing setup without overloading the lower-capacity servers or allowing the higher-capacity servers to sit idle.

This section includes the following details:

- Customizing the Hash Algorithm for Persistence across Virtual Servers
- Configuring the Redirection Mode
- Configuring per-VLAN Wildcarded Virtual Servers
- Assigning Weights to Services
- Configuring the MySQL and Microsoft SQL Server Version Setting

### Customize the hash algorithm for persistence across virtual servers

January 23, 2019

Contributed by: C

The Citrix ADC appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
• If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
• If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
• If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the CLI to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

**To change the use-port-number global setting by using the CLI**

At the command prompt, type:

```
set lb parameter -usePortForHashLb (YES NO)
```

**Example:**

```
1 > set lb parameter -usePortForHashLb NO
2    Done
3 >show lb parameter
4 Global LB parameters:
5        Persistence Cookie HttpOnly Flag: DISABLED
6        Use port for hash LB: NO
7    Done
```

**To change the use-port-number global setting by using the GUI**

2. Select or clear Use Port for Hash Based LB Methods.

**To create a new service and specify a hash identifier for a service by using the CLI**

At the command prompt, type the following commands to set the hash ID and verify the setting:

```
add service < name > (< ip > < serverName >) < serviceType > < port > -hashId < positive_integer >
```
**Example:**

```
1 show service <name>
```

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
Done
> show service flbkng
flbkng (10.101.10.1:80) - HTTP
State: DOWN
Last state change was at Thu Nov 4 10:14:52 2010
Time since last state change: 0 days, 00:00:15.990
Server Name: 10.101.10.1
Server ID : 0  Monitor Threshold : 0
Down state flush: ENABLED
Hash Id: 12345
1) Monitor Name: tcp-default
   State: DOWN  Weight: 1
Done
```

**To specify a hash identifier for an existing service by using the CLI**

Type the set service command, the name of the service, and `-hashId` followed by the ID value.

**To specify a hash identifier while adding a service group member**

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```
1 bind servicegroup <serviceGroupName> <memberName> <port> -hashId <positive_integer>
2
3 show servicegroup <serviceGroupName>
```

**Example:**

```
1 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222
2
3 >show servicegroup SRV
```
<table>
<thead>
<tr>
<th></th>
<th>SRV - HTTP</th>

</tbody>
</table>

To specify a hash identifier for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

To specify a hash identifier for an already configured service group member by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

1. Citrix ADC
2. Citrix ADC 12.1

Configure the redirection mode

January 25, 2019
Contributed by: C
The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The Citrix ADC appliance supports the following redirection modes:

- IP-Based forwarding (the default)
- MAC-Based forwarding

You can configure MAC-Based forwarding on networks that use direct server return (DSR) topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding, see Configuring MAC-Based Forwarding.

**To configure the redirection mode by using the CLI**

At the command prompt, type:

```
set lb vserver <name> -m <RedirectionMode>
```

**Example:**

```
set lb vserver Vserver-LB-1 -m MAC
```

**Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

**To configure the redirection mode by using the GUI**

2. Open a virtual server and select the redirection mode.
   
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

**Configure per-VLAN wildcarded virtual servers**

January 25, 2019

Contributed by:
C
If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

**To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI**

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
1  add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
2  3  show vserver
```

**Example:**

```
1  add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
2  3  show vserver Vserver-LB-vlan1
```

**To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in **Setting Up Basic Load Balancing**.

1. 2. 3.  

**Assign weights to services**

January 25, 2019

Contributed by:
C
In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the Citrix ADC appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

<table>
<thead>
<tr>
<th>Load Balancing Methods</th>
<th>Service Selection with Weights</th>
</tr>
</thead>
<tbody>
<tr>
<td>Round Robin</td>
<td>The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see The Round Robin Method.</td>
</tr>
<tr>
<td>Least Connection</td>
<td>The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see The Least Connection Method.</td>
</tr>
<tr>
<td>Least Response Time and Least Response Time Method using Monitors</td>
<td>The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see The Least Response Time Method.</td>
</tr>
<tr>
<td>Least Bandwidth</td>
<td>The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see The Least Bandwidth Method.</td>
</tr>
<tr>
<td>Least Packets</td>
<td>The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see The Least Packets Method.</td>
</tr>
</tbody>
</table>
### Load Balancing Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Service Selection with Weights</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom Load</td>
<td>The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see <a href="#">The Custom Load Method</a>.</td>
</tr>
<tr>
<td>Hashing methods and Token method</td>
<td>Weighting is not supported by these load balancing methods.</td>
</tr>
</tbody>
</table>

### To configure a virtual server to assign weights to services by using the CLI

At the command prompt, type:

```
set lb vserver <name> -weight <Value> <ServiceName>
```

**Example:**
```
set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
```

### To configure a virtual server to assign weights to services by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and then click in the **Services** section.
3. In the weight column for the service, assign a weight to the service.

1.  
2.  **Citrix ADC**
3.  **Citrix ADC 12.1**

### Configure the MySQL and Microsoft SQL server version setting

January 23, 2019

Contributed by: C

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you...
expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version.

**To set the Microsoft SQL server version parameter by using the CLI**

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

```bash
1 set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>
2 show lb vserver <name>
```

**Example**

```bash
1 > set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
2  Done
3 > show lb vserver myMSSQLvip
4     myMSSQLvip (190.0.2.12:1433) - MSSQL  Type: ADDRESS
5       ...
6       ...
7     MSsql Server Version: 2008R2
8     ...
9     ...
10    Done
11 >
```

**To set the MySQL server version parameter by using the CLI**

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

```bash
1 set lb vserver <name> -mysqlServerVersion <string>
2 show lb vserver <name>
```

**Example**
To set the MySQL or Microsoft SQL server version parameter by using the GUI

2. Open a virtual server of type MySQL or MSSQL, and set the server version.

Multi-IP virtual servers

The Citrix ADC supports creating a single load balancing virtual server with multiple non-consecutive/consecutive IPv4 and IPv6 addresses of type VIP. Each VIP address bound to a virtual server is treated as an individual virtual server. These virtual servers have the same protocol and other virtual server level settings. A virtual server with multiple VIP addresses is also called multi-IP virtual server.

The following are some advantages of using multi-IP virtual servers:

- A multi-IP virtual server offloads the work of creating many virtual servers with the same settings and service bindings.
- Multi-IP virtual servers effectively reduces the possibility of reaching the maximum limit on virtual server entities.
• One multi-IP virtual server can be used for clients in different subnets to connect to the same set of servers.
• Only one multi-IP virtual server can be used for IPv6 and IPv4 clients to connect to the same set of servers.

**Configure a multi-IP virtual server**

Configuring a multi-IP virtual server consists of the following tasks:

• Create an IPset and bind multiple IP addresses to it.
• Bind the IPset to load balancing virtual servers.

Note the following points related to IPset configuration:

• An IPset can have:
  – non-consecutive/consecutive IPv4 addresses and IPv6 addresses
  – combinations of IPv4 and IPv6 addresses.
• All IPv4/IPv6 addresses to be associated with virtual servers using IPset must be of type VIP.
• A single IPset can be bound to multiple virtual servers.
• IPv4/IPv6 addresses can be bound/unbound to/from IPset irrespective any existing IPset bindings to virtual servers.
• You must unset the IPset binding to a virtual server before binding a new IPset to it.

**To add an IPset and bind multiple VIP addresses to it by using the CLI**

At the command prompt, type:

```
1 add ipset <name>
2 bind ipset <name> <IPAddress1 ...>
3 bind ipset <name> <IPAddress2 ...>
4 show ipset <name>
```

**To bind the IPset to a virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -ipset <ipset name>
2 show lb vserver <name>
```
**To add an IPset and bind multiple VIP addresses to it by using the GUI**

Navigate to **System > Network > IPSets**, and create an IPset with multiple VIP addresses.

**To bind the IPSet to a virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server to which you want to bind the created IPset.
2. In **Basic Settings**, set the **IPset** parameter to the name of the created IPset.

```
> add ipset IPSET-1
Done

> bind ipset IPSET-1 9.9.9.10
Done

> bind ipset IPSET-1 1000::20
Done

> add lb vserver LBVS-1 HTTP 8.8.8.10 80 -ipset IPSET-1
Done

> add service SVC-1 3.3.3.10 HTTP 80
Done

> add service SVC-2 3.3.3.100 HTTP 80
Done

> bind lb vserver LBVS-1 SVC-1
Done
```
GSLB support for multi-IP virtual servers

In cloud deployments, floating IP addresses are not supported. These IP addresses are required for high availability deployments. With IPset support, you can associate a private IP address to each of the primary and secondary instances. One of the private IP addresses is added when creating the virtual server. The other IP address is bound to an IPset. This IPset is then associated with the virtual server. Typically a public IP is mapped to one of the private IPs based on which appliance is taking the traffic. During failover, this mapping changes dynamically to route the traffic to the new primary.

In GSLB deployments, the GSLB service represents the virtual server's IP address, port number, and service type. This IP address can be the IP address that is configured while adding the virtual server or it can be one of the IP addresses in the IPset. Irrespective of the IP address used in GSLB service, statistics and state are inherited from the same load balancing virtual server entity.

Parent child topology is also supported with IPset. The load balancing virtual servers on the child sites can have the IPset associated with it. Communication between the parent and the child sites is always using public IP address and the public port of the GSLB service.

Also, with IPset support, you can have a single virtual server endpoint for both IPv4 and IPv6 traffic. Previously, you had to configure different virtual servers for IPv4 and IPv6 traffic. With IPset support, you can associate IPv4 and IPv6 IP addresses to the same IP set. You can add different GSLB services representing the IPv4 and IPv6 endpoints.

**Note:** Only one IP address is associated with a GSLB service. You cannot associate an IPset with a GSLB service.

For details on configuring GSLB entities, see the topic [Configure GSLB entities individually](#).

2. Citrix ADC
3. Citrix ADC 12.1

Configure diameter load balancing

January 25, 2019
The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a Citrix ADC deployment:

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices situated at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The Citrix ADC appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The Citrix ADC uses message based load balancing.

**Example:**
A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

**How diameter load balancing works**

A Disconnect Peer Request (DPR) indicates the peer’s intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

**Load balancing diameter traffic**

When a client sends a request to the Citrix ADC appliance, the appliance parses the request and contextually load balances it to a Diameter server on the basis of a persist AVP. The appliance has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the appliance maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- The Citrix ADC appliance adds a route entry by putting its identity, because the client sees the appliance as a relay agent.

Note: If a Diameter message spans more than one packet, the appliance accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated.
Similarly, if a single packet contains more than one Diameter message, the appliance splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

**Disconnect a session**

A Disconnect Peer Request (DPR) indicates the peer’s intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the Citrix ADC appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

**Configure load balancing for diameter traffic**

To configure the Citrix ADC appliance to load balance diameter traffic, you must first set the Diameter parameters on the appliance, then add the diameter monitor, add the diameter services, bind the services to the monitor, add the diameter load balancing virtual server, and bind the services to the virtual server.

**To configure load balancing for diameter traffic by using the command line interface**

Configure the diameter parameters.

```
set ns diameter -identity <string> -realm <string> -serverClosePropagation <YES|NO>
```

**Example:**

```
set ns diameter -identity mydomain.org -realm org -serverClosePropagation YES
```

Add a Diameter monitor.

```
add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm <string>
```
Example:

```bash
1 add lb monitor diameter_mon DIAMETER -originHost mydomain.org -originRealm org
```

Create the Diameter services.

```bash
1 add service <name> <IP> DIAMETER <port>
```

Example:

```bash
1 add service diameter_svc0 10.102.82.86 DIAMETER 3868
2 add service diameter_svc1 10.102.82.87 DIAMETER 3868
3 add service diameter_svc2 10.102.82.88 DIAMETER 3868
4 add service diameter_svc3 10.102.82.89 DIAMETER 3868
```

Bind the Diameter services to the Diameter monitor.

```bash
1 bind service <name>@monitorName <monitorName>
```

Example:

```bash
1 bind service diameter_svc0 -monitorName diameter_mon
2 bind service diameter_svc1 -monitorName diameter_mon
3 bind service diameter_svc2 -monitorName diameter_mon
4 bind service diameter_svc3 -monitorName diameter_mon
```

Add a Diameter load balancing virtual server with Diameter persistence.

```bash
1 add lb vserver <name> DIAMETER <IPAddress> <port> -persistenceType DIAMETER -persistAVPno <positive_integer>
```

Example:

```bash
1 add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -persistenceType DIAMETER -persistAVPno 263
```

Bind the Diameter services to the Diameter load balancing virtual server.

```bash
1 bind lb vserver <name> <serviceName>
```
Example:

```
bind lb vserver diameter_vs diameter_svc0
bind lb vserver diameter_vs diameter_svc1
bind lb vserver diameter_vs diameter_svc2
bind lb vserver diameter_vs diameter_svc3
```

Save the configuration.

```
save ns config
```

**Note:** You can also configure load balancing of Diameter traffic over SSL by using the `SSL_DIAMETER` service type.

**To configure load balancing for Diameter traffic by using the configuration utility**

1. Navigate to **System > Settings > Change Diameter Parameters** and set the diameter parameters.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click **Persistence**, specify Diameter and enter a persistence AVP number.
7. Click **Save**, and click **Done**.

**Configure FIX load balancing**

January 25, 2019

Contributed by: C

Financial Information eXchange (FIX) protocol is an open message standard used in financial industry for electronic exchange of information related to securities transaction between trading partners.
FIX/SSL_FIX protocol is used extensively by buy-side and sell-side firms, trading platforms, and regulators for communicating trade information.

This feature enables you to configure a FIX or SSL_FIX load balancing virtual server to distribute incoming FIX messages and provide security in FIX messaging. Citrix ADC supports FIX message based load balancing (MBLB) for FIX 4.1, FIX 4.2, FIX 4.3 and FIX 4.4 versions.

FIX MBLB on a Citrix ADC appliance provides the following benefits:

1. Efficient management of FIX or SSL_FIX servers with superior HA and health monitoring.
2. SYN protection to all FIX or SSL_FIX servers.
3. FIX session persistence.

**How FIX load balancing works**

A FIX MBLB setup includes a FIX load-balancing virtual server and multiple load-balanced FIX servers. The FIX virtual server receives incoming client traffic, parses the incoming traffic into FIX messages, selects a FIX server for each FIX message and forwards the message to the selected FIX server. The following conceptual drawing illustrates a typical FIX load balancing set up.

In a basic FIX MBLB setup, the FIX virtual server distributes FIX messages coming from clients to the load-balanced FIX servers using the round robin load-balancing method. With persistence of type FIXSESSION enabled, the FIX virtual server selects the same server for different FIX messages belonging to the same FIX session. The FIX session is determined based on the values of FIX fields SenderCompID (tag 49) and TargetCompID (tag 56).

**Configure and monitor load balancing for FIX traffic**

Following are the configurations that you must do to load balance FIX message traffic:

1. Configuring FIX load balancing virtual server
2. Configuring SSL_FIX load balancing virtual server
3. Configuring FIX load balancing service
4. Configuring SSL_FIX load balancing service
5. Configuring FIXSESSION persistence
6. Setting persistence timeout
7. Displaying FIX/SSL_FIX stats
8. Monitoring FIX/SSL_FIX persistent sessions

**To configure a FIX load balancing server by using the command line interface**

At the command prompt, type:
To configure a SSL_FIX load balancing virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> SSL_FIX <IP> <PORT>
```

Example

```
add lb vserver vs1 SSL_FIX 10.102.82.86 3868
```

To configure a FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> FIX <port>
```

Example

```
add service_svc1 10.102.82.86 FIX 3868
```

To configure a SSL_FIX service by using the command line interface

At the command prompt, type:

```
add service <name> <ip-addr> SSL_FIX <port>
```

Example

```
add service_svc1 10.102.82.86 SSL_FIX 3868
```
To configure FIXSESSION persistence by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -persistenceType FIXSESSION
```

Example

```
set lb vserver vs1 -persistenceType FIXSESSION
```

To set persistence timeout by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -timeout <value>
```

Example

```
set lb vserver vs1 -timeout 2
```

To display FIX stats by using the command line interface

At the command prompt, type:

```
stat lb vserver <name>
```

Example

```
stat lb vserver_svc1
```

To bind FIX service to FIX virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <service name>
```

Example

```
bind lb vserver vs1 svc1
```
To display FIX persistent sessions by using the command line interface

At the command prompt, type:

```
show lb persistentSessions <name>
```

Example

```
show lb persistentSessions vs1
```

Note

Note: You can now configure the load balancing of FIX traffic over SSL by using the SSL_FIX service type. This service provides secured communication for FIX messages.

To configure FIX load balancing virtual server by using the GUI

1. Navigate to the Configuration > Traffic Management > Load Balancing > Virtual Servers page and click Add to create a FIX Load Balancing virtual server.
2. On the Load Balancing Virtual Server page, set the server parameters:
   a) Virtual Server Name
   b) Protocol type as “FIX”
   c) Server IP Address Type
   d) Server IP Address
   e) Server Port Number
3. Click OK and Continue to set additional parameters.
4. In the Services section, select or add a new FIX load balancing virtual service, and bind it to the FIX server.
5. In the Persistence section, set the following parameters:
   a) Persistence type as ‘FIXSESSION’
   b) Time-out interval
6. Click OK and then Done.

To edit a FIX load balancing virtual server by using the GUI

Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers page, select a FIX server and click Edit.
To delete a FIX load balancing virtual server by using the GUI

Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers page, select a FIX server and click Delete.

To configure FIX Load Balancing Virtual Service by using the GUI

1. Navigate to Configuration > Traffic Management > Load Balancing > Services page and click Add to create a FIX Load Balancing virtual service.
2. On the Services page, set the following parameters. You can click the ‘More’ arrow to set additional parameters such as Traffic Domain, Hash ID, Server ID, Cache Type, and Number of Active Connections.
   a) Service Name – FIX Virtual Service Name
   b) Choose Virtual Server type as (New or Existing)
   c) Protocol – Protocol Type as ‘FIX’
   d) Server – Virtual Server IP address
   e) Port – Server Port Number
3. Click OK and Continue to set other parameters such as Monitors, Threshold & Timeout, Profiles, and Policies.
4. Click OK and then Done.

To edit a FIX load balancing virtual service by using the GUI

Navigate to Configuration > Traffic Management > Load Balancing > Services page, select a FIX service and click Edit.

To delete a FIX load balancing virtual service by using the GUI

Navigate to Configuration > Traffic Management > Load Balancing > Services page, select a FIX service and click Delete.

To display FIX load balancing server statistics

Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers page and then click Statistics to display the FIX server statistics.
To display Persistent sessions for a FIX server by using the GUI

Navigate to Configuration > Traffic Management page and, under Monitor Sessions click Virtual Server Persistent Sessions.

To clear Persistent sessions for a FIX server by using the GUI

1. Navigate to Configuration > Traffic Management page and, under Monitor Sessions click Clear Persistent Sessions.
2. On the Clear Persistent Sessions page, set the following parameters:
   a) Virtual Server – Choose a FIX virtual server
   b) Persistence Parameter – Choose a FIX persistence parameter
3. Click OK.

Protect a load balancing configuration against failure

January 23, 2019
Contributed by: C

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring the Citrix ADC appliance to redirect excess traffic to an alternate URL, configuring a backup load balancing virtual server, and configuring stateful connection failover.

1.
2. Citrix ADC
3. Citrix ADC 12.1

Redirect client requests to an alternate URL

January 23, 2019
In the event that a load balancing virtual server of type HTTP or type HTTPS goes DOWN or is disabled, you can redirect requests to an alternate URL by using an HTTP 302 redirect. The alternate URL can provide information about the status of the server.

You can redirect to a page on the local server or a remote server. You can redirect to a relative URL or an absolute URL. If you configure a redirect to a relative URL consisting of a domain name with no path, the Citrix ADC appliance appends the path of the incoming URL to the domain. If you use an absolute URL, the HTTP redirect is sent to that URL with no modification.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

**To configure a virtual server to redirect the client request to a URL by using the CLI**

At the command prompt, type:

```
set lb vserver <vServerName> -redirectURL <URLValue>
```

**Example:**

```
set lb vserver Vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

**To configure a virtual server to redirect the client request to a URL by using the GUI**

2. In Advanced Settings, click **Protection**, and specify a redirect URL.

**Configure a backup load balancing virtual server**

March 4, 2019
You can configure the Citrix ADC appliance to direct requests to a backup virtual server in the event that the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you may want to configure the backup virtual server to remain in control in the event that it takes over. For example, you may want to sync updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control in the event that the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

### To set a backup virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <vServerName> -backupVserver <BackupVServerName> [-disablePrimaryOnDown]
```

**Example:**

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -disablePrimaryOnDown
```
To set a backup virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select Disable Primary When Down.

Note: Starting from Citrix ADC version 12.1 build 51.xx, the GUI displays the effective state of that server indicating if the backup is active or not.

The effective state of the current server can be one of the following:

- UP – Indicates that the server is UP
- DOWN – Indicates that the server is DOWN
- UP (Backup Active) – Indicates that either the primary or the secondary virtual server is UP and traffic is directed to the backup virtual server.
- DOWN (Backup Active) – Indicates that both the primary and the backup virtual servers are down and traffic is routed to the backup virtual server.

When the Disable Primary When Down option is enabled on the primary virtual server and the primary server goes DOWN and is back UP again, the traffic is still served by the backup virtual server until the primary virtual server is re-enabled explicitly. You can use the command **enable lb vserv** command to re-enable the primary virtual server.

Configure spillover

January 30, 2019

Contributed by:
C

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health
of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period of time after the load on the primary falls below the threshold.

**Note:** In most cases, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). Keep in mind, however, that with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a Citrix ADC rule to specify the conditions that should be met for spillover to occur. Citrix ADC rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see [Configuring a Backup Load Balancing Virtual Server](#).

### Configure a predefined spillover method

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the Citrix ADC appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests...
to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the Citrix ADC appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

**Note:** With RTSP virtual servers, the Citrix ADC appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

**To configure a predefined spillover method for a virtual server by using the command line interface**

At the command prompt, type:

```
set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <positiveInteger>
```

**Example**

```
set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

**To configure a predefined spillover method for a virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Protection, and set the spillover parameters.

**Configure policy based spillover**

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover on the basis of the virtual server’s response time, or on the basis of number of connections in the virtual server’s surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The
appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all of the backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

**Configuring a Spillover Action**

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

**To configure policy based spillover by using the command line interface**

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
1 add spillover action <name> -action SPILLOVER
2
3 show spillover action <name>
```

**Example**

```
1 add spillover action mySoAction -action SPILLOVER
2 Done

1 show spillover action mySoAction
2 1) Name: mySoAction Action: SPILLOVER
3 Done
```

**Selecting an Expression for the Spillover Policy**

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you could use one of the following expressions:

```
1 SYS.VSERVER("vserver").RESPTIME.GT(<int>)
2 SYS.VSERVER("vserver").STATE.EQ("<string>"), and
3 SYS.VSERVER("vserver").THROUGHPUT.LT (<int>)
```
In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

**Averagesurgecount**

Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

**Activeservices**

Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

**Activetransactions**

Returns the value of the virtual-server-level counter for current active transactions.

**is_dynamic_limit_reached**

Returns a Boolean TRUE if the number of connections being managed by the virtual server equals the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

<table>
<thead>
<tr>
<th>Predefined spillover method</th>
<th>Corresponding expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNECTION</td>
<td>SYS.VSERVER(“&lt;vserver-name&gt;”).CONNECTIONS, used with the GT(int) arithmetic function.</td>
</tr>
<tr>
<td>BANDWIDTH</td>
<td>SYS.VSERVER(“&lt;vserver-name&gt;”).THROUGHPUT, used with the GT(int) arithmetic function.</td>
</tr>
<tr>
<td>HEALTH</td>
<td>SYS.VSERVER(“&lt;vserver-name&gt;”).HEALTH, used with the LT(int) arithmetic function.</td>
</tr>
</tbody>
</table>
Predefined spillover method | Corresponding expression
---|---
DYNAMICCONNECTION | SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED

**Note:** If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that statistics required for spillover to work are collected.

### Configuring a Spillover Policy

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

**To configure a spillover policy by using the command line interface**

At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
1 add spillover policy <name> -rule <expression> -action <string> [-comment <string>]
2
3 show spillover policy <name>
```

**Example**

```
1 > add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT(50) -action mySoAction -comment "Triggers spillover when the vserver’s response time is greater than 50 ms."
2 Done
3
4 > show spillover policy mySoPolicy
5 1) Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action: mySoAction Hits: 0 ActivePolicy: 0
6 Comment: "Triggers spillover when the vserver’s response time is greater than 50 ms."
7 Done
8 >
```
Binding a Spillover Policy to a Virtual Server

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers. You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

To bind a spillover policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

1. `bind (lb | cs | gslb) vserver <name> -policyName <string> -priority < positive_integer> [-gotoPriorityExpression <expression>]`
2. `show (lb | cs | gslb) vserver <name>`

Example

1. `> bind lb vserver vserver1 -policyName mySoPolicy -priority 5`
2. `Done`
3. `> show lb vserver vserver1`
4. `vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS`
5. `...`
6. `1) Spillover Policy Name: mySoPolicy Priority: 5`
7. `GotoPriority Expression: END`
8. `Flowtype: REQUEST`
9. `Done`
10. `>`

Configuring a Backup Action for a Spillover Event

A backup action specifies what to do in the event that the spillover threshold is reached but one or more backup virtual serves are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).
The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests until the number of requests falls below the threshold.

**To configure a backup action for spillover by using the CLI**

At the command prompt, type the following commands to configure a backup action and verify the configuration:

1. `set lb vserver <name> -soBackupAction <soBackupAction>
2. show lb vserver <name>`

**Example**

```
set lb vserver vs1 -soBackupAction REDIRECT -redirectURL http://www.mysite.com/maintenance
Done
show lb vserver vs1
vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
State: UP
...
Redirect URL: http://www.mysite.com/maintenance
...
Done
```

**To configure a backup action for spillover by using the GUI**

2. In Advanced Settings, click **Protection**, and then specify a spillover backup action.

**Connection failover**

January 25, 2019
Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a Citrix ADC High Availability (HA) setup, connection failover (or connection mirroring - CM) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary Citrix ADC appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure connection failover in stateful mode, the download continues even after the failover.

**How connection failover works on Citrix ADC appliances**

In stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server may experience a brief disruption and retransmissions.

**Note:**

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify correct configuration of the passwords, use the show rpcnode command from command line or use the RPC option of the Network menu in GUI.

A basic HA configuration with connection failover contains the entities shown in the following figure.

**Figure 1. Connection Failover Entity Diagram**
Note

Connection failover is not supported after either of the following events:

1. An upgrade to a later release.
2. An upgrade to a later build within the same release, if the new build uses a different HA version.

Supported setup

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover will not work because the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

<table>
<thead>
<tr>
<th>Setting</th>
<th>Stateless</th>
<th>Stateful</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service type</td>
<td>ANY</td>
<td>ANY, UDP, TCP, FTP, SSL_BRIDGE.</td>
</tr>
<tr>
<td>Load balancing methods</td>
<td>All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORTHASH method must be used.</td>
<td>All methods applicable to the supported service types.</td>
</tr>
<tr>
<td>Persistence types</td>
<td>SOURCEIP persistence.</td>
<td>All types applicable to the supported service types are supported.</td>
</tr>
<tr>
<td>USIP</td>
<td>Must be ON.</td>
<td>No restriction. It can be ON or OFF.</td>
</tr>
<tr>
<td>Service bindings</td>
<td>Service can be bound to only one virtual server.</td>
<td>Service can be bound to one or more virtual servers.</td>
</tr>
<tr>
<td>Internet Protocol (IP) versions</td>
<td>IPv4 and IPv6</td>
<td>IPV4 and IPv6</td>

<tr>
<td>Redundancy support</td>
<td>Clustering and high availability</td>
<td>High availability</td>
</tr>
</tbody>
</table>
Features affected by connection failover

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects Citrix ADC Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Impact of Connection Failover</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYN protection</td>
<td>For any connection, if a failover occurs after the appliance issues SYN-ACK but before it receives the final ACK, the connection is not supported by connection failover. The client must reissue the request to establish the connection.</td>
</tr>
<tr>
<td>Surge protection</td>
<td>If the failover occurs before a connection with the server is established, the new primary appliance tries to establish the connection with the server. It also retransmits all the packets held in the course of surge protection.</td>
</tr>
<tr>
<td>Access down</td>
<td>If enabled, the access-down functionality takes precedence over connection failover.</td>
</tr>
<tr>
<td>Application firewall</td>
<td>The Application firewall feature is not supported.</td>
</tr>
<tr>
<td>INC</td>
<td>Independent network configuration is not supported in the high availability (HA) mode.</td>
</tr>
<tr>
<td>TCP buffering</td>
<td>TCP buffering is not compatible with connection mirroring.</td>
</tr>
<tr>
<td>Close on response</td>
<td>After failover, the NATPCBs may not be closed on response.</td>
</tr>
</tbody>
</table>

To configure connection failover by using GUI

Navigate to Traffic Management > Load Balancing > Virtual Servers. Open the virtual server, and in Advanced Settings, click Protection, and select Connection Failover as Stateful.

To configure connection failover by using CLI

At the command prompt:

```
set lb vserver <vServerName> -connFailover <Value>
```
When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

To disable connection failover by using CLI

At the command prompt:

```
1 set lb vserver <vServerName> -connFailover <Value>
2 show lb vserver <vServerName>
```

Example:

```
set lb vserver Vserver-LB-1 -connFailover stateful
Done
```

```
set lb vserver Vserver-LB-1 -connFailover disable
Done
```

To disable connection failover by using GUI

Navigate to Traffic Management> Load Balancing> Virtual Servers. Open the virtual server, in Protection, select Connection Failover as Disabled.

Flush the surge queue

January 23, 2019

Contributed by:
C

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides
features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
• If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
• If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
• You cannot directly specify a service group member (<servername> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <servername>. Specify the <servername> and <port> if you want to flush the surge queue for a specific service group member.
• If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
• If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <servername> <port>]
```

Examples

```
flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

```
flush ns surgeQ
```

The above command flushes all the surge queues on the appliance.

**To flush a surge queue by using the GUI**

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.
Manage a load balancing setup

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new Citrix ADC appliances, which must be configured and added to the existing setup. Old servers wear out and need to be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology may also require modifications to your load balancing setup. Therefore, you will need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of a number of other features that facilitate management of the traffic through your load balancing setup.

1. 
2. Citrix ADC
3. Citrix ADC 12.1

Manage server objects

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not already exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the Citrix ADC appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.
To enable a server by using the CLI

At the command prompt, type:

```
1 enable server <name>
```

**Example:**

```
1 enable server 10.102.29.5
```

To enable or disable a server object by using the GUI

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select the server and, in the Action list, select Enable or Disable.

To disable a server object by using the CLI

At the command prompt, type:

```
1 disable server <name> <delay>
```

**Example:**

```
1 disable server 10.102.29.5 30
```

To remove a server object by using the CLI

At the command prompt, type:

```
1 rm server <name>
```

**Example:**

```
1 rm server 10.102.29.5
```

To remove a server object by using the GUI

1. Navigate to Traffic Management > Load Balancing > Servers.
2. Select a server, and click Remove.
1.
Manage services

January 23, 2019
Contributed by:

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service’s state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the Citrix ADC configuration.

To enable or disable a service by using the command line interface

At the command prompt, type:

```
1   enable service <name>
2
3   disable service <name> <DelayInSeconds>
```

Examples:

```
1   enable service Service-HTTP-1
2   disable service Service-HTTP-1 30
```

To enable or disable a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service and, in the Action list, select Enable or Disable.

1.
2. Citrix ADC
3. Citrix ADC 12.1
Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual service’s state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFlush parameter. If downStateFlush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

**To enable or disable a virtual server by using the command line interface**

At the command prompt, type:

```
1 enable lb vserver <name>
```

```
1 disable lb vserver <name>
```

**Examples:**

```
1 enable lb vserver Vserver-LB-1
2 disable lb vserver Vserver-LB-1
```

**To enable or disable a virtual server by using the configuration utility**

2. Select a virtual server, and in the Action list, select Enable or Disable.

**To unbind a service from a virtual server by using the command line interface**

At the command prompt, type:

```
1 unbind lb vserver <name> <serviceName>
```
Example:

```bash
unbind lb vserver Vserver-LB-1 Service-HTTP-1
```

To unbind a service from a virtual server by using the configuration utility

2. Open a virtual server, and click in the Services section.
3. Select a service and click Unbind.

Load balancing visualizer

February 19, 2019
Contributed by: C

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in a graphical format. Following is an example of the Visualizer display.

Figure 1. Load Balancing Visualizer Display

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. The services in the container have the same properties, with the exception of
the name, IP address, and port, and their monitor bindings should have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services; otherwise, it is placed in its own container.

The following procedures provide only basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all of the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

To view load balancing virtual server properties by using the Visualizer

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

To view configuration details for services, service groups, and monitors by using the Visualizer

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click the entity to view the configuration details of the entity that is bound to this virtual server, you can do the following:

To view configuration details for policies and policy labels by using the Visualizer in the configuration utility

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click policies entity to view policies that are bound to this virtual server.

To modify a resource in a load balancing configuration by using the Visualizer

2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.
To add a load balancing configuration by using the Visualizer

2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click + to add the resource.

Manage client traffic

January 23, 2019
Contributed by: C

Managing client connections properly helps to ensure that your applications remain available to users even when your Citrix ADC appliance is experiencing high loads. A number of load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.
- **SureConnect.** You can use load balancing with the SureConnect feature to redirect important requests to a custom Web page, insulating them from delays due to network congestion.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the Citrix ADC appliance is experiencing high loads.
- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response.** You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

### Configure sessionless load balancing virtual servers

January 23, 2019

Contributed by: C

When the Citrix ADC appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the appliance resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode. For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.
Supported setup

Citrix ADC sessionless load balancing supports the following service types and load balancing methods:

**Service Types**

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

**Load Balancing Methods**

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

**Limitations**

Sessionless load balancing has the following limitations:

- The appliance must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address will not be changed.

**Note:**

- While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.
To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the Citrix ADC appliance.

**To add a sessionless virtual server by using the CLI**

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

```
1 add lb vserver <name>@<serviceType>@<IPAddress>@<port> -m <redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <load_balancing_method>
2
3 show lb vserver <name>
```

**Example:**

```
1 add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -lbMethod roundrobin -m ip
  Done
3 show lb vserver sesslessv1
4   sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
5   State: DOWN
6   ... 
7   Effective State: DOWN
8   Client Idle Timeout: 120 sec
9   Down state flush: ENABLED
10  ... 
11  Persistence: NONE
12  Sessionless LB: ENABLED
13  Connection Failover: DISABLED
14  L2Conn: OFF
15  1) Policy: cmp_text Priority:8680 Inherited
16  2) Policy: cmp_nocmp_ie60 Priority:8690 Inherited
```

**To configure sessionless load balancing on an existing virtual server**

At the command prompt, type:

```
1 set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <load_balancing_method>
```
### Example

```
1 set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
2 Done
```

### Note

For a service that is bound to a virtual server on which `-m MAC` option is enabled, you must bind a non-user monitor.

---

**To configure a sessionless virtual server by using the GUI**

2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

---

**Redirect HTTP requests to a cache**

January 23, 2019

Contributed by: C

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

**To configure cache redirection on a virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -cacheable <Value>
```

**Example:**
To configure cache redirection on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

To configure priority queuing on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -pq <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -pq yes
```

To configure priority queuing on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Priority Queuing.
Note: You must configure priority queuing globally for it to function correctly.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Direct requests to a custom web page

January 25, 2019
Contributed by: C

The Citrix ADC appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative web page of your choice when the server that hosts the primary web page is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see SureConnect. After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom web page in use.

Note: For SureConnect to function correctly, you must configure it globally.

To enable SureConnect on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -sc <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -sc yes
```

To enable SureConnect on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select SureConnect.
1.
Enable cleanup of virtual server connections

January 25, 2019
Contributed by: C

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

You must not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-TCP-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

<table>
<thead>
<tr>
<th>Vserver-LB-1</th>
<th>Service-TCP-1</th>
<th>State of connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>E</td>
<td>Both client and server</td>
</tr>
<tr>
<td></td>
<td></td>
<td>connections are terminated.</td>
</tr>
</tbody>
</table>
For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.

<table>
<thead>
<tr>
<th>Vserver-LB-1</th>
<th>Service-TCP-1</th>
<th>State of connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>D</td>
<td>For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.</td>
</tr>
<tr>
<td>D</td>
<td>E</td>
<td>For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.</td>
</tr>
<tr>
<td>D</td>
<td>D</td>
<td>Neither client nor server connections are terminated.</td>
</tr>
</tbody>
</table>

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown
of a service, see Graceful Shutdown of Services.

To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -downStateFlush <Value>
```

Example:

```
set lb vserver Vserver-LB-1 -downStateFlush enabled
```

To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

Rewrite ports and protocols for HTTP redirection

January 23, 2019

Contributed by:

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the Citrix ADC appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The redirectPortRewrite setting can be used in the following scenarios:
• The virtual server is of type HTTP and the services are of type SSL.
• The virtual server is of type SSL and the services are of type HTTP.
• The virtual server is of type HTTP and the services are of type HTTP.
• The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

Only SSL redirect is enabled. The virtual server can be configured on any port. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>
Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client. 

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled. The virtual server is configured on port 444. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client. The virtual server is configured on port 80. See the following table:
### The virtual server is configured on port 8080. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

### Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>
### Redirect URL from the Server | Redirect URL sent to the Client
---|---

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. See the following table:

### Redirect URL from the Server | Redirect URL sent to the Client
---|---

### To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```bash
1 set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
```

Example:

```bash
1 set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
```

### To configure HTTP redirection on a virtual server by using the GUI

2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

### To configure SSL Redirect on an SSL virtual server or service by using the CLI

At the command prompt, type:

```bash
1 set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
2
3 set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)
```
Example:

1. `set ssl vserver Vserver-SSL-1 -sslRedirect enabled`
2. `set ssl service service-SSL-1 -sslRedirect enabled`

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

Insert IP address and port of a virtual server in the request header

January 23, 2019

Contributed by: C

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

**Note:** This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the CLI

At the command prompt, type:
To insert the IP address and port of the virtual server in the client requests by using the GUI

2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

Use a specified source IP for backend communication

March 27, 2019
Contributed by: C

For communication with the physical servers or other peer devices, the Citrix ADC appliance uses an IP address owned by it as the source IP address. The Citrix ADC appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic as well as monitor probes.

In many situations, you may want the appliance to use a specific IP address or any IP address from a specific set of IP addresses for backend communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server may be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the appliance can use only the IP addresses accepted by the server as the source IP address.
The appliance can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the appliance to use a specified source IP address, create net profiles (network profiles) and configure the appliance entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. A net profile has Citrix ADC owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, the appliance dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile is used for sending traffic to all the services bound to it. If a net profile is bound to a service group, the appliance uses the profile for all the members of the service group. If a net profile is bound to a monitor, the appliance uses the profile for all the probes sent from the monitor.

Note: When a Citrix ADC appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client.

**Usage of a net profile for sending traffic**

If the Use Source IP Address (USIP) option is enabled, the appliance uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, the appliance selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, the appliance uses the default method.
- If there is a net profile only on the service/service group, the appliance uses that net profile.
- If there is a net profile only on the virtual server, the appliance uses the net profile.
- If there is a net profile both on the virtual server and service/service group, the appliance uses the net profile bound to the service/service group.

**Usage of a net profile for sending monitor probes:**

For monitor probes, the appliance selects the source IP in the following manner:

- If there is a net profile bound to the monitor, the appliance uses the net profile of the monitor.
  It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,
  - If there is a net profile on the service/service group, the appliance uses the net profile of the service/service group.
  - If there is no net profile even on the service/service group, the appliance uses the default method of selecting a source IP.
Note: If there is no net profile bound to a service, the appliance looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the Citrix ADC appliance. An IP set can consist of both SNIP and VIP addresses. For instructions, see Creating IP Sets.
2. Create net profiles. For instructions, see Creating a Net Profile.
3. Bind the net profiles to the appliance entities. For instructions, see Binding a Net Profile to a Citrix ADC Entity.

Note:
- A net profile can have only the IP addresses specified as SNIP and VIP on the Citrix ADC appliance.
- Source IP persistence is not honored for Citrix ADC initiated packets.

Manage net profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the Citrix ADC appliance uses the addresses specified in the profile as the source IP address.

- For instructions on creating a network profile, see Creating a Network Profile.
- For instructions on binding a network profile to a Citrix ADC entity, see Binding a Net Profile to a Citrix ADC Entity.

Create an IP set

An IP set is a set of IP addresses, which are configured on the Citrix ADC appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set and bind Citrix ADC owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set.

To create an IP set by using the CLI

At the command prompt, type the following commands:

```
1 add ipset <name>
2
3 bind ipset <name> <IPAddress>
```
or

```
bind ipset <name> <IPAddress>
show ipset [<name>]
```

The above command shows the names of all the IP sets on the appliance if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

**Examples**

```
1. > add ipset skpnwipset
   Done
> bind ipset skpnwipset 21.21.20.1
   Done

2. > add ipset testnwipset
   Done
> bind ipset testnwipset 21.21.21.[21-25]
   IPAddress "21.21.21.21" bound
   IPAddress "21.21.21.22" bound
   IPAddress "21.21.21.23" bound
   IPAddress "21.21.21.24" bound
   IPAddress "21.21.21.25" bound
   Done

3. > bind ipset skpipset 11.11.11.101
   ERROR: Invalid IP address
   [This IP address could not be added because this is not an IP address owned by the Citrix ADC appliance]
> add ns ip 11.11.11.101 255.255.255.0 -type SNIP
   ip "11.11.11.101" added
   Done
> bind ipset skpipset 11.11.11.101
   IPAddress "11.11.11.101" bound
   Done

4. > sh ipset
   1) Name: ipset-1
   2) Name: ipset-2
   3) Name: ipset-3
```
To create an IP set by using the GUI

Navigate to System > Network > IP Sets, and create an IP set.

Create a net profile

A net profile (network profile) consists of one or more SNIP or VIP addresses of the Citrix ADC appliance.

To create a net profile by using the CLI

At the command prompt, type:

```
add netprofile <name> [-srcIp <srcIpVal>]
```

If the srcIpVal is not provided in this command, it can be provided later by using the set netprofile command.

Examples

```
add netprofile skpnetprofile1 -srcIp 21.21.20.1
Done
add netprofile baksnp -srcIp bakipset
Done
set netprofile yahnp -srcIp 12.12.23.1
Done
```
Bind a net profile to a Citrix ADC entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor.

Note: You can bind a net profile at the time of creating a Citrix ADC entity or bind it to an existing entity.

To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```
set lb vserver <name> -netProfile <net_profile_name>
```

or

```
set cs vserver <name> -netProfile <net_profile_name>
```

Examples

```
set lb vserver skpnwvs1 -netProfile gntnp
Done
set cs vserver mmdcsv -netProfile mmdnp
Done
```

To bind a net profile to a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click Profiles, and set a net profile.

To bind a net profile to a service by using the CLI

At the command prompt, type:

```
set service <name> -netProfile <net_profile_name>
```
Example

1. set service brnssvc1 -netProfile brnsnp
2. Done

To bind a net profile to a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, click Profiles, and set a net profile.

To bind a net profile to a service group by using the CLI

At the command prompt, type:

```
set servicegroup <serviceGroupName> -netProfile <net_profile_name>
```

Example

1. set servicegroup ndhsvcgrp -netProfile ndhnp
2. Done

To bind a net profile to a service group by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups, and open a service group.
2. In Advanced Settings, click Profiles, and set a net profile.

To bind a net profile to a monitor by using the CLI

At the command prompt, type:

```
set monitor -netProfile
```

Example

1. set monitor brnsecvmon1 -netProfile brnsmonn
2. Done
To bind a net profile to a monitor by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Open a monitor, and set the net profile.

Set a time-out value for idle client connections

You can configure a virtual server to terminate any idle client connections after a configured time-out period (in seconds) elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```plaintext
set lb vserver <name> -cltTimeout <Value>
```

Example:

```plaintext
set lb vserver Vserver-LB-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, click Traffic Settings, and set the client idle time-out value in seconds.

Manage RTSP connections

January 25, 2019
Contributed by: C

The Citrix ADC appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see “IP Addressing.”

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see “Configuring Load Balancing in Direct Server Return Mode.” For more information about configuring DNS, see “Domain Name System.”

In either case, when you configure RTSP load balancing, you must also configure rtspNat to match the topology of your load balancing setup.

To configure RTSP NAT by using the CLI

At the command prompt, type:

```sh
set lb vserver <name> - RTSPNAT <ValueOfRTSPNAT>
```

Example:

```sh
set lb vserver vserver-LB-1 - RTSPNAT ON
```

To configure RTSP NAT by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server of type RTSP.
2. In Advanced Settings, click Traffic Settings, and select RTSP Natting.
1.
Manage client traffic on the basis of traffic rate

January 25, 2019
Contributed by: C

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the Citrix ADC appliance based on the traffic rate. You can throttle the traffic flow if it is too high, cache information based on the traffic rate, and if the traffic rate is too high redirect excess traffic to a different load balancing virtual server. You can apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see Rate Limiting.

Identify a connection with layer 2 parameters

January 23, 2019
Contributed by: C

Generally, to identify a connection, Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>::<destination port>) to co-exist on the Citrix ADC appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the Citrix ADC appliance, and a firewall is set up for each VLAN.
You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs. Therefore, when an nCore Citrix ADC appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

**To configure the L2 connection option by using the CLI**

At the command prompt, type:

```bash
add lb vserver <name> <serviceType> <IPAddress>@<port> -l2Conn ON
```

**Example**

```bash
add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
```

**To configure the L2 connection option by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.
   
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

**Configure the prefer direct route option**

January 23, 2019

Contributed by: C

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the Citrix ADC appliance forwards traffic according to the configured route. If you want the appliance to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a Citrix ADC appliance, the appliance directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through
another firewall. However, in some cases, you may want the traffic to go through the firewall even if
the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.
Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the Citrix ADC
appliance.

To set the prefer direct route option by using the CLI

At the command prompt, type:

```
set lb parameter -preferDirectRoute (YES | NO)
```

Example:

```
set lb parameter -preferDirectRoute YES
```

To set the prefer direct route option by using the GUI

2. Select Prefer Direct Route.

Use a source port from a specified port range for backend communication

January 23, 2019

Contributed by:
C

By default, for configurations with USIP option disabled or with USIP and use proxy port options en-
abled, the Citrix ADC appliance communicates to the servers from a random source port (greater than
1024).

The appliance supports using a source port from a specified port range for communicating to the
servers. One of the use case of this feature is for servers that are configured to identify received traf-
ic belonging to a specific set on the basis of source port for logging and monitoring purposes. For
example, identifying internal and external traffic for logging purpose.
Configuring the Citrix ADC appliance to use a source port from a port range for communicating to the servers consists of the following tasks:

- **Create a net profile and set the source port range parameter.** A source port range parameter specifies one or more port ranges. The appliance randomly selects one of the free ports from the specified port ranges and used it as the source port for each connection to servers.
- **Bind the net profile to load balancing virtual servers, services, or service groups:** A net profile with source port range setting can be bound to a virtual server, service, or a service group of a load balancing configuration. For a connection to a virtual server, the appliance randomly selects one of the free ports from the specified port ranges of a net profile and use this port as the source port for connecting to one of the bound server.

**To specify a source port range or ranges by using the CLI**

At the command prompt, type:

```
1 bind netProfile <name> (-srcPortRange <int>-<int>) ...)
2 show netprofile <name>
```

**To specify a source port range or ranges by using the GUI**

1. Navigate to **System > Network > Net Profiles**.
2. Set the **Source Port Range** parameter while adding or modifying NetProfiles.

**Sample Configuration**

In the following sample configuration, net profile PARTIAL-NAT-1 has partial NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1 > add netprofile CUSTOM-SRCPORT-NP-1
2   Done
3 > bind netprofile CUSTOM-SRCPRT-NP-1 -srcportrange 2000-3000
4   Done
5 > bind netprofile CUSTOM-SRCPRT-NP-1 -srcportrange 5000-6000
6   Done
7   Done
8   Done
```

Configure source IP persistency for backend communication

January 23, 2019
Contributed by: C

By default, for a load balancing configuration with the USIP option disabled and a net profile bound to a virtual server or services or service groups, the Citrix ADC appliance uses the round robin algorithm to select an IP address from the net profile for communicating with the servers. Because of this selection method, the IP address selected can be different for different sessions of a specific client.

Some situations require that the Citrix ADC appliance send all of a specific client’s traffic from the same IP address when sending the traffic to servers. The servers can then, for example, identify traffic belonging to a specific set for logging and monitoring purposes.

The source IP persistency option of a net profile enables the Citrix ADC appliance to use the same address, specified in the net profile, to communicate with servers about all sessions initiated from a specific client to a virtual server.

To enable source IP persistency in a net profile by using the CLI

To enable source IP persistency while adding a net profile, at the command prompt, type:

```
add netProfile <name> -srcippersistency ( ENABLED | DISABLED )
```

```
show netprofile <name>
```

To enable source IP persistency in an existing net profile, at the command prompt, type:

```
set netProfile <name> -srcippersistency ( ENABLED | DISABLED )
```

```
show netprofile <name>
```
To enable source IP persistency in a net profile by using the GUI

1. Navigate to **System > Network > Net Profiles**.
2. Select **Source IP Persistency** while adding or modifying a net profile.

**Example**

In the following sample configuration, net profile NETPROFILE-IPPRSTNCY-1 has the source IP persistency option enabled and is bound to load balancing virtual server LBVS-1.

The Citrix ADC appliance always use the same IP address (in this example, 192.0.2.11) to communicate with servers bound to LBVS-1, for all sessions initiated from a specific client to the virtual server.

```
1  > add ipset IPSET-1
2
3  Done
4  > bind ipset IPSET-1 192.0.2.[11-15]
5    IPAddress "192.0.2.11" bound
6    IPAddress "192.0.2.12" bound
7    IPAddress "192.0.2.13" bound
8    IPAddress "192.0.2.14" bound
9    IPAddress "192.0.2.15" bound
10  Done
11  > add netprofile NETPROFILE-IPPRSTNCY-1 -srcIp IPSET-1 -srcippersistency ENABLED
12
13  Done
14  > set lb vserver LBVS-1 -netprofile NETPROFILE-IPPRSTNCY-1
15
16  Done
```

**Use IPv6 link local addresses on server side of a load balancing setup**

January 23, 2019

Contributed by:
C
IPv6 link local address is supported for services, service groups, and servers of a load balancing configuration. You can specify a link local IPv6 address along with the associated VLAN ID in services, service groups, and servers configurations. The Citrix ADC appliance uses the link local SNIP6 address from the same VLAN as specified in the services, service groups, and servers configurations to communicate with them.

A link local IPv6 address and the associated VLAN ID are specified in the following format in services, service groups, and servers configurations:

```
% fe80:123:4567::a%2048:
```

For example, `fe80:123:4567::a%2048:`, `fe80:123:4567::a` is the link local address and `2048` is the VLAN ID.

```
1 > add service SERVICE-1 fe80:123:4567::a%2048 HTTP 80
2 Done
3 > bind servicegroup SERVICE-GROUP-1 fe80::1%24 80
4 Done
5 > add server SERVER-1 fe80::b:c:d::e:f:a/64%1028
6 Done
7
```

3. Citrix ADC 12.1

Advanced load balancing settings

January 25, 2019

Contributed by: C

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- Gradually step up the load on a new service with virtual server–level slow start
- The no-monitor option for services
- Protect applications on protected servers against traffic surges
- Enable cleanup of virtual server and service connections
- Graceful shutdown of services
- Enable or disable persistence session on TROFS services

© 1999-2018 Citrix Systems, Inc. All rights reserved. 2651
• Direct requests to a custom web page
• Enable access to services when down
• Enable TCP buffering of responses
• Enable compression
• Maintain client connection for multiple client requests
• Insert IP address of the client in the request header
• Retrieve location details from user IP address using geolocation database
• Use the source IP address of the client when connecting to the server
• Configure the source port for server-side connections
• Set a limit on the number of client connections
• Set a limit on the number of requests per connection to the server
• Set a threshold value for the monitors bound to a service
• Set a timeout value for idle client connections
• Set a timeout value for idle server connections
• Set a limit on the bandwidth usage by clients
• Redirect client requests to a cache
• Retain the VLAN identifier for VLAN transparency
• Configure automatic state transition based on percentage health of bound services

1. Citrix ADC
2. Citrix ADC 12.1

Gradually step up the load on a new service with virtual server–level slow start

January 25, 2019
Contributed by: C

You can configure the Citrix ADC appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (hereafter, the term “new service” is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.
This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

  Note: In automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

**Manual slow start**

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service
to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval in seconds</td>
<td>0</td>
</tr>
<tr>
<td>New service request rate</td>
<td>10, 20, 40, and 0, at intervals that you choose</td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Requests per second</td>
</tr>
</tbody>
</table>

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

<table>
<thead>
<tr>
<th></th>
<th>new service request rate = 10 req/sec (Service3added)</th>
<th>new service request rate = 20 req/sec</th>
<th>new service request rate = 40 req/sec (Service4added)</th>
<th>new service request rate = 0 req/sec (new services exit slow start mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Service1</strong></td>
<td>115</td>
<td>110</td>
<td>80</td>
<td>60</td>
</tr>
<tr>
<td><strong>Service2</strong></td>
<td>115</td>
<td>110</td>
<td>80</td>
<td>60</td>
</tr>
<tr>
<td><strong>Service3</strong></td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>60</td>
</tr>
<tr>
<td><strong>Service4</strong></td>
<td>-</td>
<td>-</td>
<td>40</td>
<td>60</td>
</tr>
</tbody>
</table>
new service request rate = 10 req/sec
(Service3added)
new service request rate = 20 req/sec
(new services exit slow start mode)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval in seconds</td>
<td>10</td>
</tr>
<tr>
<td>Increment value</td>
<td>4</td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Requests per second</td>
</tr>
</tbody>
</table>

Automated slow start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second,
the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

<table>
<thead>
<tr>
<th></th>
<th>0 sec</th>
<th>10 sec</th>
<th>20 sec</th>
<th>30 sec</th>
<th>40 sec</th>
<th>50 sec</th>
</tr>
</thead>
<tbody>
<tr>
<td>Req/sec for Service1</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec for Service2</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec for Service3</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec for Service4</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec for Service5</td>
<td>0</td>
<td>4</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
</tr>
<tr>
<td>Total req/sec (load on the virtual server)</td>
<td>100</td>
<td>100</td>
<td>100</td>
<td>100</td>
<td>100</td>
<td>100</td>
</tr>
</tbody>
</table>

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values
Parameter Value

<table>
<thead>
<tr>
<th>Interval in seconds</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Increment value</td>
<td>25</td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Percent</td>
</tr>
</tbody>
</table>

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

**Set the slow start parameters**

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

**To configure stepwise load increments for a new service by using the command line interface**

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```plaintext
1 add lb vserver <name> <serviceType> <IPAddress> <port> [newServiceRequest <positive_integer>] [newServiceRequestUnit] [newServiceRequestIncrementInterval <positive_integer>]
2
3 show lb vserver <name>
```

**Example**

```plaintext
1 set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -newServiceRequestIncrementInterval 10
2 Done
3
4 show lb vserver BR_LB
5 BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
6 State: UP
7 ...
8 ...
9 New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
```
To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:
   • New Service Startup Request Rate.
   • New Service Request Unit.
   • Increment Interval.

The no-monitor option for services

January 23, 2019
Contributed by:
C

If you use an external system to perform health checks on the services and do not want the Citrix ADC appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

• If a service for which you enabled the no-monitor option goes down, the appliance continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that
monitors the services reports that a service that is DOWN, remove the service from the Citrix ADC configuration.

- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the CLI

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```plaintext
1 add service <serviceName> <IP | serverName> <serviceType> <port> -healthMonitor (YES|NO)
```

Example:

```plaintext
1 add service nomonsrvc 10.102.21.21 http 80 -healthMonitor no
2 Done
3 show service nomonsrvc
4 nomonsrvc (10.102.21.21:80) - HTTP
5 State: UP
6 Last state change was at Mon Nov 15 22:41:29 2010
7 Time since last state change: 0 days, 00:00:00.970
8 Server Name: 10.102.21.21
9 Server ID : 0 Monitor Threshold : 0
10 ...
11 Access Down Service: NO
12 ...
13 Down state flush: ENABLED
14 Health monitoring: OFF
15 ...
16 1 bound monitor:
17 1) Monitor Name: tcp-default
18 State: UNKNOWN Weight: 1
19 Probes: 3 Failed [Total: 3 Current: 3]
20 Last response: Probe skipped - Health monitoring is turned off.
21 Response Time: N/A
22 Done
```

To set the no-monitor option for an existing service by using the CLI

At the command prompt, type the following command to set the health monitor option:
Example:

```
1  set service <name> -healthMonitor (YES|NO)

```

```
By default, the state of a service and the state of the corresponding monitor are UP.

>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP

1) Monitor Name: http-ecv
   State: UP Weight: 1
   Probes: 99992 Failed [Total: 0 Current: 0]
   Last response: Success - Pattern found in response.
   Response Time: 3.76 millisec
   Done

When the no-monitor option is set on a service, the state of the monitor changes to UNKNOWN.

set service LB-SVC1 -healthMonitor NO
Done

show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010.
Time since last state change: 5 days, 18:55:48.710
Health monitoring: OFF

1) Monitor Name: http-ecv
   State: UNKNOWN Weight: 1
   Probes: 100028 Failed [Total: 0 Current: 0]
   Last response: Probe skipped - Health monitoring is turned off.
   Response Time: 0.0 millisec
   Done

When the no-monitor option is removed, the earlier state of the monitor is resumed.

> set service LB-SVC1 -healthMonitor YES
Done

>show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010
```
Time since last state change: 5 days, 18:57:47.880

1) Monitor Name: http-ecv
State: UP Weight: 1
Probes: 100029 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 5.690 millisec

To set the no-monitor option for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

Protect applications on protected servers against traffic surges

January 25, 2019
Contributed by: C

The Citrix ADC appliance provides the surge protection option to maintain the capacity of a server or cache. The appliance regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The appliance blocks any surges passed to the server, thereby preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see “Surge Protection.”

To set surge protection on the service by using the CLI

At the command prompt, type:

```
set service <name> -sp <Value>
```

Example:

```
set service Service-HTTP-1 -sp ON
```
To set surge protection on the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a source.
2. In Advanced Settings, select Traffic Settings, and select Surge Protection.

Enable cleanup of virtual server and service connections

January 25, 2019
Contributed by: C

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes or health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN. If a service or virtual server are marked DOWN, the server and client side connections must be flushed. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. You must not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

<table>
<thead>
<tr>
<th>Vserver-LB-1</th>
<th>Service-1</th>
<th>State of Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>E</td>
<td>Both client and server connections are terminated.</td>
</tr>
</tbody>
</table>
For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.

<table>
<thead>
<tr>
<th>Vserver-LB-1</th>
<th>Service-1</th>
<th>State of Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>D</td>
<td>For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.</td>
</tr>
<tr>
<td>D</td>
<td>E</td>
<td>For some service types, such as TCP, for which the Citrix ADC appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.</td>
</tr>
<tr>
<td>D</td>
<td>D</td>
<td>Neither client nor server connections are terminated.</td>
</tr>
</tbody>
</table>

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown option, refer to the Citrix ADC documentation.
To set down state flush on the service by using the CLI

At the command prompt, type:

```
set service <name> -downStateFlush (ENABLED | DISABLED)
```

Example:

```
set service Service-HTTP-1 -downStateFlush enabled
```

To set down state flush on the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Down State Flush.

To set down state flush on the virtual server by using the CLI

At the command prompt, type:

```
set lb vserver <name> -downStateFlush (ENABLED | DISABLED)
```

Example:

```
set lb vserver vsvr1 -downStateFlush enabled
```

To set down state flush on the virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Down State Flush.

3. Citrix ADC 12.1
Graceful shutdown of services

January 25, 2019

Contributed by: C

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. You can later enable the service by using the “enable service <name>” command.

To avoid disrupting established sessions, you can place a service in the Transition Out of Service (TROFS) state by doing one of the following:

- Adding a TROFS code or string to the monitor—Configure the server to send a specific code or string in response to a monitor probe.
- Explicitly disable the service and:
  - Set a delay (in seconds).
  - Enable graceful shut down.

Adding a TROFS Code or String

If you bind only one monitor to a service, and the monitor is TROFS-enabled, it can place the service in the TROFS state on the basis of the server’s response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the persistent connections.

If multiple monitors are bound to a service, the effective state of the service is calculated on the basis of the state of all the monitors that are bound to the service. Upon receiving a TROFS response, the state of the TROFS-enabled monitor is considered as UP for the purpose of this calculation. For more information about how a Citrix ADC appliance designates a service as UP, see Setting a Threshold Value for the Monitors Bound to a Service.

Important:

- You can bind multiple monitors to a service, but must not TROFS-enable more than one of them.
- You can convert a TROFS-enabled monitor to a monitor that is not TROFS-enabled, but not vice versa.

To configure a TROFS code or string in a monitor by using the command line interface

At the command prompt, type one of the following commands:
To modify the TROFS code or string by using the command line interface

At the command prompt, type one of the following commands:

```
1  add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2  add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
3  add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
```

**Note:** You can use the set command only if a TROFS-enabled monitor was added earlier. You cannot use this command to set the TROFS code or string for a monitor that is not TROFS-enabled.

To configure a TROFS code or string in a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following:
   - Select Type as HTTP, and specify a TROFS Code.
   - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

Disabling a Service

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.
The following table describes graceful shut down options.
<table>
<thead>
<tr>
<th>State</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graceful shutdown is enabled and a wait time is specified.</td>
<td>Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.</td>
</tr>
<tr>
<td>Graceful shutdown is disabled and a wait time is specified.</td>
<td>Service is shut down only after the wait time expires, even if all established connections are served before expiration.</td>
</tr>
<tr>
<td>Graceful shutdown is enabled and no wait time is specified.</td>
<td>Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.</td>
</tr>
<tr>
<td>Graceful shutdown is disabled and no wait time is specified.</td>
<td>No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)</td>
</tr>
</tbody>
</table>

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see Enabling Cleanup of Virtual Server Connections.

**To configure graceful shutdown for a service by using the command line interface**

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

```
1  disable service <name> [<delay>] [-graceFul (YES|NO)]
2  show service <name>
```

**Example:**

```
1  > disable service svc1 6000 -graceFul YES
2  Done
3  > show service svc1
4  svc1 (10.102.80.41:80) - HTTP
5  State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
6  Last state change was at Mon Nov 15 22:44:15 2010
```
To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

Enable or disable persistence session on TROFS services

January 23, 2019
You can set the trofsPersistence flag to specify whether a service in the transition out of service (TROFS) state should maintain persistent sessions. When a monitor is TROFS enabled, it can place a service in the TROFS state on the basis of the server’s response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the active client connections. In some cases, the honored active sessions might have to include persistent sessions. But in other cases, especially those involving long-lived persistence sessions or persistence methods such as custom server ID, honoring the persistent sessions could prevent the service from transitioning to the out-of-service state.

If you set the trofsPersistence flag to ENABLED, persistent sessions are honored. If you set it to DISABLED, they are not.

To set the trofsPersistence flag by using the command line interface

At the command prompt, type one of the following commands to set the trofsPersistence flag for a new virtual server or an existing virtual server, or to return the setting to its default value:

1. **add lb vserver** <name> [-trofsPersistence ( ENABLED | DISABLED )]
2. **set lb vserver** <name> [-trofsPersistence ( ENABLED | DISABLED )]
3. **unset lb vserver** <name> [-trofsPersistence]

**Argument**

**trofsPersistence.** Honor current active client connections and new requests on persistence sessions when the service is in TROFS state.

Possible values: ENABLED, DISABLED. Default: ENABLED.

**Examples:**

1. add lb vserver v1 http 10.102.217.42 80 -persistencetype SOURCEIP -trofsPersistence ENABLED
2. set lb vserver v1 -trofsPersistence DISABLED
3. unset lb vserver v1 -trofsPersistence
For SureConnect to function correctly, you must set it globally. The Citrix ADC provides the SureConnect option to ensure the response from an application. For more information about the SureConnect option, see “Sure Connect.”

**To set SureConnect on the service by using the CLI**

At the command prompt, type:

```
set service <name> -sc <Value>
```

**Example:**

```
set service Service-HTTP-1 -sc ON
```

**To set SureConnect on the service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Sure Connect.

**Enable access to services when down**

January 25, 2019
You can enable access to a service when it is disabled or in a DOWN state by configuring the Citrix ADC appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the Access Down setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see IP Addressing.

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the access-Down parameter.

**To enable access down on a service by using the CLI**

At the command prompt, type:

```
set service <name> -accessDown <Value>
```

**Example:**

```
set service Service-HTTP-1 -accessDown YES
```

**To enable access down on a service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.

1. 2. Citrix ADC
2. Citrix ADC 12.1

**Enable TCP buffering of responses**

January 25, 2019

Contributed by:
C

The Citrix ADC appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum
speed that the client can accept them. The appliance allocates from 0 through 4095 megabytes (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting.

For more information about configuring TCP buffering globally, see “TCP Buffering.”

To enable TCP Buffering on a service by using the CLI

At the command prompt, type:

```
set service <name> -TCPB <Value>
```

Example:

```
set service Service-HTTP-1 -TCPB YES
```

To enable TCP Buffering on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select TCP Buffering.
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

Enable compression

January 25, 2019

Contributed by: C

The Citrix ADC appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally.

For more information about configuring compression globally, see Compression.
To enable compression on a service by using the CLI

At the command prompt, type:

```bash
set service <name> -CMP <YES | NO>
```

**Example:**

```bash
set service Service-HTTP-1 -CMP YES
```

To enable compression on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Compression.

1. Citrix ADC
2. Citrix ADC 12.1

Maintain client connection for multiple client requests

January 25, 2019

Contributed by: C

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a Web site open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the Citrix ADC appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client will open a new connection for every request that it sends to the Web site. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see [Client Keep-Alive](#).
To enable client keep-alive on a service by using the CLI

At the command prompt, type:

```
set service <name> -CKA <Value>
```

**Example:**

```
set service Service-HTTP-1 -CKA YES
```

To enable client keep-alive on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.

Insert the IP address of the client in the request header

January 23, 2019

Contributed by: C

A Citrix ADC uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the appliance inserts the client’s IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

**Note:** To insert multiple headers, you need to perform one of the following:

- Add rewrite policies to check CLIENT.IS_SSL and insert appropriate header.
- Bind the appropriate rewrite policy for each virtual server based on the type.

To insert client IP address in the client request by using the CLI

At the command prompt, type:
To insert client IP address in the client request by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Client IP Address.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Retrieve location details from user IP address using geolocation database

January 25, 2019
Contributed by:
C

Note: This feature is available from Citrix ADC release 12.1 build 50.x and later.

The Citrix ADC appliance can now get user location details like continent, county, and city. For any public IP address from a geolocation database. This is performed using the advanced policy infrastructure. The retrieved location details are then used in a rewrite action or a responder action for performing the following use cases.

- Insert an HTTP header with user location details (such as country, city information) when sending the client request to the back-end server.
- Add country name in the HTML page response for an invalid user.

The appliance can also log the location details using the audit logging mechanism.

Getting user location details using geolocation functions

The components interact as given below:

1. User sends a client request from a particular geographic location.
2. The Citrix ADC appliance looks for the user IP address from the client request and retrieves the geo location details (such as continent, country, region, city, ISP, organization, or custom details) from a geolocation database.

3. Once the location details are retrieved, the appliance uses either a responder policy or a rewrite policy to evaluate the request.

4. In a rewrite policy, the appliance adds a new header with the geo location details and sends it to the back-end server. For example, insert a custom HTTP header with country information.

5. In a responder policy, the appliance evaluates the HTTP request and based on policy evaluation, the appliance allows access to the users or redirects the user to an error page stating the region from where they are accessing the application does not have access.

### Setting up geolocation database

As a pre-requisite, you must have a geolocation database to run on the Citrix ADC appliance. The geolocation database files are available with Citrix ADC firmware. To download the database files from a vendor, convert it into Citrix ADC format and import it into your appliance.

For more information about geolocation database, see [Add a location file to create static proximity database](#) topic.

### Geolocation functions

The following table gives a list of geolocation functions that retrieves location details of any public IP address. These functions can be used in rewrite or responder policies.

<table>
<thead>
<tr>
<th>Geolocation function</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG</td>
<td>India</td>
</tr>
<tr>
<td>CLIENT.IP.SRC.LOCATION(3)</td>
<td>Asia.In.Karnataka</td>
</tr>
<tr>
<td>CLIENT.IP.SRC.LAT_LONG</td>
<td>12,77</td>
</tr>
<tr>
<td>CLIENT.IPV6.SRC.LOCATION(3)</td>
<td>North America.US.California</td>
</tr>
<tr>
<td>CLIENT.IPV6.SRC.LOCATION.GET(1).LOCATION_LONG</td>
<td>United States</td>
</tr>
<tr>
<td>CLIENT.IPV6.SRC.LOCATION.GET(3)</td>
<td>California</td>
</tr>
<tr>
<td>CLIENT.IPV6.SRC.LAT_LONG</td>
<td>36, -119</td>
</tr>
</tbody>
</table>
Configuring geolocation functions

To configure geolocation functions using advanced policy infrastructure, you must enable the load balancing, rewrite and responder features and then complete the following use cases.

Enable load balancing, responder, rewrite features

If you want Citrix ADC appliance to authorize user access from a particular geo location, you must enable the load balancing, rewrite and responder features.

```
enable ns feature loadbalancing rewrite responder
```

Use case 1: Configuring geolocation function for redirecting invalid users outside geo location

When a user from India is requesting access to a webpage, block the request and respond with an HTML page with country name.

Follow the steps given below to complete the configuration for this use case.

- Add responder action
- Add responder policy
- Bind responder policy to load balancing server

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic

Add responder action

Add a responder action to respond with HTML page with country name.

At the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <string>] [-responseStatusCode <positive_integer>] [-reasonPhrase <string>]
```

Example:

```
add responder action responder_act respondwith "CLIENT.REQ.VERSION + \"304 Requested Page not allowed in your country - \" + CLIENT.IP.SRC.LOCATION.GET (1).LOCATION_LONG + \"\"r\n\n""
```
Add auditlog message action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:
```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]
```

Example:
```
add audit messageaction msg1 DEBUG "Request Location: \"+CLIENT.IP.SRC.LOCATION"
```

Add responder policy

Add a responder policy to identify requests coming from India and associate the responder action to this policy.

At the command prompt, type:
```
add responder policy <name> <rule> <action> [undefAction] [-comment <string>] [-logAction <string>] [-appflowAction <string>]
```

Example:
```
add responder policy responder_pol CLIENT.IP.SRC.MATCHES_LOCATION("Asia.India.*.*.*.") responder_act -logaction log_act
```

Bind responder policy to load balancing server

Bind the responder policy to a load balancing virtual server of type HTTP/SSL.

At the command prompt, type:
```
bind lb vserver <vserver name> -policyName < policy_name > -priority <> -type <L7InlineREQUEST | L4Inline-REQUEST>
```

Example:
```
bind lb vserver http_vserver -policyName responder_pol -priority 100 -type REQUEST
```
Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond

Consider a scenario, where a Citrix ADC appliance must insert the user location in HTTP header of a request sent to the application server so that the server can use the information for some business logic.

Follow the steps given below to complete the configuration for this use case:

- Add rewrite action
- Add rewrite policy
- Bind rewrite policy to load balancing

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see Responder topic.

Add rewrite action

Add a rewrite action to insert a custom HTTP header with user geolocation details in the request and send it back-end servers.

At the command prompt, type:

```
add rewrite action <name> <type> <target> [stringBuilderExpr] [-pattern <expression> | -search <expression>] [-refineSearch <string>] [-comment <string>]
```

Example:

```
add rewrite action rewrite_act insert_http_header "User_location" CLIENT.IP.SRC,LOCATION
```

Add rewrite policy

Add a rewrite policy to evaluate if the rewrite action should be executed. In this case, all requests going to the application server must have a custom HTTP header, so the rule can be “true.”

At the command prompt, type:

```
add rewrite policy <name> <rule> <action> [undefAction] [-comment <string>] [-logAction <string>]
```

Example:

```
add rewrite policy rewrite_pol true rewrite_act -logaction log_act
```
Bind rewrite policy to load balancing

Bind the rewrite policy to the required load balancing virtual server of type HTTP/SSL.

At the command prompt, type:

```bash
bind lb vserver <vserver name> -policyName <policy_name> -priority <> -type <L7InlineREQUEST | L4Inline-REQUEST>
```

Example:

```bash
bind lb vserver http_vserver -policyName rewrite_pol -priority 100 -type REQUEST
```

Syslog support for logging geolocation details (optional)

If you prefer to log the user's geolocation details, you must specify the SYSLOG action to be performed when a request matches the policy. The appliance stores the details as a log message in the ns.log file.

For more information about SYSLOG and NSLOG auditing, see Audit logging topic.

Output for user geolocation details

If a user is trying to access an application from Bangalore location and if the appliance uses geolocation function, “CLIENT.IP.SRCLOCATION” then the following output is logged in the appliance using SYSLOG or newnslog action.

Sample output log:

```bash
07/23/2018:19:03:54 GMT Debug 0-PPE-0 : default REWRITE Message 22 0 : "Request Location: asia.in.karnataka.bangalore.*.*"

Done
```

1. 2. Citrix ADC
3. Citrix ADC 12.1

Use source IP address of the client when connecting to the server

January 25, 2019
You can configure the Citrix ADC appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see “Enabling Use Source IP Mode.”

To enable USIP mode for a service by using the CLI

At the command prompt, type:

```
set service <name> -usip (YES | NO)
```

Example:

```
set service Service-HTTP-1 -usip YES
```

To enable USIP mode for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, in the Service Settings section, select Use Source IP Address.

Use client source IP address for backend communication in a v4-v6 load balancing configuration

In a v4-to-v6 load balancing configuration, for services with USIP disabled, the Citrix ADC appliance communicates to the related servers from one of the configured IPv6 SNIP (SNIP6) addresses.

For services with USIP enabled, you must set the global USIP NAT prefix parameter for making the related servers aware of the client’s IP address of the request packets. USIP NAT prefix is a global IPv6 prefix of length 32/40/48/56/64/96 bits configured on the Citrix ADC appliance.
For a load balancing service that has USIP enabled, the appliance translates the IPv4 request packet to an IPv6 packet and sets the source IP address of the translated IPv6 packet to a concatenation of:

- the USIP NAT prefix of length of 32/40/48/56/64/96 bits.
- zeros padded if the USIP NAT prefix length is less than 96 bits. Number of bits padded with zeros = 96-USIP NAT prefix length. For example, if the USIP NAT prefix length is 64, then the number of bits padded with zeros = 96-64 = 32.
- the IPv4 source address [32 bits] that was received in the request packet. In other words, the last 32 bits of the source IPv6 address is set to the IPv4 address of the client.

On receiving an IPv6 response packet from the server, the Citrix ADC appliance translates the IPv6 packet to an IPv4 packet and sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

**Note:** This feature is not supported for Citrix Gateway configuration and, content switching and cache redirection load balancing configurations.

**Configuration Steps**

Configuring USIP for a v4-to-v6 load balancing configuration consists of the following tasks:

- **Add global USIP NAT prefix.** It is a global IPv6 prefix of length 32/40/48/56/64/96 bits to be configured on the appliance.
- **Enable global USIP mode.** For more information, see *Enable Use Source IP Mode.*
- **Enable USIP mode for load balancing services.** For more information, see *Use source IP address of the client when connecting to the server.*

**To add a global USIP NAT prefix by using the CLI:**

- set ipv6 -usipnatprefix <prefix/prefix_length>
- show ipv6

**To add a global USIP NAT prefix by using the GUI:**

1. Navigate to **System > Network**, and click **Change IPv6 Settings**.
2. On the **Configure Configuration for IPV6** screen, set the **USIP NAT Prefix** parameter.

**Sample configuration**

```
1 > set ipv6 -usipnatprefix 2001:DB8:90::/64
2     Done
3
4 > enable ns mode USIP
5     Done
```
Configure the source port for server-side connections

January 25, 2019
Contributed by:
C

When the Citrix ADC appliance connects to a physical server, it can use the source port from client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The Citrix ADC appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- Req1 is received by LBVS1 and Req2 is received by LBVS2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, they forward the response to the client.
- Consider two cases:
  - Use the client port. When the appliance uses the client port, both the virtual servers use the client's IP address (because USIP is ON) and the client's port when connecting to the
server. Therefore, when the service sends the response, the appliance cannot determine which virtual server should receive the response.

- Use proxy port. When the appliance uses a proxy port, the virtual servers use the client’s IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that should receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the Citrix ADC appliance can use the source port from the client’s request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see “Enabling Use Source IP Mode.”

You can configure the Use Proxy Port setting either globally or on a given service.

**Configure the use proxy port setting on a service**

You configure the Use Proxy Port setting on the service if you want to override the global setting.

**To configure the Use Proxy Port setting on a service by using the CLI**

At the command prompt, type:

```bash
set service <name> -useProxyPort (YES | NO)
```

**Example:**

```
set service svc1 -useproxypport YES
Done

show service svc1
svc1 (10.102.29.30:80) - HTTP
State: UP
...
Use Source IP: YES Use Proxy Port: YES
...
Done
```
To configure the Use Proxy Port setting on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Proxy Port.

Configure the use proxy port setting globally

You configure the Use Proxy Port setting globally if you want to apply the setting to all the services on the Citrix ADC appliance. The global setting is overridden by service-specific Use Proxy Port settings.

To configure the Use Proxy Port setting globally by using the CLI

At the command prompt, type the following commands to configure the Use Proxy Port setting globally and verify the configuration:

```
set ns param -useproxyport ( ENABLED | DISABLED )
```

Example:

```
1 set ns param -useproxyport ENABLED
2 Done
3 show ns param
4 Global configuration settings:
5 . . .
6 Use Proxy Port: ENABLED
7 Done
```

To configure the Use Proxy Port setting globally by using the GUI

Navigate to System > Settings > Change global system settings, and select or clear Use Proxy Port.

1.
2. Citrix ADC
3. Citrix ADC 12.1
Set a limit on the number of client connections

January 25, 2019
Contributed by: C

You can specify a maximum number of client connections that each load balanced server can handle. The Citrix ADC appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the Maximum Client setting, see Load Balancing Domain-Name Based Services.

Note: Connections that are in the process of closing are not considered for this limit.

To set a limit on the number of client connections by using the CLI

At the command prompt, type:

```
set service <name> -maxclient <Value>
```

**Example:**

```
set service Service-HTTP-1 -maxClient 1000
```

To set a limit on the number of client connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Clients.
   1. Citrix ADC
   2. Citrix ADC
   3. Citrix ADC 12.1

Set a limit on number of requests per connection to the server

January 23, 2019
The Citrix ADC appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers may have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

**To limit the number of client requests per connection by using the CLI**

At the command prompt, type:

```
set service <ServiceName> -maxReq <Value>
```

**Example**:

```
set service Service-HTTP-1 -maxReq 100
```

**To limit the number of client requests per connection by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Requests.

3. Citrix ADC
4. Citrix ADC 12.1

**Set a threshold value for the monitors bound to a service**

February 19, 2019

Contributed by: C

The Citrix ADC appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.
By default, the monitor threshold is set to 0 and monitor weights are set to 1. All monitors have equal weightage then and a service can go DOWN when any one of the monitors goes DOWN.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

To set the monitor threshold value on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -monThreshold <Value>
```

**Example:**

```
1 set service Service-HTTP-1 -monThreshold 100
```

To set the monitor threshold value on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Monitor Threshold.
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

Set a timeout value for idle client connections

January 23, 2019

Contributed by: C
You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the Citrix ADC appliance closes the client connection.

**To set a timeout value for idle client connections by using the CLI**

At the command prompt, type:

```
set service <name> -cltTimeout <Value>
```

**Example:**

```
set service Service-HTTP-1 -cltTimeout 100
```

**To set a timeout value for idle client connections by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Client Idle Time-out.

1. 2. 3. Citrix ADC
3. Citrix ADC 12.1

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the Citrix ADC appliance closes the server connection.

**To set a timeout value for idle server connections by using the CLI**

At the command prompt, type:

```
set service <name> -svrTimeout <Value>
```
Example:

```
set service Service-HTTP-1 -svrTimeout 100
```

To set a timeout value for idle server connections by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Server Idle Time-out.
   1. 
   2. [Citrix ADC](https://www.citrix.com)
   3. Citrix ADC 12.1

Set a limit on the bandwidth usage by clients

January 23, 2019

Contributed by: C

In some cases, servers may have limited bandwidth to handle client requests and may become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The Citrix ADC appliance forwards requests to a load balanced server only until this limit is reached.

To set a maximum bandwidth limit on a service by using the CLI

At the command prompt, type:

```
set service <name> -maxBandwidth <Value>
```

Example:

```
set service Service-HTTP-1 -maxBandwidth 100
```

To set a maximum bandwidth limit on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Thresholds & Timeouts, and select Maximum Bandwidth.
Redirect client requests to a cache

January 23, 2019
Contributed by: C

You can configure a service to redirect client requests to a cache, and forward the non-cacheable requests to a service chosen by the configured load balancing method.

To set cache redirection on a service by using the CLI

At the command prompt, type:

```
set service <name> -cacheable <Value>
```

Example:

```
set service Service-HTTP-1 -cacheable YES
```

To set cache redirection on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and set the Cache Type.

Retain the VLAN identifier for VLAN transparency

January 23, 2019
Contributed by: C
You can configure a load balancing virtual server to retain the client’s VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

To configure a load balancing virtual server to retain the client VLAN ID by using the CLI

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

```
1  set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED
2  
3  show lb vserver <name>
```

**Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure a load balancing virtual server to retain the client VLAN ID by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Retain VLAN ID.

Configure automatic state transition based on percentage health of bound services

January 23, 2019

Contributed by:

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.
You can also enable an SNMP alarm called ENTITY-STATE if you want the Citrix ADC appliance to notify you when the percentage health of bound services causes a virtual server to change state.

**To configure percentage based automatic state transition by using the CLI**

At the command prompt, type the following commands to configure automatic state transition for a virtual server and verify the configuration:

1. `set lb vserver <name> -healthThreshold <positive_integer>`
2. `show lb vserver <name>`

**To configure percentage based automatic state transition by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and set a Health Threshold.

**To enable the ENTITY-STATE alarm by using the CLI**

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

1. `enable snmp alarm ENTITY-STATE`
2. `show snmp alarm`

**To enable the ENTITY-STATE alarm by using the GUI**

1. Navigate to System > SNMP > Alarms.
2. Select ENTITY-STATE and, in the Action list, select Enable.

1. Citrix ADC
2. Citrix ADC 12.1

**Built-in monitors**

January 25, 2019
The Citrix ADC appliance contains a number of built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. You cannot modify or remove the built-in monitors; you can only bind a built-in monitor to a service and unbind it from the service.

Note: You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see Configuring Monitors in a Load Balancing Setup.

TCP-based application monitoring

The Citrix ADC appliance has two built-in monitors that monitor TCP-based applications: tcp-default and ping-default. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services; the ping-default monitor is bound to all non-TCP services.

You cannot delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.
<table>
<thead>
<tr>
<th>Monitor type</th>
<th>Specific parameters</th>
<th>Process</th>
</tr>
</thead>
<tbody>
<tr>
<td>tcp</td>
<td>Not applicable</td>
<td>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.</td>
</tr>
<tr>
<td>http</td>
<td><code>httprequest [&quot;HEAD /&quot;]</code> - HTTP request that is sent to the service. <code>respcodes [200]</code> - A set of HTTP response codes are expected from the service.</td>
<td>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.</td>
</tr>
<tr>
<td>tcp-ecv</td>
<td><code>send [&quot;&quot;]</code> - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes. <code>recv [&quot;&quot;]</code> - expected response from the service. The maximum permissible length of the string is 128 K bytes.</td>
<td>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.</td>
</tr>
<tr>
<td>Monitor type</td>
<td>Specific parameters</td>
<td>Process</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>---------</td>
</tr>
<tr>
<td>http-ecv</td>
<td>send [&quot;&quot;] - HTTP data that is sent to the service; recv [&quot;] - the expected HTTP response data from the service</td>
<td>The Citrix ADC appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data may be anywhere in the first 24K bytes of the HTTP body of the response.</td>
</tr>
<tr>
<td>ping</td>
<td>Not Applicable</td>
<td>The Citrix ADC appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.</td>
</tr>
</tbody>
</table>

To configure built-in monitors for TCP-based applications, see Configuring Monitors in a Load Balancing Setup.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

**SSL service monitoring**

January 23, 2019
The Citrix ADC appliance has built-in secure monitors, TCPS and HTTPS. You can use the secure monitors to monitor HTTP as well as non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and then set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and then set the secure flag. The secure monitors work as described below:

- **Secure TCP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.

- **Secure HTTP monitoring.** The Citrix ADC appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

<table>
<thead>
<tr>
<th>Monitor type</th>
<th>Probe</th>
<th>Success criteria (Direct condition)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>TCP connection; SSL handshake</td>
<td>Successful TCP connection established and successful SSL handshake.</td>
</tr>
<tr>
<td>HTTP</td>
<td>TCP connection; SSL handshake; Encrypted HTTP request</td>
<td>Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted.</td>
</tr>
<tr>
<td>TCP-ECV</td>
<td>TCP connection; SSL handshake (Data sent to a server is encrypted.)</td>
<td>Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.</td>
</tr>
<tr>
<td>HTTP-ECV</td>
<td>TCP connection; SSL handshake (Encrypted HTTP request)</td>
<td>Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.</td>
</tr>
</tbody>
</table>
To monitor FTP services, the Citrix ADC appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected on both connections is it marked UP.

Note: Monitor probes originate from the NSIP address.

The Citrix ADC appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP-EXTENDED monitor is a scriptable monitor. It uses the nsftp.pl script. The FTP-EXTENDED monitor script is enhanced to send secure probes to FTP services. You can create a monitor of type USER and specify this script name, or you can create a monitor of type FTP-EXTENDED. In the latter case, the nsftp.pl script is automatically taken from the default directory.

To send secure FTP probes to FTP services by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <string> -secure ( YES | NO )
```

Example

```
add monitor FTPS_MON USER -scriptname nsftp.pl -scriptargs "file=example;user=sam;password=sam_passwd" -secure YES
```

OR

```
add monitor mon1 FTP-EXTENDED -username root -password freebsd -filename fsdf
```
To send secure FTP probes to FTP services by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors and, for Type, specify USER or FTP-EXTENDED.

2. Depending on which type you specified, set one of the following groups of parameters:
   a. USER: In Special Parameters, specify a Script Name (nsftp.pl) and the Script Arguments.
   b. FTP-EXTENDED: In Special Parameters, specify a File Name, User Name, and Password.

To configure built-in monitors to check the state of FTP services, see Configuring Monitors in a Load Balancing Setup.

1. Citrix ADC
2. Citrix ADC 12.1

Secure monitoring of servers by using SFTP

January 23, 2019

Contributed by: C

A user script ‘nssftp.pl’ is added to support SSH File Transfer Protocol (SFTP) monitoring. It is available in the current list of in-built Citrix ADC user monitors and is located in the /netscaler/monitors directory. The SFTP monitor uses the specified username and password to check if the file is present on the server.

To configure secure monitoring using SFTP by using the CLI

At the command prompt, type:

```
add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <string> -secure ( YES | NO )
```

Example:

```
add monitor SFTP_MON USER -scriptname nssftp.pl -scriptargs "file=example.txt;user=sam;password=sam_passwd"
```
To configure secure monitoring using SFTP by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors and in Type specify USER.
2. In Special Parameters, in Script Name, select nssftp.pl.
3. Specify the Script Arguments.
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

Set SSL parameters on a secure monitor

January 25, 2019

Contributed by: C

Important
This feature is supported only on the new Default profiles. For more information about these profiles, see Enhanced SSL Profiles Infrastructure Overview.

A monitor inherits either the global settings or the settings of the service to which it is bound. If a monitor is bound to a non-SSL or non-SSL_TCP service, such as SSL_BRIDGE, you cannot configure it with SSL settings such as the protocol version or the ciphers to be used. Therefore, if your deployment requires SSL-based monitoring of the back-end servers, the monitoring is ineffective.

You can have more control over SSL-based monitoring of back-end servers, by binding an SSL profile to a monitor. An SSL profile contains SSL parameters, cipher bindings, and ECC bindings. For example, you can set server authentication, ciphers, and protocol version in an SSL profile and bind the profile to a monitor. Note that to perform server authentication, you must also bind a CA certificate to a monitor. To perform client authentication, you must bind a client certificate to the monitor. New parameters for the “bind lb monitor” command enable you to do so.

Note
The SSL settings take effect only if you add a secure monitor. Also, the SSL profile type must be BackEnd.

Monitor Types that Support SSL Profiles

SSL profiles can be bound to the following monitor types:
Citrix ADC 12.1

- HTTP
- HTTP-ECV
- TCP
- TCP-ECV
- HTTP-INLINE

To specify an SSL profile while adding a monitor by using the command line

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -secure YES -sslprofile <string>
2
3 set lb monitor <monitorName> <type> -secure YES -sslprofile <string>
```

Example:

```
1 add ssl profile prof1 -sslProfileType BackEnd
2
3 add lb monitor mon1 HTTP -secure YES -sslprofile prof1
```

To bind a certificate-key pair to a monitor by using the command line

At the command prompt, type:

```
1 bind monitor <monitor name> -certkeyName <string> [(-CA [-crlCheck (Mandatory | Optional )] | -ocspCheck ( Mandatory | Optional ))]
```

2. Citrix ADC
3. Citrix ADC 12.1

SIP service monitoring

January 23, 2019

Contributed by:
C

A Citrix ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound,
by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>sipURI</td>
<td>SIP addressing schema of the SIP server.</td>
</tr>
<tr>
<td>sipmethod</td>
<td>Type of SIP request used to probe the SIP service. Specify one of the following methods: INVITE, OPTION (the default), REGISTER</td>
</tr>
<tr>
<td>respcode</td>
<td>SIP response code with which the SIP service responds the probe request. Default: 200.</td>
</tr>
</tbody>
</table>

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

**RADIUS service monitoring**

January 25, 2019

Contributed by: C

The Citrix ADC appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.
### Parameter Specifications

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td>radKey</td>
<td>Shared secret key value that the RADIUS server uses during client authentication.</td>
</tr>
<tr>
<td>radNASid</td>
<td>NAS-ID that is encapsulated in the payload when an access request is made.</td>
</tr>
<tr>
<td>radNASip</td>
<td>The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the Citrix ADC appliance sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.</td>
</tr>
</tbody>
</table>

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor will use for authentication to the RADIUS authentication database.
2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the Citrix ADC appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all of the IP addresses.

**Caution**: If the IP address used by the appliance are not added to the RADIUS database, the RADIUS server will discard all packets.

To configure built-in monitors to check the state of RADIUS server, see [Configuring Monitors in a Load Balancing Setup](#).
Monitor accounting information delivery from a RADIUS server

January 23, 2019

Contributed by:

You can configure a monitor called a **RADIUS accounting** monitor to determine whether the Radius server used for Authentication, Authorization, and Accounting (AAA) is delivering accounting information as expected. The monitor is of type RADIUS_ACCOUNTING. The probe is generated by a Perl script called nsbmradius.pl, which is located in the /nsconfig/monitors/ directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as Acct-Status-Type and Framed-IP-Address. For information about these attributes, see RFC 2865, “Remote Authentication Dial In User Service (RADIUS),” and RFC 2866, “RADIUS Accounting.”

**To configure a RADIUS accounting monitor by using the command line interface**

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

```
add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {}
  -password }
    { -radKey }
    [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-
    radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-
    radAccountSession <string>]
show lb monitor <monitorName>
```

**Example**

```
add lb monitor radAccontMon RADIUS_ACCOUNTING -radKey "8d#9jr4rV)L7%a2-zW13sM"
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
The Citrix ADC appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007” If the DNS query succeeds, the service is marked as UP; otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN; otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.</td>
</tr>
<tr>
<td>queryType</td>
<td>The type of DNS query that is sent. Possible values: Address, Zone.</td>
</tr>
<tr>
<td>IPAddress</td>
<td>List of IP addresses that are checked against the response to the DNS monitoring probe.</td>
</tr>
<tr>
<td>IPv6</td>
<td>Select this check box if the IP address uses IPv6 format.</td>
</tr>
</tbody>
</table>

To configure the built-in DNS or DNS-TCP monitors, see Configuring Monitors in a Load Balancing Setup.
LDAP service monitoring

January 25, 2019

Contributed by: C

The Citrix ADC appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

You configure the LDAP monitor to define the search that it should perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server should start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NSIP address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDN</td>
<td>Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com.</td>
</tr>
<tr>
<td>bindDN</td>
<td>BDN name for the LDAP monitor.</td>
</tr>
<tr>
<td>filter</td>
<td>Filter for the LDAP monitor.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring LDAP servers.</td>
</tr>
<tr>
<td>attribute</td>
<td>Attribute for the LDAP monitor.</td>
</tr>
</tbody>
</table>

To configure the built-in LDAP monitor, see Configuring Monitors in a Load Balancing Setup.
MySQL service monitoring

January 25, 2019

Contributed by: C

The Citrix ADC appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Database that is used for the MySQL monitor.</td>
</tr>
<tr>
<td>sqlQuery</td>
<td>SQL query that is used for the MySQL monitor.</td>
</tr>
</tbody>
</table>

To configure built-in MySQL monitor, see Configuring Monitors in a Load Balancing Setup.

2.  Citrix ADC  
3.  Citrix ADC 12.1

SNMP service monitoring

January 25, 2019

Contributed by: C

The Citrix ADC appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NSIP address.
### NNTP service monitoring

January 25, 2019

Contributed by:

C

The Citrix ADC appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked **UP**. If the NNTP service does not respond or the search fails, the service is marked **DOWN**.

**Note:** Monitor probes originate from the NSIP address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>userName</strong></td>
<td>User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td><strong>password</strong></td>
<td>Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.</td>
</tr>
</tbody>
</table>
The Citrix ADC appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring POP3 servers.</td>
</tr>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
</tbody>
</table>

To configure the built-in POP3 monitor, see Configuring Monitors in a Load Balancing Setup.

1. Citrix ADC
2. Citrix ADC 12.1
The Citrix ADC appliance has one built-in monitor that can be used to monitor SMTP services: the SMTP monitor. It periodically checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. If the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name SMTP server. This user name is used in the probe.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring SMTP servers.</td>
</tr>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP Address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
</tbody>
</table>

To configure the built-in SMTP monitor, see Configuring Monitors in a Load Balancing Setup.
The Citrix ADC appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The Citrix ADC appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.

2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

   Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.

4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.

2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.

3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.

5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtspRequest</td>
<td>The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.</td>
</tr>
<tr>
<td>respCode</td>
<td>Set of response codes that are expected from the service.</td>
</tr>
</tbody>
</table>

For instructions on configuring an RTSP monitor, see Configuring Monitors in a Load Balancing Setup.

3. Citrix ADC 12.1

**XML broker service monitoring**

January 25, 2019

Contributed by: C

The Citrix ADC appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker services. The XML Broker services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker service. The default application is Notepad.

To configure monitors for XML Broker services, see “Configuring Monitors in a Load Balancing Setup.”

**Note**

The parameter “Application Name” for Citrix-XML-Service monitor is invalid for XA and XD versions 7 and later. It is recommended not to use this parameter in XA/XD 7. In case you configure this parameter, this parameter is not used internally. The probing criteria is different starting XA/XD 7. However, you can use the “Application Name” parameters in versions earlier to XA/XD
ARP request monitoring

January 25, 2019
Contributed by: C

The Citrix ADC appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP works with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see Configuring Monitors in a Load Balancing Setup.

XenDesktop Delivery Controller service monitoring

January 23, 2019
Contributed by: C

In desktop virtualization, the Citrix ADC appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by Citrix XenDesktop environment. The Citrix ADC appliance provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the Xen-Desktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.
The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server’s status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server’s status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether or not the user credentials (user name, password and domain) are specified on the CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services.

To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```
1   add lb monitor <monitorName> <monitorType> -userName <userName> -password <password> -ddcDomain <ddc_domain_name> -validateCred YES
2   show lb monitor <monitorName>
```

Example:

```
1   > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -password E12Dc35450a1 -ddcDomain dhop -validateCred YES
2   Done
3   > show lb monitor xdddcmon
4   1) Name........:xdddcmon Type.......:CITRIX-XD-DDC State.......: ENABLED
5   6   Standard parameters:
6   7      Interval.........:5 sec...Retries.......:3
8   8      Response timeout.......:2 sec...Down time.......:30 sec
9   9      Reverse........:NO...Transparent.......:NO
10   10     Secure..........:NO...LRTM........:ENABLED
11   11    Action........:Not applicable...Deviation.......:0 sec
12   12     Destination IP........:Bound service
```
To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <monitorType> -userName -password -ddcDomain <ddc_domain_name> -validateCred YES
```

Example:

```
set lb monitor XD_DDC_21.21.22_443_mn CITRIX-xd-ddc -userName Administrator -password D123S1R2A123 -ddcDomain dhop -validateCred YES
```

To configure an XD-DDC monitor with the validate credentials option by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type Citrix-XD-DDC.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Web interface service monitoring

January 25, 2019
Contributed by: C

In desktop virtualization, the Citrix ADC appliance can be used to load balance the Web Interface (WI) servers and Dynamic Desktop Controller (DDC) servers deployed in the Citrix XenApp and Citrix XenDesktop and environments. The Citrix ADC appliance has two built-in monitor types for monitoring the WI servers used in these environments.

A CITRIX-WEB-INTERFACE monitor can monitor the Web Interface services efficiently because it monitors a dynamic page at the location specified by the site path. The monitor checks for critical failures in resource availability.

To mark a service as UP, the appliance expects the following response from the server:

1. For the first GET request, 200 OK.
2. For the POST request with credentials, 302 Found with the required WIAuthID.
3. For the last GET request with session cookie, 200 OK.

Note: If a redirect URL is configured, 302 Found is expected in the first request before 200 OK.

Note: Monitor probes originate from the NSIP address.

When you configure a CITRIX-WEB-INTERFACE monitor, specify the site path to the location of the http page that displays the data collected by the monitor. To monitor the status of the service, in the specified site path, you can view the data updated dynamically by the monitoring script auth/nocookies.aspx.

Note: End the site path with a slash (/) to indicate that the monitored resource is dynamic.

Note: When you configure the WI-EXTENDED monitor, when specifying the site path, do not enter a slash (/) at the end of the path as the software internally adds a slash at the end of the path. For example, note the following command:

```
add monitor wi CITRIX-WI-EXTENDED -sitepath "/Citrix/DesktopWeb" -
username aaa -password bbb -domain ccc
```

A CITRIX-WI-EXTENDED monitor verifies the logging process with the Web Interface service. This monitor accesses the login page and passes the user name, password, domain, and site path that were specified while configuring the monitor. It verifies the validity of the login credentials, correct configuration of the monitor (for example, the site path), and the connection with the IIS server.

Note: The CITRIX-WI-EXTENDED monitor is supported only for the .NET version of the WI servers. This monitor will not work for the JSP version of the WI servers.

If you use the wizard for configuring load balancing of the XenDesktop servers, a CITRIX-WEB-INTERFACE monitor is automatically created and bound to the WI services. The wizard adds and binds a CITRIX-WEB-INTERFACE monitor by default. If you want to add and bind a CITRIX-WI-EXTENDED monitor, select the Validate Credentials check box and type the necessary data. If you do
not use the wizard, add a monitor corresponding to the WI services and bind it to each WI service that you create.

For instructions on using the wizard, see Configuring XenDesktop for Load Balancing or Configuring XenApp for Load Balancing.

For instructions on adding a CITRIX-WEB-INTERFACE monitor, see Creating Monitors.

For instructions on binding a monitor to a service, see Binding Monitors to Services.

**To add a WI monitor by using the command line interface**

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> -sitePath <site_path> -dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName <username> -password <password> -domain <domain_name>
```

**Examples**

```
1 add lb monitor mwie CITRIX-WEB-INTERFACE -sitePath "/Citrix/XDWI/"
2 add lb monitor mwie CITRIX-WI-EXTENDED -sitePath "/Citrix/XDWI/"
2 -dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName administrator
3 -password d83d154575d426 -encrypted -domain wi
```

**To add a WI monitor by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Monitors, and create a WI monitor of type CITRIX-WEB-INTERFACE or CITRIX-WI-EXTENDED.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

**Citrix StoreFront stores monitoring**

January 23, 2019
You can configure a user monitor for a Citrix Storefront store. The monitor determines the state of the StoreFront store by successively probing the account service, authentication service, and discovery document (in that order). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service.

Note: Monitor probes originate from the NSIP address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

Beginning with release 10.1 build 120.13, you can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member’s IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

In earlier releases, the StoreFront monitor tried to authenticate anonymous stores. As a result, a service could be marked as DOWN and you could not launch XenApp or XenDesktop by using the URL of the load balancing virtual server.

From build 64.x, the probe order has changed. The monitor now determines the state of the StoreFront store by successively probing the account service, the discovery document, and then the authentication service, and skips authentication for anonymous stores.

The hostname parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

To create a StoreFront monitor by using the command line interface

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

```
1  add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-storefrontacctservice ( YES | NO )] -secure ( YES | NO )
2  3  show lb monitor <monitorName>
```

Example
To create a StoreFront monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type STOREFRONT.

Note
For more information about the StoreFront monitors, see Load balancing with Citrix ADC.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Custom monitors

January 25, 2019

Contributed by: C

In addition to built-in monitors, you can use custom monitors to check the state of your services. The Citrix ADC appliance provides several types of custom monitors based on scripts that are included with the Citrix ADC operating system that can be used to determine the state of services based on the load on the service or network traffic sent to the service. These are the inline monitors, user monitors, and load monitors.

With any of these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

This section includes the following details:

- Configuring HTTP-Inline Monitors
- Understanding User Monitors
- How to Use a User Monitor to Check Web Sites
- Understanding the Internal Dispatcher
- Configuring a Custom User Monitor
- Understanding Load Monitors
- Configuring Load Monitors
Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured to work with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the Citrix ADC appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured down time. After the DOWN time elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see Configuring Monitors in a Load Balancing Setup.
Understand user monitors

January 25, 2019
Contributed by: C

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the Citrix ADC appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors

A user monitor requires the following components.

- **Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

  Note: You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

  In a HA setup, the dispatcher runs on both the primary and secondary Citrix ADC appliances. The dispatcher remains inactive on the secondary appliance.

- **Script.** The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

  The Citrix ADC appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a new script, add it there. If you want to customize an existing script, create a copy with a new name and modify it.

  Important: Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

  If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

  - A new directory named conflicts is created in /nsconfig/monitors/ and all the built-in scripts of the previous builds are moved to this directory.
  - All new built-in scripts are available in the /netscaler/monitors/ directory. All custom scripts are available in the /nsconfig/monitors/ directory.
• You must save a new custom script in the /nsconfig/monitors/ directory.
• After the upgrade is completed, if a custom script is created and saved in the /nsconfig/monitors/ directory, with the same name as that of a built-in script, the script in the /netscaler/monitors/ directory takes priority. That is, the custom script does not run.

If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:
• All built-in scripts are available in the /netscaler/monitors/ directory.
• The /nsconfig/monitors/ directory is empty.
• If you create a new custom script, you must save it in the /nsconfig/monitors/ directory.

For the scripts to function correctly:
• The maximum number of characters in the name of the script must not exceed 63.
• The maximum number of script arguments that can be provided to a script must not exceed 512.
• The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the nsumon-debug.pl script from the CLI. You use the script name (with its arguments), IP address, and the port as the arguments of the nsumon-debug.pl script. Users must use the script name, IP address, port, time-out, and the script arguments for the nsumon-debug.pl script.

At the CLI, type:

```
1 nsumon-debug.pl <scriptname> <IP> <port> <timeout> <partitionID> [scriptarguments][is_secure]
```

**Important:** Starting with release 10.5 build 57.x, and 11.0 script files for user monitors support IPv6 addresses and include the following changes:

• For the following protocols, new pm files have been included for IPv6 support.
  - Radius
  - NNTP
  - POP3
  - SMTP

• The following sample scripts in /netscaler/monitors/ has been updated for IPv6 support:
  - nsbmradius.pl
  - nsldap.pl
  - nsnntp.pl
  - nspop3 nssf.pl
  - nssnmp.pl
After upgrading to release 10.5 build 57.x, or 11.0, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in `/netscaler/monitors/`.

Note: The sample script nsmysql.pl does not support IPv6 address. If an IPv6 service is bound to a user monitor that uses nsmysql.pl, the probe will fail.

- The following LB monitor types have been updated to support IPv6 addresses:
  - USER
  - SMTP
  - NNTP
  - LDAP
  - SNMP
  - POP3
  - FTP_EXTENDED
  - STOREFRONT
  - APPC
  - CITRIX_WI_EXTENDED

If you are creating a new custom script that uses one of these LB monitors types, make sure that you include IPv6 support in the custom script. Refer to the associated sample script in `/netscaler/monitors/` for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be executed. The dispatcher executes the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response
code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The appliance logs the error messages to the /var/nslog/nsumond.log file when user monitor probes fail. The following table lists the user monitors and the possible reasons for failure.

<table>
<thead>
<tr>
<th>User monitor type</th>
<th>Probe failure reasons</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMTP</td>
<td>Monitor fails to establish a connection to the server.</td>
</tr>
<tr>
<td>NNTP</td>
<td>Monitor fails to establish a connection to the server.</td>
</tr>
<tr>
<td></td>
<td>Missing or invalid script arguments, which can include an invalid number of arguments or argument format.</td>
</tr>
<tr>

<tr>
<td></td>
<td>Monitor fails to create the SNMP session.</td>
</tr>
<tr>
<td></td>
<td>Monitor fails to find the object identifier.</td>
</tr>
<tr>
<td></td>
<td>The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.</td>
</tr>
<tr>
<td>RDP (Windows Terminal Server)</td>
<td>Missing or invalid script arguments, which can include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td></td>
<td>Monitor fails to create a socket.</td>
</tr>
<tr>
<td></td>
<td>Mismatch in versions.</td>
</tr>
<tr>
<td></td>
<td>Monitor fails to confirm connection.</td>
</tr>
</tbody>
</table>

You can view the log file from the CLI by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the CLI:

```bash
1  > shell
2  root@ns# cat /var/nslog/nsumond.log
3  root@ns# exit
4  >
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

**Note**

For scriptable monitors, the response timeout must be configured to a value equal to expected timeout + 1 second.

For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

**Example command:**

```bash
1 add lb monitor <name> USER -scriptname <script-name> -resptimeout 5 seconds
```

**How to use a user monitor to check web sites**

January 25, 2019

Contributed by:

C

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

<table>
<thead>
<tr>
<th>HTTP response code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 - success</td>
<td>Probe success.</td>
</tr>
<tr>
<td>503 - service unavailable</td>
<td>Probe failure.</td>
</tr>
<tr>
<td>404 - not found</td>
<td>Script not found or cannot execute.</td>
</tr>
</tbody>
</table>
### HTTP response code

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>500 - Internal server error</td>
<td>Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.</td>
</tr>
<tr>
<td>400 - bad request</td>
<td>Error parsing HTTP request.</td>
</tr>
<tr>
<td>502 - bad gateway</td>
<td>Error decoding script’s response.</td>
</tr>
</tbody>
</table>

You configure the user monitor for HTTP by using the following parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>scriptArgs</td>
<td>The strings that are added in the POST data. They are copied to the request verbatim.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>localfileName</td>
<td>The name of a monitor script file on the local system.</td>
</tr>
<tr>
<td>destPath</td>
<td>A particular location on the Citrix ADC appliance where the uploaded local file is stored.</td>
</tr>
</tbody>
</table>

To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.

1. Citrix ADC
2. Citrix ADC 12.1

**Understand the internal dispatcher**

January 25, 2019
To configure a custom user monitor, you must first write the script that performs the action that the monitor will use to check the service that is bound to it, and upload the script to the /nsconfig/monitors directory on the Citrix ADC appliance. Then you create the monitor on the appliance, as described below.

Note: Monitor probes originate from the NSIP address.
understand load monitors

January 25, 2019

Contributed by: C

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The Citrix ADC appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

Figure 1. Operation of Load Monitors

Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

<table>
<thead>
<tr>
<th>Metric name</th>
<th>OIDs</th>
<th>Weight</th>
<th>Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>1.2.3.4</td>
<td>2</td>
<td>70</td>
</tr>
<tr>
<td>Memory</td>
<td>4.5.6.7</td>
<td>3</td>
<td>80</td>
</tr>
<tr>
<td>Connections</td>
<td>5.6.7.8</td>
<td>4</td>
<td>90</td>
</tr>
</tbody>
</table>

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

2. Citrix ADC 12.1

**Configure load monitors**

January 25, 2019

Contributed by: C

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see
Creating Monitors. Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

```bash
1 add lb metricTable <metricTableName>
2
3 bind lb metricTable <metricTableName> <metric> <SNMPOID>
```

Example:

```bash
1 add metricTable Table-Custom-1
2
3 bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables and create a metric table.
2. To bind metrics, click Bind and specify a metric and an SNMP OID.

```
1
2. Citrix ADC
3. Citrix ADC 12.1
```

Unbind metrics from a metrics table

January 23, 2019

Contributed by:
C

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:
**Example:**

```
unbind lb metricTable <metricTable> <metric>
```

To unbind metrics from a metric table by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. Open a metric table, select a metric, and click Delete.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

3. Citrix ADC 12.1

**Configure reverse monitoring for a service**

January 23, 2019

Contributed by:
C

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

The Citrix ADC appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

**Configuring HTTP Reverse Monitoring for a Service**

The following table describes the conditions of HTTP direct and reverse monitoring for a service:
To configure HTTP reverse monitoring for a service by using the CLI

At the command prompt, type:

1. `add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /" -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES`
2. `bind service <Secondary_Service_Name> -monitorname <Monitor_Name>`

Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Direct</th>
<th>Reverse</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP echo reply is received.</td>
<td>Success</td>
<td>Fail</td>
</tr>
<tr>
<td>Probe timed out.</td>
<td>Fail</td>
<td>Success</td>
</tr>
</tbody>
</table>

To configure ICMP reverse monitoring for a service by using the CLI

At the command prompt, type:

1. `add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address> -reverse YES`
Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Direct</th>
<th>Reverse</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP connection is established.</td>
<td>Success</td>
<td>Fail</td>
</tr>
<tr>
<td>Probe timed out.</td>
<td>Fail</td>
<td>Fail</td>
</tr>
<tr>
<td>Response to probe is RESET.</td>
<td>Fail</td>
<td>Success</td>
</tr>
</tbody>
</table>

To configure TCP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
1 add lb monitor <Monitor_Name> TCP - destip <Primary_Service_IP_Address> -destport <primary_service_port> - reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
```

To configure reverse monitoring by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create an HTTP, ICMP, or TCP monitor and select Reverse.

1. Citrix ADC
2. Citrix ADC 12.1
Configure monitors in a load balancing setup

January 25, 2019
Contributed by: C

To configure monitors on a Web site, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see Custom Monitors. Once you have chosen or created a monitor, you then bind it to the appropriate service. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How monitors operate

As shown above, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server should fail to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- Creating Monitors
- Configuring Monitoring Parameters to Determine the Service Health
- Binding Monitors to Services
- Modifying Monitors
- Enabling and Disabling Monitors
- Unbinding Monitors
- Removing Monitors
- Viewing Monitors
- Closing Monitor Connections
- Ignoring the Upper Limit on Client Connections for Monitor Probes

1.

3. Citrix ADC 12.1

Create monitors

January 25, 2019
The Citrix ADC appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

**To create a monitor by using the CLI**

At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2 add lb mon monitor-HTTP-1 HTTP
3 add lb mon monitor-HTTP-2 TCP 2
```

**To create a monitor by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Click Add and create a monitor type that meets your requirement.

The Create Monitor screen contains two sections, Basic Parameters and Advanced Parameters.

Depending on the monitor type, the Basic Parameters section contains the parameters that must be set for each monitor. The Advanced Parameters section contains the parameters that can be used in advanced use cases.

The following figure is a sample of a Create Monitor page of the ARP monitor type.

**Note**

Prior to NetScaler release 12.0 build 56.20, Basic Parameters and Advanced Parameters are named Standard Parameters and Special Parameters respectively.

1. 
2. Citrix ADC
3. Citrix ADC 12.1

**Configure monitor parameters to determine the service health**

January 23, 2019
You can configure the following monitoring parameters to mark a service as DOWN on the basis of the monitoring probes.

**Retries**

Maximum number of probes to send to establish the state of a service for which a monitoring probe fails.

**failureRetries**

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the ten probes sent, at least six probes must fail if the service is to be marked as DOWN.

**alertRetries**

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

**Setting alertRetries to a Value Higher than the Retries Value**

The alertRetries parameter, which specifies the maximum number of consecutive monitoring-probe failures after which the Citrix ADC appliance generates an SNMP trap called monProbeFailed, can now be set to a value higher than the Retries value (which specifies the maximum number of probes to send to establish the state of a service for which a monitoring probe failed). If the alertRetries value is higher than the Retries value, the SNMP trap is not sent until after the service is DOWN.

For example, if you set Retries to 3, alertRetries to 12, and the time interval to 5 seconds, the service is marked DOWN after 15 seconds (3 * 5), but no alert is generated. If the monitor probes are still failing after 60 seconds (12 * 5), the Citrix ADC appliance generates a monProbeFailed trap. If a probe succeeds at some time between 15 and 60 seconds, the service is marked UP and no alert is generated.

Setting the alertRetries value to a value higher than the Retries value helps in generating only genuine alerts and avoid false positives during scheduled restarts.
To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> [-retries <integer>] [-alertRetries <integer>]
```

Example:

```
add lb monitor monitor-HTTP-1 HTTP -retries 3 -alertRetries 12
```

To set the alertRetries parameter value to a higher value than the Retries value by using the GUI

2. Click Add to add a new monitor or select an existing monitor and click Edit.
3. In the Retries box, type the value for the Retries parameter.
4. In the SNMP Alert Retries box, type the value for the alertRetries parameter.

Bind monitors to services

January 25, 2019

Contributed by: C

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN.

If you bind multiple monitors to a service, the Citrix ADC appliance checks the state of all the monitors and then decides the state of the service. You can configure different weights to a monitor. The weight of a monitor specifies how much that monitor contributes to designating the service as UP or DOWN. A monitor with a greater weight has a higher preference in marking the service UP or DOWN. Default weight is 1. Therefore, even if one of the monitors fails, the service is marked as DOWN. For more information, see Set a threshold value for the monitors bound to a service.

**Note:** The destination IP address of a monitor probe can be different than the server IP address and port.
To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind service <name> (-monitorName <string>)
```

Example:

```
bind service s1 -monitorName tcp
```

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Modify monitors

January 23, 2019

Contributed by:
C

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <interval> -resptimeout <resptimeout>
```

Example:
To modify an existing monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and open a monitor to modify.

1. 
2. Citrix ADC
3. Citrix ADC 12.1

Enable and disable monitors

January 23, 2019
Contributed by:
C
By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the command line interface

At the command prompt, type:

```
1  enable lb monitor <monitorName>
```

Example:

```
1  enable lb mon monitor-HTTP-1
```

To enable a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and from the Action list, select Enable or Disable.
To disable a monitor by using the command line interface

At the command prompt, type:

```
disable lb monitor <monitorName>
```

**Example:**

```
disable lb mon monitor-HTTP-1
```

Unbind monitors

January 23, 2019

Contributed by: C

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the command line interface

At the command prompt, type:

```
unbind lb monitor <monitorName>
```

**Example:**

```
unbind mon monitor-HTTP-1 Service-HTTP-1
```
To unbind a monitor from a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click Unbind.

To remove monitors

January 23, 2019
Contributed by:
C

After you unbind a monitor that you created from its service, you can remove that monitor from the Citrix ADC configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the command line interface

At the command prompt, type:

```
1 rm lb monitor <monitorName> <type>
```

Example:

```
1 rm lb monitor monitor-HTTP-1 HTTP
```

To remove a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and click Delete.  

1.  
2.  
3.

View monitors

January 23, 2019
Contributed by: C

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your Citrix ADC configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the command line interface

At the command prompt, type:

```
show lb monbindings <MonitorName>
```

Example:

```
show lb monbindings monitor-HTTP-1
```

To view monitor bindings by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and in the Action list, click Show Bindings.

To view monitors by using the command line interface

At the command prompt, type:

```
show lb monitor <monitorName>
```

Example:

```
show lb mon monitor-HTTP-1
```

To view monitors by using the configuration utility

Close monitor connections

January 23, 2019
Contributed by: C

The Citrix ADC appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the appliance and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP type monitor, you can configure the appliance to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

Note: The monitorConnectionClose setting is applicable only for type TCP and TCP-Default monitors.

To configure monitor-connection closure by using the command line interface:

At the command prompt, type:

```
set lb parameter -monitorConnectionClose <monitor_conn_close_option>
```

Example

```
set lb parameter -monitorConnectionClose RESET
```

To configure monitor-connection closure by using the configuration utility:

2. Select FIN or Reset.

Closing Monitor Connections at the Service or Service Group Level

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the monConnectionClose parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter
Citrix ADC 12.1

is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

To configure monitor-connection closure at the service level by using the CLI

At the command prompt, type:

```
set service <service_name> -monConnectionClose ( RESET | FIN )
```

To configure monitor-connection closure at the service group level by using the CLI

At the command prompt, type:

```
set serviceGroup <service_name> -monConnectionClose ( RESET | FIN )
```

To configure monitor-connection closure at the service level by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Add or edit a service, and in Basic Settings, set the Monitoring Connection Close Bit.

To configure monitor-connection closure at the service group level by using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Add or edit a service group, and in Basic Settings, set the Monitoring Connection Close Bit.
   1. 
   2. Citrix ADC
   3. Citrix ADC 12.1

Ignore the upper limit on client connections for monitor probes

January 23, 2019

Contributed by: C

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service,
the Citrix ADC appliance stops sending requests to the service when the threshold is reached and res-
sumes sending connections to the service after the number of existing connections falls to within the
limits. You can configure the appliance to skip this check when it sends monitor-probe connections
to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you spec-
ify this option, it applies to all the monitors bound to all the services configured on the Citrix ADC
appliance.

To set the Skip MaxClients for Monitor Connections option by using the command line
interface

At the command prompt, type:

```
  set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
```

Example:

```
  set lb parameter -monitorSkipMaxClient enabled
```

To set the Skip MaxClients for Monitor Connections option by using the configuration
utility

2. Select Skip MaxClients for Monitoring Connections.

Manage a large scale deployment

January 23, 2019

Contributed by:
C

The Citrix ADC appliance contains several features that are helpful when you are configuring a large
load balancing deployment. Instead of configuring virtual servers and services individually, you can
create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

Ranges of virtual servers and services

January 23, 2019
Contributed by:

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.
For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.

Creating a range of virtual servers

You create a range of virtual servers as described below.

To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb vserver <name>@<protocol> -range <rangeValue> <IPAddress> [<port>]
2
3 add lb vserver <name>@<rangeValue>] <protocol> <IPAddress[<rangeValue>]> [<port>]
```

Example:

```
1 add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
1 add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2
3 vserver "vserverP" added
4
5 vserver "vserverQ" added
6
7 vserver "vserverR" added
8
9 Done
```

To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

```
1 add lb vserver <name>@<protocol> -range <rangeValue> <IPAddress> [<port>]
2
3 add lb vserver <name>@**[***<rangeValue>***]**> <protocol> <IPAddress[<rangeValue>]> [<port>]
```
Example:

```
1  add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
1  add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2  vserver "vserverP" added
3  vserver "vserverQ" added
4  vserver "vserverR" added
5  Done
```

To create range of virtual servers by using the configuration utility

2. Add a virtual server, and specify a range.

Creating a range of services

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the command line interface

At the command prompt, type the command:

```
1  add service <name>@ <IP>@ <protocol> <port>
```

Example:

```
1  > add service serv[1-3] 10.102.29.[102-104] http 80
2  service "serv1" added
3  service "serv2" added
4  service "serv3" added
5  Done
```

1.
2. Citrix ADC
3. Citrix ADC 12.1
Configure service groups

January 23, 2019
Contributed by:
C

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the Citrix ADC appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the appliance learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the Citrix ADC appliance. A domain name will be resolved into an IP address only if the corresponding address record is present on the appliance or the name server.

Create service groups

You can configure up to 8192 service groups on the Citrix ADC appliance.

To create a service group by using the command line

At the command prompt, type:

```
add servicegroup <ServiceGroupName> <Protocol>
```

Example:

```
add servicegroup Service-Group-1 HTTP
```
To create a service group by using the configuration utility

Navigate to Traffic Management > Load Balancing > Service Groups, and add a service group.

Bind a service group to a virtual server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@<serviceGroupName>
```

Example:

bind lb vserver Vserver-LB-1 Service-Group-1

To bind a service group to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Service Groups.

Bind a member to a service group

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the configuration utility, if you want to add a domain-name based service group member, select Server Based.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
```

Examples:
To add members to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups and open a service group.

2. Click in the Service Group section, and do one of the following:
   - To add a new IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.
   
   If you want to add a domain-name based service group member, select Server Based. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box.

   Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.

4. Click Create.

Bind a monitor to a service group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:
Example:

```
bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

To bind a monitor to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group and, in Advanced Settings, click Monitors.

Retain the original state of a service group member after disabling and enabling a virtual server

From build 64.x, a new global option, –retainDisableServer, enables you to retain a service-group member’s state when a server is disabled and reenabled.

Previously, a member’s state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and reenabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those member(s) in the service group. This is a cumbersome task and prone to errors.

1. Citrix ADC
2. Citrix ADC 12.1

Manage service groups

January 25, 2019
You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group.

**Modify a service group**

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

**To modify a service group by using the command line interface**

At the command prompt, type the following command with one or more of the optional parameters:

```
set servicegroup <serviceGroupName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)] [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (**YES**|**NO**)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)]
```

**Example:**

```
1 set servicegroup Service-Group-1 -type TRANSPARENT
2 3 set servicegroup Service-Group-1 -maxClient 4096
4 5 set servicegroup Service-Group-1 -maxReq 16384
6 7 set servicegroup Service-Group-1 -cacheable YES
```

**To modify a service group by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Service Groups**, and open the service group to modify.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
**Remove a service group**

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the Citrix ADC appliance.

**To remove a service group by using the command line interface**

At the command prompt, type:

```bash
rm servicegroup <ServiceGroupName>
```

**Example:**

```bash
rm servicegroup Service-Group-1
```

**To remove a service group by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click **Delete**.

**Unbind a member from a service group**

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retains its individual settings, however, and continues to exist on the Citrix ADC appliance.

**To unbind members from a service group by using the command line interface**

At the command prompt, type:

```bash
unbind servicegroup <serviceGroupName> <IP>@ [port]
```

**Example:**

```bash
unbind servicegroup Service-Group-1 10.102.29.30 80
```
To unbind members from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click Unbind.

Unbind a service group from a virtual server

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the Citrix ADC appliance.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@<ServiceGroupName>
```

Example:

```
unbind lb vserver Vserver-LB-1 Service-Group-1
```

To unbind a service group from a virtual server by using the configuration utility

2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click Unbind.

Unbind monitors from service groups

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
unbind serviceGroup <serviceGroupName> -monitorName <string>
```

Example:
To unbind a monitor from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click Unbind.

Enable or Disable a service group

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

```
bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

Example:

```
disable servicegroup <ServiceGroupName>
```

To disable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Disable.

To enable a service group by using the command line interface

At the command prompt, type:

```
enable servicegroup <ServiceGroupName>
```

Example:
To enable a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Enable**.

View the status of service groups members

Navigate to **Traffic Management > Load Balancing > Service Groups**.

In the Service Groups page, the Effective State column displays the status of the service groups. Status UP/DOWN in the Effective State column is clickable. You can click the status and get the list of members along with their status in the same view. Select a member and click the Monitor Details button to view the reason for the status being DOWN.

**Note**: Prior to NetScaler release 12.0 build 56.20, the status in the Effective State column was not clickable.

Viewing the properties of a service group

You can view the following settings of the configured service groups: name, IP address, state, protocol, maximum client connections, maximum requests per connection, maximum bandwidth, and monitor threshold. Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

```
1  show servicegroup <ServiceGroupName>
2
3  show servicegroup <ServiceGroupName> -includemembers
```

**Example:**

```
1  show servicegroup Service-Group-1
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To view the properties of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Click the arrow next to the service group.

Viewing service group statistics

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The Citrix ADC appliance uses the statistics of a service group, such as these, to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

```
1 stat servicegroup <ServiceGroupName>
```

Example:

```
1 stat servicegroup Service-Group-1
```

To view the statistics of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click Statistics.

Load balancing virtual servers bound to a service group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port
To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
show servicegroupbindings <serviceGroupName>
```

Example:

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State : ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSVR (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>
```

To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Show Bindings.

   1.
   2. Citrix ADC
   3. Citrix ADC 12.1

Configure automatic domain based service group scaling

May 30, 2019
Contributed by:

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records
configured for the domain name, on the name server. Even if the name resolution process returns
multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a
service group, you need to manually bind and unbind additional domain based servers to and from
the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the
complete set of IP addresses returned by a DNS name server for a domain based server. To config-
ure automatic scaling, when binding a domain based server to a service group, enable the automatic
scaling option. Following are the steps for configuring a domain based service group that scales autom-
atically:

- Add a name server for resolving domain names. For more information about configuring a name
  server on the appliance, see Adding a Name Server.
- Add a domain based server. For information about adding a domain based server, see Adding
  a Server.
- Add a service group and associate the domain based server to the service group, with the au-
toscale option set to DNS. For information about adding a service group, see Configuring Service
  Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on
the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain
based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and
the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain
name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and
uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use
only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name.
With the automatic scaling option set, the appliance polls each of the IP addresses by using the default
monitor, and then includes in the service group only those IP addresses that are up and available. After
the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the
TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for
domain resolution and includes any new IP addresses in the service group. If an IP address that is
part of the service group is not present in the DNS response, the appliance removes that address from
the service group after gracefully closing existing connections to the group member, a process during
which it does not allow any new connections to be established with the member. If a domain name
that resolved successfully in the past results in an NXDOMAIN response, all the service group members
associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a
service group. You can also bind members with different domain names to a service group with the
automatic scaling option set. However, each domain name associated with a service group must be
unique within the service group. You must enable the automatic scaling option for each domain based
To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

```
1  add serviceGroup <serviceGroupName> -autoScale (YES | NO)
2
3  show serviceGroup <serviceGroupName>
```

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> add serviceGroup servGroup server1 80 -autoScale YES
Done
> sh servicegroup servGroup
  servGroup - HTTP
    State: ENABLED  Monitor Threshold : 0
    . . .
    . . .
1) 192.0.2.31:80  State: UP      Server Name: server1 (Auto scale)  Server ID: None  Weight: 1
    Monitor Name: tcp-default   State: UP
    Probes: 2  Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.
2) 192.0.2.32:80  State: UP      Server Name: server1 (Auto scale)  Server ID: None  Weight: 1
    Monitor Name: tcp-default   State: UP
    Probes: 2  Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.
3) 192.0.2.36:80  State: UP      Server Name: server1 (Auto scale)  Server ID: None  Weight: 1
    Monitor Name: tcp-default   State: UP
```
To configure a service group to scale automatically by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Create a service group, and set the autoscale mode to DNS.

Overwriting TTL values

Note: This option is supported from Citrix ADC 12.1 build 51.xx and later.

Citrix ADC appliance is configured to periodically query the DNS server for any update in SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding service group member and also globally, then the TTL value specified while binding the service group member takes precedence.
If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.
Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```bash
bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs>])
```

Example:

```bash
bind servicegroup svc_grp_1 web_serv -dbsTTL 10
```

- To overwrite the TTL value globally, at the command prompt, type:

```bash
set lb parameter [-dbsTTL <secs>]
```

Example:

```bash
set lb parameter -dbsTTL 15
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Service Groups page, select the service group that you have created and click Edit.
3. In Load Balancing Service Groups page, click Service Group Members.
4. In Service Group Members Binding page, select the server that you have created and click Edit.
5. In Domain Based Service TTL, enter the TTL value.

To overwrite the TTL value at the global level:

2. In Domain Based Service TTL, enter the TTL value.

Note: If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

Specifying different name servers for service group and domain name bindings

Note: This option is supported from Citrix ADC 12.1 build 51.xx and later.
You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

**Specifying name servers while binding a server to service groups using the CLI**

At the command prompt, type:

```bash
bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <ip_addr>] [-dbsTTL <secs>])
```

**Example:**

```bash
bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
-dbsTTL 10
```

**Specifying name servers while binding a server to service groups using the GUI**

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Service Groups page, select the service group that you have created and click Edit.
3. In Load Balancing Service Groups page, click Service Group Members.
4. In Service Group Members Binding page, select the server that you have created and click Edit.
5. In Name Server, specify the nameserver name to which the query for bound domain needs to be sent.

**Service discovery using DNS SRV records**

March 22, 2019

Contributed by:
C

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the hostname and the port number of servers for specified services. The record also defines the weight and priority of each server.
Example of an SRV record:

_http._tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.

The following table describes each item in an SRV record:

You can use the DNS SRV records to discover the service endpoints. Citrix ADC appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the Citrix ADC appliance once while bringing it up, thus making it a single touch deployment for applications.

Use case: Load balancing microservices

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with backend server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, proxies or ADC must be able to dynamically detect the backend application or service instances and absorb them into proxy configuration.

The service discovery using DNS SRV records feature aids configuration of Citrix ADC appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the Citrix ADC appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.
- Weight parameter can be used to dictate the capacity of the backend service instances and hence can be used for weighted load balancing.
- Whenever there is a change in the back-end server pool, for example a backend instance is removed from the pool, the instance is removed graciously only after all the existing client connections are honored.

Note:

- An A/AAAA records based service discovery, all resolved IP addresses have the same weight because you assign the weight to the domain being resolved.
- If the weight in SRV response is greater than 100, then services are not created.
Priority based load balancing using SRV records

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. Lesser the number, higher is the priority. One of the servers in the highest priority pool is selected for load balancing based on the server’s health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs graciously by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

To enable querying for SRV records using the CLI

You must perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

At the command prompt, type:

```
1 add server <name> <domain> [-queryType <queryType>]
```

Example:

```
1 add server web_serv example.com -queryType SRV
```

Note:

- By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.
- The SRV target domain name must not exceed 127 characters.

2. Create a service group with the autoscale mode as DNS.

At the command prompt, type:

```
1 add serviceGroup <serviceGroupName> <serviceType> [-autoScale <autoScale>]
```

Example:

```
1 add servicegroup svc_grp_1 http -autoscale dns
```
3. Bind the server created in step 1 to the service group as a member.

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> <serverName>
```

**Example:**

```
bind servicegroup svc_grp_1 web_serv
```

**Note:**
- When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

**To enable querying for SRV records using the GUI**

**Create a server**
1. Navigate to Traffic Management > Load Balancing > Servers and click Add.
2. In Create Server page, select domain name.
3. Enter the details of all the required parameters.
4. In Query Type, select SRV.
5. Click Create.

**Create a service group with autoscale mode as DNS**
1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Load Balancing Service Group page, enter details of all the required parameters.
3. In AutoScale Mode, select DNS.
4. Click OK.

**Bind server to the service group member**
1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Service Groups page, select the service group that you have created and click Edit.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.

4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.

**Note:**
- While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

**Overwriting TTL values**

Citrix ADC appliance is configured to periodically query the DNS server for any update in SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

**Overwriting the TTL values using the CLI**

- To overwrite the TTL value while binding, at the command prompt, type:

  ```
  bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs >])
  ```

  **Example:**

  ```
  bind servicegroup svc_grp_1 web_serv -dbsTTL 10
  ```

- To overwrite the TTL value globally, at the command prompt, type:

  ```
  set lb parameter [-dbsTTL <secs>]
  ```

© 1999-2018 Citrix Systems, Inc. All rights reserved. 2771
Example:

```
set lb parameter -dbsTTL 15
```

Overwriting the TTL values using the GUI

To overwrite the TTL value while binding:

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Service Groups page, select the service group that you have created and click Edit.
3. In Load Balancing Service Groups page, click Service Group Members.
4. In Service Group Members Binding page, select the server that you have created and click Edit.
5. In Domain Based Service TTL, enter the TTL value.

To overwrite the TTL value at the global level:

2. In Domain Based Service TTL, enter the TTL value.

Note: If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

Specifying different name servers for service group and domain name bindings

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
bind serviceGroup <serviceGroupName> <serverName> [-nameServer <ip_addr>] [-dbsTTL <secs>]
```

Example:

```
bind servicegroup svc grp_1 web_serv -ns.nameserver.com 10.102.27.155 -dbsTTL 10
```
Specifying name servers while binding a server to service groups using the GUI

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. In Service Groups page, select the service group that you have created and click Edit.
3. In Load Balancing Service Groups page, click Service Group Members.
4. In Service Group Members Binding page, select the server that you have created and click Edit.
5. In Name Server, specify the nameserver name to which the query for bound domain needs to be sent.

To simplify maintenance on the Citrix ADC appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server’s IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address.
original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
add server <name>@<serverDomainName> -translationIp <translationIPAddress> -translationMask <netMask> -state <ENABLED|DISABLED>
```

Example:

```
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -translationMask 255.255.0.0 -state ENABLED
```

To configure a translation IP address for a server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Servers, create a domain-based server, and specify a translation IP address.

Mask a virtual server IP address

January 25, 2019

Contributed by:
C

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a
particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works somewhat differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Additionally, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The Citrix ADC appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it will be sent to Virtual Server 2.
Note: Ports are also considered if a tie-breaker is required.

**To configure a virtual server IP address mask by using the command line interface**

At the command prompt, type:

```
add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <ipMask> <listenPort>
```

**Example:**

Pattern matching based on prefix octets:

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask 255.255.0.0 80
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask 0.0.255.255 80
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
```

**To configure a virtual server IP address mask by using the configuration utility**

2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

**Configure load balancing for commonly used protocols**

January 23, 2019

Contributed by: C
In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your Citrix ADC appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.

Load balance a group of FTP servers

January 25, 2019

Contributed by:

C

The Citrix ADC appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client’s connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vserver</td>
<td>Vserver-LB-1</td>
<td>10.102.29.25</td>
<td>21</td>
<td>FTP</td>
</tr>
<tr>
<td>Services</td>
<td>Service-FTP-1</td>
<td>10.102.29.21</td>
<td>21</td>
<td>FTP</td>
</tr>
</tbody>
</table>
The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

**Figure 2. Load Balancing FTP Servers Entity Model**

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

**To create FTP monitors by using the command line interface**

At the command prompt, type:

```bash
add lb monitor <MonitorName> FTP -interval <Interval> -userName <UserName> -password <Password>
```

**Example:**

```bash
add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password User
```

**To create FTP monitors by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.
When you request DNS resolution of a domain name, the Citrix ADC appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server</td>
<td>Vserver-LB-1</td>
<td>10.102.29.13</td>
<td>53</td>
<td>DNS</td>
</tr>
<tr>
<td>Services</td>
<td>Service-DNS-1</td>
<td>10.102.29.14</td>
<td>53</td>
<td>DNS</td>
</tr>
<tr>
<td></td>
<td>Service-DNS-2</td>
<td>10.102.29.15</td>
<td>53</td>
<td>DNS</td>
</tr>
<tr>
<td></td>
<td>Service-DNS-3</td>
<td>10.102.29.16</td>
<td>53</td>
<td>DNS</td>
</tr>
<tr>
<td>Monitors</td>
<td>monitor-DNS-1</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model

To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the param-
eters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

**To configure DNS monitors by using the command line interface**

At the command prompt, type:

```bash
add lb monitor <monitorName> DNS -query <domainName> -queryType <Address|ZONE> -IPAddress <ipAddress>
```

Example:

```bash
1 add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType Address -IPAddress 10.102.29.66
2 3 add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType Address -IPAddress 1000:0000:0000:0000:0005:0600:700a::888b-888d
```

**To configure DNS monitors by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

   3. **Citrix ADC 12.1**

**Load balance domain-name based services**

January 25, 2019

Contributed by: C

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4
or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the Citrix ADC configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor could be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

**Note:** When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

**Figure 1. Basic Load Balancing Topology for DBS Servers**

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.
The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model

To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

### To add a name server by using the command line interface

At the command prompt, type:

```
1 add dns nameServer <dnsVserverName>
```

**Example:**

```
1 add dns nameServer Vserver-LB-2
```

### To add a name server by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.
You can also add an authoritative name server that resolves the domain name to an IP address.

Note
You can add a name server of type TCP, UDP or UDP_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with truncated bit, this response is not retried over TCP name server.

Load balance a group of SIP servers

January 25, 2019
Contributed by: C

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System

A Citrix ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the Citrix ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the Citrix ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header
a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

**Server Initiated Traffic**

For SIP-server initiated outbound traffic, configure RNAT on the Citrix ADC so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the Citrix ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named `nsrnatsip-127.0.0.1-5061`.

**Support for Policies and Expressions**

The Citrix ADC default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip_udp, sip_tcp or sip_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

**Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP**

The Citrix ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- **SIP_UDP** – Used when SIP servers send SIP messages over UDP.
- **SIP_TCP** – Used when SIP servers send SIP messages over TCP.
- **SIP_SSL** – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The Citrix ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.
Figure 2. SIP Load Balancing Topology
Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:
   - **SIP_UDP** – If you are load balancing the SIP traffic over UDP.
   - **SIP_TCP** – If you are load balancing the SIP traffic over TCP.
   - **SIP_SSL** – If you are load balancing and securing the SIP traffic over TCP.

   Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.

3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The Citrix ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.

4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.

5. If you are using the Citrix ADC as the gateway for the SIP servers in your deployment, configure RNAT.

6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.
To configure a basic load balancing setup for SIP traffic by using the command line interface

Create one or more services. At the command prompt, type:

```
1 add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

**Example:**

```
1 add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
```

Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:

```
1 add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

**Example:**

```
1 add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
```

Bind each service to a virtual server. At the command prompt, type:

```
1 bind lb vserver <name> <serverName>
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
```

(Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2 3 bind lb monitor <monitorName> <ServiceName>
```

**Example:**

```
1 add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
2 3 bind monitor mon1 Service-SIP-UDP-1
```

If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:
```bash
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
```

**Example:**
```
bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
```

Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:
```
set rnat <IPAddress> <netmask>
set rnat <IPAddress> <netmask> -natip <NATIPAddress>
set rnat <aclname> [-redirectPort <port>]
set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>
```

**Example:**
```
set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix ADC internal service named nsrnatsip-127.0.0.1-5061.
```
add ssl certKey <certkeyName> -cert <string> [-key <string>]
bind ssl service <serviceName> -certkeyName <string>
```

**Example:**
```
add ssl certKey c1 -cert cert.epm -key key.ky
bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
```

If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:
Sample Configuration for load balancing the SIP traffic over UDP

```bash
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort <rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> - sip503RateThreshold <sip503_rate_threshold_value>
```

```bash
add service service-UDP-1 10.102.29.5 SIP_UDP 80
Done
add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
Done
bind lb vserver vserver-LB-1 service-UDP-1
Done
add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com - sipregURI sip:mon@test.com -rescode 200
Done
bind mon mon1 service-UDP-1
Done
set rnat 192.168.1.0 255.255.255.0
Done
set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
Done
```

Sample Configuration for load balancing the SIP traffic over TCP

```bash
add service service-TCP-1 10.102.29.5 SIP_TCP 80
Done
```
Sample Configuration for load balancing and securing SIP traffic over TCP

```plaintext
add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
Done
bind lb vserver vserver-LB-1 service-TCP-1
Done
add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
Done
bind mon mon1 service-TCP-1
Done
set rnat 192.168.1.0 255.255.255.0
Done
set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
Done
```

```plaintext
add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80
Done
add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80
Done
bind lb vserver vserver-LB-1 service-SIP-SSL
Done
add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
```
To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.
2. Click the Service section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.
3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
   a) Navigate to System > Network > Routes.
   b) On the Routes page, click the RNAT tab.
   c) In the details pane, click Configure RNAT.
   d) In the Configure RNAT dialog box, do one of the following:
      • If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
         - Network
         - Netmask
• If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL
and set the following parameters:
  – ACL Name
  – Redirect Port

e) To set a MIP or SNIP address as a NAT IP address, skip to step 7.
f) To set a unique IP address as a NAT IP, in the Available NAT IP(s) list, select the IP address
that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in
the Configured NAT IP(s) list.
g) Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the Citrix
ADC internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

a) Navigate to Traffic Management > Load Balancing > Services and click the Internal Services
   tab.
b) Select nsnatsip-127.0.0.1-5061 and click **Edit**.
c) Click the **Certificates** section and bind a certificate key pair to the internal service.

7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP
parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings,
set the various SIP parameters.

**SIP Expression and Policy Example: Compression Enabled in Client Requests**

A Citrix ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and
looks for the compression header. If the message includes a compression header, the policy responds
with “400 Bad Request,” so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
1 add responder action sipaction1 respondwith q{
2   "SIP/2.0 400 Bad Request"
}
3
4 Done
5
6 add responder policy sippol1
7
8 add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.
9     HEADER("Compression").EXISTS" sipaction1
```

1.
Load balance RTSP servers

January 25, 2019
Contributed by: C

The Citrix ADC appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of an load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server</td>
<td>Vserver-LB-1</td>
<td>10.102.29.100</td>
<td>554</td>
<td>RTSP</td>
</tr>
<tr>
<td>Services</td>
<td>Service-RTSP-1</td>
<td>10.102.29.101</td>
<td>554</td>
<td>RTSP</td>
</tr>
<tr>
<td></td>
<td>Service-RTSP-2</td>
<td>10.102.29.102</td>
<td>554</td>
<td>RTSP</td>
</tr>
<tr>
<td></td>
<td>Service-RTSP-3</td>
<td>10.102.29.103</td>
<td>554</td>
<td>RTSP</td>
</tr>
<tr>
<td>Monitors</td>
<td>Monitor-RTSP-1</td>
<td>None</td>
<td>554</td>
<td>RTSP</td>
</tr>
</tbody>
</table>

The following diagram shows the load balancing entities used in RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model

To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the command line interface

At the command prompt, type:
add lb monitor <monitorName> <type>

Example:
add lb monitor Monitor-RTSP-1 RTSP

To configure RTSP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.
2. Citrix ADC
3. Citrix ADC 12.1

Load balance remote desktop protocol (RDP) servers

January 25, 2019
Contributed by: C

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the Citrix ADC appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the Citrix ADC RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.
When a TCP connection is established between the client and the load balancing virtual server, the Citrix ADC applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the Citrix ADC appliance forwards the response to the client.

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the Citrix ADC appliance, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the Citrix ADC reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP

Note

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The Citrix ADC appliance supports only IP-based cookies.
- The nsrdp.pl script is supported only for monitoring Windows 2000 and Windows 2008 servers. The nsrdp.pl script is not supported on Windows 2012 servers and later.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177(v=ws.10)#BKMK_2

When you add an RDP service, by default, Citrix ADC adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, Citrix ADC marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the Citrix ADC opens a TCP connection to the specified server and sends an RDP packet. The monitor
marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the Citrix ADC can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the Citrix ADC at /nsconfig/monitors/n-srdp.pl. When you configure the user monitor, the Citrix ADC runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

**To configure RDP load balancing services by using the command line interface**

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```bash
add service <name>@<serverName> <serviceType> <port>
```

Note: Repeat the above command to add more services.

**Example**

```
1 > add service ser1 10.102.27.182 RDP 3389
2 Done
3 > add service ser2 10.102.27.183 RDP 3389
4 Done
5 > show service ser1
6 ser1 (10.102. 27.182:3389) - RDP
7 State: UP
8 ...  
9 Server Name: 10.102.27.182
10 Server ID : 0 Monitor Threshold : 0
11 Down state flush: ENABLED
12 ...  
13 1) Monitor Name: tcp-default
14 State: UP Weight: 1
15 ...  
16 Response Time: 4.152 millsec
17 Done
```

**To configure RDP load balancing services by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Services, and create services of type RDP.
To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

```
1 add lb vserver <name>@<serviceType> <ipAddress> <port>
2 bind lb vserver <name>@<serviceName>
3 Bind all the RDP services to be load balanced to the virtual server.
```

Example:

This example has two RDP services bound to the RDP virtual server.

```
1 add lb vs v1 rdp 10.102.27.186 3389
2 Done
3 bind lb vs v1 ser1
4 service "ser1" bound
5 bind lb vs v1 ser2
6 service "ser2" bound
7 Done
8
9 sh lb vs v1
10 v1 (10.102.27.186:3389) - RDP Type: ADDRESS
11 State: UP
12 ... 
13 No. of Bound Services : 2 (Total) 2 (Active)
14 Configured Method: LEASTCONNECTION
15 Current Method: Round Robin, Reason: A new service is bound
16 Mode: IP
17 Persistence: NONE
18 L2Conn: OFF
19
20 1) ser1 (10.102.27.182: 3389) - RDPState: UP Weight: 1
21 2) ser2 (10.102.27.183: 3389) - RDPState: UP Weight: 1
22 Done
```

To configure an RDP load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server of type RDP, and bind RDP services to this virtual server.
To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

```
1  add lb monitor <monitorName> USER -scriptName nsrdp.pl
2  bind lb monitor <monitorName> <rdpServiceName>
```

Example:

```
1  add service ser1 10.102.27.182 RDP 3389
2  add lb monitor RDP_MON USER -scriptName nsrdp.pl
4  bind lb monitor RDP_MON ser1
```

To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

Use case 1: SMPP load balancing

January 25, 2019

Contributed by:

Citrix ADC

Citrix ADC 12.1

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The Citrix ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The Citrix ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.
Load balancing of SMPP messages by the Citrix ADC provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

Introduction to SMPP

SMPP is an application layer protocol for transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.

Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receive messages. The ESME sends the MC one of the three messages (also known as PDUs): bind_transmitter, bind_receiver, or bind_transceiver. The MC responds with a bind_transmitter_resp, bind_receiver_resp, or bind_transceiver_resp, as appropriate for the request.

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit_sm or data_sm message, receive a deliver_sm or data_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query_sm, replace_sm, and cancel_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends an alert_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.
Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.

**Limitation:**

The Citrix ADC appliance does not support outbind operations. That is, a message center cannot initiate an SMPP session with an ESME through the Citrix ADC appliance.

**How SMPP Load Balancing Works on the Citrix ADC**

An ESME (client) sends a bind message to open a connection to the Citrix ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The Citrix ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

**Messages Originating from the ESMEs**

Each ESME must be added as a user on the Citrix ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.

Before forwarding the response (submit_sm_resp or data_sm_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver_sm or data_sm messages from the message centers to the clients.
**Messages Originating from a Message Center**

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver_sm message to the Citrix ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, Citrix ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.

Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit_sm(1) to NetScaler
6. ESME1 sends submit_sm(2) to NetScaler
7. NetScaler forwards submit_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit_sm(2) to MC2
11. MC1 sends submit_sm_resp(1) to NetScaler
12. MC2 sends submit_sm_resp(2) to NetScaler
13. NetScaler forwards submit_sm_resp(1) to ESME1
14. NetScaler forwards submit_sm_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler
16. NetScaler sends bind response to ESME2
17. ESME2 sends submit_sm(3) to NetScaler
18. NetScaler forwards submit_sm(3) to MC1
19. MC2 sends deliver_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit_sm_resp(3) to NetScaler
21. NetScaler forwards submit_sm_resp(3) to ESME2
22. NetScaler forwards deliver_sm to ESME2
23. ESME2 sends deliver_sm_resp to NetScaler
24. MC1 sends alert_notification to NetScaler (ESME1 serves the address range specified in the mes-
Health Monitoring of Message Centers

By default, a TCP_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the Citrix ADC to content switch these requests on the basis of the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.
  
  **Example:**
  ```
  SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS("988")
  ```

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.
  
  **Example:**
  ```
  SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")
  ```

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.
  
  **Example:**
  ```
  SMPP.BINDINFO.SYSTEM_TYPE.EQ("VMS")
  ```

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)
  
  **Example:**
  ```
  SMPP.BINDINFO.ADDR_TON.EQ(1)
  ```

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)
  
  **Example:**
  ```
  SMPP.BINDINFO.ADDR_NPI.EQ(0)
  ```
Example:
SMPP.BINDINFO.ADDR_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

Example:
SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The Citrix ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the Citrix ADC responds with an error message.

Configuring SMPP Load Balancing on the Citrix ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.
4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.
To configure SMPP load balancing by using the command line

At the command prompt, type:

```
1 add smpp user <username> -password <password>
2 add service <name> <IP> SMPP <port> -customserverID <customserverID>
3 add lb vserver <name> <IP> SMPP <port>
4 bind lb vserver <name> <service name>
5 set smpp param
```

Example

```
1 add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
2 add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -
    encrypted -encryptmethod ENCMTHD_2
3 add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -
    svrTimeout 360 -CustomServerID ab -CKA NO -TCPB NO -CMP NO
4 add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -
    maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -
    svrTimeout 360 -CustomServerID xy -CKA NO -TCPB NO -CMP NO
5 add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -
    cltTimeout 180
6 bind lb vserver smppvs smmpsvc2
7 bind lb vserver smppvs smmpsvc
8 set smpp param -addrrange "d*"
```

To configure SMPP load balancing by using the configuration utility

1. Navigate to System > User Administration > SMPP Users, and add an SMPP user.
2. Navigate to Traffic Management > Load Balancing > Configure SMPP Parameters, and set the
   parameters as required by your deployment.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of
   type SMPP.
4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream

January 23, 2019
Contributed by: C

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called “FIX fields”). The field format is \(<\text{tag}>=\langle \text{value} \rangle<\text{delimiter}>\). This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting “Start of Header” (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

\(8=\text{FIX.4.1} 9=61 35=A 49=\text{INVMGR} 56=\text{BRKR} 34=1 52=20000426-12:05:06 98=0 108=30 10=157\)

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the
SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule "CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T(=,’\’).VALUE(\"49\")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the Citrix ADC appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T(=,’\’).SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace `<tag>` with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression `CLIENT.TCP.PAYLOAD(300).BEFORE_STR("\’").AFTER_STR("<tag>=")`.
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression `CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST_NVLIST_T(=,’\’).VALUE("<tag>")`.
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression `CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T(=,’\’).VALUE("<tag>",2)`.
  
Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the (n+1)th instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- `CLIENT.TCP.PAYLOAD(100)`
Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the Citrix ADC appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the Citrix ADC appliance does not replace the load balancing virtual server’s IP address with the destination server’s IP address. Instead, it forwards packets to a service by using the server’s MAC address. The VIP must be configured on the server and ARP...
must be disabled for the VIP which is configured on the server to prevent the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user needs to configure VIP in the loopback interface and disable the ARP for the same VIP.

- The appliance obtains the server’s MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the Citrix ADC appliance, do not learn a server’s MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the Citrix ADC appliance, the ARP requests always resolve to the MAC address of the Citrix ADC interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the Citrix ADC appliance. The following table lists the names and values of the entities configured on the Citrix ADC appliance in DSR mode.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>

</table>

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.
After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

**To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

```bash
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

**Example**

```bash
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless enabled
```

**Note**

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

**To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility**

2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.

**To configure a service to use source IP address by using the command line interface**

At the command prompt, type:

```bash
set service <ServiceName> -usip <Value>
```

**Example:**
To configure a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Traffic Settings, select Use Source IP Address.

Some additional steps are required in certain situations, which are described in the succeeding sections.

2. Citrix ADC 12.1

Use case 4: Configure LINUX servers in DSR mode

January 23, 2019
Contributed by: C

The LINUX operating system requires that you set up a loopback interface with the Citrix ADC appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the Citrix ADC appliance’s VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
ifconfig dummy0 up
ifconfig dummy0:0 inet <netcaler vip> netmask 255.255.255.255 up
echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore
echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
```

Then, run the software that re-maps the TOS id to VIP.
Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

C

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the TCP packet header. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the Citrix ADC appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the TOS field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The Citrix ADC appliance in DSR mode with TOS

The TOS feature is specifically customized for a controlled environment, as described below:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client will not understand the message, as the source IP address will be the IP address of the load balanced server and not the Citrix ADC VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.
### Entity Type | Name               | IP Address   | Protocol |
<table>
<thead>
<tr>
<th></th>

</tbody>
</table>

DSR with TOS requires that load balancing be set up on layer 3. To configure a basic load balancing setup for Layer 3, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

**To configure the redirection mode for the virtual server by using the command line interface**

At the command prompt, type:

```bash
set lb vserver <vServerName> -m <Value> -tosId <Value>
```

**Example:**

```bash
set lb vserver Vserver-LB-1 -m TOS -tosId 3
```

**To configure the redirection mode for the virtual server by using the configuration utility**

2. Open a virtual server, and in Redirect Mode, select TOS ID.

**To configure the transparent monitor for TOS by using the command line interface**

At the command prompt, type:

```bash
add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -tosId <Value>
```
Example:

```
| add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3 |
```

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

Wildcard TOS Monitors

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the TOS field is set to the encoded value of the VIP address. It then sends the probe packets to the servers represented by the services of a load balancing configuration.

With a large number of load balancing configurations, creating a separate custom TOS monitor for each configuration is a big, cumbersome task. Managing these TOS monitors is also a big task. Now, you can create wildcard TOS monitors. You need to create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- **Type** = `<protocol>`
- **TOS** = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

To create a wildcard TOS monitor by using the CLI

At the command prompt, type:
To bind a wildcard TOS monitor to a service by using the CLI

At the command prompt, type:

1. `add lb monitor <monitorName> <Type> -tos YES`
2. `show lb monitor <monitorName>`

To create a wildcard TOS monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Add a monitor with the following parameter settings:
   - `Type = <protocol>`
   - `TOS = YES`

To bind a wildcard TOS monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2, S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4, and S5 are bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4, and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with TOS field set to the encoded VIP address (203.0.113.1) of V1 and the other with the VIP address (203.0.113.2) of V2. The Citrix ADC then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

1. `add lb monitor WLCD-TOS-MON TCP -tos YES`
2. `Done`
add lb vserver V1 ANY 203.0.113.1 * -m TOS -tosID 1
Done

add lb vserver V2 ANY 203.0.113.2 * -m TOS -tosID 2
Done

add lb vserver V3 ANY 203.0.113.3 * -m TOS -tosID 3
Done

add service S1 198.51.100.1 ANY *
Done

add service S2 198.51.100.2 ANY *
Done

add service S3 198.51.100.3 ANY *
Done

add service S4 198.51.100.4 ANY *
Done

add service S5 198.51.100.5 ANY *
Done

bind lb monitor WLCD-TOS-MON S1
Done

bind lb monitor WLCD-TOS-MON S2
Done

bind lb monitor WLCD-TOS-MON S3
Done

bind lb monitor WLCD-TOS-MON S4
You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the Citrix ADC appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a Citrix ADC appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the appliance.
Consider an example where a load balancing virtual server LBVS1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The Citrix ADC appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

The following table lists the settings used in this example.

<table>
<thead>
<tr>
<th>Entities</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 address of client C1</td>
<td>C1_IP (for reference purposes only)</td>
</tr>
<tr>
<td>Load balancing virtual server on NS1</td>
<td>LBVS1</td>
</tr>
<tr>
<td>IPv6 address of LBVS1</td>
<td>LBVS1_VIP6 (for references purpose only)</td>
</tr>
<tr>
<td>TOS value</td>
<td>TOS_LBSV1_VIP6 (for references purpose only)</td>
</tr>
<tr>
<td>Service for server S1 on NS1</td>
<td>SVC_S1</td>
</tr>
<tr>
<td>IPv6 address for server S1</td>
<td>S1_IP (for references purpose only)</td>
</tr>
<tr>
<td>Service for server S2 on NS1</td>
<td>SVC_S2</td>
</tr>
<tr>
<td>IPv6 address for server S1</td>
<td>S2_IP (for references purpose only)</td>
</tr>
<tr>
<td>Service for server S3 on NS1</td>
<td>SVC_S3</td>
</tr>
<tr>
<td>IPv6 address for server S1</td>
<td>S3_IP (for references purpose only)</td>
</tr>
</tbody>
</table>

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1’s load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   • TOS field set to TOS_LBSV1_VIP6.
   • Source IP address as C1_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the appliance, with:
   • Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

**To configure load balancing in DSR Mode using TOS by using the command line interface**

At the command prompt, type:

```
1. enable ns mode USIP
2. add service <serviceName> <IP> <serviceType> <port>
```

Repeat the above command as many times as necessary to add each server as a service on the Citrix ADC appliance.

```
1. add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -tosId <positive_integer>
2. bind lb vserver <vservername> <servicename>
```

**To enable USIP mode by using the configuration utility**

Navigate to System > Settings > Configure Modes, and select Use Source IP Address.

**To create services by using the configuration utility**

Navigate to Traffic Management > Load Balancing > Services, and create a service.

**To create a load balancing virtual server and bind services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

Use case 7: Configure load balancing in DSR mode by using IP Over IP

January 25, 2019
Contributed by: C

You can configure your Citrix ADC appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called IP over IP configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the Citrix ADC appliance, improving response times and throughput. As with standard DSR mode, the Citrix ADC appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the Citrix ADC appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the Citrix ADC appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your Citrix ADC appliance, you must do the following:

- Create a load balancing virtual server. Set the protocol to ANY and set the mode to IPTUNNEL.
- Create services. Create a service for each of your back-end applications. Bind the services that you created to the virtual server.
- Configure for decapsulation. You can configure either a Citrix ADC appliance or a backend server to act as a decapsulator.

Configure a load balancing virtual server

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

```
1  add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>
2
```
Example:

In the following example, we have selected the load balancing method as sourceIPHash and configured sessionless load balancing.

```
add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -m IPTUNNEL -sessionless enabled
```

To create and configure a load balancing virtual server for IP over IP DSR by using the configuration utility

2. Create a virtual server, and specify Redirection Mode as IP Tunnel Based.

Configure services for IP over IP DSR

After creating your load-balanced server, you must configure one service for each of your applications. The service handles traffic from the Citrix ADC appliance to those applications, and allows the Citrix ADC appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

```
add service <serviceName> <serverName> <serviceType> <port> -usip <usip >
add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <iptunnel>
bind service <serviceName> -monitorName <monitorName>
```

Example:

In the following example, we are creating a monitor of type IPTUNNEL:
To configure a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, and select IP Tunnel.

To create and configure a service for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a service and, in Settings, select Use Source IP Address.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-DSR-1
```

Using the Client IP address in the Outer Header of Tunnel Packets

The Citrix ADC supports using the client IP address as the source IP address in the outer header of tunnel packets related to direct server return mode using IP tunneling. This feature is supported for DSR with IPv4 and DSR with IPv6 tunneling modes. For enabling this feature, enable the `use client source IP address` parameter for IPv4 or IPv6. This setting is applied globally to all the DSR configurations that use IP tunneling.
**To use client IP address as the source IP address on outer header of IPv4 tunnel packets by using the CLI**

**At the command prompt, type:**

```
set iptunnelparam -useclientsourceip [YES NO]
```

•

• `show iptunnelparam`

**To use client source IP address as the source IP address on outer header of IPv6 tunnel packets by using the CLI**

**At the command prompt, type:**

```
set ip6tunnelparam -useclientsourceip [YES NO]
```

•

• `show ip6tunnelparam`

Following is a sample load balancing configuration in DSR mode using IPv4 tunneling. LBVS-IPIP-1 is the load balancing virtual server, and services SERVICE-DSR-IPIP-1 and SERVICE-DSR-IPIP-2 are bound to LBVS-IPIP-1.

```
> set iptunnelparam -useclientsourceip YES

Done

> add service SERVICE-DSR-IPIP-1 192.0.2.91 ANY * -usip yes

Done

> add service SERVICE-DSR-IPIP-2 192.0.2.92 ANY * -usip yes

Done

> add lb vserver LBVS-IPIP-1 ANY 203.0.113.9 * -m IPTUNNEL
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Decapsulator configuration

- When a Citrix ADC appliance is used as a decapsulator, an IP tunnel must be created in the Citrix ADC appliance. For details, see Configuring IP Tunnels.

Example configuration:

```
add lb vserver v1 any 1.1.1.1 * -m IPTUNNEL
add service s1 2.2.2.2 ANY *
bind lb vserver v1 s1
add iptunnel tun1 <snip_in_encap> netmask *
add ns ip 1.1.1.1 255.255.255.255 -type vip -arp disabled
add lb vserver v1 any 1.1.1.1 *
add service s1 <actualserverip> ANY *
bind lb vserver v1 s1
```

- When a backend server is used as a decapsulator, the backend configuration varies depending on the server type. The steps involved in configuring a backend server as a decapsulator are;
  1. Configure a loop back interface.
  2. Add a route through tunnel interface.

**Note:** Make sure that the tunnel modules are installed in the system.

Example configuration:
In this example, 1.1.1.1 is the Citrix ADC virtual IP (VIP) address and 2.2.2.2 is the backend server IP address.

The VIP address is configured in the loopback interface and a route is added through the tunnel interface. The modprobe ipip command is used for enabling the tunnel interface.

```bash
1 add lb vserver v1 ANY 1.1.1.1 80 -m IPTUNNEL
2 add service svc1 2.2.2.2 ANY 80 -usip YES -useproxyport NO
3 bind lb vserver v1 svc1
4 ifconfig lo inet 1.1.1.1 netmask 255.255.255.255
5 modprobe ipip
6 echo 1 > /proc/sys/net/ipv4/conf/tunl0/arp_ignore
7 echo 2 > /proc/sys/net/ipv4/conf/tunl0/arp_announce
8 ifconfig tunl0 1.1.1.1 netmask 255.255.255.255 up
9 route add -host 1.1.1.1 dev tunl0
```

3. Citrix ADC 12.1

**Use case 8: Configure load balancing in one-arm mode**

January 25, 2019

Contributed by:

C

In a one-arm setup, you connect the Citrix ADC appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure 1. Load balancing in one-arm mode
In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>

<td>None</td>
</tr>
</tbody>
</table>

To configure a load balancing setup in one-arm mode, see “Setting Up Basic Load Balancing.”

1. Citrix ADC
2. Citrix ADC 12.1

Use case 9: Configure load balancing in the inline mode

January 25, 2019
Contributed by: C

In an inline mode (also called two-arm mode) setup, you connect the Citrix ADC appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.

Figure 1. Load balancing in inline mode

The configuration and the entity diagram for inline mode are the same as described in Configuring Load Balancing in One-arm Mode.

1. Citrix ADC
2. Citrix ADC 12.1
Use case 10: Load balancing of intrusion detection system servers

January 25, 2019

Contributed by: C

To enable the Citrix ADC appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the Citrix ADC appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers

Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>*</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td>Services</td>
<td>Service-ANY-1</td>
<td>10.102.29.101</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td></td>
<td>Service-ANY-2</td>
<td>10.102.29.102</td>
<td>*</td>
<td>ANY</td>
</tr>
</tbody>
</table>
Entity type | Name | IP address | Port | Protocol
---|---|---|---|---
Service-ANY-3 | 10.102.29.103 | * | ANY |
Monitors | Ping | None | None | None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.

**To enable MAC-based forwarding by using the command line interface**

At the command prompt, type:

```
1 enable ns mode <ConfigureMode>
```

**Example:**

```
1 enable ns mode MAC
```

**To enable MAC-based forwarding by using the configuration utility**

Navigate to System > Settings > Configure Modes, and select MAC Based Forwarding.

Next, see “Setting Up Basic Load Balancing”, to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

**To configure LB method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:
Example:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

Note

For a service that is bound to a virtual server on which `-m MAC` option is enabled, you must bind a non-user monitor.

To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility

2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

To set a service to use source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

Example:

```
set service Service-ANY-1 -usip yes
```

To set a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Settings select Use Source IP Address.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see “IP Addressing.”
Use case 11: Isolating network traffic using listen policies

January 25, 2019
Contributed by:
C

A very common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IDP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multi-tenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a Citrix ADC appliance identifies network domains and controls the traffic across the domains. The Citrix ADC solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on a number of client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

<table>
<thead>
<tr>
<th>Category</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet protocol</td>
<td>Source MAC address, destination MAC address</td>
</tr>
<tr>
<td>Network interface</td>
<td>Network ID, receiving throughput, sending throughput, transmission throughput</td>
</tr>
<tr>
<td>IP protocol</td>
<td>Source IP address, destination IP address</td>
</tr>
<tr>
<td>IPv6 protocol</td>
<td>Source IPv6 address, destination IPv6 address</td>
</tr>
<tr>
<td>TCP protocol</td>
<td>Source port, destination port, maximum segment size, payload, and other options</td>
</tr>
</tbody>
</table>
Table 1. Client Parameters Used to Define Listen Policies

On the Citrix ADC appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

**How network paths are isolated**

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path

**Traffic within network domain 1**

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the Citrix ADC for all the traffic that originates from a client.
Traffic between network domain 1 and network domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VLAN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.
  - Enable the L2 Connection option on both the virtual servers.
    Generally, to identify a connection, the Citrix ADC appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.
- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all of the firewall services to the shadow virtual server.
To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

```bash
1 add policy expression <expressionName> <listenPolicyExpression>
2 add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -listenPolicy <expressionName>
```

Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

```bash
1 add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <expressionName>
```

Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

**Example:**

```bash
1 add policy expression e110 client.vlan.id==110
2 add policy expression e210 client.vlan.id==210
3 add policy expression e310 client.vlan.id==310
4 add policy expression e11 client.vlan.id==11
5 add policy expression e22 client.vlan.id==22
6 add policy expression e33 client.vlan.id==33
7 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -listenPolicy e11 -cltTimeout 180 -l2Conn ON
8 add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -listenPolicy e22 -cltTimeout 180 -l2Conn ON
9 add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -listenPolicy e33 -cltTimeout 180 -l2Conn ON
10 add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN -listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout 120
11 add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN -listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout 120
```
To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in “Creating a Service.”
2. Add each firewall as a service:
   a) Navigate to Traffic Management > Load Balancing > Services
   b) Create a service, specifying protocol as ANY, server as firewall’s IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

1.
2. Citrix ADC
3. Citrix ADC 12.1

**Use case 12: Configure XenDesktop for load balancing**

January 25, 2019

Contributed by: C

For an improved performance in the delivery of virtual desktop applications, you can integrate the Citrix ADC appliance with Citrix XenDesktop and use the Citrix ADC load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

The DDC also authenticates users and manages the assembly of the users’ virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user’s device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a Citrix ADC appliance working with XenDesktop.

**Figure 1. Load Balancing of XenDesktop**

*Note*

Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the Citrix ADC appliance. You can use the HTTP protocol for communication between the Citrix ADC and the DDC servers even though you use the SSL protocol for communication with the client.
To configure load balancing for XenDesktop by using the GUI

1. Create a service.
   a) Navigate to Configuration > Traffic Management > Load Balancing > Services and click Add.
   b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click OK.
2. Create a load balancing virtual server.
   a) Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers and click Add.
   b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click OK.
3. Bind the service to the load balancing virtual server.
   a) Click Edit.
   b) In the Services and Service Groups, click > and click Add Binding.
   c) Select the service you want to bind and enter the weight value.
   d) Click Bind.

To configure load balancing for XenDesktop by using the command line interface

• To create a service, at the command prompt, type:

```bash
1 add service <name> <serverName> <serviceType> <port>
```

Example:

```bash
1 add service Service-HTTP-1 192.0.2.5 HTTP 80
```

• To create a virtual server, at the command prompt, type:

```bash
1 add lb vserver <name> <serviceType> <ip> <port>
```

Example:

add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80

• To bind a service to a load balancing virtual server, at the command prompt, type:

```bash
1 bind lb vserver <name> <serviceName>
```

Example:
Use case 13: Configure XenApp for load balancing

January 25, 2019
Contributed by: C

For efficient delivery of applications, you can integrate the Citrix ADC appliance with Citrix XenApp and use the Citrix ADC load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. Load Balancing of XenApp

The Web Interface servers provide secure access to XenApp application resources through the user’s Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user’s device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user’s permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. On the basis of the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using the Citrix ADC appliance. Configure one virtual server to load balance all of the Web Interface servers and another for all of the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

Note
Although you can use the HTTP protocol, Citrix recommends that you use SSL for communica-
tion between the client and the Citrix ADC. You can use the HTTP protocol for communication between the Citrix ADC and the WI servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenApp by using the GUI

1. Create a service.
   a) Navigate to Configuration > Traffic Management > Load Balancing > Services and click Add.
   b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click OK.
2. Create a load balancing virtual server.
   a) Navigate to Configuration > Traffic Management > Load Balancing > Virtual Servers and click Add.
   b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click OK.
3. Bind the service to the load balancing virtual server.
   a) Click Edit.
   b) In the Services and Service Groups, click > and click Add Binding.
   c) Select the service you want to bind and enter the weight value.
   d) Click Bind.

To configure load balancing for XenApp by using the command line interface

- To create a service, at the command prompt, type:

  ```bash
  add service <name> <serverName> <serviceType> <port>
  ```

  **Example:**
  ```bash
  add service Service-HTTP-1 192.0.2.5 HTTP 80
  ```

- To create a virtual server, at the command prompt, type:

  ```bash
  add lb vserver <name> <serviceType> <ip> <port>
  ```

  **Example:**
  ```bash
  add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
  ```
To bind a service to a load balancing virtual server, at the command prompt, type:

```bash
bind lb vserver <name> <serviceName>
```

**Example:**

```bash
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

1. Citrix ADC

   3. Citrix ADC 12.1

**Use case 14: ShareFile wizard for load balancing Citrix ShareFile**

January 25, 2019

Contributed by:

C

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up load balancing configuration for ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the diagram below.

Figure 1. ShareFile Data Load Balancing

You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to Traffic Management > Virtual Servers and Services > Virtual Servers. You cannot manually remove the virtual servers created using the ShareFile wizard. Use the wizard to remove the virtual servers.

Citrix ADC uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

**To configure a Citrix ADC appliance for load balancing Citrix ShareFile**

1. In the navigation pane, click Load Balancing.
4. On the Setup Load Balancing for ShareFile page, provide the following information:
   • Name: Name of the content switching virtual server.
   • IP Address: IP address of the content switching virtual server.
   • If you want to setup load balancing for CIFS or SharePoint, click the StorageZone Connector for Network File Shares/SharePoint checkbox and then click Continue. By default ShareFile Data checkbox is selected.

5. Provide a valid certificate. If you have a certificate, click Choose Certificate and from the drop-down list select the certificate. If you have to install a certificate, click Install Certificate and provide the Certificate-Key pair.

6. Click Continue.

7. In the Add New StorageZone Controller dialog box, specify the values of the following parameters:
   • StorageZone Controller IP Address— IP address
   • Port— Port number. The default value is 443.
   • Protocol— Select from HTTPS or HTTP

8. Click Create and then click Done. The wizard automatically creates a service and autogenerate the name of the service.

9. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:
   • AAAVServer IP Address— IP address of AAA virtual server
   • LDAP Server IP Address— IP Address of the LDAP server
   • Port— Port number. The default value is 389
   • Time out— The time out value in minutes
   • Single Sign-on Domain— Single sign-on domain name
   • Base DN— Base domain name
   • Administrator Bind DN— LDAP account name with the domain name, for example, administrator@domainname.com
   • Logon Name— Logon name is the sAMAccount name
   • Password and Confirm Password— Enter the password and confirm the password

10. Click Continue and then click Done.

**To remove load balancing configuration for ShareFile**

1. Click on Configuration > Traffic Management > Load Balancing.
Troubleshooting

January 23, 2019
Contributed by: C

If the load balancing does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for Troubleshooting Load Balancing

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Latest ns.conf file
- Relevant newnslog files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistence related issues.
- The Wireshark application customized for the Citrix ADC trace files.

Troubleshooting Load Balancing Issues

- Issue

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which -m MAC option is enabled.

- Resolution

Bind a non-user monitor to the service.

- Issue

I created a user script for monitoring, but it is not working.
Resolution
Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the CLI to debug the script.

• Issue
I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to turn off the monitor probes?

Resolution
You can turn off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

• Issue
I have set up monitors for services, but connections are still directed to servers that are DOWN.

Resolution
You probably need to decrease the monitor probe intervals. The Citrix ADC appliance does not detect the DOWN state until the monitor sends a probe.

• Issue
A metric bound to the monitor is present in the local and custom metric tables.

Resolution
Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don’t need to add any prefix.

• Issue
The monitor probes to a service are not reaching the service.

Resolution
Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

• Issue
I am able to ping the servers, but the state of the services is always shown as DOWN.

Resolution
Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor should change the state of the service to UP.
• **Issue**

Setting a weight for load monitors does not help in deciding the state of the service.

**Resolution**

Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

• **Issue**

A service is not stable.

**Resolution**

Consider troubleshooting the following components:

- Verify that a correct server is bound to the service.
- Verify the type of monitor bound to the service.
- Verify the reasons for the monitor failures. You can open service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
- If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- You can record packet traces on the Citrix ADC appliance and verify the monitor probes and server response for further investigation.

• **Issue**

The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify that the load balancing feature is licensed.
- Verify that the feature is enabled.
- Verify that an appropriate service is bound to the virtual server.
- If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service should be Out-Of-Service. In such a case, you must enable the service and verify if the issue is resolved.
- Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
- If the VIP address is not stable, all the services bound to the virtual server should fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the Citrix ADC appliance and the servers.
• Issue

The site is experiencing uneven load balancing.

Resolution

Consider troubleshooting the following components:

– Verify the load balancing method configured on the appliance.
– Verify weights associated with the services are as expected.
– If the load balancing method is other than round robin, verify the number of connections to the server logged in the newnslog file. You can run the following command to verify the number on the newnslog file:

```
## nsconmsg -K <newnslog_file> -s ConLb=2 -d oldconmsg
```

Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), Hits, Persistent Hits and persistent rate (P) to troubleshoot the issue further.

– If the load balancing method is round robin, verify the persistent Hits as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue.

– Verify if persistency is configured on the appliance.

– Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

• Issue

The service status is displayed as DOWN.

Resolution

Consider troubleshooting the following components:

– Verify whether a SNIP or MIP address is configured.
– Verify that appropriate monitors are bound to the service.
– If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
– Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this could be due to the MIP address being unable to communicate to the server.

• Issue

There is an issue with the response time.
Resolution
Consider troubleshooting the following components:

- Verify the server response time from the service stats either by running the following command:

  ## nsconmsg -K <newnslog_file> -s ConLb=2 -d oldconmsg

- Check for service not stable and service status being displayed as DOWN issues.

• Issue
One of the servers is serving more requests than the other load balanced servers.

Resolution
Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given server might be carrying a heavier load to maintain its session, especially if the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

• Issue
Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

Resolution
Consider troubleshooting the following components:

- Verify the load balance method. If it is round robin, consider changing the method to least connections.
- Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to server which is functional.
- If the connections are stalled for a long period, surge-queue might build. Consider flushing the surge-queue to avoid a sudden spike in load on the server.
- If the servers are working at their maximum level, consider adding a new server for better performance.

• Issue
A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.
Resolution

Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server’s IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

Troubleshooting Tips

For other issues, consider following tips to troubleshoot an issue not listed above:

- If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
- If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
- When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if status of at least one of the custom load monitors is not UP.
- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
- The CUSTOMLOAD load balancing method also follows startup round robin.
- If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
- When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message “5xx - server busy error” is displayed.
- A maximum of 10 metrics from a custom table can be bound to the monitor.
- The OIDs must be scalar variables.
- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
- A user cannot modify the local table.

3. Citrix ADC 12.1
**Load balancing FAQs**

February 19, 2019

Contributed by: C

What are the various load balancing policies I can create on the Citrix ADC appliance

You can create the following types of load balancing policies on the Citrix ADC appliance:

1. Least Connections
2. Round Robin
3. Least response time
4. Least bandwidth
5. Least packets
6. URL hashing
7. Domain name hashing
8. Source IP address hashing
9. Destination IP address hashing
10. Source IP - Destination IP hashing
11. Token
12. LRTM

Can I achieve the Web farm security by implementing load balancing using the Citrix ADC appliance?

Yes. You can achieve Web farm security by implementing load balancing using the Citrix ADC appliance. Citrix ADC appliance enables you to implement the following options of the load balancing feature:

1. **IP Address hiding**: Enables you to install the actual servers to be on **private** IP address space **for** security reasons and **for** IP address conservation. This process is transparent to the end-user because the Citrix ADC appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the **private** subnet, such as FTP or a Telnet server, through a different VIP on the appliance **for** that service.
2. **Port Mapping**: Enables the actual TCP services to be hosted on non-standard ports **for** security reasons. This process is transparent to
the end-user as the Citrix ADC appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

What are various devices that I can use to load balance with a Citrix ADC appliance?

You can load balance following devices with a Citrix ADC appliance:

1 - Server farms  
2 - Caches or Reverse Proxies  
3 - Firewall devices  
4 - Intrusion detection systems  
5 - SSL offload devices  
6 - Compression devices  
7 - Content Inspection servers

Why should I implement the load balancing feature for the website?

You can implement the Load balancing feature for the website to take the following advantages:

1 - Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.  
2 - Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the backend server that is not available.

Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

1 - If you enable the MBF option, the Citrix ADC appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen for the return traffic.
Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

IP Addressing

January 23, 2019
Contributed by: C

Before you can configure the Citrix ADC appliance, you must assign the NSIP address, also known as the Management IP address. You can also create other Citrix ADC-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

Configuring Citrix ADC-owned IP addresses

January 23, 2019
Contributed by: C

The Citrix ADC-owned IP addresses—NSIP address, Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), Mapped IP Addresses (MIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—
exist only on the Citrix ADC appliance. The NSIP uniquely identifies the Citrix ADC on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The Citrix ADC terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP. You can configure some Citrix ADC-owned IP addresses to provide access for management applications.

3. Networking

**Configuring the NSIP address**

January 23, 2019
Contributed by: C

The NSIP address is the IP address at which you access the Citrix ADC appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the Citrix ADC for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization’s LAN.

If you modify this address, you must reboot the Citrix ADC appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

**Important**

Configuring the NSIP address is mandatory.

Changing the NSIP address of a Citrix ADC appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.
Command Line Procedures

To change the NSIP address by using the CLI:

At the command prompt, type:

- `set ns config -IPAddress <ip_addr> -netmask <netmask>
- `show ns config`

To add a default route by using the CLI:

At the command prompt, type:

- `add route 0 0 <gateway IP address>
- `show route`

To save the configuration by using the CLI:

At the command prompt, type:

- `save config`

To restart the Citrix ADC appliance by using the CLI:

At the command prompt, type:

- `reboot`

GUI Procedures

To configure the NSIP address by using the GUI:

1. Click the gear icon in the top-right corner of the Configuration page.
2. Click the **NSIP address** pane.
3. On the **NSIP address** page, set the following parameters, and then click **Done**:
   - NSIP address
   - Netmask

To add a default route by using the GUI:

Navigate to **System** > **Network** > **Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the Citrix ADC by using the GUI:

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

**Sample configuration**

In the following example, the NSIP address of a Citrix ADC appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

```
> set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0

Warning: The configuration must be saved and the system rebooted for these settings to take effect

> add route 0 0 192.0.2.1

Warning: The configuration must be saved and the system rebooted for these settings to take effect

> save config

Done

> reboot
```

2. Citrix ADC 12.1
3. Networking

**Configuring and Managing Virtual IP (VIP) Addresses**

January 25, 2019

Contributed by:

C

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the Citrix ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see [Load Balancing](#).

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple Citrix...
ADC appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the appliance sends, and then responds to, ARP requests. VIPs are the only Citrix ADC-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests. As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the CLI:

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type <type>`
- `show ns ip <IPAddress>`

**Example:**

```
1 > add ns ip 10.102.29.59 255.255.255.0 -type VIP
2 Done
```

To create a range of VIP addresses by using the CLI:

At the command prompt, type:

- `add ns ip <IPAddress> <netmask> -type <type>`
- `show ns ip <IPAddress>`

**Example:**

```
1 > add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
2 ip ”10.102.29.60” added
3 ip ”10.102.29.61” added
4 ip ”10.102.29.62” added
5 ip ”10.102.29.63” added
6 ip ”10.102.29.64” added
7 Done
```

To enable or disable an IPv4 VIP address by using the CLI:

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- `enable ns ip <IPAddress>`
- `show ns ip <IPAddress>`
- `disable ns ip <IPAddress>`
- `show ns ip <IPAddress>`

**Example:**

```
1 > enable ns ip 10.102.29.79
2 Done
```
To configure a VIP address by using the GUI:

Navigate to **System > Network > IPs > IPV4s**, and add a new IP address or edit an existing address.
To create a range of VIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable a VIP address by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. Do one of the following:
   • Select a VIP address.
   • Hold down the Ctrl key and select multiple server address entries.
   • Hold down the Shift key and select a range of server address entries.
   • Select all the addresses by selecting the checkbox on the left side of the header row.
3. From the Action list, select Disable or Enable.

**Detecting a Citrix ADC Appliance in a UDP Load Balancing Setup through TTL Updates**

The following table displays how a Citrix ADC appliance handles the TTL value of received packets in different functionalities.

<table>
<thead>
<tr>
<th>Functionality</th>
<th>TTL value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server</td>
<td>TTL is set to 255 when forwarding the request to the backend servers. TTL is decremented by 1 when forwarding the response to the client.</td>
</tr>
<tr>
<td>L2 Mode</td>
<td>TTL is not changed.</td>
</tr>
<tr>
<td>L3 Mode</td>
<td>TTL is set to 255.</td>
</tr>
<tr>
<td>INAT</td>
<td>TTL is set to 255 when forwarding the request to the backend server. TTL is decremented by 1 when forwarding the response to the client.</td>
</tr>
</tbody>
</table>

Some enterprises/scenarios running a monitoring application requires the Citrix ADC appliance of a load balancing setup to be detected as one of the hop in a traceroute. A Citrix ADC appliance of a load balancing setup is not detected in a traceroute because the appliance, by default, sets the TTL value to 255 instead of decrementing it when forwarding the request to a backend server.

To meet this requirement, **Decrement TTL** parameter of a VIP address can be used. This parameter applies to all UDP virtual servers using this VIP.

When you enable the **Decrement TTL** parameter of a VIP, the Citrix ADC appliance decrements the TTL value by 1 instead of setting it to 255 when forwarding requests, which are received on the UDP virtual servers that uses this VIP.
Monitoring applications using traceroute data can now detect the presence of a Citrix ADC appliance of a UDP load balancing setup.

**Before You Begin**

Before you begin configuring a Citrix ADC appliance to be detected in a traceroute of a load balancing setup, note the following points:

- Decrement TTL parameter is supported only for UDP load balancing virtual servers.
- Decrement TTL parameter is supported for IPv4 VIP as well as IPv6 VIP (VIP6) addresses.
- Decrement TTL parameter is supported for standalone Citrix ADC appliances as well as for high availability (HA) and cluster setups.

**Configuration Steps**

Configuring a Citrix ADC appliance to be detected in a traceroute of a UDP load balancing setup consists of the following tasks:

- Create a UDP load balancing configuration
- Enable the Decrement TTL parameter for the VIP address

**CLI Procedures**

To enable the decrement TTL option for a VIP address by using the CLI:

- To enable the decrement TTL option for a VIP address while adding the VIP address, at the command prompt, type:
  - `add ns ip <ip> <mask> -type VIP -decrementTTL ENABLED`
  - `show ns ip <VIP address>`

- To enable the decrement TTL option for an existing VIP address, at the command prompt, type:
  - `set ns ip <ip> <mask> -decrementTTL ENABLED`
  - `show ns ip <VIP address>`

To enable the decrement TTL option for a VIP6 address by using the CLI:

- To enable the decrement TTL option for a VIP6 address while adding the VIP6 address, at the command prompt, type:
  - `add ns ip6 <IP6/prefix> <mask> -type VIP -decrementTTL ENABLED`
  - `show ns ip6 <VIP6/prefix>`

- To enable the decrement TTL option for an existing VIP6 address, at the command prompt, type:
  - `set ns ip6 <ip6/prefix> <mask> -decrementTTL ENABLED`
GUI Procedures

To enable the decrement TTL option for a VIP address by using the GUI:

Navigate to System > Network > IPs > IPv4s, and enable the Decrement TTL parameter while adding a new VIP address or editing an existing address.

To enable the decrement TTL option for a VIP6 address by using the GUI:

Navigate to System > Network > IPs > IPv6s, and enable the Decrement TTL parameter while adding a new VIP6 address or editing an existing address.

2. Citrix ADC 12.1
3. Networking

Configuring ARP response Suppression for Virtual IP addresses (VIPS)

January 25, 2019
Contributed by:
C

You can configure the Citrix ADC appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a Citrix ADC appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE.** The Citrix ADC appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER.** The Citrix ADC appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER.** The Citrix ADC appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of Citrix ADC appliance for a VIP configured with two virtual servers:

<table>
<thead>
<tr>
<th>Associated virtual servers for a VIP</th>
<th>STATE 1</th>
<th>STATE 2</th>
<th>STATE 3</th>
<th>STATE 4</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NONE</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>V1</td>
<td>UP</td>
<td>UP</td>
<td>DOWN</td>
<td>DOWN</td>
</tr>
<tr>
<td>V2</td>
<td>UP</td>
<td>DOWN</td>
<td>UP</td>
<td>DOWN</td>
</tr>
<tr>
<td>Respond to an ARP request for this VIP?</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>ONE VSERVER</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>V1</td>
<td>UP</td>
<td>UP</td>
<td>DOWN</td>
<td>DOWN</td>
</tr>
<tr>
<td>V2</td>
<td>UP</td>
<td>DOWN</td>
<td>UP</td>
<td>DOWN</td>
</tr>
<tr>
<td>Respond to an ARP request for this VIP?</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td><strong>ALL VSERVER</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>V1</td>
<td>UP</td>
<td>UP</td>
<td>DOWN</td>
<td>DOWN</td>
</tr>
<tr>
<td>V2</td>
<td>UP</td>
<td>DOWN</td>
<td>UP</td>
<td>DOWN</td>
</tr>
<tr>
<td>Respond to an ARP request for this VIP?</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on Citrix ADC appliances NS1 and NS2. Let’s call the shared VIP address VIP1.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2
Citrix ADC 12.1

does not respond to any ARP request for VIP1.

Figure 1.

The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1’s load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request for VIP1.
10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the CLI:

At the command prompt, type:

- set ns ip -arpResponse <arpResponse>
- sh ns ip <IPAddress>

**Example:**

```
> set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
> Done
```

To configure ARP response suppression by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. Open an IP address entry and select the type of ARP Response.
1.
2. Citrix ADC
A subnet IP address (SNIP) is a Citrix ADC owned IP address that is used by the Citrix ADC to communicate with the servers.

The Citrix ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers. Depending on your network topology, you might have to configure one or more SNIPs for different scenarios.

To configure a SNIP address on a Citrix ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode. As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:
```
> add ns ip 10.102.29.203 255.255.255.0 -type SNIP

Done
```

To create a range of SNIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example:
```
> add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
2 ip "10.102.29.205" added
3 ip "10.102.29.206" added
```
To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

• enable ns mode USNIP
• disable ns mode USNIP

To configure a SNIP address by using the GUI:

Navigate to System > Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

• enable ns mode USNIP
• disable ns mode USNIP

To enable or disable USNIP mode by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

**Using SNIPs for a Directly Connected Server Subnet**

To enable communication between the Citrix ADC and a server that is either connected directly to the Citrix ADC or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.
Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a Citrix ADC, see [Load Balancing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1’s load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:
   - Source IP = SNIP1 (192.0.1.10)
   - Destination IP = IP address of S2 (192.0.1.30)
6. S2’s response returns by the same path.

### Using SNIPs for Server Subnets Connected through a Router

To enable communication between the Citrix ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

Citrix ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

For more information about configuring load balancing on a Citrix ADC, see [Load Balancing](#).

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1’s routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.
Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a Citrix ADC, see IP Routing.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1’s load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
   - Source IP address = SNIP1 (192.0.1.10)
   - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3’s response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a Citrix ADC, you must configure at least one SNIP address for each of the server subnets, so that the Citrix ADC can communicate with these server subnets.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on Citrix ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a Citrix ADC, see Load Balancing.

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a Citrix ADC, see Configuring a VLAN.

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring
probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNP1, and to S2 from address SNP2.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   • Source IP = IP address of the client (198.51.100.10)
   • Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1’s load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNP2 and S2.
   Note: If S1 is selected, NS1 opens a connection between SNP1 and S1.
5. NS1 sends the request packet to S2 from SNP2. The request packet has:
   • Source IP = SNP1 (192.0.2.10)
   • Destination IP = IP address of S2 (192.0.2.20)
6. S2’s response returns by the same path.

Configuring GSLB Site IP Addresses (GSLBIP)

January 25, 2019

Contributed by:

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the Citrix ADC appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see Global Server Load Balancing.

Removing a Citrix ADC-owned IP address

January 25, 2019
Contributed by: C

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

<table>
<thead>
<tr>
<th>IP address type</th>
<th>Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subnet IP address (SNIP)</td>
<td>If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another Citrix ADC-owned IP address.</td>
</tr>
<tr>
<td>Virtual Server IP address (VIP)</td>
<td>Before removing a VIP, you must first remove the virtual server associated with it. For information about removing the virtual server, see Load Balancing.</td>
</tr>
<tr>
<td>GSLB-Site-IP address</td>
<td>Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see Global Server Load Balancing.</td>
</tr>
</tbody>
</table>

To remove an IP address by using the CLI:

At the command prompt, type:

```
rm ns ip <IpAddress>
```

**Example:**

```
1  > rm ns ip 10.102.29.54
2  Done
```

To remove an IP address by using the GUI:

Navigate to **System > Network > IPS > IPV4s**, delete the IP address.
Configuring Application Access Controls

May 6, 2019
Contributed by: C

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see Access Control Lists (ACLs).

The Citrix ADC appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

<table>
<thead>
<tr>
<th>Management Access</th>
<th>Telnet (State Configured on the Citrix ADC)</th>
<th>Telnet (Effective State at the IP Level)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>

You can access and manage the Citrix ADC by using applications such as Telnet, SSH, GUI, and FTP.

**Note:** Telnet and FTP are disabled on the Citrix ADC for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the Citrix ADC to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the Citrix ADC appliance's attack prevention capabilities.

You can block access to these non-management applications on a SNIP or NSIP. When access is blocked, a user connecting to a Citrix ADC by using the SNIP or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the CLI:

At the command prompt, type:

```
set ns ip <IPAddress> -mgmtAccess <value> -telnet <value> -ftp <value> -gui <value> -ssh <value> -snmp <value> -restrictAccess (ENABLED | DISABLED)
```

**Example:**

```
1 To enable management access and restrict access for a Citrix ADC owned IP address:
2 > set ns ip 192.0.2.20 -mgmtAccess enabled -restrictAccess ENABLED
4 Done
```
To disable GUI access for a NSIP or SNIP address:

```
> set ns ip 192.0.2.10 -gui disabled
Done
```

To enable management access for an IP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Open an IP address entry, and select the **Enable Management Access control** to support the listed applications option.

How the Citrix ADC Proxies Connections

January 25, 2019

Contributed by: C

When a client initiates a connection, the Citrix ADC appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see **Load Balancing**.

You can configure the Citrix ADC to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the Citrix ADC to retain the source IP address of the packets by enabling Use Source IP mode.

How the Destination IP Address Is Selected

Traffic sent to the Citrix ADC appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The Citrix ADC terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.
Packets destined for a service are sent directly to the appropriate server, and the Citrix ADC does not modify the destination IP addresses. In this case, the Citrix ADC functions as a proxy.

### How the Source IP Address Is Selected

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. Citrix ADC maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, Citrix ADC selects a specific SNIP address.

**Note:** If the Use Source IP (USIP) option is enabled, appliance uses the IP address of the client.

1. Citrix ADC
2. Citrix ADC 12.1
3. Networking

### Enable Use Source IP Mode

January 25, 2019

Contributed by: C

When the Citrix ADC appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of selecting a SNIP address depends on the subnet in which the physical server resides.

If necessary, you can configure the Citrix ADC appliance to use the client’s IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client’s IP address in the web access log is used for billing purposes or usage analysis.
- Client’s IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Google provide content relevant to the location to which the user belongs.
- The application must know the client’s IP address to verify that the request is from a trustworthy source.
• Sometimes, even though an application server does not need the client’s IP address, a firewall placed between the application server and the Citrix ADC may need the client’s IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want the Citrix ADC to use the client’s IP address for communication with the servers.

The following figure shows how the appliance uses IP addresses in USIP mode.

**Before you begin**

Before you enable USIP mode, note the following points:

• Enable USIP in the following situations:
  – Load balancing of Intrusion Detection System (IDS) servers
  – SMTP load balancing
  – Stateless connection failover
  – Sessionless load balancing
  – If you use the Direct Server Return (DSR) mode

• When USIP is enabled, you must set server’s gateway to one of the Citrix ADC owned IP addresses (of type Subnet IP (SNIP) so that server’s response always go through the Citrix ADC appliance.

• If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.

• For transparent cache redirection, if you enable USIP, enable L2CONN also.

• Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.

• As an alternative to USIP mode, you have the option of inserting the client’s IP address (CIP) in the request header of the server-side connection for an application server that needs the client’s IP address.

• In earlier Citrix ADC releases, USIP mode had the following source-port options for server-side connections:
  – **Use the client’s port.** With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
  – **Use proxy port.** With this option, connection reuse is possible for all requests from the same client.
In the later Citrix ADC releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

**Note:** If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

For more information about the Use Proxy Port option, see [Configure the source port for server-side connections](#).

### Configuration Steps

Enable Use Source IP mode (USIP) mode if you want Citrix ADC to use the client’s IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the Citrix ADC or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client’s IP address is used only for the traffic directed to that service.

#### CLI procedures

To globally enable or disable USIP mode by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns mode USIP`
- `disable ns mode USIP`

To enable USIP mode for a service by using the CLI:

At the command prompt, type:

```
set service <name>@ -usip (YES | NO)
```

**Example:**

```
1 > set service Service-HTTP-1 -usip YES
2 Done
```

#### GUI procedures

To globally enable or disable USIP mode by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change Modes**.
2. Select or clear the **Use Source IP** option.
To enable USIP mode for a service by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Services**, and edit a service.
2. In **Advanced Settings**, select **Service Settings**, and select **Use Source IP Address**.

**Configuring Network Address Translation**

January 23, 2019
Contributed by: C

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the Citrix ADC appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the Citrix ADC. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The Citrix ADC supports the following types of network address translation:

- **Inbound NAT (INAT)**. The Citrix ADC replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- **Reverse NAT (RNAT)**. The Citrix ADC replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

**INAT**

January 23, 2019
Contributed by: C
When a client sends a packet to a Citrix ADC appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet’s public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping:** A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance translates the packet’s public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

- **IPv4-IPv6 Mapping:** A public IPv4 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.

- **IPv6-IPv4 Mapping:** A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv4 server. The Citrix ADC appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.

- **IPv6-IPv6 Mapping:** A public IPv6 address on the Citrix ADC appliance listens to connection requests on behalf of a private IPv6 server. The Citrix ADC appliance translates the packet’s public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the appliance uses a subnet IP address (SNIP) as the source IP address.
- If USNIP mode is disabled and USIP mode is disabled, the appliance uses a mapped IP address (MIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the appliance uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the Citrix ADC to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the Citrix ADC attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the Citrix ADC from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you may want to disable them.
Configure INAT

You can create, modify, or remove an INAT entry.

CLI procedures

To create an INAT entry by using the CLI:

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- `add inat <name> <publicIP> <privateIP> [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr|ipv6_addr>]`
- `show inat [<name>]`

Example:

```
1 > add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
2  Done
```

To modify an INAT entry by using the CLI:

To modify an INAT entry, type the `set inat` command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the CLI:

At the command prompt, type:

- `rm inat <name>`

Example:

```
1 > rm inat ip4-ip4
2  Done
```

GUI procedures

To configure an INAT entry by using the GUI:

Navigate to **System > Network > Routes > INAT**, and add a new INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the GUI:

Navigate to **System > Network > Routes > INAT**, delete the INAT configuration.
Coexistence of INAT and Virtual Servers

January 23, 2019
Contributed by: C

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the Citrix ADC device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

<table>
<thead>
<tr>
<th>Case</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>You have configured a virtual server and a service to send all data packets received on a specific Citrix ADC port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.</td>
<td>All packets received on the Citrix ADC, except those received on the specified port, pass through the TCP engine.</td>
</tr>
<tr>
<td>You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the Citrix ADC, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.</td>
<td>Only packets received on the specified port pass through the TCP engine.</td>
</tr>
</tbody>
</table>

**Stateless NAT46**

January 25, 2019

Contributed by:

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the Citrix ADC appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

A stateless NAT46 configuration on the Citrix ADC appliance has the following components:

- **IPv4-IPv6 INAT entry.** An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

  The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then
sent to the client.

- **NAT46 IPv6 prefix.** A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, Citrix ADC appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.

The following table lists the settings used in this example:

<table>
<thead>
<tr>
<th>Entities</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of the client</td>
<td>Client_IPv4 (for reference purposes only)</td>
<td>192.0.2.60</td>
</tr>
<tr>
<td>IPv6 address of the server</td>
<td>Sevr_IPv6 (for reference purposes only)</td>
<td>2001:DB8:5001::30</td>
</tr>
<tr>
<td>IPv4 address defined in the INAT entry for IPv6 server S1</td>
<td>Map-Sevr-IPv4 (for reference purposes only)</td>
<td>192.0.2.180</td>
</tr>
<tr>
<td>IPv6 prefix for NAT 46 translation</td>
<td>NAT46_Prefix (for reference purposes only)</td>
<td>2001:DB8:90::</td>
</tr>
</tbody>
</table>

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the Citrix ADC appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
   - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
   - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the Citrix ADC appliance with:
• Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
• Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30

6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).

7. The appliance creates an IPv4 response packet with:
   • Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)
   • Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)

8. The appliance sends the translated IPv4 response to client CL1.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

• Translation of IPv4 options is not supported.
• Translation of IPv6 routing headers is not supported.
• Translation of hop-by-hop extension headers of IPv6 packets is not supported.
• Translation of ESP and EH headers of IPv4 packets is not supported.
• Translation of multicast packets is not supported.
• Translation of destination option headers and source routing headers is not supported.
• Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

Configure Stateless NAT46

Creating the required entities for stateless NAT46 configuration on the Citrix ADC appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Create a NAT46 IPv6 prefix.

CLI procedures

To configure an INAT mapping entry by using the CLI:

At the command prompt, type:
To create an INAT mapping entry by using the CLI:

At the command prompt, type:

```
set inatparam -nat46v6Prefix <ipv6_addr>
```

Example:

```
1 > add inat exmpl-com-stls-nat46 192.0.2.180
2 2001:DB8:5001::30 -mode stateless
3 Done
4
5 > set inatparam -nat46v6Prefix 2001:DB8:90::/96
6 Done
```

**GUI procedures**

To create an INAT mapping entry by using the GUI:

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
   - Name*
   - Public IP Address*
   - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
   - Mode (Select Stateless from the drop down list.)

   * A required parameter

To create a NAT46 prefix by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**, and set the **Prefix** parameter.
Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the CLI:

At the command prompt, type:

```
set inatparam
```

- `[-nat46IgnoreTOS (YES NO)]` - specifies whether to ignore TOS in the packet.
- `[-nat46ZeroCheckSum (ENABLED DISABLED)]` - specifies whether to zero the checksum.
- `[-nat46v6Mtu <positive_integer>]` - specifies the MTU size for IPv6 packets.
- `[-nat46FragHeader (ENABLED DISABLED)]` - specifies whether to include fragmentation header.

Example:

```
$ set inatparam -nat46IgnoreTOS YES -nat46ZeroCheckSum DISABLED -nat46v6Mtu 1400 -nat46FragHeader DISABLED
```

To set global parameters for stateless NAT46 by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**.

DNS64

January 25, 2019

Contributed by:

C

The Citrix ADC DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery
of the IPv4 domain by the IPv6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the Citrix ADC appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the Citrix ADC appliance. The Citrix ADC appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a Citrix ADC appliance with DNS64 and NAT64 configuration can deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the Citrix ADC appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the Citrix ADC appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a Citrix ADC appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, and DNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter cacherecords is enabled on the Citrix ADC appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example: DNS64 example settings.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on Citrix ADC appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1’s load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.

7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.

8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.

9. NS1 synthesizes an AAAA record for the site www.example.com with:
   - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60

10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

**Points to Consider for a DNS64 Configuration**

Before configuring DNS64 on a Citrix ADC appliance, consider the following points:

- The DNS64 feature of the Citrix ADC appliance is compliant with RFC 6174.

- The DNS64 feature of the Citrix ADC appliance does not support DNSSEC. The Citrix ADC appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.

- The Citrix ADC appliance supports DNS64 prefix of length of only 96 bits.

- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the Citrix ADC appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a Citrix ADC appliance, see Stateful NAT64.

- The following are the different cases of DN64 processing by the Citrix ADC appliance:
  - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the Citrix ADC appliance for the particular DNS64 configuration. The Citrix ADC removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the Citrix ADC appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records.
if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.

- If the response from the DNS server includes RCODE=1 (format error), the Citrix ADC appliance forwards the same to the client. If there is no response before the timeout, the Citrix ADC appliance sends a response with RCODE=2 (server failure) to the client.

- If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the Citrix ADC appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.

- The DNS64 feature of the Citrix ADC appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR.ARP domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The Citrix ADC appliance uses the response from the DNS server to synthesize response for the initial PTR request.

### Configuration Steps

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the Citrix ADC appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see [Load Balancing](#).

- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.

- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see [Load Balancing](#).

**Note:** The CLI has separate commands for these two tasks, but the GUI combines them in a single dialog box.
Enable caching of DNS records. Enable the global parameter for the Citrix ADC appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see Domain Name System.

CLI procedures

To create a service of type DNS by using the CLI:

At the command prompt, type:

• add service <name> <IP> <serviceType> <port> …

To create a DNS64 action by using the CLI:

At the command prompt, type:

• add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the CLI:

At the command prompt, type:

• add dns policy64 <name> -rule <expression> -action <string>

To create a DNS load balancing virtual server by using the CLI:

At the command prompt, type:

• add lb vserver <name> DNS <IPAddress> <port> -dns64 ( ENABLED | DISABLED ) [-bypassAAAA ( YES | NO )] …

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the CLI:

At the command prompt, type:

• bind lb vserver <name> <serviceName> …
• bind lb vserver <name> -policyName <string> -priority <positive_integer> …

GUI procedures

To create a service of type DNS by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
   • Service Name*
Citrix ADC 12.1

- Server
- Protocol (Select DNS from the drop down list.)
- Port

To create a DNS64 action by using the GUI:

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the GUI:

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
   - Name
   - IP Address
   - Protocol (Select DNS from the drop down list.)
   - Port
3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

**Sample Configuration**

```bash
> add service SVC-DNS-1 203.0.113.50 DNS 53
Done

> add service SVC-DNS-2 203.0.113.60 DNS 53
Done

> add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
Done

> add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC_IN_SUBNET (2001:DB8:5001::/64)"
-action DNS64-Action-1
Done

> add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-1
```
The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the Citrix ADC appliance.

A stateful NAT64 configuration on the Citrix ADC appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of Citrix ADC owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.
  
  Note: Currently the Citrix ADC appliance supports only one prefix to be used commonly with all NAT 64 rules.

The Citrix ADC appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the Citrix ADC appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the Citrix ADC appliance considers the IPv6 packet for translation.
The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The Citrix ADC appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, Citrix ADC appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate with IPv4 server S1.

The following table lists the settings used in this example: Stateful NAT64 translation example settings.

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The Citrix ADC appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the Citrix ADC considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
   - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)
   - Source IP address field containing one of the IPv4 address bound to Netprofile-1 (in this case, 192.0.2.100)
4. The Citrix ADC appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv64 server S1 responds by sending an IPv4 packet to the Citrix ADC appliance with:
   - Destination IP address field containing 192.0.2.100
   - Source IP address field containing the address of Sevr_IPv4 (192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
7. The appliance creates a translated IPv6 response packet with:
   - Destination IP address field = Client_IPv6 = 2001:DB8:5001::30
• Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits) = 2001:DB8:300::192.0.2.60

8. The appliance sends the translated IPv6 response to client CL1.

Limitations of Stateful NAT64

The following limitations apply to stateful NAT64:

• Translation of IPv4 options is not supported.
• Translation of IPv6 routing headers is not supported.
• Translation of hop-by-hop extension headers of IPv6 packets is not supported.
• Translation of ESP and EH headers of IPv6 packets is not supported.
• Translation of multicast packets is not supported.
• Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

Configuring Stateful NAT64

Creating the required entities for stateful NAT64 configuration on the Citrix ADC appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACL6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

CLI procedures

To add an ACL6 rule by using the CLI:

At the command prompt, type:

• add ns acl6 <acl6name> <acl6action> …

To add an IPSet and bind multiple IPs to it by using the CLI:

At the command prompt, type:

• add ipset <name>
• bind ipset <name> <IPAddress …>
To add a netprofile by using the CLI:

At the command prompt, type:

```
• add netprofile <name> -srcIP <IPaddress or IPset>
```

To add a NAT64 rule by using the CLI:

At the command prompt, type:

```
• add nat64 <name> <acl6name> -netProfile <string>
```

To add a NAT64 prefix by using the CLI:

At the command prompt, type:

```
set ipv6 -natprefix <ipv6_addr>
```

Example:

```
1 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:db8:5001::30
  Done

4 > apply acl6s
  Done

7 > add ip 192.0.2.100 255.255.255.0 -type SNIP
  Done

10 > add ip 192.0.2.102 255.255.255.0 -type SNIP
  Done

13 > add ipset IPset-1
  Done

16 > bind ipset IPset-1 192.0.2.100 192.0.2.102
  IPAddress "192.0.2.100" bound
  IPAddress "192.0.2.102" bound
  Done

21 > add netprofile Netprofile-1 -srcIP IPset-1
  Done

24 > add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
  Done
```
GUI procedures

To add a NAT64 rule by using the GUI:

Navigate to System > Network > Routes > NAT64, and a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

RNAT

January 25, 2019
Contributed by: C

In Reverse Network Address Translation (RNAT), the Citrix ADC appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a SNIP address as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

Note: The ephemeral port range for RNAT on the Citrix ADC appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.

- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the Citrix ADC appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:
1. Configure the ACL.
2. Configure RNAT to change the source IP address and Destination Port.
3. Apply the ACL.

The following diagram illustrates RNAT configured with an ACL.

Figure 1. RNAT with an ACL

You have the following basic choices for the type of NAT IP address:

- **Using a SNIP as the NAT IP Address.** When using a SNIP as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the a SNIP. Therefore, the SNIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the Citrix ADC can use a subnet IP address (SNIP) as the NAT IP address.

- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the Citrix ADC appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public Citrix ADC-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

This configuration is illustrated in the following diagram.

Figure 2. Using a Unique IP Address as the NAT IP Address

**Before you begin**

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the Citrix ADC appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule. This behavior does not apply when a unique NAT IP address is used.

- In a topology where the Citrix ADC appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see [Link Load Balancing](#).

**Configure RNAT**

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the GUI, all of the variations can be configured in the same dialog box, so there is only one procedure for GUI users.
**CLI procedures**

To create an RNAT entry by using the CLI:

At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

- `set rnat <IPAddress> <netmask>`
- `set rnat IPAddress <netMask>-natip <NATIPAddress>`
- `set rnat <aclname> [-redirectPort <port>]`
- `set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>`

Use the following command to verify the configuration:

- `show rnat`

**Examples:**

```
1 A network address as the condition and a MIP or SNIP as the NAT IP address:

  3 > set rnat 192.168.1.0 255.255.255.0
  4 Done

6 A network address as the condition and a unique IP address as the NAT IP address:

  8 > set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
  9 Done

11 If instead of a single NAT IP address you specify a range, RNAT entries are created with all the Citrix ADC-owned IP addresses, except the NSIP, that fall within the range specified:

  13 > set rnat 192.168.1.0 255.255.255.0 -natIP 10.102.29.[50-110]
  14 Done

16 An ACL as the condition and a MIP or SNIP as the NAT IP address:

  18 > set rnat acl1
  19 Done

21 An ACL as a condition and a unique IP address as the NAT IP address:
```
GUI procedures

To create an RNAT entry by using the GUI:

1. Navigate to System > Network > NATs, and then click the RNAT tab.
2. In the Action list, select Configure RNAT to create or modify an RNAT entry.

Monitor RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

The following table describes the statistics associated with RNAT and RNAT IP.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes received</td>
<td>Bytes received during RNAT sessions</td>
</tr>
<tr>
<td>Bytes sent</td>
<td>Bytes sent during RNAT sessions</td>
</tr>
<tr>
<td>Packets received</td>
<td>Packets received during RNAT sessions</td>
</tr>
<tr>
<td>Packets sent</td>
<td>Packets sent during RNAT sessions</td>
</tr>
<tr>
<td>Syn sent</td>
<td>Requests for connections sent during RNAT sessions</td>
</tr>
<tr>
<td>Current sessions</td>
<td>Currently active RNAT sessions</td>
</tr>
</tbody>
</table>

To view RNAT statistics by using the CLI:

At the command prompt, type:

- `stat nat`

Example:
Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the Citrix ADC owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address.** When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s.** When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of Citrix ADC owned SNIP6 and VIP6 addresses for an RNAT6 rule. The Citrix ADC appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.

- Do not specify any Citrix ADC owned SNIP6 or VIP6 address for an RNAT6 rule. The Citrix ADC appliance uses any one of the Citrix ADC owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

### Configure RNAT6

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

### Configure RNAT6

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

### Configure RNAT6

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

### Configure RNAT6

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

### Configure RNAT6

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.
CLI procedures

To create an RNAT6 rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- `add rnat6 <name> (<network> | (<acl6name> [-redirectPort <port>])))`
- `bind rnat6 <name> <natIP6>@ ...`
- `show rnat6`

To modify or remove an RNAT6 rule by using the CLI:

- To modify an RNAT6 rule whose condition is an ACL6, type the `set rnat6 <name>` command, followed by a new value for the `redirectPort` parameter.
- To remove an RNAT6 rule, type the `clear rnat6 <name>` command.
- `show rnat6`

GUI procedures

To configure an RNAT6 rule by using the GUI:

Navigate to `System > Network > NATs`, click the `RNAT6` tab, and add a new RNAT6 rule, or edit an existing rule.

Monitor RNAT6

You can display statistics related to the RNAT6 feature to monitor the performance or to troubleshoot problems related to RNAT6 feature. You can display a summary of statistics of the RNAT6 rules or of a particular RNAT6 rule. The statistical counters reflect events since the Citrix ADC appliance was last restarted. All these counters are reset to 0 when the Citrix ADC appliance is restarted.

The following lists some of the statistics counters associated with the RNAT6 feature:

- `Bytes received` - Total bytes received during RNAT6 sessions.
- `Bytes sent` - Total number of bytes sent during RNAT6 sessions.
- `Packets received` - Total number of packets received during RNAT6 sessions.
- `Packets sent` - Total number of packets sent during RNAT6 sessions.
- `Syn sent` - Total number of requests for connections sent during RNAT6 sessions
- `Current sessions` - Currently active RNAT6 sessions

To display a summarized statistics of all RNAT6 rules by using the CLI:

At the command prompt, type:

- `stat rnat6`
To display statistics for a specified RNAT6 rule by using the CLI:

At the command prompt, type:

- `stat rnat6 [rnat6 rule name]`

To display RNAT6 statistics by using the GUI:

Navigate to `System > Network > NATs`, click the `RNAT6` tab, and then click `Statistics`.

```
> stat rnat6

**Log Start Time and Connection Closure Reasons in RNAT Log Entries**

For diagnosing or troubleshooting problems related to RNAT, the Citrix ADC appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- Citrix ADC owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address
- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the Citrix ADC appliance for this RNAT session
- Total bytes received by the Citrix ADC appliance for this RNAT session
- Reason for closure of the RNAT session. The Citrix ADC appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - **TCP FIN.** The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - **TCP RST.** The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - **TIMEOUT.** The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

<table>
<thead>
<tr>

Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The Citrix ADC appliance now supports stateful connection failover for connections related to RNAT rules in a Citrix ADC High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary Citrix ADC appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client’s perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the connFailover (Connection Failover) parameter of that specific RNAT rule by using either CLI or GUI.

To enable connection failover for a RNAT rule by using the CLI:

At the command prompt, type:

- `set rnat <name> -connfailover (ENABLED | DISABLED)`
- `show rnat`

To enable connection failover for a RNAT rule by using the GUI:

1. Navigate to `System > Network > NATs`, and then click the `RNAT` tab.
2. Select `Connection Failover` while adding a new RNAT rule, or while editing an existing rule.
Removing RNAT Sessions

You can remove any unwanted or inefficient RNAT sessions from the Citrix ADC appliance. The appliance immediately releases resources (such as the port of the NAT IP address, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected RNAT sessions from the Citrix ADC appliance.

To clear all RNAT sessions by using the CLI:

At the command prompt, type:

```
• flush rnatsession
```

To clear selective RNAT sessions by using the CLI:

At the command prompt, type:

```
• flush rnatsession ((-network <ip_addr> -netmask <netmask>) | -natIP <ip_addr> | -aclname <string>)
```

To clear all or selective RNAT sessions by using the GUI:

1. Navigate to System > Network > **NATs, and then click the RNAT tab.
2. In the Actions Menu, click Flush RNAT Sessions to remove all or selective RNAT sessions (for example, removing RNAT sessions with a specific RNAT IP, or belonging to a specific Network or ACL based RNAT rule).

Sample Configurations:

<table>
<thead>
<tr>
<th></th>
<th>Clear all RNAT sessions existing on a Citrix ADC appliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; flush rnatsession</td>
</tr>
<tr>
<td>2</td>
<td>Done</td>
</tr>
<tr>
<td>3</td>
<td>Clear all RNAT sessions belonging to network based RNAT rules that has 203.0.113.0/24 network as the matching condition.</td>
</tr>
<tr>
<td>4</td>
<td>&gt; flush rnatsession -network 203.0.113.0 -netmask 255.255.255.0</td>
</tr>
<tr>
<td>5</td>
<td>Done</td>
</tr>
<tr>
<td>6</td>
<td>Clear all RNAT sessions with RNAT IP 192.0.2.90.</td>
</tr>
<tr>
<td>7</td>
<td>&gt; flush rnatsession -natIP 192.0.2.90</td>
</tr>
<tr>
<td>8</td>
<td>Done</td>
</tr>
</tbody>
</table>
Configuring Prefix-Based IPv6-IPv4 Translation

January 25, 2019

Contributed by:

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the Citrix ADC appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The Citrix ADC appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the Citrix ADC appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the Citrix ADC so that the IPv6-IPv4 translation is done by the Citrix ADC.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on Citrix ADC NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the CLI:

At the command prompt, type:
The Citrix ADC appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The Citrix ADC appliance supports IP prefix NAT for load balancing configurations of the following types: ANY, UDP, DNS, TCP, and HTTP.

**Use Case: Zonification of Clients for a Deployment of a Citrix ADC appliance and an Optimization Device**

IP prefix NAT is very useful in a deployment that includes a Citrix ADC appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located
client networks, which share the same network address. The Citrix ADC appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the Citrix ADC appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The Citrix ADC appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the Citrix ADC appliance, IP prefix NAT entities named natrule-1 and natrule-2 are configured for these two zones. Before the appliance forwards a packet from Z1, natrule-1 translates the last octet of the packet’s source IP address to 100. Similarly, for packets from Z2, natrule-2 translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the Citrix ADC appliance translates the source IP address of CL1-Z1’s packets to 100.0.2.30 and of CL1-Z2’s packets to 200.0.2.30. The optimization device to which the Citrix ADC appliance sends the translated packets is configured to use a packet’s source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

**Configuration Steps**

Configuring IP prefix NAT consists of the following steps:

- **Create a net profile and set the NAT Rule parameter of a net profile.** A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.

- **Bind the net profile to load balancing virtual servers or services.** A net profile with NAT rule setting can be bound to a virtual server or service of type ANY, UDP, DNS, TCP, and HTTP. After binding a net profile to a virtual server or service, the Citrix ADC appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The Citrix ADC then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line:

At the command prompt, type:

```plaintext
bind netProfile <name> (-natRule <ip_addr> <netmask> <rewriteIp>)
show netprofile <name>
```

To configure IP prefix NAT by using the GUI:
1. Navigate to System > Network > Net Profiles.

2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.
   - IP Address
   - Netmask
   - Rewrite IP

Sample configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the Citrix ADC appliance translates the last octet of the packet’s source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the Citrix ADC appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1  >  add netprofile PARTIAL-NAT-1
2   Done
3
4  >  bind netprofile PARTIAL-NAT-1 - natrule 192.0.0.0 255.0.0.0 100.0.0.0
5   Done
6
7  >  add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
8   Done
```

Static ARP

January 23, 2019

Contributed by: C

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.
To add a static ARP entry by using the CLI:

At the command prompt, type:

- `add arp -IPAddress <ip_addr> -mac <mac_addr> -ifnum <interface_name>`
- `show arp <IPAddress>`

**Example:**

```diff
1 > add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
2 Done
```

To remove a static ARP entry by using the CLI:

At the command prompt, type the `rm arp` command and the IP address.

To add a static ARP entry by using the GUI:

Navigate to **System > Network > ARP Table**, and add a static ARP entry.

**Specify a VLAN in a Static ARP Entry**

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The Citrix ADC appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don’t specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say Citrix ADC interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The Citrix ADC appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don’t specify a VLAN ID, the Citrix ADC appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a static ARP entry by using the CLI:

At the command prompt, type:

- `add arp -IPAddress <ip_addr> -mac <mac_addr> -ifnum <interface_name> [-vlan <positive_integer>]
- `show arp <IPAddress>`

**Example:**

```diff
```
Set the Timeout for Dynamic ARP Entries

January 23, 2019

Contributed by:
C

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time. You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the CLI:

At the command prompt, type:

- \texttt{set arpparam \texttt{-timeout} <positive\_integer>}
- \texttt{show arpparam}

Example:

```
1 > set arpparam -timeout 500
2 Done
```

To set the time-out for dynamic ARP entries to its default value by using the CLI:

At the command prompt, type:

- \texttt{unset arpparam}
- \texttt{show arpparam}

Example:

```
1 > unset arpparam
2 Done
```
To set the time-out for dynamic ARP entries by using the GUI:

Navigate to System > Network, in the Settings group, click Configure ARP Global Parameters, and set the ARP Table Entry Timeout parameter.

**Neighbor Discovery**

January 23, 2019

Contributed by: C

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

- **Router Discovery**: Enables a host to discover the local routers on an attached link and automatically configure a default router.

- **Prefix Discovery**: Enables the host to discover the network prefixes for local destinations.

  **Note**: The Citrix ADC appliance does not support Prefix Discovery.

- **Parameter Discovery**: Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.

- **Address Autoconfiguration**: Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The Citrix ADC does not support Address Autoconfiguration for Global IPv6 addresses.

- **Address Resolution**: Equivalent to ARP in IPv4, enables a node to resolve a neighboring node’s IPv6 address to its link-layer address.

- **Neighbor Unreachability Detection**: Enables a node to determine the reachability state of a neighbor.
**Configuration Steps**

Configuring neighbor discovery consists of the following tasks:

- Adding IPv6 neighbors
- (Optional) Removing IPv6 neighbors

**CLI procedures**

To add an IPv6 neighbor by using the CLI:

At the command prompt, type:

- `add nd6 <neighbor> <mac> <ifnum> [-vlan <integer>]`
- `sh nd6`

**Example:**

```
1 > add nd6 2001::1 00:04:23:be:3c:06 1/1 - vlan 1
2 Done
3
4 > show nd6
5 Neighbor      MAC-Address(Vlan, Interface)      State
6 ------ ---------------------------- -----  
7 1) ::1      00:d0:68:0b:58:da( 1, LO/1) REACHABLE
8 2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da( 1, LO/1) REACHABLE
9 3) 2001::1 00:04:23:be:3c:06( 1, 1/1) REACHABLE
10 Done
```

To remove a neighbor discovery entry by using the CLI:

At the command prompt, type:
Citrix ADC 12.1

- `rm nd6 <Neighbor> -vlan <VLANID>`

**Example:**

```
1  rm nd6 3ffe:100:100::1 -vlan 1
```

To remove all neighbor discovery entries by using the CLI:

At the command prompt, type:

- `clear nd6`

**GUI procedures**

To add an IPv6 neighbor by using the GUI:

Navigate to System > Network > IPv6 Neighbors, and add a new IPv6 neighbor.

To remove a neighbor discovery entry by using the GUI:

Navigate to System > Network > IPv6 Neighbors, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the GUI:

Navigate to System > Network > IPv6 Neighbors, and click Clear.

**IP Tunnels**

January 25, 2019

Contributed by:

C

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The Citrix ADC appliance implements IP Tunneling in the following ways:

- **Citrix ADC as an Encapsulator (Load Balancing with DSR Mode):** Consider an organization that has multiple data centers across different countries, where the Citrix ADC maybe at one
location and the back-end servers are located in a different country. In essence, the Citrix ADC and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this Citrix ADC, the packet sent from the source subnet is encapsulated by the Citrix ADC and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the Citrix ADC.

**Citrix ADC as a Decapsulator:** Consider an organization having multiple data centers each having Citrix ADCs and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another Citrix ADC. The Citrix ADC processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the Citrix ADC must be able to decapsulate the packet before sending it to the back-end servers. To enable the Citrix ADC to function as a decapsulator, a tunnel is added between the router and the Citrix ADC. When the encapsulated packet, with additional header information, reaches the Citrix ADC, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

The Citrix ADC can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

## Configure IP Tunnels

Configuring IP tunnels on a Citrix ADC appliance consists of creating IP tunnel entities. An IP tunnel entity specifies the local and remote tunnel end-point IP addresses and the protocol to be used for the IP tunnel.

**Note:** While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP address.

### CLI procedures

To create an IP tunnel by using the CLI:

At the command prompt type:

```
• add iptunnel <name> <remote> <remoteSubnetMask> <local> -type -protocol (ipoverip | GRE)
• show iptunnel
```

To remove an IP tunnel by using the CLI:

To remove an IP tunnel, type the `rm iptunnel` command and the name of the tunnel.

To create an IPv6 tunnel by using the CLI:
At the command prompt type:

- `add ip6tunnel <name> <remoteIp> <local>`
- `show ip6tunnel`

To remove an IPv6 tunnel by using the CLI:

To remove an IPv6 tunnel, type the `rm ip6tunnel` command and the name of the tunnel.

**GUI procedures**

To create an IP Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels**, add a new IP tunnel.

To create an IPv6 Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels > IPv6 Tunnels**, and add a new IPv6 tunnel.

**Customizing IP Tunnels Globally**

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the Citrix ADC appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

**CLI procedures**

To globally customize IP tunnels by using the CLI:

At the command prompt, type:

- `set ipTunnelParam -srcIP <sourceIPAddress> -srcIPRoundRobin (YES | NO) -dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>`
- `show ipTunnelParam`

**Example:**

```bash
1 > set iptunnelparam -srcIP 12.12.12.22 -dropFrag Yes -dropFragCpuThreshold 50
2   Done
3
4 > set iptunnelparam -srcIPRounRobin YES -dropFrag Yes -dropFragCpuThreshold 50
5   Done
```
To globally customize IPv6 tunnels by using the CLI:

At the command prompt, type:

- `set ip6tunnelparam -srcIP <IPv6Address> -srcIPRoundRobin (YES | NO) -dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>`

- `show ip6tunnelparam`

**GUI procedures**

To globally customize IP tunnels by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **IPv4 Tunnel Global Settings**.

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

To globally customize IPv6 tunnels by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

**GRE Payload Options in a GRE IP Tunnel**

For a configured GRE IP tunnel, the Citrix ADC appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between Citrix ADC appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a Citrix ADC appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPSec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

- **Ethernet with DOT1Q**. Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains information from the ARP and bridge table of the Citrix ADC appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

  - **Ethernet**. Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the
tunnel, the Citrix ADC can forward these packet to the specified VLAN. If the tunnel is set as a
next hop in a PBR rule, the Citrix ADC routes the packets that are received on the tunnel. The
encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the following format:

- **IP**: Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do
  not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next
  hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes
  or routes it. The encapsulated (GRE) packet sent from the Citrix ADC tunnel end point has the
  following format:

To drop Layer 2 headers of packets in a GRE IP tunnel by using the CLI:

- **add ipTunnel** `<name> <remote> <remoteSubnetMask> <local> [-protocol <GRE> [-vlan <positive_integer>]] [-grepayload <grepayload>] [-ipsecProfileName <string>]`
- **show ipTunnel** `<tunnelname>`

**Example:**

```plaintext
1 > add ipTunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 -protocol GRE -grepayload Ethernet -ipsecProfileName IPTUNNEL-IPSEC -1
2 Done
```

**IPv6 Traffic through GRE IPv4 Tunnels**

The Citrix ADC appliance supports transferring IPv6 traffic through an IPv4 GRE tunnel. This feature
can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4
infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through
which you want the Citrix ADC to send and receive IPv6 traffic. The source IPv6 address and destination
IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4
GRE tunnel.

**Note**: IPSec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the CLI:

At the command prompt, type:

- **add ipTunnel** `<name> <remote> <remoteSubnetMask> <local> -protocol GRE`
- **show ipTunnel** `<name>`

To associate a PBR6 rule with a GRE IPv4 tunnel by using the CLI:

- **add ns pbr6** `<pbrName> ALLOW -srcIPv6 <network-range> -dstIPv6 <network-range> -ipTunnel <tunnelName>`
• show pbr

Sample configuration

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these IPv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
1 > add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -
   protocol GRE
2   -ipsecProfileName None
3   Done
4 > add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8:
   :1:255 -destIPv6 = 1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4
```

Send Response Traffic Through an IP-IP Tunnel

You can configure a Citrix ADC appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another Citrix ADC or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the Citrix ADC appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the Citrix ADC appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

CLI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the CLI:

At the command prompt, type:
• **add ns pbr** `<pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel = <tunnel_name>`
• **apply ns pbrs**
• **show ns pbrs** `<pbr_name>`

To enable MAC-based forwarding by using the CLI:

At the command prompt, type:

• **enable ns mode MBF**
• **show ns mode**

**GUI procedures**

To create a PBR rule and associate the IP-IP tunnel to it by using the GUI:

1. Navigate to **System > Network > PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings** in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

**Sample configuration**

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two Citrix ADC appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, its routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

```
1 > add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99 - protocol IPIP
2
3 Done
```
Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

By default, the Citrix ADC appliance drops any packets if they contain any class E IPv4 address in the source IP or the destination IP fields. If your setup is using class E IPv4 addresses, you can configure the Citrix ADC appliance to process class E IPv4 packets.

Before you begin configuring a Citrix ADC appliance to process class E IPv4 packets, note the following points:

- Citrix ADC appliances do not support configuring any Citrix ADC owned IPv4 address (for example, SNIP and VIP) in the class E range. Citrix ADC appliances only support processing of class E IPv4 packets.
- A Citrix ADC appliance internally uses class E IPv4 addresses for the IPv6 feature. The Citrix ADC appliance does not support both features (processing class E IPv4 packets and IPv6 support).
working at the same time. The Citrix ADC appliance imposes a restriction to not enable the IPv6
feature when processing of class E IPv4 packets is enabled, and vice versa.

Configuration steps

Configuring a Citrix ADC appliance to process class E IPv4 packets consist of the task of enabling the
IPv4 Class E address clients (allowClassEIPv4) Layer 3 parameter.

CLI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the CLI:

At the command prompt, type:

```
set l3param -allowClassEIPv4 {ENABLED | DISABLED}
```

•

• show l3param

Sample Configuration:

```
1 > set l3param -allowClassEIPv4 ENABLED
2 Done
3 > sh l3param
4
5 Network L3 related Configuration Parameters
6  icmpgen_rate_threshold : 100
7  srcnat : ENABLED
8  override_rnat : DISABLED
9  drop_df_flag : DISABLED
10 .
11 .
12 .
13 .
14 .
15 .
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
GUI procedures

To configure the Citrix ADC appliance to process Class E IPv4 packets by using the GUI:

1. Navigate to System > Network, and then in the Settings section, click Configure Layer 3 Parameters.
2. Select IPv4 Class E address clients and click OK.

Interfaces

January 23, 2019

Contributed by:
C

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix ADC appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANS to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC (VMAC) address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. Citrix ADC appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a Citrix ADC deployment and configure interfaces, channels, VLANS, and bridge groups.
With MAC-based forwarding (MBF) enabled, when a request reaches the Citrix ADC appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the Citrix ADC is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the Citrix ADC caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the Citrix ADC appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the Citrix ADC initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see Load Balancing.

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:
- **When you configure link load balancing.** In this case, asymmetric traffic flows are desirable because of link costs.

- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the Citrix ADC and server.
  
  Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.

- **When firewall clustering is used.** Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the appliance uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the appliance uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the Citrix ADC looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the Citrix ADC requests the ARP entries.

To enable or disable MAC-based forwarding by using the CLI:

At the command prompt, type:

- `enable ns mode MBF`
- `disable ns mode MBF`

To enable or disable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure modes**.
2. Select or clear the **MAC-based forwarding** option.

**MAC based forwarding for a load balancing setup**

Some load balancing setups require that the Citrix ADC appliance bypasses the global MBF (if enabled) for these setups and instead use the route/ARP lookups for sending packets to the destination.

The MBF parameter of a net profile is used to enable or disable MBF for a specific load balancing configuration. MBF can be set for the client side as well as the server side of a load balancing configuration by binding net profiles (MBF enabled or disabled) to the virtual server and the services.

For example, if a net profile with MBF disabled is bound to the virtual server of a load balancing configuration, the Citrix ADC appliance bypasses the global MBF (if enabled) and instead use the route/ARP lookups for sending response packets to clients.
Before you begin

Before you begin configuring MBF for a load balancing configuration, note the following points:

- In a load balancing configuration, the client side (virtual server) and the server side (service/service groups) can have different MBF settings.
- A load balancing configuration inherits global MBF setting if MBF is not set explicitly in the net profiles bound to the virtual server and the services.
- In a load balancing configuration, server side (service) inherits client side MBF setting of net profile bound to the virtual server if no net profile is bound to the service.
- In a load balancing configuration with direct server return mode, client side inherits the MBF setting in the net profile bound to the service.
- In a content switching configuration, client side takes the MBF setting in the net profile bound to the content switching virtual server instead of from the target load balancing virtual server.

Limitations

Before you begin configuring MBF for a load balancing configuration, note the following limitations:

- MBF setting for load balancing configurations is not supported in a cluster setup.
- For a load balancing virtual server with MAC mode or L2Conn settings, MBF is enabled irrespective of the MBF setting in the bound net profile to the virtual server.
- The Citrix ADC appliance does not support setting MBF for load balancing monitors using net profile. In other words, the MBF setting of a net profile is not applied to the monitors to which the net profile is bound. The global MBF setting is applied to monitors irrespective of the MBF setting of the bound net profile.

Configure MBF for load balancing configuration

Configuring MBF for a load balancing configuration consists of the following tasks:

- Enable MBF parameter in a net profile.
- Bind the net profile to a load balancing virtual server or services.

To enable MBF in a net profile by using the CLI:

- To enable MBF while adding a net profile, at the command prompt, type:
  - `add netProfile <name> -MBF ( ENABLED | DISABLED )`
  - `show netprofile <name>`
- To enable MBF in an existing net profile, at the command prompt, type:
  - `set netProfile <name> -MBF ( ENABLED | DISABLED )`
  - `show netprofile <name>`
To enable MBF in a net profile by using GUI**

1. Navigate to System > Network > Net Profiles.
2. Enable the MBF parameter while adding or modifying a net profile.

```
1 In the following sample configuration, net profile NETPROFILE-MBF-LBVS has MBF enabled and is bound to load balancing virtual server LBVS-1. Also, net profile NETPROFILE-MBF-SVC has MBF enabled and is bound to a load balancing service SVC-1.

2 > add netprofile NETPROFILE-MBF-LBVS -MBF ENABLED
3 Done
4
5 > add netprofile NETPROFILE-MBF-SVC -MBF ENABLED
6 Done
7
8 > set lb vserver LBVS-1 -netprofile NETPROFILE-MBF-LBVS
9 Done
10
11 > set service SVC-1 -netprofile NETPROFILE-MBF-SVC
12 Done
13
14
15
16
17
```

**Configuring Network Interfaces**

January 25, 2019

Contributed by:

C

Network interfaces in the Citrix ADC appliance are numbered in <slot>/<port> notation. After configuring your interfaces, you should display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you might have to enable some interfaces and disable others. You
can reset an interface to renegotiate its settings. You can clear the accumulated statistics for an interface. To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Setting the Network Interface Parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

To set the network interface parameters by using the CLI:

At the command prompt, type:

```
• set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <positive_integer>][-bandwidthHigh <positive_integer>][-bandwidthNormal <positive_integer>]
• show interface [<id>]
```

Example:

```
1 > set interface 1/8 -duplex full
2  Done
```

To set the network interface parameters by using the GUI:

Navigate to System > Network > Interfaces, select the network interface that you want to modify (for example, 1/8), click Edit, and then set the parameters.

Enabling and Disabling Network Interfaces

By default, the network interfaces are enabled. You must disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause failover.

For more information about high availability, see High Availability.

To enable or disable a network interface by using the CLI:

At the command prompt, type:

```
• enable interface <interface_num>
• show interface <interface_num>
• disable interface <interface_num>
```
• show interface <interface_num>

Example:

```
1  > enable interface 1/8
2   Done
3  > show interface 1/8
4   Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
5      flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg, 802.1q>
6      MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
7      Requested: media UTP, speed AUTO, duplex FULL, fctl OFF,
8          throughput 0
9      RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
10     TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
11     NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
12   Done
```

To enable or disable a network interface by using the GUI:

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Enable or Disable.

**Resetting Network Interfaces**

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the CLI:

At the command prompt, type:

- reset interface <interface_num>
- show interface <interface_num>

**Example:**

```
1  > reset interface 1/8
2   Done
```

To reset a network interface by using the GUI:

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Reset Interface.
Monitoring a Network Interface

You can display network interface statistics to monitor parameters such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors, and use the information to check the health of the network interface. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the CLI:

At the command prompt, type:

- `stat interface <interface_num>`

**Example:**

```
1 > stat interface 1/8
2  Done
```

To clear a network interface's statistics by using the CLI:

At the command prompt, type:

- `clear interface <interface_num>`

**Example:**

```
1 > clear interface 1/8
2  Done
```

To display the statistics of an Interface by using the GUI:

Navigate to System > Network > Interfaces, select the network interface, and click Interface Statistics.

To clear a network interface's statistics by using the GUI:

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Clear Statistics.

Configuring Forwarding Session Rules
By default, the Citrix ADC appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the Citrix ADC. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address.** When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule.** When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix.** When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule.** When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the CLI:

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- `add forwardingSession <name> [network <netmask>] [-aclname <string>] -connfailover (ENABLED | DISABLED)
- `show forwardingSession`

**Example:**

```
1 A network address as the condition:
2  > add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
3  Done
4
5 An ACL as the condition:
6  > add forwardingSession fs-acl-1 acl1
7  Done
```
To configure an IPv4 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the CLI:

- At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:
  - add forwardingSession <name> [IPv6 prefix] | [-acl6name <string>]
  - show forwardingSession

Example:

```
1 An IPv6 prefix as the condition:
> add forwardingSession fsv6-pfx-1 3ffe::/64
  Done

2 An ACL6 rule as the condition:
> add forwardingSession fsv6-acl6-1 - acl6name ACL6-FS
  Done
```

To configure an IPv6 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

**Assigning an ACL rule to an Existing Forwarding Session Rule**

You can assign an ACL rule to a Network-address/IPv6-prefix based forwarding session rule, in which case it becomes an ACL based forwarding session rule. You can also change an existing ACL rule to another ACL rule in an ACL based forwarding session rule. After the existing related forwarding session entries (if any) have timed out, the rules start using the newly assigned ACL to identify IPv4/IPv6 traffic for which to create a forwarding-session entry.

To assign an extended ACL rule to an existing IPv4 forwarding session rule by using the CLI:

At the command prompt, type

- **set forwardingSession** <name> [-aclname <string>]
- **show forwardingSession** <name>
To assign an ACL6 rule to an existing IPv6 forwarding session rule by using the CLI:

At the command prompt, type

- **set forwardingSession** <name> [-acl6name <string>]
- **show forwardingSession** <name>

**Example:**

```
1 > add forwardingSession FS-1 -aclname ACL-9
2 Done
3
4 > add forwardingSession FS6-1 - acl6name ACL6-9
5 Done
```

**Disabling Steering for Forwarding Sessions on a Cluster Setup**

The default behavior of a Citrix ADC cluster is for the node that receives traffic (flow receiver) to direct the traffic to another node (flow processor), which processes the traffic. Directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

Steering can be an overhead for real-time processing or when the setup includes high-latency links. Steering for forwarding sessions can now be disabled so that the processing becomes local to the flow receiver. That is, the flow receiver becomes the flow processor.

**Before you begin**

Note the following points before configuring forwarding session rules in a cluster setup:

- You must configure linksets to be used for forwarding sessions.
- You must enable MAC Based Forwarding (MBF) on the cluster setup.

**Configuring Forwarding Session Rules in a Cluster Setup**

Disabling steering for forwarding session rules in a cluster setup can be done at the following two levels:

- **Specific forwarding session rule level.** Enable the Process Local parameter while adding a new forwarding session rule or editing an existing forwarding session rule.
- **Global level.** Enable the Process Local parameter while adding a new cluster instance or editing an existing cluster instance. The global setting takes precedence over the forwarding session rule setting.
CLI procedures

To disable steering for a forwarding session rule on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new forwarding session rule:
  - `add forwardingSession <name> [(<network> [<netmask>]) | -acl6name <string> | -aclname <string>] -processLocal ENABLED`
  - `show forwardingSession <name>`

- If reconfiguring an existing forwarding session rule:
  - `set forwardingSession <name> -processLocal ENABLED`
  - `show forwardingSession <name>`

To disable steering for all (global level) forwarding session rules on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new cluster instance:
  - `add cluster instance <clid> -processLocal Enabled`
  - `show cluster instance <clid>`

- If reconfiguring an existing cluster instance:
  - `set cluster instance <clid> -processLocal Enabled`
  - `show cluster instance <clid>`

Sample configuration:

Following are two examples of disabling steering at the forwarding session rule level, and an example of disabling steering at the global level.

```
1 An IPv4 forwarding session rule:
2  > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV4=1 10.102.105.51 255.255.255.255 -processLocal Enabled
3  Done
4
5 An IPv6 forwarding session rule:
6  > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV6=1 -acl6name ACL6-FWD-SESSN=1 -processLocal Enabled
7  Done
8
9 A cluster setup, with an instance ID 10, has steering disabled at global level:
10
11
12 © 1999-2018 Citrix Systems, Inc. All rights reserved.
```
GUI procedures

To disable steering for a forwarding session rule on a cluster setup by using the GUI:

Navigate to **System > Network > Forwarding Sessions**, select **Process Local** while adding a new forwarding session rule or editing an existing forwarding session rule.

To disable steering for all (global level) forwarding session rules on a cluster setup by using the GUI:

Navigate to **System > Cluster**, and select **Process Local** while adding a cluster configuration or modifying an existing cluster configuration.

2. Citrix ADC
3. Citrix ADC 12.1
4. Networking

Understanding VLANs

January 23, 2019

Contributed by:
C

A Citrix ADC appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The Citrix ADC then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The Citrix ADC supports the following types of VLANs:

- **Port-Based VLANs.** The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the Citrix ADC are members of VLAN 1.

  If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.
• **Default VLAN.** By default, the network interfaces on the Citrix ADC are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

• **Tagged VLANs.** 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the Citrix ADC) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the Citrix ADC connects must be on the same VLAN as the Citrix ADC network interface.

**Note:** This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

### Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

• **Ingress rules.** Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:

  - If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
  - If frame has a tag value equal to FFF, the frame is dropped.
  - If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.
• **Egress Rules.** The following egress rules are applied:
  
  – If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
  – During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the Citrix ADC.
  – A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

**VLANs and Packet Forwarding on the Citrix ADC**

The forwarding process on the Citrix ADC appliance is similar to that on any standard switch. However, the Citrix ADC performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

• Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
• Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the Citrix ADC. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the Citrix ADC are processed at the upper layers.
• All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
• A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
• If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the Citrix ADC supports prefix-based VLANs.
Configuring a VLAN

January 23, 2019
Contributed by: C

You can implement VLANs in the following environments:
- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the Citrix ADC. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the Citrix ADC to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other Citrix ADC appliances. The Citrix ADC forwards packets between configured IP subnets (VLANs).

When you configure the Citrix ADC, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the Citrix ADC appliance.

Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the Citrix ADC appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.
The correct VLAN configuration is implemented automatically when the configuration is synchronized between the Citrix ADC appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other Citrix ADC appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

CLI procedures

To create a VLAN by using the CLI:

At the command prompt, type:

• add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED|DISABLED)]
• sh vlan <id>

Example:

```
1 > add vlan 2 -aliasName “Network A”  Done
```

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

• bind vlan <id> -ifnum <slot/port>
• sh vlan <id>

Example:

```
1 > bind vlan 2 -ifnum 1/8 Done
```

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

• bind vlan <id> -IPAddress <IPAddress> <netMask>
• sh vlan <id>

Example:
To remove a VLAN by using the CLI:

At the command prompt, type:

- `rm vlan <id>`

**GUI procedures**

To configure a VLAN by using the GUI:

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

**Monitoring VLANs**

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the CLI:

At the command prompt, type:

- `stat vlan <vlanID>`

**Example:**

```
1  stat vlan 2
```

To view the statistics of a VLAN by using the GUI:

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.
Configuring VLANS on a Single Subnet

January 25, 2019
Contributed by: C

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the Citrix ADC and the servers is Router 1.
2. Layer 2 mode must be enabled on the Citrix ADC for the Citrix ADC to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the Citrix ADC appliance.

To configure a VLAN on a single subnet, follow the procedures described in Configuring a VLAN.

1. 
2. Citrix ADC
3. Citrix ADC 12.1
4. Networking

Configuring VLANS on Multiple Subnets

January 25, 2019
Contributed by: C

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN

To configure a single VLAN across multiple subnets, perform the following tasks:

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see Packet forwarding modes.
2. Add a VIP address. For the procedure to add a VIP address, see Configuring and Managing Virtual IP Addresses (VIPs).
3. Configure RNAT rule. For the procedure to configure the RNAT ID, see Configuring RNAT.

1. Citrix ADC
2. Citrix ADC 12.1
3. Networking

Configuring Multiple Untagged VLANs across Multiple Subnets

January 25, 2019
Contributed by: C

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

For procedures on these tasks, see Configuring a VLAN.

1. Citrix ADC
2. Citrix ADC 12.1
3. Networking

Configuring Multiple VLANs with 802.1q Tagging

January 25, 2019
Contributed by: C

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.
Figure 1. Multiple VLANs with IEEE 802.1q Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the Citrix ADC to VLAN 2 as an untagged network interface.
3. Bind the IP address and netmask to VLAN 2.
4. Add VLAN 3.
5. Bind the 1/2 network interface of the Citrix ADC to VLAN 3 as a tagged network interface.
6. Bind the IP address and netmask to VLAN 3.

For procedures on these tasks, see Configuring a VLAN.

Associate an IP Subnet with a Citrix ADC Interface by Using VLANs

January 25, 2019
Contributed by: C

By default, a Citrix ADC appliance does not provide any differentiation between network interfaces. All network traffic is transmitted on all interfaces. The appliance functions more like a network hub than a switch. This can lead to Layer 3 network loops where duplicated traffic is transmitted on multiple interfaces.

In such scenarios, depending on network design, it is possible that a request could be transmitted on one interface and the corresponding response is received on a different interface.

For example, a SYN packet sent on one interface and the SYN-ACK response received on a different interface can result in a failed connection, as the appliance expects to receive the SYN-ACK on the same interface that sent the original SYN packet.

To resolve such issues, the appliance can use internal or external VLANs, to associate specific subnets with interfaces.

**Before you begin**

Before you begin associating an IP Subnet with a Citrix ADC interface by using VLANs, note the following points:
• The network connectivity might be accidentally lost when associating a VLAN to the subnet or interface that is currently being used to access the Citrix ADC GUI or command line interface. Therefore, in such scenarios, it is highly recommended that the change is made by accessing the command line interface through the serial console of a physical Citrix ADC appliance or through the virtual serial console of a Citrix ADC VPX.

• Citrix ADC management interfaces lack certain hardware optimization features which makes them less desirable for use with production data traffic. As such, it is recommended that the Citrix ADC be configured to only use the management interfaces for management (NSIP) traffic. In the default configuration, there is no logical differentiation between the management interfaces and data interfaces on a hardware NetScaler. In order to accomplish this goal, it is recommended that the NSIP be on a separate VLAN from data traffic, which allows management traffic to be on a separate interface.

Although the concept is the same, to change the VLAN associations of the subnet that contains the NSIP address, you must configure NSVLAN instead of the below instructions. Such changes will also require a reboot of the Citrix ADC in order to take effect. For more information, see Configuring NSVLAN.

• On Citrix ADC SDX, it is highly recommended that the NSIP of each instance be on the same subnet and VLAN as the SDX’s SVM (Management Service GUI) and XenServer. The SVM communicates with instances via the network. If the SVM, XenServer, and instances are not on the same VLAN and subnet, management traffic must flow outside of the SDX. In this situation, network issues can cause Instance state to show up as yellow or red and can prevent the management and configuration changes of the Citrix ADC instances.

**Configuration Steps**

Associate an IP subnet with a Citrix ADC Interface consists of the following tasks:

**Add a VLAN.** While adding a VLAN, if you are tagging the VLAN, then you must select a VLAN number that is defined in the network switch for the associated switch port. If the VLAN is untagged and is internal to the appliance, then it is recommended that you select the VLAN number that is available in the switch configuration for easy reference.

**Bind an interface to the VLAN.** While binding, if you are using Link Aggregation, associate the VLAN with the LA channel (for example, LA/1) instead of the physical interface. The VLAN must be associated with only one network interface.

If you want to tag the traffic on the interface, use the tagged (Tag) option. Else, the traffic leaves the appliance untagged and is associated with the native VLAN of the switch port.

**Bind an IP address to the VLAN.** While binding, if you bind more than one IP address from the same subnet, an error occurs. When an IP address is associated with a VLAN, all IP addresses in that subnet
are automatically associated with the VLAN.

**CLI procedures**

To add a VLAN by using the CLI:

At the command prompt, type:

- `add vlan <id>`
- `sh vlan <id>`

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -ifnum <slot/port>`
- `sh vlan <id>`

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -IPAddress <IPAddress> <netMask>`
- `sh vlan <id>`

**Example:**

```
1 > add vlan 100
2
3 > bind vlan 100 -ifnum 1/1
4
5 > bind vlan 100 - IPAddress 10.0.1.0 255.255.255.0
```

**GUI procedures**

To configure a VLAN by using the GUI:

1. Navigate to **System > Network > VLANS**, add a new VLAN.

2. To bind a network interface to a VLAN, under **Interface Bindings**, select the **Active** option corresponding to the interface that you want to bind to the VLAN.

3. To bind an IP address to a VLAN, under **IP Bindings**, select the **Active** option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The **Type** column displays the IP address type for each IP address in the **IP Address** column.
NSVLAN is a VLAN to which the Citrix ADC management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the Citrix ADC appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the Citrix ADC IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface. If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN1, restoring the default NSVLAN.

To configure NSVLAN by using the CLI:
At the command prompt, type:

- set ns config -nsvlan <positive_integer> -ifnum <interface_name> … [-tagged (YES|NO)]
- show ns config

Note: The configuration takes effect after the Citrix ADC appliance is rebooted.

Example:

```bash
1 > set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
2   Done
3
4 > save config
5   Done
```

To restore the default NSVLAN configuration by using the CLI:
At the command prompt, type:

- unset ns config -nsvlan
- show ns config

Example:
To configure NSVLAN by using the GUI:

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

**Setting the MTU on the NSVLAN**

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throughput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- `set vlan <id> -mtu <positive_integer>`
- `show vlan <id>`

To set the MTU of the NSVLAN by using the GUI:

Navigate to System > Network > VLANs, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

**Sample configuration:**

In the following sample configuration, VLAN 100 is the NSVLAN.

```plaintext
> unset ns config -nsvlan
Done

To configure NSVLAN by using the GUI:

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

**Setting the MTU on the NSVLAN**

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throughput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- `set vlan <id> -mtu <positive_integer>`
- `show vlan <id>`

To set the MTU of the NSVLAN by using the GUI:

Navigate to System > Network > VLANs, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

**Sample configuration:**

In the following sample configuration, VLAN 100 is the NSVLAN.

```plaintext
> set ns config -nsvlan 100 -ifnum 1/1 -tagged no
Warning: The configuration must be saved and the system rebooted for these settings to take effect
> set vlan 100 -mtu 1600
Done
> sh vlan
1) VLAN ID: 1
   Link-local IPv6 addr:
   fe80::947b:52ff:fead:12d5/64
   Interfaces : 1/2 LO/1
2) VLAN ID: 100 VLAN Alias Name:
```
Citrix ADC accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the Citrix ADC appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the Citrix ADC appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and sends tagged packets related to the specified VLANs without the need for explicitly configuring these VLANs on the appliance.

Points to Consider before Configuring Allowed VLAN List

Consider the following points before configuring allowed VLAN list:
In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.

The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.

A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.

The Citrix ADC appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see Redundant Interface Set.

Allowed VLAN list is not supported on a Citrix ADC cluster configuration.

The Citrix ADC appliance does not support allowed VLAN list for Bridge groups.

The Citrix ADC appliance does not support allowed VLAN list for VXLANs.

**Configuring Allowed VLAN List**

To configure allowed VLAN list by using the CLI:

At the command prompt, type:

- `set interface <id> -trunkmode (ON|OFF) -trunkAllowedVlan <int[-int]> …`
- `show interface <id>`

To configure allowed VLAN list by using the GUI:

Navigate to **System > Network > Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

**Sample Configuration:**

In the following sample configuration, VLANS in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

```
> set int 1/2 -trunkmode on -trunkallowedVlan 100-120 190-200 300-330
Done
> sh int 1/2
1) Interface 1/2 (Gig Ethernet 10/100/1000 MBits) #6
   flags=0xc020
   <ENABLED, UP, UP, AUTONEG OFF, HEARTBEAT, 802.1q, trunkmode>
   Trunk Allowed Vlans: 100-120 190-200 300-330
```
Configuring Bridge Groups

January 23, 2019

Contributed by: C

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANs can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the Citrix ADC appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The Citrix ADC accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bridge Group feature and Bridge BPDU mode cannot work together.</td>
</tr>
</tbody>
</table>

To add a bridge group and bind VLANs by using the CLI:

At the command prompt, type:

- `add bridgegroup <id> [-ipv6DynamicRouting ( ENABLED | DISABLED )]`
- `bind bridgegroup <id> -vlan <positive_integer>`
To add a bridge group by using the CLI:

At the command prompt, type:

- `show bridgegroup <id>`

**Example:**

```
1 > add bridgegroup 12
2  Done
```

To remove a bridge group by using the CLI:

At the command prompt, type:

- `rm bridgegroup <id>`

**Example:**

```
1  rm bridgegroup 12
```

To configure a bridge group by using the GUI:

Navigate to **System > Network > Bridge Groups**, add a new bridge group, or edit an existing bridge group.

### Configuring VMACs

January 25, 2019

Contributed by: C

The primary and secondary nodes in a high availability (HA) setup share the Virtual MAC address (VMAC) floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages.
Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a VMAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a VMAC, see Configuring Virtual MAC Addresses.

1. Citrix ADC
2. Citrix ADC 12.1
3. Networking

### Configuring Link Aggregation

January 25, 2019

Contributed by: C

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the Citrix ADC appliance and other connected devices. An aggregated link is also referred to as a “channel.”

You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.
Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

CLI procedures

To create a link aggregation channel by using the CLI:

At the command prompt, type:

• add channel <id> [-ifnum <interfaceName> …] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )][-tagall ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
  • show channel

Example:

  1 > add channel LA/1 -ifnum 1/8
  2 Done

To bind an interface to or unbind an interface from an existing link aggregation channel by using the CLI:

At the command prompt, type one of the following commands:

  • bind channel <id> <interfaceName>
  • unbind channel <id> <interfaceName>

Example:

  1 bind channel LA/1 1/8

To modify a link aggregation channel by using the CLI:

At the command prompt, type the set channel command, the channel ID, and the parameters to be changed, with their new values.

To remove a link aggregation channel by using the CLI:

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

• rm channel <id>
Example:

```
1  > rm channel LA/1
2   Done
```

GUI procedures

To configure a link aggregation channel by using the GUI:

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the GUI:

```
Important:
When a channel is removed, the network interfaces bound to it induce network loops that de-
crease network performance. You must disable the network interfaces before you remove the
channel.
```

Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation
information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on net-
work interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for mod-
ifying link aggregation channels than you do for creating link aggregation channels. To remove a chan-
nel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchro-
nized.

Configuring the LACP System Priority

The LACP system priority determines which peer device of an LACP LA channel can have control over
the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the
value, the higher the priority.

To configure the LACP system priority by using the CLI:

At the command prompt, type the following commands to set the priority for a standalone appliance
and verify the configuration:
To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- `set lacp -sysPriority <positive_integer>`
- `show lacp`

**Example:**
```
1 set lacp -sysPriority 50
```

To configure the LACP system priority by using the GUI:

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

### Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

**Note:**

- When enabling LACP on a network interface, you must specify the LACP Key.
- By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the CLI:

At the command prompt, type:

- `set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT )]`
- `show interface [<id>]`

To create an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.
Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel by using the CLI:

At the command prompt, type:

- set channel <id> [-ifnum <interfaceName> …] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer>] [-bandwidthNormal <positive_integer>]
- show channel

Example:

```
1 > set channel LA/3 -state ENABLED -speed 10000
2 Done
```

To modify an LACP channel by using the GUI:

Navigate to System > Network > Channels, and modify an existing LACP channel.

Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the CLI:

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

To remove an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

Link Redundancy using LACP channels

Link Redundancy using LACP channels enables the Citrix ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.
A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a Citrix ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the lrMinThroughput parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the lrMinThroughput value, link failover occurs and a standby subchannel becomes active.

If you unset the lrMinThroughput parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

Example

Consider an example of link redundancy configured between Citrix ADC NS1 and switches SW1 and SW2.

NS1 is connected to network device NW-A through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.

When the lrMinThroughput parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

Link Redundancy using LACP channels in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (lrMinThroughput parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the lrMinThroughput parameter.
The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the lrMinThroughput parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels’ maximum supported throughput meet the lrMinThroughput parameter value.
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has Citrix ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.

Following are the LACP-parameter settings in this example:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throughput</td>
<td>2000</td>
</tr>
<tr>
<td>lrMinThroughput</td>
<td>2000</td>
</tr>
</tbody>
</table>

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2’s maximum supported throughput also falls below the lrMinThroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:
Configure Link Redundancy using LACP channels

To configure link redundancy for a LACP channel by using the CLI:

At the command prompt, type the following commands to configure the channel and verify the configuration:

- `set channel <id> -lrMinThroughput <positive_integer>`
- `show channel`

**Example:**

```
1 > set channel la/1 -lrMinThroughput 2000
2 Done
3 > set channel la/2 -throughput 2000 -lrMinThroughput 2000
4 Done
```

To configure link redundancy for a LACP channel by using GUI

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

Redundant Interface Set

January 23, 2019

Contributed by: C

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the Citrix ADC appliance and a peer device by providing backup links between them.
Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.

In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

**Note**

Redundant Interface Set was formerly known as ‘NIC bundling’ when first introduced in 10.5 release.

### How Redundant Interface Set Works

For a redundant interface set, the Citrix ADC appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface’s own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority.** This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.

- **Binding order of the member interfaces.** If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.
Points to Consider for Configuring Redundant Interface Sets

Consider the following points before you configure a redundant interface set:

- In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.
- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- You can configure a maximum of four redundant interface sets on a Citrix ADC appliance.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a link aggregate (LA) channel.
- LA channels cannot be bound to a redundant interface set.
- Redundant interface sets cannot be bound to an LA channel.
- In a cluster setup:
  - Redundant interface sets cannot be bound to a cluster link aggregation.
  - A link redundant set is specified in N/LR/X notation (for example, 1/LR/3). Where:
    - N is the ID of the cluster node on which the redundant interface set is to be created.
    - X is a link-redundant set identifier on a cluster node. X can range from 1-4.
  - A cluster link aggregation cannot be bound to a redundant interface set.
  - A redundant interface set can include only the interfaces of the node to which the redundant interface set belongs.
  - An Existing elink redundancy set configuration on a standalone appliance automatically changes to cluster notation (N/LR/X) after the appliance is added to a cluster setup.

Configuration Steps

Configuring redundant interface set on a Citrix ADC appliance consists of the following tasks:

- **Create a redundant interface set.** Use the channel command operation for creating a redundant interface set.
  
  In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.
  
  In a cluster setup, a link redundant set is specified in N/LR/X (for example, 1/LR/3), where: N is the ID of the cluster node on which the redundant interface set is to be created, X is link redundant set identifier on a cluster node. X can range from 1-4.

- **Bind interfaces to the redundant interface set.** Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.
• (Optional) **Set a redundant interface priority on the member interface.** Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the CLI:

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the CLI:

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the CLI:

At the command prompt:

- set interface <ID> -lrsetpriority <positive_integer>
- show interface <ID>

**Sample configuration 1:**

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set LR/1.

```plaintext
1 > add channel lr/1
2 Done
3 > bind channel lr/1 1/1 1/2 1/3 1/4
4 Done
5 > show channel
6 1) Interface LR/1 (Link Redundant) #23
7     flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
8     MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
9     Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
10        throughput 0
11     Actual: throughput 1000
12     LLDP Mode: NONE,
13     RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
14     TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
15     NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
16     Bandwidth thresholds are not set.
```
Sample configuration 2:

In the following example, redundant interface priority of the member interface 1/4 is set to 100, which is lower than the set redundant interface priority of all the other member interfaces of LR/1.

Output of the show channel command displays that the interface 1/4 is the current active interface for the redundant interface set LR/1.

```
> set interface 1/4 -lrsetPriority 100
Done
> show channel
 1) Interface LR/1 (Link Redundant) #23
    flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
    MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
    Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
      throughput 0
    Actual: throughput 1000
    LLDP Mode: NONE,
    RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
    TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
    NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
    Bandwidth thresholds are not set.
  1/1: UTP-1000-FULL-OFF  Active Member
       UP 0h14m06s  LR
  1/2: UTP-1000-FULL-OFF  Active Member
       UP 0h14m06s  LR
  1/3: UTP-1000-FULL-OFF  Active Member
       UP 0h14m06s  LR
  1/4: UTP-1000-FULL-OFF  Active Member
       UP 0h14m06s  LR
```

Sample configuration 3:

Consider a cluster setup of four nodes N1, N2, N3, and N4. In this example, redundant interface set 1/LR/3 is created on node N1, and interfaces 1/1/1, 1/1/2, and 1/1/3 are bound to it. The redundant
interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command indicates that interface 1/1/1 is the current active interface for redundant interface set 1/LR/3.

```
> add channel 1/LR/3
Done
> bind channel 1/LR/3 1/1/1 1/1/2 1/1/3
Done
> show channel
  1) Interface 1/LR/3 (Link Redundant) #14
    flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
    MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
    Requested: media NONE, speed AUTO, duplex NONE, fctl OFF, throughput 0
    Actual: throughput 1000
    LLDP Mode: NONE,
    RX: Pkts(66) Bytes(4406) Errs(0) Drops(82) Stalls(0)
    TX: Pkts(55) Bytes(2626) Errs(0) Drops(145) Stalls(0)
    NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted (0)
    Bandwidth thresholds are not set.
    1/1/1: UTP-1000-FULL-OFF UP 0h14m06s LR Active Member
    1/1/2: UTP-1000-FULL-OFF UP 0h14m06s LR Inactive Member
    1/1/3: UTP-1000-FULL-OFF UP 0h14m06s LR Inactive Member
```

**Binding an SNIP address to an Interface**

January 25, 2019

Contributed by:
You can now bind a Citrix ADC owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the Citrix ADC appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.

The following tables describe the example settings for the scenario:

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNIP addresses on NS1</td>
<td>SNIP2 (for reference purpose only)</td>
<td>10.10.10.2</td>
</tr>
<tr>
<td></td>
<td>SNIP3 (for reference purpose only)</td>
<td>10.10.10.3</td>
</tr>
<tr>
<td></td>
<td>SNIP4 (for reference purpose only)</td>
<td>10.10.10.4</td>
</tr>
<tr>
<td></td>
<td>SNIP5 (for reference purpose only)</td>
<td>10.10.10.5</td>
</tr>
<tr>
<td>LLB virtual server on NS1</td>
<td>LLB_VSERVER1</td>
<td>-</td>
</tr>
<tr>
<td>Transparent monitor on NS1</td>
<td>TRANS_MON</td>
<td>-</td>
</tr>
<tr>
<td>LLB services on NS1</td>
<td>LLB_SVC2</td>
<td>10.10.10.240</td>
</tr>
<tr>
<td></td>
<td>LLB_SVC3</td>
<td>10.10.10.120</td>
</tr>
<tr>
<td></td>
<td>LLB_SVC4</td>
<td>10.10.10.60</td>
</tr>
<tr>
<td></td>
<td>LLB_SVC5</td>
<td>10.10.10.30</td>
</tr>
<tr>
<td>MAC address of interface 1/2 on NS1</td>
<td>NS_MAC_2 (for reference purpose only)</td>
<td>00:e0:ed:0f:bc:e0</td>
</tr>
<tr>
<td>MAC address of interface 1/3 on NS1</td>
<td>NS_MAC_3 (for reference purpose only)</td>
<td>00:e0:ed:0f:bc:df</td>
</tr>
<tr>
<td>MAC address of interface 1/4 on NS1</td>
<td>NS_MAC_4 (for reference purpose only)</td>
<td>00:e0:ed:0f:bc:de</td>
</tr>
<tr>
<td>MAC address of interface 1/5 on NS1</td>
<td>NS_MAC_5 (for reference purpose only)</td>
<td>00:e0:ed:1c:89:53</td>
</tr>
<tr>
<td>IP address of Router R1</td>
<td>Router_IP (for reference purpose only)</td>
<td>10.10.10.1</td>
</tr>
</tbody>
</table>
To configure the example settings:

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see Configuring Subnet IP Addresses (SNIPs).

   CLI example:

   ```
   1 > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
   2 Done
   3 > add ns ip 10.10.10.3 255.255.255.128 - type SNIP
   4 Done
   5 > add ns ip 10.10.10.4 255.255.255.192 - type SNIP
   6 Done
   7 > add ns ip 10.10.10.5 255.255.255.224 - type SNIP
   8 Done
   ```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see Set up basic load balancing.

   CLI example:

   ```
   1 > add service LLB_SVC2 10.10.10.240 any *
   2 Done
   3 > add service LLB_SVC3 10.10.10.120 any *
   4 Done
   5 > add service LLB_SVC4 10.10.10.60 any *
   6 Done
   7 > add service LLB_SVC5 10.10.10.30 any *
   8 Done
   ```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see Configure monitors in a load balancing setup.

   CLI example:

   ```
   1 > add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
   2 Done
   ```
4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see Configuring a Basic LLB Setup.

**CLI example:**

```bash
1 > add lb vserver LLB_VSERVER1 any
2 Done
3 > set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
4 Done
5 > bind lb vserver LLB_VSERVER1 LLB_SVC2
6 Done
7 > bind lb vserver LLB_VSERVER1 LLB_SVC2
8 Done
9 > bind lb vserver LLB_VSERVER1 LLB_SVC2
10 Done
11 > bind lb vserver LLB_VSERVER1 LLB_SVC2
12 Done
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see Configuring a Basic LLB Setup.

**CLI example:**

```bash
1 > add lb route 0.0.0.0 0.0.0.0 LLB_VSERVER1
2 Done
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see Configuring Static ARP.

**CLI example:**

```bash
1 > add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum 1/2
2 Done
3 > add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum 1/3
```
7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see Configuring Static ARP.

**CLI example:**

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
Done
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
Done
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
Done
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
Done
```
• set l2param -bridgeagetimeout <positive_integer>
• show l2param

Example:

```
1 > set l2param -bridgeagetimeout 90
2   Done
```

To view the statistics of a bridge table by using the CLI:

At the command prompt, type:

• stat bridge

To set the aging time of bridge table entries by using the GUI:

Navigate to System > Network. On the Network page, in the Settings section, click Configure Layer2 Parameters and set the Timeout Value For The Bridge Table Entries (seconds) parameter.

To view the statistics of a bridge table by using the GUI:

Navigate to System > Network > Bridge Table, select the MAC address, and click Statistics.

**Citrix ADC Appliances in Active-Active Mode Using VRRP**

January 25, 2019

Contributed by: C

An active-active deployment, in addition to preventing downtime, makes efficient use of all the Citrix ADC appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all Citrix ADC appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

The active VIP is called the master VIP, and the corresponding VIPs on the other Citrix ADC appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the Citrix ADC appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.
Citrix ADC appliances in active-active mode can be configured so that no Citrix ADC is idle. In this configuration, different sets of VIPs are active on each Citrix ADC. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration

The Citrix ADC appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the VMAC (for example VMAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with VMAC1 and VIP1.
6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2.
8. S2 replies to the SNIP or MIP on the Citrix ADC.
9. NS1 sends S2’s reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the Citrix ADC appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, VMAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for VMAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

**Health Tracking**

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.
For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If all virtual servers are UP, then EP = BP. If all virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

**Note:** If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

**Preemption**

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

**Sharing**

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure **An Active-Active Configuration** VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

January 23, 2019
Contributed by:
C

On each Citrix ADC appliance that you want to deploy in active-active mode, you must add a Virtual MAC (VMAC) and bind the VMAC to a VIP. The VMAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each Citrix ADC and bound to VIP 10.102.29.5 on each Citrix ADC. When you bind a VMAC to a VIP, the appliance sends VRRP advertisements to each VLAN that is bound to that VIP. The VMAC can be shared by different VIPs configured on the same Citrix ADC.

Configuring IPv4 Active-Active Mode

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:

- **Add a VMAC address.** Add a VMAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.

- **Add a VIP address and associate the VMAC's VRID.** Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and preemption) are bound to this VIP address.

  **Note:** The same VIP address must be added to all the other Citrix ADC appliances.

To add a VMAC address by using the CLI

At the command prompt, type:

```
add vrID <id> [-priority <positive_integer>] [-preemption (ENABLED|DISABLED)] [-sharing (ENABLED|DISABLED)] [-tracking <tracking>]
```

```
show vrID
```

To add a VIP address by using the CLI:

At the command prompt, type:

```
add ns ip <IPv4Address> -type VIP -vrid <value>
```

```
show ns ip
```

To configure a VMAC by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC** tab, add a new VMAC, or edit an existing VMAC.
2. Set the following parameters:
   • Virtual Router ID
   • Priority
   • Tracking
   • Preemption
   • Sharing

To configure a VIP address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

**Sample Configuration:**

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a VMAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100). 

```
1 Settings on NS1
2   > add vrid 10 - Priority 100 - Preemption Enabled - sharing Enabled
3       Done
4
5   > add ns ip 203.0.113.10 - type VIP - vrid 10
6       Done
7
8 Settings on NS2
9
10   > add vrid 30 - Priority 200 - Preemption Enabled - sharing Enabled
11       Done
12
13   > add ns ip 2001:db8::5001 - type VIP - vrid 30
14       Done
```

**Configuring IPv6 Active-Active Mode**

Perform the following tasks on each of the Citrix ADC appliances to be included in the active-active configuration:
• **Add a VMAC6 address.** Add a VMAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.

• **Add a VIP6 address.** Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created VMAC6. The attributes of the VMAC6 (for example, priority and preemption) are bound to this VIP6 address.

  **Note:** The same VIP6 address must be added to all the other Citrix ADC appliances.

To add a VMAC6 address by using the CLI:

At the command prompt, type:

```
add vrID6 <id> [-priority <positive_integer>] [-preemption { ENABLED | DISABLED }] [-sharing { ENABLED | DISABLED }]
```

To add a VIP6 address by using the CLI:

At the command prompt, type:

```
add ns ip6 <IPv6Address> -type VIP -vrId <value>
```

To configure a VMAC6 by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC6** tab, add a new VMAC6, or edit an existing VMAC6.

2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Preemption
   - Sharing

To configure a VIP6 address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.

2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

**Sample Configuration:**

The following sample configuration is for deploying Citrix ADC appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a VMAC6 address. 2001:db8::5001 is master on NS2, because it’s priority (200) on NS2 is higher than on NS1 (100).

**Configuring Send to Master**

January 25, 2019

Contributed by: C

Usually, the traffic destined to a VIP reaches the Citrix ADC appliance on which the VIP is active, because an ARP request with the VIP and a VMAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a Citrix ADC appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

To enable send to master by using the CLI:

At the command prompt, type:
Citrix ADC 12.1

**Example:**

```
1 > set vrIDParam -sendToMaster ENABLED
2 Done
```

To enable send to master by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. Select the **Send to Master** option.

---

**Configuring VRRP Communication Intervals**

January 25, 2019

Contributed by: C

In an active-active deployment, all Citrix ADC nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval.** Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval.** Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the CLI:

At the command prompt, type:
• set vrIDParam [-helloInterval <msecs>] [-deadInterval <secs>]
• sh vrIDParam

**Example:**

```
1 > set vrIDParam -helloInterval 500 -deadInterval 2
2 Done
```

To configure VRRP communication intervals by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. In **Configure Virtual Router Parameter**, set the **Hello Interval** and **Dead Interval** parameters.
3. Click **OK**.

**Example 1: Nodes with the Same VRRP Dead Intervals**

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes. The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn, apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node. Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: [VRRP interval example 1 settings](#).

The execution flow is as follows:

1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.
2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master) because its VRID priority (60) is higher than that of VIP1 of NS2 (30).
Example 2: Nodes with Different VRRP Dead Intervals

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: VRRP interval example 2 settings.

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2’s dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3’s larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

Example 3: Nodes with Different Dead Intervals and Preemption Enabled

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example: VRRP interval example 3 settings.

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2’s set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

Configuring Health Tracking based on Interface State

January 25, 2019
Contributed by:
C

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP. This feature is a per node configuration for each VIP address.

Example

Consider an active-active deployment consisting of Citrix ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (trackifNumPriority) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example: Health tracking example settings.

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1’s reduced priority value), because interface 1/3 is associated with VIP1:
   • Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
   • Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4’s reduced priority value (55).
   • Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
- Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145

6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

**Configuration Steps for IPv4 Active-Active Mode**

To configure this feature on a node for a VIP address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface’s state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (trackifNumPriority) value.

To set reduced priority and bind interfaces to the virtual router ID by using the CLI:

At the command prompt, type:

```
• set vrID <id> [-trackifNumPriority <positive_integer>]
• bind vrID <id> -trackifNum <interface_name>
• show vrID <id>
```

**Example:**

```
1  > set vrID 125 -trackifNumPriority 10
2   Done
3
4  > bind vrID 125 -trackifNum 1/4 1/5
5   Done
```

To set reduced priority and bind interfaces to the virtual router ID by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure VMAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

**Configuration Steps for IPv6 Active-Active Mode**

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface’s state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (trackifNumPriority) value.
To change the priority of a VIP address automatically by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new VMAC6:
  
  - `add vrID6 <id> [-trackifNumPriority <positive_integer>]`
  - `bind vrID6 <id> -trackifNum <interface_name>`
  - `show vrID6 <id>`

- If reconfiguring an existing VMAC6:
  
  - `set vrID6 <id> [-trackifNumPriority <positive_integer>]`
  - `bind vrID6 <id> -trackifNum <interface_name>`
  - `show vrID6 <id>`

**Example:**

```
1  > set vrID6 130 -trackifNumPriority 10
2       Done
3
4  > bind vrID6 130 -trackifNum 1/4 1/5
5       Done
```

---

**Delaying Preemption**

January 23, 2019

Contributed by: C

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP’s node.
The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP’s node.

**Example: Delaying Preemption**

Consider an active-active deployment consisting of Citrix ADC appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

<table>
<thead>
<tr>
<th>Entity and Parameters</th>
<th>Settings on NS1</th>
<th>Settings on NS2</th>
</tr>
</thead>
<tbody>
<tr>
<td>VIP1 (for reference purposes only)</td>
<td><strong>IP address:</strong> 192.0.1.10, <strong>VRID:</strong> 10, <strong>Priority:</strong> 100, <strong>Preemption:</strong> Enabled, <strong>Preemption delay time:</strong> 1000 seconds</td>
<td><strong>IP address:</strong> 192.0.1.10, <strong>VRID:</strong> 10, <strong>Priority:</strong> 200, <strong>Preemption:</strong> Enabled, <strong>Preemption delay time:</strong> 2000 seconds</td>
</tr>
</tbody>
</table>

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).
  - VIP1
    - **VRID:** 30
    - **IP address:**
    - **Priority:** 300
    - **Preemption delay time:** 3000 seconds
- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.
- If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
- If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.
Configuring Delay Preemption for IPv4 Active-Active Mode

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated VMAC address. You can set this parameter when you add the address, or you can modify an existing VMAC address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a VMAC, at the command prompt, type:
  - `add vrid <id> -preemptiondelaytimer <secs>`
  - `show vrid`

- To set the preemption delay time while modifying a VMAC, at the command prompt, type:
  - `set vrid <id> -preemptiondelaytimer <secs>`
  - `show vrid`

To configure preemption delay time by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC** tab. While adding a new VMAC, or editing an existing VMAC, set the **Preemption Delay Timer** parameter.

**Sample configuration:**

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

```
Settings on NS1
> set vrid param -deadInterval 1
Done
> add ns ip 192.0.1.10 255.255.255.255 -type VIP
Done
> add vrid 10 -Priority 100 -Preemption Enable -preemptiondelaytimer 1000
Done
> bind ns ip 192.0.1.10 255.255.255.255 -vrid 10
Done
```

```
Settings on NS2
```
Configuring Delay Preemption for IPv6 Active-Active Mode

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated VMAC6 address. You can set this parameter when you add the VMAC6 address, or you can modify an existing VMAC6 address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a VMAC6, at the command prompt, type:
  
  - `add vrid6 **<id>** -preemptiondelaytimer** <secs>`
  - `show vrid6`

- To set the preemption delay time while modifying a VMAC6, at the command prompt, type:
  
  - `set vrid6 <id> -preemptiondelaytimer <secs>`
  - `show vrid6`

To configure preemption delay time by using the GUI:

1. Navigate to System > Network > VMAC.
2. On the VMAC6 tab. While adding a VMAC6 address, or editing an existing VMAC6 address, set the Preemption Delay Timer parameter.
Keeping a VIP Address in the Backup State

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated VMAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

To force a VIP address to stay in the backup state by using the CLI:

- To set the priority while adding a VMAC, at the command prompt, type:
  - `add vrID <id> -priority 0`
  - `show vrID`
- To set the priority while modifying a VMAC, at the command prompt, type:
  - `set vrID <id> -priority 0`
  - `show vrID`

To force a VIP address to stay in backup state by using the GUI:

1. Navigate to System > Network > VMAC.
2. On the VMAC tab, while adding a new VMAC or editing an existing VMAC, set the Priority parameter to zero.

Network Visualizer

January 23, 2019
The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a Citrix ADC appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer:

1. Citrix ADC
2. Citrix ADC 12.1
3. Networking

**Configuring Link Layer Discovery Protocol**

January 25, 2019
Contributed by: C

The Citrix ADC supports the industry standard (EEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the Citrix ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices. Using LLDP, the Citrix ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs).

An LLDPDU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The Citrix ADC sends the following TLVs in each LLDPDU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

Note: You cannot specify the TLVs to be sent in LLDP messages.

Citrix ADC interfaces support the following LLDP modes:

- **NONE.** The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER.** The interface transmits LLDP messages to the directly connected device but does not receive LLPD messages from the directly connected device.
- **RECEIVER.** The interface receives LLDP messages from the directly connected device but does not transmit LLPD messages to the directly connected device.
- **TRANSCEIVER.** The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings: Interface and global level LLDP modes.

Note the following points related to LLDP messages transmitted or received by the Citrix ADC:

- **Transmitting LLDP messages.** The Citrix ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

Following are the global LLDP transmitting parameters on the Citrix ADC:

- **Timer.** Interval, in seconds, between LLDPUs that the Citrix ADC sends to a directly connected device.
- **Holdtime Multiplier.** A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the Holdtime Multiplier parameter value multiplied by the Timer parameter value.

- **Receiving LLDP Messages.** The Citrix ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The Citrix ADC retains this LLDP information for the duration specified in the received LLDPDU.

If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.
Configuration Steps

Configuring LLDP on a Citrix ADC appliance consists of the following tasks:

1. **Set global level LLDP parameters.** In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.

2. **Set the interface level LLDP parameters.** In this task, you set the LLDP mode for an interface.

3. **(Optional) Display neighbor-device information.** You can display the neighbor-device LLDP information collected on all of the Citrix ADC’s interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a Citrix ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).

2. Verify that you have configured LLDP on the desired directly connected devices.

**CLI procedures**

To set global level LLDP parameters by using the CLI:

At the command prompt, type:

- `set lldp param [-holdtimeTxMult <positive_integer>] [-timer <positive_integer>] [-Mode <Mode>]`
- `show lldp param`

To configure an interface for LLDP by using the CLI:

At the command prompt, type:

- `set interface <id> -lldpmode <lldpmode>`
- `show interface <id>`

To display neighbor device information by using the CLI:

At the command prompt, type one of the following commands:

- `show lldp neighbors`
- `show lldp neighbors <ifnum>`

**GUI procedures**

To set the global level LLDP parameters by using the GUI:

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
   - Hold Timer Multiplier
   - Timer
   - Mode

To configure an interface for LLDP by using the GUI:
Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the GUI:
Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

**LLDP Support in a Cluster Setup**

In a cluster setup, the GUI and CLI display the LLDP neighbour configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level LLDP mode on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the `show lldp neighbor -summary` operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbour information of all these nodes.

```
> show lldp neighbor -summary

Jumbo Frames

January 23, 2019

Contributed by: C

Citrix ADC appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A Citrix ADC appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The Citrix ADC appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS
Configuring Jumbo Frames Support on a Citrix ADC Appliance

January 23, 2019
Contributed by: C

To enable the Citrix ADC appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the Citrix ADC appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a Citrix ADC appliance

1. Jumbo frames are not supported on Citrix ADC MPX 15000 and MPX 17000 Platforms.
2. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
3. The MTU for a channel is propagated to all the bound interfaces.
4. When an interface is bound to the channel whose MTU is different from the interface’s MTU, the interface goes onto the inactive list.
5. When you change the MTU of a member interface, the interface goes onto the inactive list.
6. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
7. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
8. You cannot set the MTU on the default VLAN. The Citrix ADC appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
9. For TCP based traffic on a load balancing configuration on a Citrix ADC appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
   - For a connection between a client and a load balancing virtual server on the Citrix ADC appliance, the MSS on the Citrix ADC appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
   - For a connection between the Citrix ADC appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the Citrix ADC appliance.
By default, a TCP profile nstcp_default_profile is bound to all TCP based load balancing servers and services on the Citrix ADC appliance.

For supporting jumbo frames, you can either change the MSS value of the TCP profile nstcp_default_profile, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.

The default MSS value of any TCP profile is 1460.

CLI procedures

To set the MTU of an interface by using the CLI:
At the command prompt, type:

- `set interface <id> -mtu <positive_integer>
- `show interface <id>

Example:

```
1> set interface 10/1 -mtu 9000
Done
```

To set the MTU of a channel by using the CLI:
At the command prompt, type:

- `set channel <id> -mtu <positive_integer>
- `show channel <id>

Example:

```
1> set channel LA/1 -mtu 9000
Done
```

To set the MTU of a VLAN by using the CLI:
At the command prompt, type:

- `add vlan <id> -mtu <positive_integer>
- `show vlan <id>

Example:

```
1> set vlan 20 -mtu 9000
Done
```
GUI procedures

To set the MTU of an interface by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the GUI:

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the GUI:

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

Use Case 1 – Jumbo to Jumbo Setup

January 25, 2019

Contributed by: C

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on Citrix ADC appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.

The following table lists the settings used in the example.
**Citrix ADC 12.1**

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of client CL1</td>
<td>-</td>
<td>192.0.2.10</td>

<tr>
<td></td>
<td>VLAN 10</td>
<td>9000</td>
</tr>
<tr>
<td></td>
<td>VLAN 20</td>
<td>9000</td>
</tr>
<tr>
<td>Services on NS1 representing servers</td>
<td>SVC-S1</td>
<td>IP address: 198.51.100.19, Protocol: SIP, Port: 5060</td>
</tr>
<tr>
<td></td>
<td>SVC-S2</td>
<td>IP address: 198.51.100.20, Protocol: SIP, Port: 5060</td>
</tr>
<tr>
<td>Load balancing virtual server on VLAN 10</td>
<td>LBVS-1</td>
<td>IP address: 203.0.113.15, Protocol: SIP, Port: 5060, Bound services: SVC-S1, SVC-S2</td>
</tr>
</tbody>
</table>

Following is the traffic flow of CL1’s request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
   - Size of the first IP fragment = \( [\text{IP header} + \text{UDP header} + \text{SIP data segment}] = [20 + 8 + 8972] \) = 9000
   - Size of the second IP fragment = \( [\text{IP header} + \text{SIP data segment}] = [20 + 8980] \) = 9000
   - Size of the last IP fragment = \( [\text{IP header} + \text{SIP data segment}] = [20 + 2048] \) = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1’s load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.

- Size of the first IP fragment = \([\text{IP header} + \text{UDP header} + \text{SIP data segment}] = [20 + 8 + 8972] = 9000\]
- Size of the second IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 8980] = 9000\]
- Size of the last IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 2048] = 2068\]

Following is the traffic flow of S1’s response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.

2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.

- Size of the first IP fragment = \([\text{IP header} + \text{UDP header} + \text{SIP data segment}] = [20 + 8 + 8972] = 9000\]
- Size of the second and third IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 8980] = 9000\]
- Size of the last IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 3068] = 3088\]

3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.

4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.

5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1’s IP address.

- Size of the first IP fragment = \([\text{IP header} + \text{UDP header} + \text{SIP data segment}] = [20 + 8 + 8972] = 9000\]
- Size of the second and third IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 8980] = 9000\]
- Size of the last IP fragment = \([\text{IP header} + \text{SIP data segment}] = [20 + 3068] = 3088\]

**Configuration Tasks**

**Use Case 2 – Non-Jumbo to Jumbo Setup**

January 25, 2019

Contributed by:
C

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a Citrix ADC appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10.

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S2) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp_default_profile is used that is by default bound to LBVS-1 and has the MSS set to the default value of 1460.

The following table lists the settings used in this example.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Details</th>

### Entity Name Details

<table>
<thead>
<tr>
<th>Services on NS1 representing servers</th>
<th>SVC-S1</th>
<th>IP address: 198.51.100.19, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVC-S2</td>
<td></td>
<td>IP address: 198.51.100.20, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)</td>
</tr>
<tr>
<td>Load balancing virtual server on VLAN 10</td>
<td>LBVS-1</td>
<td>IP address = 203.0.113.15, Protocol: HTTP, Port:80, Bound services: SVC-S1, SVC-S2, TCP Profile: nstcp_default_profile (MSS:1460)</td>
</tr>
</tbody>
</table>

Following is the traffic flow of CL1’s request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1’s MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.
   
   **Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240**
4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1’s load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1’s MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.
   
   **Size of the request packet = [IP Header + TCP Header + [TCP Request] = [20 + 20 + 200] = 240**

Following is the traffic flow of S1’s response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
   - Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

3. NS1 receives the response packets at interface 10/2.

4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.

5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
   - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

**Configuration Tasks**

### Use Case 3 – Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

January 25, 2019

Contributed by:

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on Citrix ADC appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.
CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

The effective MTU on a Citrix ADC interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.

The following table lists the settings used in this example: Jumbo frames use case 3 example settings.

Following is the traffic flow of CL1’s request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
3. Because NS1’s MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1’s MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
   • Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
   • Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1’s load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1’s MSS and sends these segments in IP packets tagged as VLAN 20 to S1.
   • Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
   • Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1’s response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1’s MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1’s IP address and destined to the SNIP address of NS1.
   • Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1’s MSS size)] = [20 + 20 + 8960] = 9000
   • Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1’s MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS’s IP address and destined to CL1’s IP address.
   • Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1’s MSS size)] = [20 + 20 + 8960] = 9000
- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

**Configuration Tasks**

**Citrix ADC Support for Microsoft Direct Access Deployment**

January 25, 2019

Contributed by: C

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise’s internal networks, without the need to establish a separate VPN connection. Unlike VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise’s internal networks whenever the client connects to the Internet.

Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support.

In a Direct Access deployment, Citrix ADC appliances provide high availability, scalability, high performance, and security. Citrix ADC load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

**Architecture**

The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external Citrix ADC appliances. Clients connect to an application server through a Direct Access server. An external Citrix ADC appliance load
balance the client traffic to a Direct Access server, and an Internal Citrix ADC appliance forwards the
client traffic from the Direct Access server to the destination application server. Direct Access is used
for tunneling the client’s IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on
the external Citrix ADC appliance load balances the client’s tunneled traffic to one of the Direct Access
servers. The Direct Access server extracts the IPv6 packets from the received client’s IPv4 packets
and sends them to the destination application server through the internal Citrix ADC appliance. The
Internal Citrix ADC appliance has forwarding session rules with the source route cache option enabled
for storing Layer 2 and Layer 3 connection information about the client’s traffic from the Direct Access
Server. The Citrix ADC appliance stores the following Layer 2 and Layer 3 information in a table called
the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the Citrix ADC appliance that received the packet
- Interface ID of the Citrix ADC appliance that received the packet

The Citrix ADC appliance uses the information in the source route cache table for forwarding a re-
sponse to the same Direct Access server because it has the tunneling information to reach the client.
Also, the Internal appliance uses the source route cache table to forward application server’s Manage-
out traffic to the appropriate Direct Access server to reach a particular client.

Configuring the Internal Citrix ADC Appliance in a Microsoft Direct Access Deployment

To configure the Internal Citrix ADC appliance for forwarding an application server’s response and
manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In
each rule, set the sourceroutecache parameter to ENABLED.

To create a forwarding session rule by using the CLI:

At the command prompt, type:

```
• add forwardingSession <name> ((<network> [<netmask>] | -acl6name <string> | -aclname
  <string>) -sourceroutecache ( ENABLED | DISABLED )
• show forwardingssession <name>
```

Sample configuration:

In the following example, forwarding-session rule MS-DA-FW-1 is created on the internal Citrix ADC
appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets
from a Direct Access server that matches source IPv6 prefix 2001:DB8::/96.

```
1 > add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -
   ENABLED
2   Done
```
Displaying the Source Route Cache Table

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the CLI:

At the command prompt, type:

- `show sourceroutecachetable`

Example:

```
1 > show sourceroutecachetable
2 SOURCEIP                MAC            VLAN INTERFACE
4 2001:DB8:5003:30   60:54:35:3e:04:bd   60       1/3
5 Done
```

Clearing the Source Route Cache Table

You can clear all the entries from the source route cache table on a Citrix ADC appliance.

To clear the source route cache table by using the CLI:

At the command prompt, type:

- `flush ns sourceroutecachetable`

Access Control Lists

January 25, 2019

Contributed by:

C

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the Citrix ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other
departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the Citrix ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- **ALLOW**—Process the packet.
- **BRIDGE**—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- **DENY**—Drop the packet.

ACL rules are the first level of defense on the Citrix ADC.

Citrix ADC supports the following types of ACLs:

- **Simple ACLs** filter packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.
- **Extended ACLs** filter data packets on the basis of various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the Citrix ADC to process the packet, bridge the packet, or drop the packet.

**Nomenclature**

In the Citrix ADC user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

**ACL Precedence**

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The Citrix ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s.

If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence

1.
Simple ACLs and Simple ACL6s

January 23, 2019
Contributed by: C

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a Citrix ADC can include the following tasks.

- Create simple ACLs or simple ACL6s. Creating simple ACLs or simple ACL6s to drop (deny) packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.
- Remove simple ACLs or simple ACL6s. These ACLs cannot be modified once created. If you need to modify a simple ACL or simple ACL6, you must remove it and create a new one.

CLI procedures

To create a simple ACL by using the CLI:

At the command prompt, type:

- add ns simpleacl <aclname> DENY -srcIP <ip_addr> [-destPort<port> -protocol (TCP | UDP)] [-TTL <positive_integer>]  
- show ns simpleacl [<aclname>]

Example:
To create a simple ACL6 by using the CLI:

At the command prompt, type:

```
• add ns simpleacl6 <aclname> DENY -srcIPv6 <ipv6_addr>null> [-destPort<port> -protocol (TCP | UDP )][-TTL <positive_integer>]
• show ns simpleacl6 [<aclname>]
```

**Example:**

```
1 > add ns simpleacl6 rule1 DENY -srcIPv6 3ffe:192:168:215::82 -destPort 80 -Protocol TCP -TTL 9000
2  Done
```

To remove a single simple ACL by using the CLI:

At the command prompt, type:

```
• rm ns simpleacl <aclname>
• show ns simpleacl
```

To remove a single simple ACL6 by using the CLI:

At the command prompt, type:

```
• rm ns simpleacl6 <aclname>
• show ns simpleacl6
```

To remove all simple ACLs by using the CLI:

At the command prompt, type:

```
• clear ns simpleacl
• show ns simpleacl
```

To remove all simple ACL6s by using the CLI:

At the command prompt, type:

```
• clear ns simpleacl6
• show ns simpleacl6
```

**GUI procedures**

To create a simple ACL by using the GUI:
Navigate to System > Network > ACLs and, on the Simple ACLs tab, add a new simple ACL.

To create a simple ACL6 by using the GUI:

Navigate to System > Network > ACLs and, on the Simple ACL6s tab, add a new simple ACL6.

To remove a single simple ACL by using the GUI:

Navigate to System > Network > ACLs and, on the Simple ACLs tab, delete the simple ACL.

To remove a single simple ACL6 by using the GUI:

Navigate to System > Network > ACLs and, on the Simple ACL6s tab, delete the simple ACL6.

To remove all simple ACLs by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the Simple ACLs tab, in the Action list, click Clear.

To remove all simple ACL6s by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the Simple ACL6s tab, in the Action list, click Clear.

Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of hits, the number of misses, and the number of simple ACLs configured.

The following table describes statistics you can display for simple ACLs and simple ACL6s.

<table>
<thead>
<tr>
<th>Statistics</th>
<th>Indicates</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACL hits</td>
<td>Packets matching an ACL</td>
</tr>
<tr>
<td>ACL misses</td>
<td>Packets not matching any ACL</td>
</tr>
<tr>
<td>ACL count</td>
<td>Number of ACLs configured</td>
</tr>
</tbody>
</table>

CLI procedures

To display simple ACL statistics by using the CLI:

At the command prompt, type:

- stat ns simpleacl

Example:
To display simple ACL6 statistics by using the CLI:

At the command prompt, type:

- `stat ns simpleacl6`

**GUI procedures**

To display simple ACL statistics by using the GUI:

Navigate to System > Network > ACLs and, on the Simple ACLs tab, select the ACL and click Statistics.

To display simple ACL6 statistics by using the GUI:

Navigate to System > Network > ACLs and, on the Simple ACL6s tab, select the simple ACL6 and click Statistics.

**Terminating Established Connections**

For a simple ACL or simple ACL6, the Citrix ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the CLI or the GUI.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the Citrix ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate a large number of connections from a particular network without taking the time to terminate them one by one.
Before you begin

- When you run flush, the Citrix ADC searches through all of its established connections and terminates those that match conditions specified in any of the simple ACLs configured on the ADC.
- If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all of the simple ACLs and then running flush only once.

CLI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the CLI:

At the command prompt, type:

- `flush simpleacl -estSessions`

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the CLI:

At the command prompt, type:

- `flush simpleacl6 -estSessions`

GUI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the GUI:

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.
Extended ACLs and Extended ACL6s

January 25, 2019
Contributed by: C

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data on the basis of parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

**Note:** If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the Citrix ADC to log details for packets that match an extended ACL. However, you cannot log details of packets that match an extended ACL6.

**Applying Extended ACLs and Extended ACL6s:** Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the Citrix ADC do not work until they are applied. Also, if you make any modifications to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must reapply the extended ACLs or ACL6s. You must also reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the Citrix ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you reenable them, even if they are reapplied.

**Renumbering the priorities of Extended ACLs and Extended ACL6s:** Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the Citrix ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might
assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

## Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a Citrix ADC consists of the following tasks.

- **Create an extended ACL or ACL6.** Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.

- **(Optional) Modify an extended ACL or ACL6.** You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.

- **Apply extended ACLs or ACL6s.** After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.

- **(Optional) Renumber the priorities of extended ACLs or ACL6s.** If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

### CLI procedures

To create an extended ACL by using the CLI:

At the command prompt, type:

```
```

Example:

```
1 > add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -protocol TCP
2  Done
```

To create an extended ACL6 by using the CLI:

At the command prompt, type:

• **show ns acl6** `<aclName>`

**Example:**

```bash
> add ns acl6 rule6 DENY -sport 45-1024 -destIPv6 2001::45 -protocol TCP
Done
```

To modify an extended ACL by using the CLI:

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

To modify an extended ACL6 by using the CLI:

To modify an extended ACL6, type the **set ns acl** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

To disable or enable an extended ACL by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl** `<aclname>`
- **enable ns acl** `<aclname>`

To disable or enable an extended ACL6 by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl6** `<aclname>`
- **enable ns acl6** `<aclname>`

To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply ns acls**

To apply extended ACL6s by using the CLI:

At the command prompt, type:

- **apply ns acls6**

To renumber the priorities of extended ACLs by using the CLI:

At the command prompt, type:
To renumber the priorities of extended ACLs by using the CLI:

At the command prompt, type:

- `renumber ns acls`

**GUI procedures**

To configure an extended ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

To configure an extended ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

To apply extended ACLs by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To apply extended ACL6s by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

To renumber the priorities of extended ACLs by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority(s)**.

To renumber the priorities of extended ACL6s by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority(s)**.

**Sample Configurations**

The following table shows examples of configuring extended ACL rules through the command line interface: **ACLs sample configurations**.
Logging Extended ACLs

You can configure the Citrix ADC to log details for packets that match extended ACLs.

**Note:** You cannot enable logging for extended ACL6s.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the nslog file, depending on the type of global logging (syslog or nslog) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence. For more information about enabling logging globally, see “.”

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet’s details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the Citrix ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

**Note:** You must apply ACLs after you enable logging.

**CLI procedures**

To configure extended ACL Logging by using the CLI:

At the command prompt, type the following commands to configure logging and verify the configuration:

1. `set ns acl <aclName> [-logState (ENABLED | DISABLED)] [-rateLimit <positive_integer>]`
2. `show ns acl [<aclName>]`

**Example:**

```
1 > set ns acl restrict -logstate ENABLED -ratelimit 120
2 Warning: ACL modified, apply ACLs to activate change
```

**GUI procedures**

To configure extended ACL Logging by using the GUI:

1. Navigate to System > Network > ACLs and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
• **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.
• **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

**Extended ACL6 Logging**

You can configure the Citrix ADC appliance to log details for packets that match an extended ACL6 rule. In addition to the ACL6 name, the logged details include packet-specific information, such as the source and destination IP addresses. The information is stored either in a syslog or nslog file, depending on the type of logging (syslog or nslog) that you have configured in the Citrix ADC appliance.

To optimize logging, when multiple packets from the same flow match an ACL6, only the first packet’s details are logged. The counter is incremented for every other packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP
- Destination IP
- Source port
- Destination port
- Protocol (TCP or UDP)

If an incoming packet is not from the same flow, a new flow is created. The total number of different flows that can be logged at any given time is limited to 10,000.

**CLI procedures**

To configure logging for an extended ACL6 rule by using the CLI:

- To configure logging while adding the extended ACL6 rule, at the command prompt, type:
  
  ```
  – add acl6 **<acl6Name> <acl6action> [-logState** [ENABLED | DISABLED]] [-rateLimit <positive_integer>]
  – show acl6 [<acl6Name>]
  – apply acls6
  ```

- To configure logging for an existing extended ACL6 rule, at the command prompt, type:

  ```
  – set acl6 **<acl6Name> [-logState** [ENABLED | DISABLED]] [-rateLimit <positive_integer>]
  – show acl6 [<acl6Name>]
  – apply acls6
  ```

**GUI procedures**

To configure extended ACL6 Logging by using the GUI:
1. Navigate to System > Network > ACLs and, then click the Extended ACL6s tab.
2. Set the following parameters while adding, or modifying an existing extended ACL6 rule.
   - **Log State**—Enable or disable logging of events related to the extended ACL6s rule. The log messages are stored in the configured syslog or auditlog server.
   - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

**Example:**

```
1 > set acl6 ACL6-1 -logstate ENABLED -ratelimit 120
2       Done
3
4 > apply acls6
5       Done
```

### Displaying Extended ACL and Extended ACL6s Statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow ACL hits</td>
<td>Packets matching ACLs with processing mode set to ALLOW. The Citrix ADC processes these packets.</td>
</tr>
<tr>
<td>NAT ACL hits</td>
<td>Packets matching a NAT ACL, resulting in a NAT session.</td>
</tr>
<tr>
<td>Deny ACL hits</td>
<td>Packets dropped because they match ACLs with processing mode set to DENY.</td>
</tr>
<tr>
<td>Bridge ACL hits</td>
<td>Packets matching a bridge ACL, which in transparent mode bypasses service processing.</td>
</tr>
<tr>
<td>ACL hits</td>
<td>Packets matching an ACL.</td>
</tr>
<tr>
<td>ACL misses</td>
<td>Packets not matching any ACL.</td>
</tr>
</tbody>
</table>
**CLI procedures**

To display the statistics of all extended ACLs by using the CLI:

At the command prompt, type:

```
• stat ns acl
```

To display the statistics of all extended ACL6s by using the CLI:

At the command prompt, type:

```
• stat ns acl6
```

**GUI procedures**

To display the statistics of an extended ACL by using the GUI:

Navigate to System > Network > ACLs, on the **Extended ACLs** tab, select the extended ACL, and click *Statistics*.

To display the statistics of an extended ACL6 by using the GUI:

Navigate to System > Network > ACLs, on the **Extended ACL6s** tab, select the extended ACL, and click *Statistics*.

**Stateful ACLs**

A stateful ACL rule creates a session when a request matches the rule and allows the resulting responses even if these responses matches a deny ACL rule in Citrix ADC appliance. A stateful ACL offloads the work of creating additional ACL rules/forwarding session rules for allowing these specific responses.

Stateful ACLs can be best used in an edge firewall deployment of a Citrix ADC appliance having the following requirements:

- The Citrix ADC appliance must allow requests initiated from internal clients and the related responses from the Internet.
- The appliance must drop the packets from the Internet that are not related to any client connections.

**Before you begin**

Before you configure stateful ACL rules, note the following points:

- The Citrix ADC appliance supports stateful ACL rules as well as stateful ACL6 rules.
• In a high availability setup, the sessions for a stateful ACL rule are not synchronized to the secondary node.
• You cannot configure an ACL rule as stateful if the rule is bound to any Citrix ADC NAT configuration. Some examples of Citrix ADC NAT configurations are:
  – RNAT
  – Large Scale NAT (large scale NAT44, DS-Lite, large scale NAT64)
  – NAT64
  – Forwarding session
• You cannot configure an ACL rule as stateful if TTL and Established parameters are set for this ACL rule.
• The sessions created for a stateful ACL rule continue to exist till timeout irrespective of the following ACL operations:
  – Remove ACL
  – Disable ACL
  – Clear ACL
• Stateful ACLs are not supported for the following protocols:
  – Active FTP
  – TFTP

Configure stateful IPv4 ACL rules

Configuring a stateful ACL rule consists of enabling the stateful parameter of an ACL rule.

To enable the stateful parameter of an ACL rule by using the CLI:

• To enable the stateful parameter while adding an ACL rule, at the command prompt, type:
  – add acl <name> ALLOW -stateful (ENABLED | DISABLED )
  – apply acls
  – show acl <name>

• To enable the stateful parameter of an existing ACL rule, at the command prompt, type:
  – set acl <name> -stateful (ENABLED | DISABLED )
  – apply acls
  – show acl <name>

To enable the stateful parameter of an ACL rule by using the CLI:

1. Navigate to System > Network > ACLs and, on the Extended ACLs tab.
2. Enable the Stateful parameter while adding, or modifying an existing ACL rule.

```
1 > add acl ACL-1 allow -srciP 1.1.1.1 -stateful Yes
2
3 Done
```
```plaintext

Configure stateful ACL6 rules

Configuring a stateful ACL6 rule consists of enabling the stateful parameter of an ACL6 rule.

To enable the stateful parameter of an ACL6 rule by using the CLI:

- To enable the stateful parameter while adding an ACL6 rule, at the command prompt, type:
  - `add acl6 <name> ALLOW -stateful (ENABLED | DISABLED)`
  - `apply acls6`
  - `show acl6 <name>`

- To enable the stateful parameter of an existing ACL6 rule, at the command prompt, type:
```
```
```
To enable the stateful parameter of an ACL6 rule by using the CLI:

1. Navigate to System > Network > ACLs and, on the Extended ACL6s tab.
2. Enable the Stateful parameter while adding, or modifying an existing ACL6 rule.

```
> add acl6 ACL6-1 allow -srcipv6 1000::1 - stateful Yes
Done

> apply acls6
Done

> show acl6
1) Name: ACL6-1
   Action: ALLOW                      Hits: 0
   srcIPv6 = 1000::1
   destIPv6
   srcMac:
   Protocol:
   Vlan:                                Interface:
   Active Status: ENABLED               Applied Status: NOTAPPLIED
   Priority: 10                          NAT: NO
   TTL:
   Forward Session: NO
   Stateful: YES
```

1.
2. Citrix ADC
A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be matched against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the CLI:

At the command prompt, type:
To specify a range of source MAC addresses in an ACL6 rule by using the CLI:

At the command prompt, type:

```
add ns acl6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
```

Example:

```
1 > add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
   - srcMacMask 000000001111
2 Done
```

Blocking Traffic on Internal Ports

January 23, 2019

Contributed by:
C

The Citrix ADC appliance does not block traffic that matches an ACL rule if the traffic is destined to the appliance’s NSIP address, or one of its SNIP addresses, and a port in the 3008-3011 range.

This behavior is now specified by the default setting of the new Implicit ACL Allow (implicitACLAllow) parameter (of the L3 param command). You can disable this parameter if you want to block traffic to ports in the 3008-3011 range. An appliance in a high availability configuration makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

To disable or enable this parameter by using the CLI:

At the command prompt, type:
**set l3param -implicitACLAllow** [ENABLED | DISABLED]

- set l3param
- sh l3param

**Note:** The parameter implicitACLAllow is enabled by default.

**Example:**

```
1 > set l3param -implicitACLAllow DISABLED
2 Done
```

**IP Routing**

January 23, 2019

Contributed by:

Citrix ADC appliances support both dynamic and static routing. Because simple routing is not the primary role of a Citrix ADC, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most Citrix ADC implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.
Configuring Dynamic Routes

January 25, 2019
Contributed by: C

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone Citrix ADC appliances. Dynamic routing on a Citrix ADC appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see Dynamic Routing Protocol Command Reference Guides and Unsupported Commands.

The Citrix ADC supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in Citrix ADC

In a Citrix ADC appliance, the Citrix ADC kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the add ns ip command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and
any static routes added through the CLI (CLI). The entries in this table are used by the Citrix ADC in packet forwarding. From the CLI, they can be inspected with the show route command.

**FreeBSD Routing Table**

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a Citrix ADC appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the Citrix ADC establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the route command. The FreeBSD routing table can be inspected by using the netstat command from any UNIX shell.

**Network Services Module (NSM) FIB**

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

- **Connected routes.** IP subnets that are directly reachable from the Citrix ADC. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.

- **Kernel routes.** All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the CLI that have the - advertise option enabled. Alternatively, if the Citrix ADC is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.

- **Static routes.** Normally, any static route configured in VTSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.

- **Learned routes.** If the Citrix ADC is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTSH.
Dynamic Routing in a High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the GUI or a command-line interface. The Citrix ADC supports two independent command-line interfaces: the CLI and the Virtual Teletype Shell (VTYSH). The CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The Citrix ADC routing suite is based on ZebOS, the commercial version of GNU Zebra.

Note:

Citrix recommends that you use VTYSH for all commands except those that can be configured only on the CLI. Use of the CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the Citrix ADC appliance: Dynamic routing protocol reference guides and
Routing Information Protocol (RIP) is a Distance Vector protocol. The Citrix ADC supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

**Enabling and Disabling RIP**

Use either of the following procedures to enable or disable RIP. After you enable RIP, the Citrix ADC appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the CLI:

At the command prompt, enter one of the following commands to enable or disable RIP:

- `enable ns feature RIP`
- `disable ns feature RIP`

To enable or disable RIP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the RIP Routing option.

**Advertising Routes**

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.
To configure RIP to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router rip</td>
<td>Start the RIP routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>redistribute static</td>
<td>Redistribute static routes.</td>
</tr>
<tr>
<td>redistribute kernel</td>
<td>Redistribute kernel routes.</td>
</tr>
</tbody>
</table>

**Example:**

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router rip
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
```

**Limiting RIP Propagations**

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router rip</td>
<td>Start the RIP routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>passive-interface &lt; vlan_name&gt;</td>
<td>Suppress routing updates on interfaces bound to the specified VLAN.</td>
</tr>
</tbody>
</table>
```
Example:

1. `VTYSH`
2. `NS# configure terminal`
3. `NS(config)# router rip`
4. `NS(config-router)# passive-interface VLAN0`

Verifying the RIP Configuration

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line:

At the command prompt, type the following commands in the following order:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td><code>sh rip</code></td>
<td>Display updated RIP routing table.</td>
</tr>
<tr>
<td><code>sh rip interface &lt;vlan_name&gt;</code></td>
<td>Displays RIP information for the specified VLAN.</td>
</tr>
</tbody>
</table>

Example:

1. `NS# VTYSH`
2. `NS# sh rip`
3. `NS# sh rip interface VLAN0`

Configuring OSPF

January 23, 2019

Contributed by:

C
The Citrix ADC supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the Citrix ADC are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the Citrix ADC.
- The Citrix ADC can advertise Type-1 or Type-2 external metrics for all routes.
- The Citrix ADC can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the Citrix ADC.
- The Citrix ADC supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

**Enabling and Disabling OSPF**

To enable or disable OSPF, you must use either the CLI or the GUI. When OSPF is enabled, the Citrix ADC starts the OSPF process. When OSPF is disabled, the Citrix ADC stops the OSPF routing process.

To enable or disable OSPF routing by using the CLI:

At the command prompt, type one of the following commands:

1. `enable ns feature OSPF`
2. `disable ns feature OSPF`

To enable or disable OSPF routing by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **OSPFRouting** option.
Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure OSPF to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>router OSPF</td>
<td>Start OSPF routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>network A.B.C.D/M area &lt;0-4294967295&gt;</td>
<td>Enable routing on an IP network.</td>
</tr>
<tr>
<td>redistribute static</td>
<td>Redistribute static routes.</td>
</tr>
<tr>
<td>redistribute kernel</td>
<td>Redistribute kernel routes.</td>
</tr>
</tbody>
</table>

Example:

1. `>VTYSH`
2. `NS# configure terminal`
3. `NS(config)# router OSPF`
4. `NS(config-router)# network 10.102.29.0/24 area 0`
5. `NS(config-router)# redistribute static`
6. `NS(config-router)# redistribute kernel`

Limiting OSPF Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
</tbody>
</table>
Verifying the OSPF Configuration

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>sh OSPF neighbor</td>
<td>Displays current neighbors.</td>
</tr>
<tr>
<td>sh OSPF route</td>
<td>Displays OSPF routes.</td>
</tr>
</tbody>
</table>

Example:

1. `>VTYSH`
2. `NS# configure terminal`
3. `NS(config)# router OSPF`
4. `NS(config-router)# passive-interface VLAN0`

Configuring Graceful Restart for OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of
packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node’s learned routes from their routing databases. Using the old primary node’s routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>VTYSH</td>
<td>Enters VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>NS# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>router-id &lt;id&gt;</td>
<td>NS(config)# router-id 1.1.1.1</td>
<td>Sets a router identifier for the Citrix ADC appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup.</td>
</tr>
<tr>
<td>ospf restart grace-period</td>
<td>NS(config)# ospf restart grace-period 170</td>
<td>Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.</td>
</tr>
<tr>
<td>ospf restart helper</td>
<td>NS(config)# ospf restart helper max-grace-period 180</td>
<td>This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.</td>
</tr>
</tbody>
</table>
The Citrix ADC appliance supports BGP (RFC 4271). The features of BGP on the Citrix ADC are:

- The Citrix ADC advertises routes to BGP peers.
- The Citrix ADC injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The Citrix ADC generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

**Prerequisites for IPv6 BGP**

Before you begin configuring IPv6 BGP, do the following:
• Make sure that you understand the IPv6 BGP protocol.
• Install the IPv6PT license on the Citrix ADC appliance.
• After installing the IPv6PT license, enable the IPv6 feature.

Enabling and Disabling BGP

To enable or disable BGP, you must use either the CLI or the GUI. When BGP is enabled, the Citrix ADC appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the CLI:

At the command prompt, type one of the following commands:

• `enable ns feature BGP`
• `disable ns feature BGP`

To enable or disable BGP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

You can configure the Citrix ADC appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router BGP &lt; ASnumber&gt;</td>
<td>BGP autonomous system. &lt; ASnumber&gt; is a required parameter. Possible values: 1 to 4,294,967,295.</td>
</tr>
<tr>
<td>Neighbor &lt; IPv4 address&gt; remote-as &lt; as-number&gt;</td>
<td>Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td>Address-family ipv4</td>
<td>Enter address family configuration mode.</td>
</tr>
</tbody>
</table>
Advertising IPv6 BGP Routes

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone Citrix ADC appliances. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure BGP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router BGP &lt; ASnumber&gt;</td>
<td>BGP autonomous system. &lt;ASnumber&gt; is a required parameter. Possible values: 1 to 4,294,967,295.</td>
</tr>
<tr>
<td>Neighbor &lt; IPv6 address&gt; remote-as &lt; as-number&gt;</td>
<td>Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.</td>
</tr>
</tbody>
</table>
Command | Specifies
---|---
Address-family ipv6 | Enter address family configuration mode.
Neighbor < IPv6 address> activate | Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel | Redistribute kernel routes.
redistribute static | Redistribute static routes.

**Example:**

```plaintext
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router BGP 5
4 NS(config-router)# Neighbor a1bc::102 remote-as 100
5 NS(config-router)# Address-family ipv6
6 NS(config-router-af)# Neighbor a1bc::102 activate
7 NS(config-router)# redistribute kernel
8 NS(config-router)# redistribute static
```

**Verifying the BGP Configuration**

You can use VTYS to display BGP settings.

To view the BGP settings using the VTYS command line

At the command prompt, type:

```plaintext
1 VTYS
2 You are now in the VTYS command prompt. An output similar to the following appears:
3 NS170#
4 At the VTYS command prompt, type:
5 NS170# sh ip BGP
6 NS170# sh BGP
7 NS170# sh ip BGP neighbors
8 NS170# sh ip BGP summary
9 NS170# sh ip BGP route-map <map-tag>
```
As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router’s Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the Citrix ADC.

With AS-Override enabled for a peer device, when the Citrix ADC appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the VTYSH command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router BGP &lt; ASnumber&gt;</td>
<td>BGP autonomous system. &lt; ASnumber&gt; is a required parameter.</td>
</tr>
<tr>
<td>Neighbor &lt; IPv4 address&gt; remote-as &lt; as-number&gt;</td>
<td>Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td>Neighbor &lt;IPv4 address&gt; as-override</td>
<td>Enable BGP as-override for the specified neighbor.</td>
</tr>
</tbody>
</table>

1. > VTYSH NS# configure terminal
2. NS(config)# router BGP 200
3. NS(config-router)# Neighbor 192.0.2.100 remote-as 100
4. NS(config-router)# Neighbor 10.102.29.100 as-override

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line:
### Command & Specifies

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>configure terminal</strong></td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td><strong>router BGP &lt; ASnumber&gt;</strong></td>
<td>BGP autonomous system. &lt; ASnumber&gt; is a required parameter.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;peer group name&gt; peer-group</strong></td>
<td>Create a BGP peer group.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;IPv4 address&gt; peer-group &lt;peer group name&gt;</strong></td>
<td>Associate neighbors to the specified peer group.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;peer group name&gt; remote-as &lt;as-number&gt;</strong></td>
<td>Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;peer group name&gt; as-override</strong></td>
<td>Enable BGP as-override for all the neighbors that are associated with the specified peer group.</td>
</tr>
</tbody>
</table>

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line:

```plaintext
1  > VTYS NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# neighbor external-peers-1 peer-group
4 NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
5 NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
6 NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
7 NS(config-router)# Neighbor external-peers-1 remote-as 100
8 NS(config-router)# Neighbor external-peers-1 as-override
```

### Command & Specifies

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>configure terminal</strong></td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td><strong>router BGP &lt; ASnumber&gt;</strong></td>
<td>BGP autonomous system. &lt; ASnumber&gt; is a required parameter.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;IPv6 address&gt; remote-as &lt;as-number&gt;</strong></td>
<td>Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;IPv6 address&gt; as-override</strong></td>
<td>Enable BGP as-override for the specified neighbor.</td>
</tr>
<tr>
<td><strong>Address-family ipv6</strong></td>
<td>Enter address family configuration mode.</td>
</tr>
</tbody>
</table>
## Command Specifies

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Neighbor</strong> <code>&lt;IPv6 address&gt; activate</code></td>
<td>Exchange prefixes for the IPv6 router family between the specified neighbor and the Citrix ADC by using the link local address.</td>
</tr>
<tr>
<td><strong>Neighbor &lt;IPv6 address&gt; as-override</strong></td>
<td>Enable BGP as-override for the specified neighbor.</td>
</tr>
</tbody>
</table>

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line:

```
1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200

Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped. Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node’s learned routes from their routing databases. Using the old primary node’s routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Configuring MD5 Authentication for IPv4 BGP

The Citrix ADC appliance supports MD5 authentication for Border Gateway Protocol (BGP). When authentication is enabled, any TCP segment belonging to BGP exchanged between the Citrix ADC appliance and its peer device is verified and accepted only if authentication is successful. For authentication to be successful, both the peers must be configured with the same MD5 password. If authentication fails, the BGP neighbor relationship is not being established. MD5 authentication support for BGP in the Citrix ADC appliance is compliant with RFC 2385.

Before you Begin

Before you start configuring BGP MD5 authentication, consider the following points:

- Make sure that you understand the different components of BGP MD5 authentication, described in RFC 2385.
- BGP MD5 authentication is not supported for Citrix ADC admin partitions.
- BGP MD5 authentication is not supported for IPv6 BGP configurations.
- BGP MD5 authentication is supported for Citrix ADC cluster configurations as well as for high availability configurations.
- Because of the following issue in FreeBSD, Citrix recommends to set a low keep-live and hold-time values (for example, 5 and 15) and configure graceful restart for a BGP session in a Layer 2 high availability configuration. Otherwise, with MD5 authentication enabled, BGP might take a longer time to re-establish a connection with the neighbour after a failover.
  - Last ACK from FreeBSD does not contain md5 digest:

**Configuring IPv6 RIP**

January 23, 2019

Contributed by: C

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6...
RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

**Prerequisites for IPv6 RIP**

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

**Advertising IPv6 RIP Routes**

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertisement enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ipv6 rip</td>
<td>Start IPv6 RIP routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>redistribute static</td>
<td>Redistribute static routes.</td>
</tr>
<tr>
<td>redistribute kernel</td>
<td>Redistribute kernel routes.</td>
</tr>
</tbody>
</table>

**Example:**

1. \>$VTYSH
2. NS# configure terminal
3. NS(config)# router ipv6 rip
4. NS(config-router)# redistribute static
5. NS(config-router)# redistribute kernel

Limiting IPv6 RIP Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ipv6 rip</td>
<td>Start IPv6 RIP routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>passive-interface &lt; vlan_name&gt;</td>
<td>Suppress routing updates on interfaces bound to the specified VLAN.</td>
</tr>
</tbody>
</table>

Example:

```
1  >VTYSH
2  NS# configure terminal
3  NS(config)# router ipv6 rip
4  NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 RIP Configuration

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Commands</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>sh ipv6 rip</td>
<td>Display updated IPv6 RIP routing table.</td>
</tr>
<tr>
<td>sh ipv6 rip interface &lt;vlan_name&gt;</td>
<td>Display IPv6 RIP information for the specified VLAN.</td>
</tr>
</tbody>
</table>
IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the Citrix ADC appliance.
- Enable the IPv6 feature.

Advertising IPv6 Routes

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone Citrix ADC devices. Route advertising enables an upstream router to track network entities located behind the Citrix ADC.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:
### Commands Specifies

<table>
<thead>
<tr>
<th>Commands</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ipv6 OSPF</td>
<td>Start IPv6 OSPF routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>redistribute static</td>
<td>Redistribute static routes.</td>
</tr>
<tr>
<td>redistribute kernel</td>
<td>Redistribute kernel routes.</td>
</tr>
</tbody>
</table>

#### Example:

```
1   > VTMYH
2   NS# configure terminal
3   NS(config)# router ipv6 OSPF
4   NS(config-router)# redistribute static
5   NS(config-router)# redistribute kernel
```

### Limiting IPv6 OSPF Propagations

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Commands</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ipv6 OSPF</td>
<td>Start IPv6 OSPF routing process and enter configuration mode for the routing process.</td>
</tr>
<tr>
<td>passive-interface &lt; vlan_name &gt;</td>
<td>Suppress routing updates on interfaces bound to the specified VLAN.</td>
</tr>
</tbody>
</table>

#### Example:

```
1   > VTMYH
2   NS# configure terminal
```
Verifying the IPv6 OSPF Configuration

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>sh ipv6 OSPF neighbor</td>
<td>Display current neighbors.</td>
</tr>
<tr>
<td>sh ipv6 OSPF route</td>
<td>Display IPv6 OSPF routes.</td>
</tr>
</tbody>
</table>

Example:

```
1 >VTYSH
2 NS# sh ipv6 OSPF neighbor
3 NS# sh ipv6 OSPF route
```

OSPFv3 Authentication

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The Citrix ADC appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPSec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The Citrix ADC appliance supports only the AH protocol for OSPFv3 authentication.

OSPFv3 authentication uses manually defined IPSec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The
settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a Citrix ADC appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: `OSPFv3 authentication VLAN commands`.

**Example:**

```
1 > VTYSH NS# configure terminal
2 NS(config)# interface vlan2
3 NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789ABCDEF0
```

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: `OSPFv3 authentication OSPF area commands`.

**Example:**

```
1 > VTYSH NS# configure terminal
2 ns(config)#router ipv6 ospf 30
3 ns(config-router)# area 1 authentication ipsec spi 256 md5123456789ABCDEF0123456789ABCDEF0
```

**Configuring Graceful Restart for IPv6 OSPF**

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing

</tr>
<tr>
<td>IPv6 ospf restart helper</td>
<td>NS(config)# IPv6 ospf restart helper max-grace-period 180</td>
<td>This is an optional command to limit the maximum grace period for which the Citrix ADC appliance will be in the helper mode. If the Citrix ADC appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the Citrix ADC is not placed in helper mode.</td>
</tr>
<tr>
<td>interface &lt;VLANID&gt;</td>
<td>NS(config)#interface vlan3</td>
<td>Enters VLAN configuration mode.</td>
</tr>
</tbody>
</table>
The Citrix ADC appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:
• Make sure that you understand the ISIS protocol.
• For IPV6 routes, enable:
  – IPv6 protocol translation feature.
  – IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

**Enabling ISIS**

Use either of the following procedures to enable the ISIS routing feature on the Citrix ADC appliance.

To enable ISIS routing by using the CLI:

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

**Creating an ISIS Routing Process and Starting It on a VLAN**

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Displays VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>router ISIS [tag]</td>
<td>Creates an ISIS routing process and configuration mode for the routing process.</td>
</tr>
</tbody>
</table>
## Command Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `net` XX..XXXX.YYYY.YYYY.00 | Specifies a NET value for the routing process, where:  
· XX.. .XXXX is the Area Address (can be 1-13 bytes),  
· YYYY.YYYY.YYYY is the System ID (6 bytes),  
· 00 is the N-selector (1 byte). |
| `is-type` (level-1) | level-1-2 level-2-only | Sets the ISIS routing process to the specified level of routing. Default:  
level-1-2. |
| `ns IPv6-routing` | Starts the IPv6 dynamic routing daemon.                                         |
| `interface`     | Enters the VLAN configuration mode.                                            |
| `ip router ISIS` | Enables the ISIS routing process on the VLAN for IPv4 route exchanges.          |
| `ipv6 router ISIS` | Enables the ISIS routing process on the VLAN for IPv6 route exchanges.          |

### Example:

```plaintext
1  > VTYSH
2  NS# configure terminal
3  NS(config)# router isis 11
4  NS(config-router)# net 15.aabb.ccdd.0097.00
5  NS(config-router)# is-type level-1
6  NS(config-router)# exit
```
Advertising Routes

Route advertisement enables an upstream router to track network entities located behind the Citrix ADC appliance.

To configure ISIS to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Displays the VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>router ISIS [tag]</td>
<td>Starts the ISIS routing instance and enter configuration mode for the routing process.</td>
</tr>
</tbody>
</table>
| redistribute connected (level-1 or level-1-2 or level-2) | Redistributes connected routes, where:  
  level-1: Redistribute connected routes into Level-1,  
  level-1-2: Redistribute connected routes into Level-1 and Level-2,  
  level-2: Redistribute connected routes into Level-2. |
| redistribute kernel (level-1 or level-1-2 or level-2) | Redistributes kernel routes, where:  
  level-1: Redistribute kernel routes into Level-1,  
  level-1-2: Redistribute kernel routes into Level-1 and Level-2,  
  level-2: Redistribute kernel routes into Level-2. |

Example:

```
1  >VTYSH
2  NS# configure terminal
3  NS(config)# router isis 11
4  NS(config-router)# redistribute connected level-1
5  NS(config-router)# redistribute kernel level-1
```
Limiting ISIS Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Displays the VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>router isis [tag]</td>
<td>Enters the configuration mode for the routing process.</td>
</tr>
<tr>
<td>passive-interface &lt;vlan_name&gt;</td>
<td>Suppresses routing updates on interfaces bound to the specified VLAN.</td>
</tr>
</tbody>
</table>

Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# passive-interface VLAN0
```

Verifying the ISIS Configuration

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Displays the VTYSH command prompt.</td>
</tr>
<tr>
<td>show ip isis route</td>
<td>Displays updated IPv4 ISIS routing table.</td>
</tr>
<tr>
<td>show ipv6 isis route</td>
<td>Displays updated IPv6 ISIS routing table.</td>
</tr>
<tr>
<td>sh isis interface &lt;vlan_name&gt;</td>
<td>Displays IPv6 ISIS information for the specified VLAN.</td>
</tr>
</tbody>
</table>
Example:

```
1 NS# VTYSH
2 NS# show ip isis route
3 NS# show ipv6 isis route
4 NS# sh isis interface VLAN0
```

**Install Routes to the Citrix ADC Routing Table**

January 23, 2019

Contributed by:
C

The Citrix ADC appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line:

At the CLI, type the following commands as appropriate for the routes that you want to install:

<table>
<thead>
<tr>
<th>Commands</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTYSH</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>ns route-install Default</td>
<td>Install IPv4 default routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install RIP</td>
<td>Install IPv4 RIP specific routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install BGP</td>
<td>Install IPv4 BGP specific routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install OSPF</td>
<td>Install IPv4 OSPF specific routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install IPv6 Default</td>
<td>Install IPv6 default routes to the internal routing table.</td>
</tr>
</tbody>
</table>
Citrix ADC 12.1

<table>
<thead>
<tr>
<th>Commands</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns route-install IPv6 RIP</td>
<td>Install IPv6 RIP specific routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install IPv6 BGP</td>
<td>Install IPv6 BGP specific routes to the internal routing table.</td>
</tr>
<tr>
<td>ns route-install IPv6 OSPF</td>
<td>Install IPv6 OSPF specific routes to the internal routing table.</td>
</tr>
</tbody>
</table>

Example:

1. VTYSH
2. NS# configure terminal
3. NS# ns route-install Default
4. NS(config)# ns route-install RIP
5. NS(config)# ns route-install BGP
6. NS(config)# ns route-install OSPF
7. NS# ns route-install IPv6 Default
8. NS(config)# ns route-install IPv6 RIP
9. NS(config)# ns route-install IPv6 BGP
10. NS(config)# ns route-install IPv6 OSPF

Advertisement of SNIP and VIP Routes to Selective Areas

January 23, 2019

Contributed by:

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.
The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

**Advertise SNIP Routes to Selective Areas**

To configure the network route and tag parameters of a SNIP address by using the CLI:

At the command prompt, type:

- If adding a new SNIP address:
  
  ```
  addnsip <IPAddress>@<netmask>-typeSNIP-networkroute (ENABLED|DISABLED) -tag<positive_integer>
  ```
  
  ```
  shownsip <IPAddress>
  ```

- If reconfiguring an existing SNIP address:
  
  ```
  setnsip <IPAddress>@<netmask>-typeSNIP-networkroute (ENABLED|DISABLED) -tag<positive_integer>
  ```
  
  ```
  shownsip <IPAddress>
  ```

To configure the network route and tag parameters of a SNIP address by using GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Set the **Network Route** and **Tag** parameters while adding a Subnet IP (SNIP) address or modifying an existing Subnet IP address.

**Advertise VIP Routes to Selective Areas**

To configure the host route and tag parameters of a VIP address by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new VIP address:
  
  ```
  add nsip <IPAddress>@<netmask>-typeVIP -hostRoute (ENABLED|DISABLED) -tag<positive_integer>
  ```
  
  ```
  show nsip <IPAddress>
  ```

- If reconfiguring an existing VIP address:
To configure the network route and tag parameters of a VIP address by using the GUI:

1. Navigate to System > Network > IPs > IPv4s.
2. Set the Host Route and Tag parameters while adding a VIP address or modifying an existing VIP address.

Bidirectional Forwarding Detection (BFD) protocol is a mechanism for fast detection of failures of forwarding paths. BFD detects path failures in the order of milliseconds. BFD is used in conjunction with dynamic routing protocols.

In BFD operation, routing peers exchange BFD packets at a negotiated interval. If a packet is not received from a peer within the negotiated interval plus grace interval, the peer is considered to be dead and a notification will be sent to the set of registered routing protocols. In turn, the routing protocols recalculate the best path and reprogram the routing table. BFD supports smaller time interval, when compared to the timers provided by the routing protocols, thus resulting in faster detection of failures.

The Citrix ADC appliance supports BFD for the following routing protocols: BGP (IPv4 and IPv6), OSPFv2 (IPv4), and OSPFv3 (IPv6). BFD support in the Citrix ADC appliance is compliant with RFCs 5880, 5881, and 5883.

Points to Consider for Configuring Bidirectional Forwarding Detection

Before you start configuring BFD, consider the following points:

- Make sure that you understand the different components of BFD, described in RFCs 5880, 5881, and 5883.
- BFD on a Citrix ADC appliance is supported for the following routing protocols:
- BGP (IPv4 and IPv6)
- OSPFv2 (IPv4)
- OSPFv3 (IPv6)

- BFD on a Citrix ADC appliance is not supported for the following routing protocols:
  - ISIS
  - RIP (IPv4)
  - RIPng (IPv6)

- The following BFD features are not supported on a Citrix ADC appliance:
  - BFD Echo mode
  - BFD Authentication
  - BFD Demand asynchronous mode

- The minimum value for BFD interval and BFD Rx timers are 100 milliseconds.
- When BFD is used in a topology with shared IP addresses (for example, Layer 2 high availability setup with SNIP addresses or a cluster setup with striped IP addresses), BFD brings down the active sessions during a failover because the BFD failure detection time (order of milliseconds) is lesser than the HA failover detection interval (3-4 seconds). Therefore, Citrix recommends usage of Graceful restart in layer-2 HA topologies as the routes are retained during the failover process.

**Configuration Steps**

Configuring BFD on a Citrix ADC appliance consists of the following tasks:

- Configure BFD Parameters
- Configure BFD Support for Dynamic Routing Protocols

**Configure BFD Parameters**

The Citrix ADC appliance provides separate BFD session parameters for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. If you do not configure BFD parameters for a type of session, the default values are applied for that session.

The default value of each BFD parameter is same for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. The following table displays the default value of each BFD parameter.

<table>
<thead>
<tr>
<th>BFD Parameter Name</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval</td>
<td>750 milliseconds</td>
</tr>
<tr>
<td>Minimum Rx</td>
<td>500 milliseconds</td>
</tr>
<tr>
<td>Multiplier</td>
<td>3</td>
</tr>
</tbody>
</table>
Configuring BFD Parameters for a Single Hop Session

To configure BFD parameters for a single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>interface &lt;vlan ID&gt;</td>
<td>Enter the interface configuration mode.</td>
</tr>
<tr>
<td>bfd singlehop-peer interval &lt;num&gt;</td>
<td>Configure the BFD parameters on the specified interface.</td>
</tr>
<tr>
<td>minrx &lt;num&gt; multiplier &lt;num&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Sample configuration:

1. vtysh
2. ns# configure terminal
3. ns(config)# interface vlan3
4. ns(config-if)# bfd singlehop-peer interval 200 minrx 200 multiplier 5
5. ns(config-if)# exit

Configuring BFD Parameters for IPv4 Multiple Hop Sessions

To configure BFD parameters for IPv4 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>bfd multihop-peer &lt;ipv4addr&gt;</td>
<td>Configure the BFD parameters for IPv4 multiple hop sessions.</td>
</tr>
<tr>
<td>interval &lt;num&gt; minrx &lt;num&gt; multiplier</td>
<td></td>
</tr>
<tr>
<td>&lt;num&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Sample configuration:
Configuring BFD Parameters for IPv6 Multiple Hop Sessions

To configure BFD parameters for IPv6 multiple hop sessions by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>bfd multihop-peer ipv6 &lt;ipv6addr&gt; interval &lt;num&gt; minrx &lt;num&gt; multiplier &lt;num&gt;</td>
<td>Configure the BFD parameters for IPv6 multiple hop sessions.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
> vtysh
ns# configure terminal
ns(config)# bfd multihop-peer ipv6 2002:0:138 interval 300 minrx 300 multiplier 5
ns(config)# exit
```

Configure BFD Support for Dynamic Routing Protocols

You can enable BFD for a dynamic routing protocol for a type of session with a peer, for example, single hop and multiple hop. The Citrix ADC appliance applies the relevant BFD parameter settings to the session.
Configuring BFD for an IPv4 BGP Single Hop Session

To configure BFD for an IPv4 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router bgp &lt;asnumber&gt;</td>
<td>BGP autonomous system. &lt; asnumber&gt; is a required parameter.</td>
</tr>
<tr>
<td>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</td>
<td>Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td>neighbor &lt;ipv4addr&gt; fall-over bfd</td>
<td>Enable BFD for the specified neighbor.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
1   > vtysh
2
3   ns# configure terminal
4
5   ns(config)#router bgp 1
6
7   ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9   ns(config-router)#neighbor 20.20.20.138 fall-over bfd
10
11  ns(config-router)#redistribute kernel
12
13  ns(config-router)#exit
```

Configuring BFD for an IPv4 BGP Multiple Hop Session

To configure BFD for an IPv4 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
</tbody>
</table>
Citrix ADC 12.1

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router bgp &lt;asnumber&gt;</td>
<td>BGP autonomous system. &lt; asnumber&gt; is a required parameter.</td>
</tr>
<tr>
<td>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</td>
<td>Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td>neighbor &lt;ipv4addr&gt; fall-over bfd multihop</td>
<td>Enable BFD for the specified neighbor.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
> vtysh
ns# configure terminal
ns(config)#router bgp 1
ns(config-router)#neighbor 20.20.20.138 remote-as 1
ns(config-router)#neighbor 20.20.20.138 fall-over bfd multihop
ns(config-router)#redistribute kernel
ns(config-router)#exit
```

Configuring BFD for an IPv6 BGP Single Hop Session

To configure BFD for an IPv6 BGP single hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router bgp &lt;asnumber&gt;</td>
<td>BGP autonomous system. &lt; asnumber&gt; is a required parameter.</td>
</tr>
</tbody>
</table>
### Command Specifies

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>neighbor &lt;ipv6addr&gt; remote-as &lt;num&gt;</td>
<td>Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.</td>
</tr>
<tr>
<td>neighbor &lt;ipv6addr&gt; fall-over bfd</td>
<td>Enable BFD for the specified neighbor.</td>
</tr>
<tr>
<td>address-family ipv6</td>
<td>Enter address family configuration mode.</td>
</tr>
<tr>
<td>neighbor &lt;ipv6addr&gt; activate</td>
<td>Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.</td>
</tr>
</tbody>
</table>

**Sample configuration:**

```plaintext
> vtysh
ns# configure terminal ns(config)#router bgp 1
ns(config-router)#neighbor 30fe:123::124 remote-as 1
ns(config-router)#neighbor 30fe:123::124 fall-over bfd
ns(config-router)#address-family ipv6
ns(config-router-af)#neighbor 30fe:123::124 activate
ns(config-router-af)#redistribute kernel
ns(config-router-af)#exit
```

**Configuring BFD for an IPv6 BGP Multiple Hop Session**

To configure BFD for an IPv6 BGP multiple hop session by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router bgp &lt;asnumber&gt;</td>
<td>BGP autonomous system. &lt; asnumber&gt; is a required parameter.</td>
</tr>
</tbody>
</table>
Command | Specifies
---|---
neighbor <ipv6addr> remote-as <num> | Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
neighbor <ipv6addr> fall-over bfd multihop | Enable BFD for the specified neighbor.
address-family ipv6 | Enter address family configuration mode.
neighbor <ipv6addr> activate | Exchange prefixes for the IPv6 router family between the peer and the local node by using the link-local address.

Sample configuration:

```
1  > vtysh
2
3  ns# configure terminal
4
5  ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx 500 multiplier 5
6
7  ns(config)#router bgp 1
8
9  ns(config-router)#neighbor 20fe:125::138 remote-as 1
10
11 ns(config-router)#neighbor 20fe:125::138 fall-over bfd multihop
12
13 ns(config-router)#address-family ipv6
14
15 ns(config-router-af)#neighbor 20fe:125::138 activate
16
17 ns(config-router-af)#redistribute kernel
18
19 ns(config-router-af)#end
```

Configuring BFD for OSPFv2 (IPv4) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv2 protocol. To configure BFD for OSPFv2 on all interfaces by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:
<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ospf &lt;process tag&gt;</td>
<td>Enter OSPFv2 configuration mode.</td>
</tr>
<tr>
<td>bfd all-interfaces</td>
<td>Enable BFD on all interfaces that use OSPFv2.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
> vtysh
ns# configure terminal
ns(config)#router ospf 1
ns(config-router)#bfd all-interfaces
ns(config-router)#redistribute kernel
ns(config-router)#exit
```

To configure BFD for OSPFv2 on a specific interface by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>interface &lt;vlan ID&gt;</td>
<td>Enter the interface configuration mode.</td>
</tr>
<tr>
<td>ip ospf bfd</td>
<td>Enable BFD on the specified interface that uses OSPFv2.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
> vtysh
ns# configure terminal
ns(config)# interface vlan5
```
Configuring BFD for OSPFv3 (IPv6) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv3 protocol. To configure BFD for OSPFv3 on all interfaces by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>router ipv6 ospf &lt;process tag&gt;</td>
<td>Enter OSPFv3 configuration mode.</td>
</tr>
<tr>
<td>bfd all-interfaces</td>
<td>Enable BFD on all interfaces that use OSPFv3.</td>
</tr>
</tbody>
</table>

Sample configuration:

```
> vtysh
ns# configure terminal
ns(config-if)# router ipv6 ospf 10
ns(config-router)# bfd all-interfaces
ns(config-router)# redistribute kernel
ns(config-router)# exit
```

To configure BFD for OSPFv3 on a specific interface by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>vtysh</td>
<td>Display VTYSH command prompt.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>interface &lt;vlan ID&gt;</td>
<td>Enter the interface configuration mode.</td>
</tr>
</tbody>
</table>
Command | Specifies
--- | ---
ipv6 ospf bfd | Enable BFD on the specified interface that uses OSPFv3.

Sample configuration:

```
1. > vtysh
2. ns# configure terminal
3. ns(config)# interface vlan15
4. ns(config-if)# ipv6 ospf bfd
5. ns(config-if)# exit

Configuring Static Routes

January 25, 2019

Contributed by: C

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

**Monitored Static Routes.** If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the Citrix ADC appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are
transmitted and received by the Citrix ADC. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

**Note:** In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a Citrix ADC is load balancing traffic to a site across multiple servers.

Router R1 moves traffic between the client and the Citrix ADC appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers’ subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the Citrix ADC points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the Citrix ADC marks it as DOWN. The Citrix ADC now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The Citrix ADC supports monitoring of IPv4 and IPv6 static routes. You can configure the Citrix ADC to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the Citrix ADC to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

**Weighted Static Routes.** When the Citrix ADC appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The Citrix ADC then uses both the weight and the hashed value for balancing the load.

**Null Routes.** If the route chosen in a routing decision is inactive, the Citrix ADC appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

### Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the
parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

**CLI procedures**

To create a static route by using the CLI:

At the command prompt, type:

- `add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise ( DISABLED | ENABLED )]
- `show route [<network> <netmask> [gateway]] [<routeType>] [-detail]

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise ENABLED
2   Done
```

To create a monitored static route by using the CLI:

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- `add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>] [-msr ( ENABLED | DISABLED ) [-monitor <string>]]
- `show route [<network> <netmask> [gateway]] [<routeType>] [-detail]

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6 -msr ENABLED -monitor PING
2   Done
```

To create a null route by using the CLI:

At the command prompt type:

- `add route <network> <netmask> null
- `show route <network> <netmask>

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 null
2   Done
```

To remove a static route by using the CLI:
At the command prompt, type:

```
rm route <network> <netmask> <gateway>
```

**Example:**

```
1 > rm route 10.102.29.0 255.255.255.0 10.102.29.3
2 Done
```

**GUI procedures**

To configure a static route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

**Configuring IPv6 Static Routes**

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

**CLI procedures**

To create an IPv6 route by using the CLI:

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

```
• add route6 <network> <gateway> [-vlan <positive_integer>]
• show route6 [<network> [<gateway>]
```

**Example:**

```
1 > add route6 ::/0 FE80::67 -vlan 5
2 Done
```

To create a monitored IPv6 static route by using the CLI:
At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- `add route6 <network> <gateway> [-msr ( ENABLED | DISABLED ) [-monitor <string>]]`
- `show route6 [<network> [<gateway>]]`

**Example:**

```
1 > add route6 ::/0 2004::1 -msr ENABLED -monitor PING
2  Done
```

To remove an IPv6 route by using the CLI:

At the command prompt, type:

`rm route6 <network> <gateway>`

**Example:**

```
1 > rm route6 ::/0 FE80::67
2  Done
```

**GUI procedures**

To configure an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPv6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPv6 tab, delete the IPv6 route.

3. Networking

**Route Health Injection Based on Virtual Server Settings**

January 23, 2019

Contributed by:
C
The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the Citrix ADC appliance for advertising the route of a VIP address.

- **VSVR_CNTRLD.** It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.

- **RHI STATE.** It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the Citrix ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.
- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the Citrix ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The Citrix ADC appliance has two virtual servers V1 and V2 associated with the VIP address:

<table>
<thead>
<tr>
<th>Associated virtual servers for a VIP</th>
<th>State 1</th>
<th>State 2</th>
<th>State 3</th>
<th>State 4</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RHI State set to PASSIVE on all virtual servers</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>V1</td>
<td>UP</td>
<td>UP</td>
<td>DOWN</td>
<td>DOWN</td>
</tr>
<tr>
<td>V2</td>
<td>UP</td>
<td>DOWN</td>
<td>UP</td>
<td>DOWN</td>
</tr>
<tr>
<td>Advertise the route for this VIP address?</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

| **RHI State set to ACTIVE on all virtual servers** |         |         |         |         |
| V1                                  | UP      | UP      | DOWN    | DOWN    |
To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR_CNTRLD for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using the CLI:

At the command prompt, type:

```
set nsip <IPAddress> [-vserverRHILevel <vserverRHILevel>]
```

To set the RHI State parameter of a virtual server by using the CLI:

At the command prompt, type:

```
set lb vserver <name> [-RHIstate ( PASSIVE | ACTIVE )]
```

To set the vServer RHI Level for a VIP address by using GUI

1. Navigate to System > Network > IPs.
2. Select a VIP address, and then click Edit.
3. Set the Vserver RHI Level parameter to VSVR_CNTRLD, and then click OK.
To set the RHI State parameter of a virtual server by using GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers.**
2. Select a load balancing virtual server, and then click **Edit.**
3. Set the **RHI State** parameter, and then click **OK.**

---

**Configuring Policy-Based Routes**

January 23, 2019
Contributed by: C

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the Citrix ADC appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the Citrix ADC applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the Citrix ADC to route the packet. These actions are known as “processing modes.” The processing modes are:

- **ALLOW.** The appliance sends the packet to the designated next-hop router.
- **DENY.** The Citrix ADC applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.
Policy-Based Routes (PBR) for IPv4 Traffic

January 23, 2019
Contributed by: C

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBRs. When you create a PBR without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR, the Citrix ADC compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the Citrix ADC and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

CLI procedures

To create a PBR by using the CLI:

At the command prompt, type:

```
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To modify the priority of a PBR by using the CLI:

At the command prompt, type the following commands to modify the priority and verify the configuration:

- show ns pbr

Example:

```
1 > set ns pbr pbr1 -priority 23
2 Done
```

To remove one or all PBRs by using the CLI:

At the command prompt, type one of the following commands:

- rm ns pbr <name>
- clear ns pbrs

Example:

```
1 > rm ns pbr pbr1
2 Done
3
4 > clear ns PBRs
5 Done
```
GUI procedures

To create a PBR by using the GUI:
Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.
To remove one or all PBRs by using the GUI:
Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not
disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1-
p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied
and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must
follow this procedure after disabling a PBR.

Note: PBRs created on the Citrix ADC appliance do not work until they are applied.

To apply a PBR by using the CLI:
At the command prompt, type:
apply ns PBRs
To apply a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the Citrix ADC appliance
automatically compares incoming packets against the configured PBRs. If a PBR is not required in
the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs
are applied. After the PBRs are applied, the Citrix ADC does not compare incoming packets against
disabled PBRs.

To enable or disable a PBR by using the CLI:
At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>
Example:

```
1  > enable ns PBR pbr1
2    Done
3  > show ns PBR pbr1
4     1) Name: pbr1
5          Action: ALLOW            Hits: 0
6          srcIP = 10.102.37.252
7          destIP = 10.10.10.2
8          srcMac:                  Protocol:
9          Vlan:                    Interface:
10         Active Status: ENABLED   Applied Status: APPLIED
11         Priority: 10
12         NextHop: 10.102.29.77
13    Done
14
15  > disable ns PBR pbr1
16     Warning: PBR modified, use 'apply pbrs' to commit this operation
17  > apply pbrs
18    Done
19
20  > show ns PBR pbr1
21     1) Name: pbr1
22          Action: ALLOW            Hits: 0
23          srcIP = 10.102.37.252
24          destIP = 10.10.10.2
25          srcMac:                  Protocol:
26          Vlan:                    Interface:
27          Active Status: DISABLED Applied Status: NOTAPPLIED
28          Priority: 10
29          NextHop: 10.102.29.77
30    Done
31
32```

To enable or disable a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

**Renumbering PBRs**

You can automatically renumber the PBRs to set their priorities to multiples of 10.
To renumber PBRs by using the CLI:

At the command prompt, type:

- renumber ns pbrs

To renumber PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

**Use Case - PBR with Multiple Hops**

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on Citrix ADC appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The Citrix ADC appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - DESTIPHASH
  - SOURCEIPHASH
  - WEIGHTDRR
  - SRCIPDESTIP_HASH
  - LTRM
  - CUSTOM LOAD
- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP
The following table lists the names and values of the entities configured on the Citrix ADC appliance:
To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

**Example:**

```
1  > add service Router1 1.1.1.254 ANY *
2       Done
3  > add service Router2 2.2.2.254 ANY *
4       Done
5  > add service Router3 3.3.3.254 ANY *
6       Done
```

To create a service by using the GUI:

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the CLI:

At the command prompt, type:

- add lb vservice <name> <serviceType>
Citrix ADC 12.1

- bind lb vserver < name> <serviceName>
- show lb vserver < name>

**Example:**

```
1 > add lb vserver LLB1 ANY
2  Done
3 > bind lb vserver LLB1 Router1 Router2 Router3
4  Done
```

To create a link load balancing virtual server and bind a service by using the GUI:

   
   Note: Make sure that **Directly Addressable** is unchecked.

2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

**Example:**

```
1 > add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
2  Done
3 > add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
4  Done
```

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

**Policy-Based Routes (PBR6) for IPv6 Traffic**

January 23, 2019

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3083
Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the Citrix ADC appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the Citrix ADC automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the Citrix ADC performs an action. If the packet does not match the condition defined by the PBR6, the Citrix ADC compares the packet against the PBR6 with the next highest priority.

CLI procedures

To create a PBR6 by using the CLI:

At the command prompt, type:

To modify or remove a PBR6 by using the CLI:

To modify a PBR6, type the set pbr6 <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the CLI:

At the command prompt, type one of the following commands:
• \texttt{rm ns pbr6 <name>}
• \texttt{clear ns pbr6}

\textbf{GUI procedures}

To create or modify a PBR6 by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

\textbf{Applying PBR6s}

You must apply a PBR6 to activate it. The following procedure reappplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

\textbf{Note:} PBR6s created on the Citrix ADC appliance do not work until they are applied.

To apply PBR6s by using the CLI:

At the command prompt, type:

• \texttt{apply ns PBR6}

To apply PBR6s by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

\textbf{Enabling or Disabling a PBR6}

By default, the PBR6s are enabled. This means that when PBR6s are applied, the Citrix ADC appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the Citrix ADC does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the CLI:
At the command prompt, type one of the following commands:

- `enable ns pbr <name>`
- `disable ns pbr <name>`

To enable or disable a PBR6 by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

**Renumbering PBR6s**

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the CLI:

At the command prompt, type:

- `renumber ns pbr6`

To renumber PBR6s by using the GUI:

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

3.  Citrix ADC 12.1
4.  Networking

**MAC Address Wildcard Mask for PBRs**

January 23, 2019

Contributed by:

C

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero
The wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the CLI:

At the command prompt, type:

- `add ns pbr <name> <action> -srcMac <mac_addr> -srcMacMask <string>`
- `show ns pbr <pbrname>

Example:

```
> add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a -srcMacMask 000000111111 -nexthop 198.51.100.1
> show ns pbr PBR-1
```

Done

To specify a range of source MAC addresses in an PBR6 rule by using the CLI:

At the command prompt, type:

- `add ns pbr6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
- `show pbr6 <pbr6name>

Example:

```
```
Using NULL Policy Based Routes to Drop Outgoing Packets

January 23, 2019
Contributed by: C

Some situations might demand that the Citrix ADC appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The Citrix ADC appliance drops outgoing packets that match a NULL PBR.

Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the CLI:

At the command prompt, type:

```bash
• add ns pbr <name> ALLOW [-td <positive_integer>] [-srcIP | <operator> | srcIPVal] [-srcPort | <operator> | srcPortVal] [-destIP | <operator> | destIPVal] [-destPort | <operator> | destPortVal] [-nextHop NULL] [srcMac | <mac_addr>] [srcMacMask | <string>] [-protocol | <protocol> | protocolNumber | <positive_integer>] [-vlan | <positive_integer> | vxlan | <positive_integer>] [-interface | <interface_name>] [-priority | <positive_integer>] [-msr (ENABLED | DISABLED)] [-monitor | <string>] [-state (ENABLED | DISABLED)] [-ownerGroup | <string>]

• apply ns pbrs

• show ns pbrs id>
```

To configure a NULL PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new NULL PBR, or edit an existing NULL PBR.
Sample configuration

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

```
1  > add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW -nextHop NULL -interface 1/5
2  Done
3
4  > apply ns pbr6
5  Done
```

Troubleshooting Routing Issues

January 23, 2019

Contributed by:
C

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the Citrix ADC appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
Generic Routing FAQs

January 23, 2019
Contributed by: C

Users typically have the following questions about how to troubleshoot generic routing issues:

• How do I save the config files?

  The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from CLI to save both ns.conf and ZebOS.conf files.

• If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

• How do I block the advertisement of default routes?

  The default route is not injected into ZebOS.

• How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

  ```
  ns(config)# log file /var/ZebOS.log
  ```

  You can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

  ```
  ns# terminal monitor
  ```
How do I collect cores of running daemons?

You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

```
gcore [-s] [-c core] [executable] pid
```

The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

```
root@ns#gcore -s -c nsm.core /netscaler/nsm 342
```

How do I run a batch of ZebOS commands?

You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
! 1.
2. router bgp 234
3. network 1.1.1.1 255.255.255.0
4.  
5. route-map bgp-out2 permit 10
6. set metric 9900
7. set community 8602:300
8.  
```

Troubleshooting OSPF-Specific Issues

January 23, 2019

Contributed by: C
Before you start debugging any OSPF specific issue, you must collect information from the Citrix ADC appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
   - If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
   - If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:
   ```
   gcore -s -c xyz.core /netscaler/ospfd <pid>
   ```

   **Note:** The gcore command is non-disruptive.

Collect additional information from the Citrix ADC as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:
   ```
   ns(config)# log file /var/ospf.log
   ```
2. Enable debugging ospf events and log them by using the following command:
   ```
   ns(config) #log file /var/ospf.log
   ```

   Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).
Internet protocol version 6 (IPv6)

May 31, 2019
Contributed by: C

A Citrix ADC appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services.

The following table lists some of the IPv6 features that the Citrix ADC appliance supports.

Table 1. Some Supported IPv6 Features

<table>
<thead>
<tr>
<th>IPv6 features</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)</td>
</tr>
<tr>
<td>Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)</td>
</tr>
<tr>
<td>Management Applications (ping6, telnet6, ssh6)</td>
</tr>
<tr>
<td>Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)</td>
</tr>
<tr>
<td>Port Based VLANs</td>

</tbody>
</table>

Implementing IPv6 support

You must enable IPv6 feature on a Citrix ADC appliance before you can use or configure it. If IPv6 is disabled, the Citrix ADC does not process IPv6 packets. It displays the following warning when you run an unsupported command:
"Warning: Feature(s) not enabled [IPv6PT]"

Use either of the following procedures to enable or disable IPv6.

**CLI procedures**

To enable or disable IPv6 by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns feature ipv6pt`
- `disable ns feature ipv6pt`

**GUI procedures**

To enable or disable IPv6 by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure Advanced Features**.
2. Select or clear the **IPv6 Protocol Translation** option.

**VLAN support**

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the Citrix ADC appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN. For more information about ND6 and VLANs, see Configuring Neighbor Discovery.

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

**Simple deployment scenario**

Following is an example of a simple load balancing set-up consisting of an IPv6 virtual server and IPv4 services, as illustrated in the following topology diagram.

**Figure 1. IPv6 Sample Topology**

The following table summarizes the names and values of the entities that must be configured on the Citrix ADC.

**Table 2. Sample Values for Creating Entities**
The following figure shows the entities and values of the parameters to be configured on the Citrix ADC.

Figure 2. IPv6 Entity Diagram

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB virtual server.
3. Bind the services to the virtual server.

GUI procedures

To create IPv4 services by using the CLI:

At the command prompt, type:

- `add service <Name> <IPAddress> <Protocol> <Port>`
- `show service <Name>`

**Example:**

```
1 add service SVC1 10.102.29.1 HTTP 80
2 add service SVC2 10.102.29.2 HTTP 80
```

To create IPv6 virtual server by using the CLI:

At the command prompt, type:

- `add lb vserver <Name> <IPAddress> <Protocol> <Port>`
- `sh lb vserver <Name>`

**Example:**

```
1 add lb vserver VS1_IPv6 2002::9 HTTP 80
```

To bind a service to an LB virtual server by using the CLI:

At the command prompt, type:

- **bind lb vserver** `<name> <service>`
- **sh lb vserver** `<name>`

**Example:**

```
bind lb vserver VS1_IPv6 SVC1
```

**GUI procedures**

To create IPv4 services by using the GUI:

Navigate to **Traffic Management > Load Balancing > Services**, click **Add**, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 virtual server by using the GUI:

2. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the **Load Balancing Virtual Servers** page, select the virtual server for which you want to bind the service (for example, VS1_IPv6).
3. Click **Open**.
4. In the **Configure Virtual Server (Load Balancing)** dialog box, on the **Services** tab, select the **Active** check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click **OK**.
6. Repeat steps 1-4 to bind the service (for example, SVC2 to the virtual server).
**Host header modification**

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the virtual server.

**CLI procedures**

To change the IPv6 address in the host header to an IPv4 address by using the CLI:

At the command prompt, type:

- `set ns ip6 <IPv6Address> -map <IPAddress>`
- `sh ns ip6 <IPv6Address>`

**Example:**

```plaintext
set ns ip6 2002::9 -map 200.200.200.200
```

**GUI procedures**

To change the IPv6 address in the host header to an IPv4 address by using the GUI:

1. Navigate to **System > Network > IPs** and, on the **IPVs** tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the **Mapped IP** text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

**VIP insertion**

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP. Then, you can enable VIP insertion feature to enable insertion of the IPv4 VIP address and port number in the HTTP requests sent to the servers.

**CLI procedures**

To configure a map IPv6 address by using the CLI:

At the command prompt, type:

`set ns ip6 <IPv6Address> -map <IPAddress>`

**Example:**
To enable VIP insertion by using the CLI:

At the command prompt, type:

- `set lb vserver <name> -insertVserverIPPort <Value>`
- `sh lb vserver <name>`

**Example:**

```
set lb vserver VS1_IPv6 -insertVserverIPPort ON
```

**GUI procedures**

To configure a map IPv6 address by using the GUI:

1. Navigate to System > Network > IPs, on the IPv6s tab, select the IP address for which you want to configure a map IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the Mapped IP text box, type the map IP address that you want to configure, for example, 200.200.200.200.

To enable VIP insertion feature by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, select the virtual server that you want to enable port insertion, and select Edit.
2. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion list, click VIPADDR.
3. In the Vserver IP Port Insertion text box, type the vip header.

**Traffic Domains**

February 11, 2019

Contributed by:

C
Warning

Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see Admin Partitioning page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a Citrix ADC appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a Citrix ADC appliance are the following:

- **Use of duplicate IP addresses in a Network.** Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a Citrix ADC appliance, as long as each of the duplicate address belongs to a different traffic domain.

- **Use of Duplicate entities on the Citrix ADC appliance.** Traffic domains also allow you to use duplicate Citrix ADC feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
  
  Note: Duplicate entities with same name is not supported.

- **Multitenancy.** Using traffic domains, you can provide hosting services for multiple customers by isolating each customer’s type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANS. The isolation functionality of the traffic domain depends on the VLANS bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A Citrix ADC appliance has a preconfigured traffic domain, called the default traffic domain, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the Citrix ADC appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.
Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported Citrix ADC Features in Traffic Domains.

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the Citrix ADC appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work

The following table lists the settings used in the example.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Client connected to TD1</td>
<td>CL-TD1 (for reference purposes only)</td>
<td>IP address: 192.0.2.3</td>
</tr>
<tr>
<td>Load balancing virtual server in TD1</td>
<td>LBVS-TD1</td>
<td>IP address: 10.10.33.14</td>
</tr>
</tbody>
</table>
### Entity Name Details

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service bound to virtual server LBVS-TD1</td>
<td>SVC1-TD1</td>
<td>IP address: 192.0.2.36</td>
</tr>
<tr>
<td>Service bound to virtual server LBVS-TD1</td>
<td>SVC2-TD1</td>
<td>IP address: 192.0.2.37</td>
</tr>
<tr>
<td>SNIP</td>
<td>SNIP-TD1 (for reference purposes only)</td>
<td>IP address: 192.0.2.27</td>
</tr>
</tbody>
</table>

### Settings in traffic domain 2

| VLAN bound to traffic domain 2 | VLAN 3 | VLAN Id: 3 Interfaces bound: 1/3, 1/4 |
| Client connected to TD2 | CL-TD2 (for reference purposes only) | IP address: 192.0.2.3 |
| Load balancing virtual server in TD2 | LBVS-TD2 | IP address: 10.10.33.14 |
| Service bound to virtual server LBVS-TD2 | SVC3-TD2 | IP address: 192.0.2.36 |
| Service bound to virtual server LBVS-TD2 | SVC4-TD2 | IP address: 192.0.2.37 |
| SNIP in TD2 | SNIP-TD2 (for reference purposes only) | IP address: 192.0.2.29 |

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 10.10.33.14.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 10.10.33.14. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 10.10.33.14.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 10.10.33.14. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1’s load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2’s reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 10.10.33.14.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2’s ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 10.10.33.14. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 10.10.33.14. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 10.10.33.14. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2’s load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2’s reply to client CL-TD2.

**Supported Citrix ADC Features in Traffic Domains**

The Citrix ADC features in the following list are supported in all traffic domains.

---
**Important**

Any Citrix ADC feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
• MSR
• MSR6
• Net profiles
• SNMP MIBs
• Fragmentation
• Monitors (Scriptable monitors are not supported)
• Content Switching
• Cache Redirection
• Persistency
• Service (Domain based services are not supported)
• Servicegroup (Domain based service groups are not supported)
• Policies (*)
• PING
• TRACEROUTE
• PMTU
• High Availability (connection mirroring is not supported)
• Cluster (Supported on L2 clusters. Not supported on L3 clusters)
• Cookie Persistency
• MSS
• Logging
• Priority Queuing
• Surge Protection
• HTTP DOSP (**)
• Load balancing (The following types are not supported:)
  – TFTP
  – RTSP
  – Diameter
  – SIP
  – SMPP
• NAT46
• NAT64
• DNS64
• Forwarding Session Rules
• SNMP

Note
• * Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.
• ** HTTP DOSP policies do not have global binding points for traffic domains. However,
HTTP DOSP policies can be bound to a specific load balancing service of a traffic domain.

- Global Server Loading Balancing (GSLB) and ADNS features in Citrix ADC are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see http://support.citrix.com/article/CTX202277.

Configuring Traffic Domains

Configuring a traffic domain on the Citrix ADC appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain.** Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a traffic domain identifier (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled How Traffic Domains Work.

The CLI has two commands for these two tasks, but the GUI combines them in a single dialog box.

**CLI procedures**

To create a VLAN and bind interfaces to it by using the CLI:

At the command prompt, type:

- add vlan <id>
- bind vlan <id> -ifnum <slot/port>
- show vlan <id>

To create a traffic domain entity and bind VLANs to it by using the CLI:

At the command prompt, type:

- add ns trafficdomain <td>
Citrix ADC 12.1

- **bind ns trafficdomain** `<td> -vlan <id>`
- **show ns trafficdomain** `<td>`

To create a service by using the CLI:

At the command prompt, type:

- **add service** `<name> <IP> <serviceType> <port> -td <id>`
- **show service** `<name>`

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- **add lb vserver** `<name> <serviceType> <IPAddress> <port> -td <id>`
- **bind lb vserver** `<name> <serviceName>`
- **show lb vserver** `<name>`

**GUI procedures**

To create a VLAN by using the GUI:

Navigate to **System > Network > VLANs**, click **Add**, and set the parameters.

To create a traffic domain entity by using the GUI:

Navigate to **System > Network > Traffic Domains**, click **Add**, and in the **Create Traffic Domain** dialog box, set the parameters.

To create a service by using the GUI:

Navigate to **Traffic Management > Load Balancing > Services**, click **Add**, and set the parameters.

To create a load balancing virtual server by using the GUI:

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, click **Add**, and set the parameters.

2. Citrix ADC 12.1
3. Networking

**Inter Traffic Domain Entity Bindings**

January 23, 2019
You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing bind lb vserver command or the related GUI procedure.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a Citrix ADC is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant’s traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on Citrix ADC appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

2. Citrix ADC
3. Citrix ADC 12.1
4. Networking

**VMAC Based Traffic Domains**

January 25, 2019
You can associate a traffic domain with a VMAC address instead of with VLANs. The Citrix ADC then sends the traffic domain’s VMAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the VMAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.

Consider an example in which two traffic domains, with IDs 1 and 2, are configured on Citrix ADC appliance NS1. The Citrix ADC creates a VMAC address VMAC1 and associates it with traffic domain 1. Similarly, the Citrix ADC created another VMAC address VMAC2 and associates with traffic domain 2.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the Citrix ADC appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the Citrix ADC to communicate with S1 and S2. Because VMAC1 is associated with traffic domain 1, the appliance sends VMAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the Citrix ADC appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the Citrix ADC to communicate with S3 and S4. Because VMAC2 is associated with traffic domain 2, the appliance sends VMAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The Citrix ADC segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is VMAC1 or VMAC2.

The following table lists the settings used in the example: VMAC based traffic domain example settings.

### Before you Begin

Following are points to consider before you configure VMAC based traffic domain:

1. VMAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because VMAC based traffic domains segregate network traffic based on VMAC addresses and not VLANs, you cannot create duplicate IP addresses on different VMAC based traffic domains on a Citrix ADC.
3. VMAC based traffic domains do not work when the Citrix ADC is deployed only in L2 Mode.
4. Both VLAN and VMAC based traffic domains can coexist on a Citrix ADC. VMAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

**Configuration Steps**

Configuring a VMAC based traffic domain on a Citrix ADC appliance consists of the following tasks:

- Create a traffic domain entity and enable the VMAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the VMAC option. After creating the traffic domain entity, the Citrix ADC creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. Citrix ADC owned network entities created in a VMAC based traffic domain are associated with the VMAC address, which is associated with the traffic domain. The Citrix ADC then sends the traffic domain’s VMAC address in ARP announcements and ARP responses for these network entities.

**CLI procedures**

To create a VMAC based traffic domain by using the CLI:

At the command prompt, type:

```
add ns trafficDomain <td> [-vmac ( ENABLED DISABLED )]
```

- show ns trafficdomain <td>

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP –td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the CLI:
At the command prompt, type:

- `add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>`
- `bind lb vserver <name> <serviceName>`
- `show lb vserver <name> -td <id>`

Example:

```bash
$> add ns trafficDomain 1 -vmac ENABLED
Done
$> add ns trafficDomain 2 -vmac ENABLED
Done
$> add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
Done
$> add service SVC-S1-TD1 192.0.2.10 HTTP 80 -td 1
Done
$> add service SVC-S2-TD1 192.0.2.20 HTTP 80 -td 1
Done
$> add lb vserver LBVS-TD1 HTTP 203.0.113.15 80 -td 1
Done
$> bind lb vserver LBVS-TD1 SVC-S1-TD1
Done
$> bind lb vserver LBVS-TD1 SVC-S2-TD1
Done
$> add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
Done
$> add service SVC-S3-TD2 192.0.2.30 HTTP 80 -td 2
Done
$> add service SVC-S4-TD2 192.0.2.40 HTTP 80 -td 2
Done
$> add lb vserver LBVS-TD1 HTTP 203.0.113.16 80 -td 1
Done
$> bind lb vserver LBVS-TD2 SVC-S3-TD2
Done
$> bind lb vserver LBVS-TD2 SVC-S3-TD2
Done
```

GUI procedures

To create a VMAC based traffic domain by using the GUI:

1. Navigate to System > Network > Interfaces.
2. In the details pane, click Add.
3. On the Create Traffic Domain page, set the following parameters:
   - Traffic Domain ID*
   - Enable Mac
4. Click Create.

To configure a SNIP address by using the GUI:

1. Navigate to System > Network > IPs > IPv4
2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add
4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - IP Address
   - Netmask
   - IP Type
   - Traffic Domain ID
5. Click Create.

To create a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Service Name
   - Server
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the GUI:

2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Name
   - IP Address
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, on the Service Pane, click >.
5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
6. Click Continue, and click Done.
7. Repeat steps 2-5 to create another virtual server

VXLAN

January 25, 2019
Contributed by: C

Citrix ADC appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the *VXLAN Network Identifier (VNI).* Only network devices within the same VXLAN can communicate with each other.

VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.

- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.
How VXLANS Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as a tunnel between two VTEPs, where one VTEP encapsulates a Layer 2 frame with a UDP header and an IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A Citrix ADC is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.

The following illustration displays the format of a VXLAN packet.

VXLANs on a Citrix ADC use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- **Unicast mode**: In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a Citrix ADC. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- **Multicast mode**: In this mode, you specify a multicast group IP address while configuring a VXLAN on a Citrix ADC. Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol. Citrix ADCs rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

Similar to a Layer 2 bridge table, Citrix ADCs maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP IP addresses for a particular VXLAN. The Citrix ADC uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Because VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.

**VXLAN Use Case: Load Balancing across Datacenters**

To understand the VXLAN functionality of a Citrix ADC, consider an example in which Example Corp hosts a site at www.example.com. To ensure application availability, the site is hosted on three
servers, S0, S1, and S2. A load balancing virtual server, LBVS, on Citrix ADC NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.

The following table lists the settings used in this example:

<table>
<thead>
<tr>
<th>VXLAN settings</th>
</tr>
</thead>
</table>

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

1. NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
   - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
   - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
2. NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
3. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on VXLAN-9000. The encapsulated packet has:
   - Source IP address = SNIP-VTEP-0 (203.0.100.100).
4. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
5. From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
6. Dev-VTEP-2 sends the ARP packet to S2. S2’s response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
7. S2 responds with its MAC address (MAC-S2). The ARP response packet has:
8. S2’s response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.

9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2’s ARP response. NS-ADC updates its VXLAN mapping table for S2’s MAC address (MAC-S2) with Dev-VTEP-2’s IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates its ARP table for S2’s IP address (192.0.1.102) with S2’s MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:
   - Source IP address = IP address of client CL (198.51.100.90)
   - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100

2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.

3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:
   - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
   - Destination IP address = IP address of S2 (192.0.1.102)

4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.

5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.

6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
   - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
   - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)

7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.

8. Dev-VTEP-2 then forwards the packet to S2.

9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
   - Source IP address = IP address of S2 (192.0.1.102)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.

11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.

12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
   - Source IP address = IP address of client CL (198.51.100.90)
   - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

**Points to Consider for Configuring VXLANs**

Consider the following points before configuring VXLANs on a Citrix ADC:

- A maximum of 2048 VXLANs can be configured on a Citrix ADC.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.
- Citrix ADCs do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. Citrix ADCs rely on the IGMP protocol of its upstream router to join a multicast group, which share a common multicast group IP address. You can specify a multicast group IP address while creating VXLAN bridge table entries but the multicast group must be configured on the upstream router. The Citrix ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.
- VXLAN encapsulation adds an overhead of 50 bytes to each packet:
  
  Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

*Important*: Jumbo frames are not supported on the Citrix ADC VPX virtual appliances, Citrix ADC SDX appliances, and Citrix ADC MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.

- On Citrix ADC SDX appliances, VLAN filtering does not work for VXLAN packets.
You cannot set a MTU value on a VXLAN.

You cannot bind interfaces to a VXLAN.

Configuration Steps

Configuring a VXLAN on a Citrix ADC appliance consists of the following tasks.

- **Add a VXLAN entity.** Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. You can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over this VXLAN. If no VLANs are bound to the VXLAN, the Citrix ADC allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.

- **Bind the local VTEP IP address and to the VXLAN entity.** Bind one of the configured SNIP address to the VXLAN to source outgoing VXLAN packets.

- **Add a bridgetable entry.** Add a bridgetable entry specifying the VXLAN ID and the remote VTEP IP address for the VXLAN to be created.

- **(Optional) Bind different feature entities to the configured VXLAN.** VXLANs function similarly to VLANs, most of the Citrix ADC features that support VLAN as a classification parameter also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

- **(Optional) Display the VXLAN mapping table.** Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a host is reachable through the VTEP on a particular VXLAN. The Citrix ADC learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The Citrix ADC uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the Citrix ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

CLI procedures

To add a VXLAN entity by using CLI:

At the command prompt, type

- `add vxlan <id>`
- `show vxlan <id>`
To bind the local VTEP IP address to the VXLAN by using CLI:

At the command prompt, type

- `bind vxlan <id> -SrcIP <IPaddress>`
- `show vxlan <id>`

To add a bridgetable by using CLI:

At the command prompt, type

- `add bridgetable -mac <macaddress> -vxlan <ID> -vtep <IPaddress>`
- `show bridgetable`

To display the VXLAN forwarding table by using the command line:

At the command prompt, type:

- `show bridgetable`

**GUI procedures**

To add a VXLAN entity and bind a local VTEP IP address by using the GUI:

Navigate to System > **Network** > **VXLANs**, and add a new VXLAN entity or modify an existing VXLAN entity.

To add a bridgetable by using the GUI:

Navigate to System > **Network** > **Bridge Table**, set the following parameters while adding or modifying a VXLAN bridge table entry:

- MAC
- VTEP
- VXLAN ID

To display the VXLAN forwarding table by using the GUI:

Navigate to System > **Network** > **Bridge Table**.

<table>

Support of IPv6 Dynamic Routing Protocols on VXLANs

The Citrix ADC appliance supports IPv6 dynamic routing protocols for VXLANs. You can configure various IPv6 Dynamic Routing protocols (for example, OSPFv3, RIPng, BGP) on VXLANs from the VTYSH command line. An option IPv6 Dynamic Routing Protocol has been added to VXLAN command set for enabling or disabling IPv6 dynamic routing protocols on a VXLAN. After enabling IPv6 dynamic routing protocols on a VXLAN, processes related to the IPv6 dynamic routing protocols are required to be started on the VXLAN by using the VTYSH command line.

To enable IPv6 Dynamic routing protocols on a VXLAN by using the CLI:

- add vxlan <ID> [-ipv6DynamicRouting ( ENABLED | DISABLED )]
- show vxlan

In the following sample configuration, VXLAN-9000 is created and has IPv6 dynamic routing protocols enabled on it. Then, using the VTYSH command line, process for the IPv6 OSPF protocol is started on the VXLAN.

```
> add vxlan 9000 -ipv6DynamicRouting ENABLED
Done
> bind vxlan 9000 -srcIP 203.0.100.100
Done
> add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep 203.0.101.101
Done
```

```
NS# configure terminal
NS(config)# ns IPv6-routing
NS(config)# interface VXLAN-9000
NS(config-if)# ipv6 router OSPF area 3
```
Extending VLANs from Multiple Enterprises to a Cloud using VXLAN-VLAN Maps

CloudBridge Connector tunnels is used to extend an enterprise's VLAN to a cloud. VLANs extended from multiple enterprises can have overlapping VLAN IDs. You can isolate each enterprise’s VLANs, by mapping them to a unique VXLAN in the cloud. On a Citrix ADC appliance, which is the CloudBridge connector endpoint in the cloud, you can configure a VXLAN-VLAN map that links an enterprise’s VLANs to a unique VXLAN in the cloud. VXLANs support VLAN tagging for extending multiple VLANs of an enterprise from CloudBridge Connector to the same VXLAN.

Perform the following tasks for extending VLANs of multiple enterprises to a cloud:

1. Create a VXLAN-VLAN map.
2. Bind the VXLAN-VLAN map to a network bridge based or PBR based CloudBridge Connector tunnel configuration on the Citrix ADC appliance on cloud.
3. (Optional) Enable VLAN tagging in a VXLAN configuration.

CLI procedures

To add a VXLAN-VLAN map by using the CLI:

- `add vxlanVlanMap <name>`
- `show vxlanVlanMap <name>`

To bind a VXLAN and VLANS to a VXLAN-VLAN map by using the CLI:

- `bind vxlanVlanMap <name> [-vxlan <positive_integer> -vlan <int-int> ...]`
- `show vxlanVlanMap <name>`

To bind a VXLAN-VLAN map to a network bridge based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new network bridge:

- `add netbridge <name> [-vxlanVlanMap <string>]`
- `show netbridge <name>`

if reconfiguring an existing network bridge:

- `set netbridge <name> [-vxlanVlanMap <string>]`
- `show netbridge <name>`

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new PBR:

- `add pbr <name> ALLOW [-ipTunnel <ipTunnelName> [-vxlanVlanMap <name>]]`
• **show pbr** <name>

if reconfiguring an existing PBR:

• **set pbr** <name> **ALLOW** (-ipTunnel <ipTunnelName> [-vxlanVlanMap <name>])

• **show pbr** **<name>**

To include VLAN tags in packets related to a VXLAN by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new VXLAN:

• **add vxlan** <vnid> **-vlanTag** (ENABLED | DISABLED)
  • **show vxlan** <vnid>

if reconfiguring an existing VXLAN:

• **set vxlan** <vnid> **-vlanTag** (ENABLED | DISABLED)
  • **show vxlan** <vnid>

GUI procedures

To add a VXLAN-VLAN map by using the GUI:

Navigate to **System > Network > VXLAN VLAN Map**, add a VXLAN VLAN map.

To bind a VXLAN-VLAN map to a netbridge based CloudBridge Connector tunnel by using the GUI:

Navigate to **System > CloudBridge Connector > Network Bridge**, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new network bridge, or reconfiguring an existing network bridge.

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by by using the GUI:

Navigate to **System > Network > PBRs**, on the Policy Based Routing (PBRs) tab, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new PBR, or reconfiguring an existing PBR.

To include VLAN tags in packets related to a VXLAN by using the GUI:

Navigate to **System > Network > VXLANs**, enable **Inner VLAN Tagging** while adding a new VXLAN, or reconfiguring an existing VXLAN.

| 1 | > add vxlanVlanMap VXLANVLAN-DC1 |
| 2 | Done |
| 3 |  |
| 4 |  |
| 5 | > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3000 -vlan 3 |
| 6 | Done |
| 7 |  |
The priority load balancing feature enables you to assign a priority number for each of the services or service groups that are bound to a priority load balancing virtual server. A service or a service group with the lowest number has the highest priority. The application traffic is distributed only to this service or a service group as long as this service or the service group is UP. The service or the service group that is assigned the next priority number becomes operational only when all the services or members in the service group with the highest priority are DOWN. However, when any of the services or a member in the service group with the highest priority becomes available again, the traffic is re-directed to that service or the service group.
For example, consider the service groups SVG1, SVG2, and SVG3 that are bound to a priority load balancing virtual server. The maximum number of priority groups is set to three. You assign the priority for each group as follows:

- SVG1 – priority 1
- SVG2 – priority 2
- SVG3 – priority 3

In this scenario, the application traffic is directed to service group SVG1 because this group is assigned the lowest priority number. If all the members in SVG1 are DOWN, the traffic is distributed to service group SVG2 as this group is assigned the next lower priority number. If all the members in SVG2 are also DOWN, the traffic is distributed to SVG3. However, when any of the members in SVG1 is UP, the traffic is redirected to SVG1 because SVG1 is assigned the lowest number and has the highest priority.

Assigning priorities to a service or a service group enables you to upgrade the specific service or service group that has the highest priority, whenever required with minimal or no impact to the production traffic.

Also, if the upgrade is not successful, you can safely switch to the service or the service group that is next in the priority, with minimal or no impact to the production traffic.

Note
Priority load balancing does not support SSL deployments.

The following figure illustrates the priority load balancing feature.

To configure priority load balancing

Note
The Citrix ADC priority load balancing configuration is supported only through the GUI. You cannot configure priority load balancing by using the CLI.

1. Navigate to Traffic Management > Priority Load Balancing > Virtual Servers and specify the protocol for the virtual server, the IP address, and the port number of the virtual server.

2. In the Maximum Priority Groups box, enter the number of priority services or the service groups that can be bound to this virtual server. Default value is 2, and the maximum priority that can be set is 10. This parameter is noneditable after it is configured.

Note:
After you specify the maximum number of priority groups and click OK, a content switching virtual server and “n” number of backup load balancing virtual servers are created. The alphabet “n” represents the maximum number of priority groups.
For example, if you have entered the virtual server name as vs1, and have set the maximum priority group as 5, then a content switching virtual server with the name _Pri.LB#vs1#MaxPri=5 and the following 5 load balancing virtual servers are created.

- _Pri.LB#vs1#MaxPri=5_LB1
- _Pri.LB#vs1#MaxPri=5_LB2
- _Pri.LB#vs1#MaxPri=5_LB3
- _Pri.LB#vs1#MaxPri=5_LB4
- _Pri.LB#vs1#MaxPri=5_LB5

3. After you specify the maximum number of priority groups and click OK, you are prompted to choose the services or service groups that must be bound to this content switching virtual server.

- To bind services to the virtual server, click Insert in the Services section. Next, either select an existing service or create a service and set the priority for this service. Also, set the priority number at which this service should be bound.
- To bind service groups to the virtual server, click Insert in the Service Groups section. Next, either select an existing service group or create a service group and set the priority for this service group. Also, set the priority number at which this service group should be bound.

Repeat step 3, depending on the maximum number of priority groups that you have entered.

**Note:**

- The service or the service group with the highest priority is bound to the load balancing virtual server that represents the highest priority.

For example, if you have assigned priority 1 and 2 to service groups SG_App1 and SG_App2 respectively, then SG_App1 is bound to virtual server _Pri.LB#vs1#MaxPri=5_LB1 and SG_App2 is bound to virtual server _Pri.LB#vs1#MaxPri=5_LB2 created in step 2.

- To change the priority of the service group or service, click the edit icon in the Priority Load Balancing Virtual Server page and change the priority as required.
- You cannot set the load balancing methods and persistence for each virtual server explicitly, because the configuration of all load balancing virtual servers is identical.

4. From the Advanced Setting sections, complete the other configuration that meets your requirement.

**Important**

The entities created during priority load balancing configuration must not be modified from other tabs in the GUI. It is recommended that you modify the priority load balancing entities from the Priority Load Balancing tab only.
Citrix ADC Extensions

January 25, 2019

Contributed by:

C

Citrix ADC extensions can be used to customize a Citrix ADC appliance by writing extension code. Presently, policy extensions and protocol extensions are supported. Policy extensions can be used to extend the policy language. Protocol extensions can be used to add support for custom protocols on a Citrix ADC appliance.

This document includes the following information:

- Citrix ADC Extensions - Language Overview
- Citrix ADC Extensions - Library Reference
- Citrix ADC Extensions API Reference
- Protocol Extensions
- Policy Extensions

Citrix ADC extensions - language overview

January 23, 2019

Contributed by:

C

The extension language is based on the Lua 5.2 programming language. Lua provides a compact execution engine with good performance that is designed for embedding in C programs, like Citrix ADC software.

The extension language is dynamically typed, which means each object carries its own type information. Any variable can hold any type at any time during execution, so variable types are not declared.
The language is also free form, where white space between tokens is ignored. Statements may be separated by semicolons, but that is not required and usually not done. Blocks of statements are typically terminated by end. There are no brackets around blocks like the { and } in C or Java.

Identifiers are sequences of letters (a through z and A through Z), digits (0 through 9), and underscores (_), not starting in a digit. Identifiers are case-sensitive, so var, VAR, and Var are all different identifiers.

Comments are started by –. Everything after – is ignored to the end of the line. Example:

```
-- This is a comment.
```

Simple types

January 23, 2019

Contributed by: C

The language allows values of the following simple types:

- Numbers
- Strings
- Boolean
- Nil
- Other Types

Numbers

All numbers (even integers) are represented by IEEE 754 floating point values. Integers up to 2^54 have exact representations. Numeric values can be represented by:

- Signed and unsigned decimal integers (examples: 10, -5)
- Real numbers with decimal points (10.5, 3.14159)
- Real numbers with exponents (1.0e+10)
- Hexadecimals (0xffff0000)

Citrix ADC policy expressions have three numeric types:

- 32-bit integers (num_at)
- 64-bit integers (unsigned_long_at)
- 64-bit floating point (double_at)

All of these are converted into the number type when passed into an extension function, and numbers are converted to the expected policy numeric type when returned.

**Strings**

Strings are byte sequences of any length. They correspond to the policy **text_at** type. Strings can contain null (0x00) bytes. Arbitrary binary data can be held in strings, including any character code representation (e.g. UTF-8 and full Unicode). However, string functions **like string.upper()** assume 8-bit ASCII.

Strings are automatically allocated when used. There is no need (or even way) to explicitly allocate buffers for strings. Strings are also automatically deallocated by garbage collection when no longer in use. There is no need (or even way) to explicitly free strings. This automatic allocation and deallocation avoids some common problems in languages like C, such as memory leaks and dangling pointers.

String literals are character strings enclosed in double or single quotes. There is no difference between the two types of quotes: "a string literal" is the same as 'a string literal'. The usual backslash escaping is available: \s (bell), \b (backspace), \f (form feed), \n (newline/line feed), \t (horizontal tab), \ (backslash), " (double quote), and ' (single quote). Decimal byte values can be entered by a backslash and one to three digits (\d, \dd, \ddd). Hexadecimal byte values can be entered by a backslash and an x, and two hex digits (\xhh).

A special syntax call the long bracket notation can be used for long, multi-line string literals. This notation encloses the string in double square brackets with zero or more equal signs between the brackets – the idea is to come up with a combination of brackets and equals that is not in the string. No escape sequences are honored in the string. Some examples:

```
[[This is a multi-line string
using long bracket notation.]]

[=[This is a multi-line string
using long notation
with [[ and ]] and
and an unescaped in it.]=]
```

Long bracket notation can be used to make a multi-line comment. Example:

```
-[[
This is a multi-line
comment.
-]]
```
Boolean

The usual true and false boolean values are provided. Note that boolean values are different than number values, in contrast to C where zero is assumed to be false and any non-zero value is true.

Nil

nil is a special value that means “no value”. It is its own type and is not equivalent to any other value, in contrast to C where NULL is defined to be zero.

Other types

There are two other types, userdata and threads. These are advanced topics and are not covered here.

3. Citrix ADC 12.1
4. Citrix ADC Extensions

Variables

January 23, 2019

Contributed by:
C

Variables hold values that may change during extension execution. Because of dynamic typing, any variable may hold values of any type. There are no type declarations for variables. Instead, a variable’s type is determined at run time. In fact, the type of a variable’s value may change during execution, although this is not a recommended practice. A variable initially has the value nil.

Variable names are identifiers, so are strings of letters, digits, and underscores not beginning in a digit. Examples: headers, combined_headers.

Global variables

In Lua, variables that are not otherwise declared are global within the program. However, global variables are not allowed in policy extension functions, because there are multiple Packet Engines in which a function can be executed, and each Packet Engine has its own memory.
If you use a global variable in your extension, you will get a runtime error: attempt to update or create a global reported in `/var/log/ns.log`.

Typos in variable names are a potential problem, because the variable with the typo will be interpreted as another, global variable, and will not cause a syntax error as in language like C or Java. As noted above, you will get a runtime error instead.

**Local variables**

A variable may be declared to be local to a block of statements, such as a function. This is done by local variable-name. The variable will be scoped to the block, that is, it will only exist within the block. The local declaration may optionally assign a value to the variable.

**Examples:**

```plaintext
local headers = {}
local combined_headers = {}
```

**Expressions**

January 30, 2019

Contributed by:

C

Expressions compute values from variable and literal values.

- Arithmetic Operations
- Relational Operations
- Logical Operations
- Concatenation
- Length
- Precedence
Arithmetic operations

Arithmetic operations are performed on number values. If a string value is used in an arithmetic operation, it is converted to a number – if that fails, an error is returned.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a + b</td>
<td>add a and b</td>
</tr>
<tr>
<td>a - b</td>
<td>subtract b from a</td>
</tr>
<tr>
<td>a * b</td>
<td>multiply a and b</td>
</tr>
<tr>
<td>a / b</td>
<td>divide a by b</td>
</tr>
<tr>
<td>a % b</td>
<td>modulo = a - math.floor(a/b)*b</td>
</tr>
<tr>
<td>a ^ b</td>
<td>raise a to the b power; b can be any number</td>
</tr>
<tr>
<td>-a</td>
<td>negate a</td>
</tr>
</tbody>
</table>

Relational operations

Relational operations compare two values and return true if the relation is satisfied and false if it is not. Relational operations can be performed between values of any type. If the values are not the same type, false is returned. Numbers are compared in the usual way. Strings are compared using the collating sequence for the current locale.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a == b</td>
<td>a is equal to b</td>
</tr>
<tr>
<td>a ~= b</td>
<td>a is not equal to b</td>
</tr>
<tr>
<td>a &lt; b</td>
<td>a is less than b</td>
</tr>
<tr>
<td>a &gt; b</td>
<td>a is greater than b</td>
</tr>
<tr>
<td>a &lt;= b</td>
<td>a is less than or equal to b</td>
</tr>
<tr>
<td>a &gt;= b</td>
<td>a is greater than or equal to b</td>
</tr>
</tbody>
</table>

Logical operations

Logical operations are traditionally performed on Boolean values, but in this language they can be performed on any two values. nil and false is considered false and any other value is considered true.
Logical operations use short-cut evaluation, where if the first value determines the result of the operation, the second value is not evaluated.

<table>
<thead>
<tr>
<th>a and b</th>
<th>if a is false or nil then return a else return b</th>
</tr>
</thead>
<tbody>
<tr>
<td>a or b</td>
<td>if a is not false and not nil then return a else return b</td>
</tr>
<tr>
<td>not a</td>
<td>if a is not false or nil return false else return true</td>
</tr>
</tbody>
</table>

The and and or operations can be used for conditional evaluation within an expression:

<table>
<thead>
<tr>
<th>a or b</th>
<th>can be used to provide a default value b if a is uninitialized (nil). This is useful for optional parameters in functions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>a and b or c</td>
<td>can be used to chose non-nil b or c based on the condition a. If a is true, then a and b returns b, and b or c returns b. If a is false, then a and b returns false and false or c returns c. This is equivalent to a ? b : c in the C programming language.</td>
</tr>
</tbody>
</table>

**Concatenation**

String concatenation is `s1 .. s2`. This creates a new string large enough to hold the contents of s1 and s2 and copies the contents to the new string. An error results if s1 or s2 are not strings. Note that repeated concatenation may have considerable copying overhead. If you build a string of n bytes by concatenating one byte at a time, this will copy \(n^*(n+1)/2\) bytes. For better performance, you can put pieces of a string to be concatenated into a table (discussed later) and then use the table.concat() function. An example of this is shown in the COMBINE_HEADERS() example.

**Length**

The length of a string s is returned by `#s`. The # operator is also used with array tables, as discussed later.
### Precedence

Operator precedence determines the order in which operations are performed in an expression, with higher precedence operations done before those with lower precedence. Precedence order can as usual be overridden by parentheses. For example, in `a + b \* c`, \* has higher precedence than +, so the expression is evaluated as `a + (b \* c)`.

<table>
<thead>
<tr>
<th>highest</th>
<th>^</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>not # - (unary)</td>
</tr>
<tr>
<td>-</td>
<td>* / %</td>
</tr>
<tr>
<td>-</td>
<td>..</td>
</tr>
<tr>
<td>-</td>
<td>= ~= &lt; &gt; &lt;= &gt;=</td>
</tr>
<tr>
<td>-</td>
<td>and</td>
</tr>
<tr>
<td>lowest</td>
<td>or</td>
</tr>
</tbody>
</table>

Operations with the same precedence are performed left to right (left associative), except `^` and `..` that are performed right to left (right associative). So `a ^ b ^ c` is evaluated as `a ^ (b ^ c)`.

### Assignment

January 23, 2019

Contributed by: C

The assignment statement evaluates an expression and assigns the resulting value to a variable.

```
variable = expression
```

As noted earlier, values of any type can be assigned to any variable, so the following is allowed:

```
local v1 = "a string literal"
v1 = 10
```
An assignment statement can actually set multiple variables, using the form
variable1, variable2, … = expression1, expression2, …
If there are more variables than expressions, the extra variables are assigned nil. If there are more ex-
pressions than variables, the extra expression values are discarded. The expressions are all evaluated
before the assignments, so this can be used to succinctly exchange the values of two variables:

v1, v2 = v2, v1

is equivalent to

tmp = v1
v2 = v1
v1 = tmp

Tables

January 23, 2019
Contributed by:

C

Tables are collections of entries with keys and values. They are the only aggregate data structure
provided. All other data structures (arrays, lists, sets, and so on) are built from tables. Table keys and
values can be any type, including other tables. Keys and values within the same table can mix types.

• Table Constructors
• Table Usage
• Tables as Arrays
• Tables as Records

Table constructors

Table constructors allow you to specify a table with keys and associated values. The syntax is:

{{key1} = value1, [key2] = value2, …}

where the keys and values are expressions. If the keys are strings that are not reserved words, the
brackets and quotes around the keys can be omitted. Example:
{key1 = “value1”, key2 = “value2”, key3 = “value3”}

An empty table is specified simply by {}.

A table constructor may be used in an assignment to set a variable to refer to a table. Examples:

local t1 = {} – set t1 to an empty table
local t2 = {key1 = “value1”, key2 = “value2”, key3 = “value3”}

Note that tables themselves are anonymous. More than one variable may refer to the same table. Continuing the above example:

local t3 = t2 – both t2 and t3 refer to the same table

**Table usage**

As you would expect, you can use keys to find values in a table. The syntax is table[key], where table is a table reference (typically a variable assigned a table), and key is an expression providing the key. If this is used in an expression and the key exists in the table, this returns the value associated with the key. If the key is not in the table, this returns nil. If this is used as the variable in an assignment, and the key does not exist in the table, it creates a new entry for the key and value. If the key already exists in the table, it replaces the key’s value with the new value. Examples:

local t = {} – sets t to an empty table

v1 = t[“k1”] – creates an entry for key “k1” and value “v1”

v1 = t[“k1”] – sets v1 to the value for key “k1” = “v1”

v1 = t[“k1”] = “new_v1” – sets the value for key “k1” to “new_v1”

**Table as arrays**

The traditional array can be implemented using a table with integer keys as indices. An array can have any indices, including negative ones, but the convention is to start arrays at index 1 (not 0 as is the case with languages like C and Java). There is a special purpose table constructor for such arrays:

{value1, value2, value3, … }

Array references are then array[index].

The length operator # returns the number of elements in an array with consecutive indices starting at 1. Example:

local a = {“value1”, “value2”, “value3”}
local length = #a – sets length to the length of array a = 3

Arrays can be sparse, where only the defined elements are allocated. But # cannot be used on a sparse array with non-consecutive indices. Example:
local sparse_array = {} – set up an empty array
sparse_array[1] = “value1” – add an element at index 1
sparse_array[99] = “value99” – add an element at index 99
Multidimensional arrays can be set up as tables of tables. For example, a 3x3 matrix could be set up by:
local m = {{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}
local v22 = m[2][2] – sets v22 to 5

Tables as records
Records with fields can be implemented as tables with field name keys. The reference form table.field can be used for table[“field”]. Examples:
local person = {name = “John Smith”, phone = “777-777-7777”}
local name = person.name – sets name to “John Smith”
An array of tables can be used for a sequence of records. Example:
local people = {
{name = “John Smith”, phone = “777-777-7777”},
{name = “Jane Doe”, phone = “888-888-8888”}
…
}
name = people[2].name – sets name to “Jane Doe”

Control structures
January 23, 2019
Contributed by:
C
The extension function language provides the usual statements to control program execution.
• If Then Else
• While Do and Repeat Until
If statements select blocks of statements to execute based on one or more conditions. There are three forms:

If then Form

1 \textbf{if} expression \textbf{then}
2 \hspace{1em} statements to execute if expression is not \textbf{false} or \textbf{nil}
3 \textbf{end}

If then else Form

1 \textbf{if} expression \textbf{then}
2 \hspace{1em} statements to execute if expression is not \textbf{false} or \textbf{nil}
3 \textbf{else}
4 \hspace{1em} statements to execute if expression is \textbf{false} or \textbf{nil}
5 \textbf{end}

If then elseif else Form

1 \textbf{if} expression1 \textbf{then}
2 \hspace{1em} statements to execute if expression1 is not \textbf{false} or \textbf{nil}
3 \textbf{elseif} expression2 \textbf{then}
4 \hspace{1em} statements to execute if expression2 is not \textbf{false} or \textbf{nil}
5 \textbf{else}
6 \hspace{1em} statements to execute if all expressions are \textbf{false} or \textbf{nil}
7 \textbf{end}

Example:

1 \textbf{if} headers[name] \textbf{then}
2 \hspace{1em} local next_value_index = #(headers[name]) + 1
headers[name][next_value_index] = value

else
headers[name] = {
name .. ":" .. value }
end

Note:

- The expression is not enclosed in parentheses as is the case in C and Java.
- There is no equivalent to the C/Java switch statement. You have to use a series of if elseif statements to do the equivalent.

**While Do and Repeat Until**

The **while** and **repeat** statements provide loops controlled by an expression.

while expression do
  statements to execute while expression is not false or nil
end

repeat
  statements to execute until expression is not false or nil
until expression

Example for while:

local a = {
  1, 2, 3, 4 }
local sum, i = 0, 1 -- multiple assignment initializing sum and i
while i <= #a do -- check if at the end of the array
  sum = sum + a[i] -- add array element with index i to sum
  i = i + 1 -- move to the next element
end

Example for repeat:

sum, i = 0, 1 -- multiple assignment initializing sum and i
Of course it is possible to write a loop that does not terminate, for example, if you omit the \( i = i + 1 \) statement in either of these examples. When such a function is executed, Citrix ADC will detect that the function did not complete in a reasonable time and will kill it with a runtime error:

```
Cpu limit reached. Terminating extension execution in [[string "function extension function..."]]: line line-number.
```

will be reported in /var/log/ns.log.

**Numeric For**

There are two types of for loops. The first is the numeric for, which is similar to the usual use of the for statement in C and Java. The numeric for statement initializes a variable, tests if the variable has passed a final value, and if not executes a block of statements, increments the variable, and repeats. The syntax for the numerical for loop is:

```
for variable = initial, final, increment do
    statements in the loop body
end
```

where initial, final, and increment are all expressions that yield (or can be converted to) numbers. variable is considered to be local to the for loop statement block; it cannot be used outside of the loop. increment can be omitted; the default is 1. The expressions are evaluated once at the beginning of the loop. The terminating condition is variable > final if the increment is positive and variable < final if the increment is negative. The loop terminates immediately if the increment is 0.

Example (equivalent to the while and repeat loops in the preceding section):

```
sum = 0
for i = 1, #a do -- increment defaults to 1
    sum = sum + a[i]
end
```

The second type of for loop is the generic for, which can be used for more flexible types of loops. It involves the use of functions, so will be discussed later after functions have been introduced.
Break

The break statement is used inside a while, repeat, or for loop. It will terminate the loop and resume execution at the first statement after the loop. Example (also equivalent to the preceding while, repeat, and for loops):

```
1 sum, i = 0, 1
2 while true do
3     if i > #a then
4         break
5     end
6     sum = sum + a[i]
7     i = i + 1
8 end
```

Goto

The goto statement can be used to jump forward or backward to a label. The label is an identifier, and its syntax is ::label::. The goto statement is goto label. Example (once again equivalent to the preceding loops):

```
1 sum, i = 0, 1
2 ::start_loop::
3     if i > #a then
4         goto end_loop -- forward jump
5     end
6     sum = sum + a[i]
7     i = i + 1
8     goto start_loop -- backwards jump
9 ::end_loop::
10 ...
```

There has been a long running controversy over using gotos in programming. In general, you should try to use the other control structures to make your functions more readable and reliable. But occasional judicious use of gotos may lead to better programs. In particular, gotos may be useful in handling errors.

Functions

January 23, 2019

Contributed by: C

Functions are a basic building block of programming – they are a convenient and powerful way to group statements that perform a task. They are the interface between the Citrix ADC appliance and extension code. For policies, you define policy extension functions. For protocols, you implement callback functions for the protocol behaviors. Functions consist of function definitions that specify what values are passed into and out of the function and what statements are executed for the function, and function calls, which execute functions with specific input data and get results from the function.

Protocol behavior callback functions

The TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments. So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

Prototype of TCP client callback function:

```
Function client on_data (ctxt, payload)
   //.code
end
```

where,

- `ctxt` - TCP client processing context
- `payload` – event payload
  - `payload.data` - TCP data received, available as a stream of bytes
Policy extension functions

Since the NetScaler policy expression language is strongly typed, the definition of an extension function must specify the types of its inputs and its return value. The Lua function definition has been extended to include these types:

```
function self-type: function-name(parameter1: parameter1-type, etc.):
    return-type
    statements
end
where, the types are NSTEXT, NSNUM, NSBOOL, or NSDOUBLE.
```

self-type is the type of the implicit self parameter that is passed into the function. When the extension function is used in an Citrix ADC policy expression, this is the value generated by the expression to the left of the function. Another way to view this is that the function extends that type in the Citrix ADC policy language.

The parameter-types are the types of each parameter specified in the extension function call in the policy expression. An extension function can have zero or more parameters.

return-type is the type of the value returned by the extension function call. It will be the input to the part of the policy expression, if any, to the right of the function, or else is the value of the expression result.

Example:

```
function NSTEXT:COMBINE_HEADERS(): NSTEXT
```

Use of the extension function in a policy expression:

```
HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\n").COMBINE_HEADERS()
```

Here the self parameter is the result of HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\n"), which is a text value. The result of the COMBINE_HEADERS() call is text, and since there is nothing to the right of this call, the result of the entire expression is text.

Local function definition

Besides extension functions, no global functions can be defined in an extension file. But local functions can be defined within extension functions using the normal Lua function statement. This declares the name of the function and the names of its parameters (also known as arguments), and like all declarations in Lua, does not specify any types. The syntax for this is:
The function and parameter names are all identifiers. (The function name is actually a variable and the function statement is shorthand for local function-name = function(parameter1, etc.), but you don’t have to understand this subtlety to use functions.)

Note that etc. is used here for continuation of the pattern of parameter names instead of the usual ….

This is because … itself actually means a variable parameter list, which will not be discussed here.

**Function body and return**

The block of statements between the function and end statements is the function body. In the function body, the function parameters act like local variables, with values supplied by the function calls, as described previously.

The return statement supplies values to be returned to the caller of the function. It must appear at the end of a block (in a function, if then, for loop, and so on; It can be in its own block do return … end). It may specify no, one, or more than one return values:

```
return -- returns nil
return expression -- one return value
return expression1, expression2, ... -- multiple return values
```

**Examples:**

```
local function fsum(a)
  local sum = 0
  for i = 1, #a do
    sum = sum + a[i]
  end
  return sum
end

local function fsum_and_average(a)
  local sum = 0
  for i = 1, #a do
    sum = sum + a[i]
  end
  return sum, sum/#a
end
```
**Function calls**

A function call executes the body of a function, supplying values for its parameters, and receiving results. The syntax for a function call is `function-name(expression1, expression2, etc.)`, where the function parameters are set to the corresponding expressions. The number of expressions and parameters need not be the same. If there are fewer expressions than parameters, the remaining parameters are set to nil. So you can make one or more parameters at the end of the call optional, and your function can check if they are specified by checking if they are not nil. A common way to do this is with the `or` operation:

```plaintext
function f(p1, p2) -- p2 is optional
    p2 = p2 or 0 -- if p2 is nil, set to a default of 0
... end
```

If there are more expressions than parameters, the remaining expression values are ignored.

As noted previously, functions can return multiple values. These returns can be used in a multiple assignment statement. Example:

```plaintext
local my_array = {1, 2, 3, 4}
local my_sum, my_ave = sum_and_average(my_array)
```

**Iterator functions and generic for loops**

Now that we have introduced functions, we can talk about generic for loops. The syntax for the generic for loop (with one variable) is:

```plaintext
for variable in iterator(parameter1, parameter2, etc.) do
    statements in the for loop body
end
```

where `iterator()` is a function with zero or more parameters that provides a value for `variable` on each iteration of the loop body. The iterator function keeps track of where it is in the iteration using a technique called closure, which you don’t have to worry about here. It signals the end of the iteration by returning nil. Iterator functions can return more than one value, for use in a multiple assignment.

Writing an iterator function is beyond the scope of this paper, but there are a number of useful built-in iterators that illustrate the concept. One is the `pairs()` iterator, which iterates through the entries in a table and returns two values, the key and the value of the next entry.

**Example:**
local t = {
    k1 = "v1", k2 = "v2", k3 = "v3"
}

local a = {
    -- array to accumulate key-value pairs
}
local n = 0 -- number of key-value pairs
for key, value in pairs(t) do
    n = n + 1
    a[n] = key .. " = " .. value -- add key-value pair to the array
end
local s = table.concat(a, "; ") -- concatenate all key-value pairs into one string

Another useful iterator is the string.gmatch() function, which will be used in the following COMBINE_HEADERS() example.

Citrix ADC extensions - library reference

January 23, 2019
Contribution by:
C

The list of libraries supported in policy extensions.

- Basic library
- String library
- Regular Expression Patterns - Character Classes
- Regular Expression Patterns - Pattern Items
- Table library
- Math library
- Bitwise library
- Operating System library
- Citrix ADC library
## Basic library

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assert(v[,message])</code></td>
<td>Issues an error, with an optional message, when v is false.</td>
</tr>
<tr>
<td><code>error(message)</code></td>
<td>Terminates a function and reports the error message.</td>
</tr>
<tr>
<td><code>ipairs(a)</code></td>
<td>Iterator for an array a. Returns an index and value for each iteration.</td>
</tr>
<tr>
<td><code>pairs(t)</code></td>
<td>Iterator for a table t. Returns a key and value for each iteration.</td>
</tr>
<tr>
<td><code>tonumber(e[,base])</code></td>
<td>Converts e to a number, with an optional base.</td>
</tr>
<tr>
<td><code>tostring(v)</code></td>
<td>Converts v to a string</td>
</tr>
<tr>
<td><code>type(v)</code></td>
<td>Returns the type of v: number, string, boolean, table, etc.</td>
</tr>
<tr>
<td><code>getmetatable (object)</code></td>
<td>Returns nil if the object does not have a metatable. Otherwise, if the object's metatable has a &quot;__metatable&quot; field, returns the associated value. Otherwise, returns the metatable of the given object.</td>
</tr>
<tr>
<td><code>setmetatable (table, metatable)</code></td>
<td>Sets the metatable for the given table. (You cannot change the metatable of other types from Lua, only from C.) If metatable is nil, removes the metatable of the given table. If the original metatable has a &quot;__metatable&quot; field, raises an error.</td>
</tr>
<tr>
<td><code>select (index, …)</code></td>
<td>Returns all arguments after argument number index. If index is string &quot;#&quot;, then it returns the total number of extra arguments it received.</td>
</tr>
<tr>
<td><code>pcall (f [, arg1, …])</code></td>
<td>Calls function f with the given arguments in protected mode. It returns status code as first result which tells whether call succeeded or not. If call succeeded, then along with status code it also returns all results from the call, otherwise returns error message.</td>
</tr>
</tbody>
</table>
xpcall (f, msg, arg1, ...) This function is similar to pcall, except that it also takes an argument for error handling.

_VERSION Returns the current interpreter version.

### String library

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string.byte(s[i,j])</td>
<td>Returns the byte values for s[i] to s[j]. Default i = 1 and j = i</td>
</tr>
<tr>
<td>string.char(...)</td>
<td>Returns a string constructed of the integer parameters.</td>
</tr>
<tr>
<td>string.find(s,pattern[,init[,plain]])</td>
<td>Looks for the first match of a regular expression pattern in s. Return the first and last indices of match or nil. init is index to start, default 1. plain = true means pattern is not a regex.</td>
</tr>
<tr>
<td>string.format(form,...)</td>
<td>Returns a formatted version of the parameters.</td>
</tr>
<tr>
<td>string.gmatch(s,pattern)</td>
<td>Iterator for searching s with the regex pattern. Returns matching values.</td>
</tr>
<tr>
<td>string.gsub(s,pattern,repl[,n])</td>
<td>Returns a copy of s in which all (or n) occurences of the pattern have been replaced by repl.</td>
</tr>
<tr>
<td>string.len(s)</td>
<td>Returns the string length.</td>
</tr>
<tr>
<td>string.lower(s)</td>
<td>Returns a copy of the string converted to lowercase.</td>
</tr>
<tr>
<td>string.match(s,pattern[,init])</td>
<td>Looks for the first match of the regex pattern in s and returns the captures or the whole pattern. init is the index to start, default 1.</td>
</tr>
<tr>
<td>string.rep(s,n[,sep])</td>
<td>Returns a string that is n copies of s, with separator sep, default no separator</td>
</tr>
<tr>
<td>string.reverse(s)</td>
<td>Returns a string that is s reversed.</td>
</tr>
<tr>
<td>string.sub(s,i[,j])</td>
<td>Returns the substring of s from s[i] to s[j], default j is the end of the string.</td>
</tr>
<tr>
<td>String Method</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>string.upper(s)</td>
<td>Returns a copy of the string converted to uppercase.</td>
</tr>
<tr>
<td>string.dump (function)</td>
<td>Returns a string containing a binary representation of the given function.</td>
</tr>
</tbody>
</table>

Regular expression patterns - character classes

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>the character x, except for magic characters <code>^$().[]*+?</code></td>
</tr>
<tr>
<td>.</td>
<td>any character</td>
</tr>
<tr>
<td>%a</td>
<td>any letter</td>
</tr>
<tr>
<td>%c</td>
<td>any control character</td>
</tr>
<tr>
<td>%d</td>
<td>any digit</td>
</tr>
<tr>
<td>%g</td>
<td>any printable character except space</td>
</tr>
<tr>
<td>%l</td>
<td>any lowercase letter</td>
</tr>
<tr>
<td>%p</td>
<td>any punctuation character</td>
</tr>
<tr>
<td>%s</td>
<td>any white space character</td>
</tr>
<tr>
<td>%u</td>
<td>any uppercase letter</td>
</tr>
<tr>
<td>%w</td>
<td>any alphanumeric letter</td>
</tr>
<tr>
<td>%x</td>
<td>an escaped magic character x (for example %%%)</td>
</tr>
<tr>
<td>[set]</td>
<td>a set of characters: sequence of individual characters, ranges x-y, and % classes</td>
</tr>
<tr>
<td>[^set]</td>
<td>characters not in the set.</td>
</tr>
</tbody>
</table>

Regular expression patterns - pattern items

<p>| X         | a character class                                                           |</p>
<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X*</td>
<td>0 or more longest repetitions of characters in X</td>
</tr>
<tr>
<td>X+</td>
<td>1 or more repetitions of characters in X</td>
</tr>
<tr>
<td>X-</td>
<td>0 or more shortest repetitions of characters in X</td>
</tr>
<tr>
<td>X?</td>
<td>0 or 1 character in X</td>
</tr>
<tr>
<td>%n</td>
<td>n=1 to 9; matches nth captured string</td>
</tr>
<tr>
<td>%bxy</td>
<td>matches substring between two balanced characters x and y. Example %b() matches substring between two balanced parentheses.</td>
</tr>
<tr>
<td>%f[set]</td>
<td>matches an empty string at any position such that the next character belongs to set and the previous character does not belong to set.</td>
</tr>
</tbody>
</table>

A pattern is a sequence of pattern items. ^pattern matches the beginning of a string and pattern$ matches the end of the string.

Matched substrings can be captured using (pattern). Parentheses with no pattern () capture the current string position (a number).

**Table library**

<table>
<thead>
<tr>
<th>Table function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table.concat(list[,sep[,i[,j]]])</td>
<td>Returns a string list[i] .. sep .. list[i+1] .. sep .. list[j]. Default sep is the empty string. Default i is 1, j is #list.</td>
</tr>
<tr>
<td>table.insert(list,[pos,]value)</td>
<td>Inserts value into list at index pos. Default for pos is #list (end of the list).</td>
</tr>
<tr>
<td>table.pack(…)</td>
<td>Returns an array containing the parameters starting at index 1, and a key n with the total number of parameters.</td>
</tr>
<tr>
<td>table.remove(list[,pos])</td>
<td>Removes from list the element at position pos, shifting elements to fill the position. Returns the removed element. Default for pos is #list (end of the list).</td>
</tr>
</tbody>
</table>
### table.sort(list[,comp])
Sort the elements of list in place. comp is the comparison function to use. Default for comp is `<`.

### table.unpack(list[,i[,j]])
Returns list[i] through list[j]. Default for i is 1 and j is #list<ode>.

## Math library

Various trigonometric and logarithmic functions not shown.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>math.abs(x)</td>
<td>Returns the absolute value of x.</td>
</tr>
<tr>
<td>math.ceil(x)</td>
<td>Returns the smallest integer &gt;= x.</td>
</tr>
<tr>
<td>math.floor(x)</td>
<td>Returns the largest integer &lt;= x.</td>
</tr>
<tr>
<td>math.fmod(x,y)</td>
<td>Returns the remainder of x/y rounding the quotient towards zero.</td>
</tr>
<tr>
<td>math.huge</td>
<td>A value &gt;= any other number.</td>
</tr>
<tr>
<td>math.max(x,...)</td>
<td>Returns the maximum argument.</td>
</tr>
<tr>
<td>math.min(x,...)</td>
<td>Returns the minimum argument.</td>
</tr>
<tr>
<td>math.modf(x)</td>
<td>Returns the integral and fractional parts of x.</td>
</tr>
<tr>
<td>math.random()</td>
<td>Returns a pseudo-random number between 0 and 1.</td>
</tr>
<tr>
<td>math.random(m)</td>
<td>Returns a pseudo-random integer between 1 and m.</td>
</tr>
<tr>
<td>math.random(m, n)</td>
<td>Returns a pseudo-random integer between m and n.</td>
</tr>
<tr>
<td>math.randomseed(x)</td>
<td>Sets the pseudo-random number generator set to x.</td>
</tr>
<tr>
<td>math.sqrt(x)</td>
<td>Returns the square root of x (x^0.5)</td>
</tr>
<tr>
<td>math.acos(x)</td>
<td>Returns the arc cosine of x (in radians).</td>
</tr>
<tr>
<td>math.asin(x)</td>
<td>Returns the arc sine of x (in radians).</td>
</tr>
<tr>
<td>math.atan(x)</td>
<td>Returns the arc tangent of x (in radians).</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>math.atan2(y, x)</code></td>
<td>Returns the arc tangent of y/x (in radians).</td>
</tr>
<tr>
<td><code>math.cos(x)</code></td>
<td>Returns the cosine of x.</td>
</tr>
<tr>
<td><code>math.cosh(x)</code></td>
<td>Returns the hyperbolic cosine of x.</td>
</tr>
<tr>
<td><code>math.sin(x)</code></td>
<td>Returns the sine of x.</td>
</tr>
<tr>
<td><code>math.sinh(x)</code></td>
<td>Returns the hyperbolic sine of x.</td>
</tr>
<tr>
<td><code>math.tan(x)</code></td>
<td>Returns the tangent of x.</td>
</tr>
<tr>
<td><code>math.tanh(x)</code></td>
<td>Returns the hyperbolic tangent of x.</td>
</tr>
<tr>
<td><code>math.deg(x)</code></td>
<td>Returns the angle x (given in radians) in degrees.</td>
</tr>
<tr>
<td><code>math.exp(x)</code></td>
<td>Returns the value e^x.</td>
</tr>
<tr>
<td><code>math.frexp (x)</code></td>
<td>Returns m and e such that x = m2e, e is an integer and the absolute value of m is in the range [0.5, 1).</td>
</tr>
<tr>
<td><code>math.ldexp (m, e)</code></td>
<td>Returns m2e (e should be an integer).</td>
</tr>
<tr>
<td><code>math.log (x [, base])</code></td>
<td>Returns the logarithm of x in the given base. The default for base is e.</td>
</tr>
<tr>
<td><code>math.pow (x, y)</code></td>
<td>Returns x^y.</td>
</tr>
<tr>
<td><code>math.rad (x)</code></td>
<td>Returns the angle x (given in degrees) in radians.</td>
</tr>
<tr>
<td><code>math.pi</code></td>
<td>The value of π.</td>
</tr>
</tbody>
</table>

### Bitwise library

Unless otherwise stated:

- All functions accept numeric arguments in the range (-2^-51,+2^-51).
- Each argument is normalized to the remainder of its division by 2^-32 and truncated to an integer (in some unspecified way), so that its final value falls in the range [0,2^-32 - 1].
- All results are in the range [0,2^-32 - 1].

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bit32.arshift(x,disp)</code></td>
<td>Returns x arithmetically shifted disp bits to the right (+disp) or left (-disp).</td>
</tr>
</tbody>
</table>
bit32.band(…)  Returns the bitwise and of the arguments.

bit32.bnot(x)   Returns the bitwise negation of x.

bit32.bor(…)   Returns the bitwise or of the arguments.

bit32.btest(…) Returns true if the bitwise and of the arguments is not zero.

bit32.bxor(…)  Returns the bitwise exclusive or of the arguments.

bit32.extract(n,field[,width]) Returns the bits in n from field to field + width - 1 (bits number from most to least significant). Default for width is 1.

bit32.replace(n,v,field[,width]) Returns a copy of n with bits from field to field + width -1 replaced by v. Default width is 1.

bit32.lrotate(x,disp) Returns x rotated disp bits to the left (+disp) or right (-disp).

bit32.lshift(x,disp) Returns x shifted disp bits to the left (+disp) or right (-disp).

bit32.rrotate(x,disp) Returns x rotated disp bits to the right (+disp) or left (-disp).

bit32.rshift(x,disp) Returns x shifted disp bits to the right (+disp) or left (-disp).

---

Operating system library

os.clock ()   Returns an approximation of the amount in seconds of CPU time.

os.date ([format [, time]]) Returns a string or a table containing date and time, formatted according to the given string format.

os.time ([table]) Returns the current time when called without arguments, or a time representing the date and time specified by the given table.
os.difftime (t2, t1) Returns the number of seconds from time t1 to time t2.

Citrix ADC library

ns.logger:level(message) To log messages where level is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C printf() function: a format string, and a variable number of arguments to supply values for the % specifiers in the format string.

Citrix ADC extensions API reference

March 5, 2019
Contributed by:
C
Behaviors are a formalization of common programmable patterns that are available on a Citrix ADC appliance. For example, a TCP virtual server supports a TCP client behavior and a TCP server behavior. A behavior is a pre-defined set of callback functions. You can implement behaviors by providing callback functions. For example, a TCP client behavior can consist of the on_data function, which processes the TCP data stream.

TCP client behavior

**on_data** - function callback for TCP client data events. The callback takes two arguments:
• **ctxt** - TCP client processing context
• **payload** – event payload
  – **payload.data** - TCP data received, available as a stream of bytes

**TCP server behavior**

**on_data** - function callback for TCP server data events, the callback takes two arguments:
• **ctxt** - TCP server processing context
• **payload** – event payload
  – **payload.data** - tcp data received, available as a stream of bytes

**TCP client context**

The context that is passed to the TCP client event callbacks:
• **ctxt.output** - The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message. The EOM event may or may not have TCP data with it. An EOM event with TCP data can be sent without a preceding DATA event to send a whole protocol message data and mark the end of message. The load balancing decision is made, downstream by the load balancing virtual server, on the first data received. A new load balancing decision is made after the receipt of the EOM message. So, to stream protocol message data, send multiple DATA events with the last event as EOM. All the contiguous DATA events and the following EOM events are sent to the same server connection selected by the load balancing decision on the first DATA event in the sequence.
• **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
• **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
• **ctxt.vserver** - The virtual server context.
• **ctxt.client** – Client connection processing context. This processing context can be used to send data to the client, and to fetch some connection related information like IP address, source and destination ports.
• **ctxt:close()** – Close the client connection by sending FIN to the client. After calling this API, the client processing context is no longer usable and gives error on any usage.
TCP server context

The context that is passed to the TCP server event callbacks:

- **ctxt.output** – The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message.

- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.

- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.

- **ctxt.vserver** - The virtual server context.

- **ctxt.server** - Server connection processing context. This processing context can be used to send data to the server, and to fetch some connection related information like IP address, source and destination ports.

- **ctxt:reuse_server_connection()** - This API is used to allow the server connection to be reused for other client connections in the server context only. This API can be used only if an EOM event is used (in ns.send() API) to send the data in the client context. Otherwise, the ADC appliance throws an error.

To allow a server connection to be reused by other clients, this API must be called at the end of each response message. After calling this API, if more data is received on this server connection, this is treated as an error and the server connection is closed. If this API is not used, then the server connection can be used only for that client for which it was opened. Also, if the same server is selected for another load balancing decision for that client, then the same server connection is used to send the client data. After using this API, server connection stops being tied to the client connection for which it was opened, and can be reused for a new load balancing decision for any other client connection. After calling this API, the server context is no longer usable and throws an error on any usage.

**Note:** This API is available in Citrix ADC 12.1 build 49.xx and later.

- **ctxt:close()** – Close the server connection by sending FIN to the server. After calling this API, the client processing context is no longer usable and displays an error on any usage.

**Note:** This API is available in Citrix ADC 12.1 build 50.xx and later.
Vserver context

The user virtual server context available through the contexts passed to callbacks:

- `vserver:counter_increment(counter_name)` - Increments the value of a virtual server counter passed as argument. Currently the following built-in counters are supported.
  - `-invalid_messages` – Number of invalid requests/responses on this virtual server.
  - `-invalid_messages_dropped` – Number of invalid requests/responses dropped by this virtual server.
- `vserver.params` - The configured parameters for the user virtual server. Parameters provide configurability of extensions. The extension code can access parameters that are specified in the CLI to add a user virtual server.

Client connection context

Client connection processing context to get connection related information.

- `client.ssl` – SSL context
- `client.tcp` – TCP context
- `client.is_ssl` – True if client connection is SSL-based

Server connection context

Server connection processing context to get connection related information.

- `server.ssl` – SSL context
- `server.tcp` – TCP context
- `server.is_ssl` – True if server connection is SSL-based

TCP context

TCP context operates on TCP protocol.

- `tcp.srcport` – Source port as a number
- `tcp.dstport` – Destination port as a number

IP context

IP context works on IP or IPv6 protocol data.

- `ip.src` - Source IP address context.
- `ip.dst` - Destination IP address context.
**IP address context**

IP address context works on IP or IPv6 address data.

- `<address>.to_s` - The address string in the appropriate ASCII notation.
- `<address>.to_n` - The address' numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 bytes for IPv6).
- `<address>.version` - Returns 4 for IPv4 and 6 for IPv6.
- `<address>:subnet(<prefix value>)` - Returns the subnet address string after applying the prefix number.
  - For IPv4 address, value must be between 0 and 32
  - For IPv6 address, value must be between 0 and 128.
- `<address>:apply_mask(<mask string>)` - Returns the address string after applying mask string. API validates the version of argument and does appropriate error checking.
- `<address:eq(<address string>)` - Returns true or false based on whether the argument is equivalent to the address object. API validates the version of the arguments.

**SSL context**

The SSL context provides information related to frontend SSL connection.

- `ssl.cert` - SSL certificate context. For the client connection, it provides client certificate context and for the server connection, it provides server certificate context.
- `ssl.version` - A number that represents the SSL protocol version of the current transaction, as follows:
  - 0: The transaction is not SSL-based
  - 0x002: The transaction is SSLv2
  - 0x300: The transaction is SSLv3
  - 0x301: The transaction is TLSv1
  - 0x302: The transaction is TLSv1.1
  - 0x303: The transaction is TLSv1.2
- `ssl.cipher_name` - SSL Cipher name as string if invoked from an SSL connection, otherwise gives NULL string.
- `ssl.cipher_bits` – Number of bits in cryptographic key.
SSL certificate context

- `Cert.version` – Version number of the certificate. If the connection is not SSL based, returns 0.
- `Cert.valid_not_before` – Date in string format before which certificate is not valid.
- `Cert.valid_not_after` – Date in string format after which certificate is no longer valid.
- `Cert.days_to_expire` – Number of days before which certificate is valid. Returns -1 for expired certificate.
- `Cert.to_pem` – Certificate in binary format.
- `cert.issuer` - Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=” is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

Following is an example of the returned DN:
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.com

- `cert.auth_keyid` – Context of Authority Key Identifier extension of the X.509 V3 certificate.
  - `auth_keyid.exists` - TRUE if the certificate contains an Authority Key Identifier extension.
  - `auth_keyid.issuer_name` - Issuer Distinguished Name in the certificate as a name-value list.
    An equals sign (“=” is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.
    Following is an example:
    /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.com
  - `auth_keyid.keyid` - KeyIdentifier field of the Authority Key Identifier as a blob
  - `auth_keyid.cert_serialnumber` - SerialNumber field of the Authority Key Identifier as a blob.
- `cert.pk_algorithm` - Name of the public key algorithm used by the certificate.
- `cert.pk_size` - Size of the public key used in the certificate.
- `cert.serialnumber` - Serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certificate, this gives an empty string.
- `cert.signature_algorithm` - Name of the cryptographic algorithm used by the CA to sign this certificate.
- `cert.subject_keyid` - Subject KeyID of the client certificate. If there is no Subject KeyID, this gives a zero-length text object.
- `cert.subject` - Distinguished Name of the Subject as a name-value. An equals sign (“=” separates names and values and a slash (“/”) delimit name-value pairs.
Following is an example:
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.com

**Citrix ADC libraries**

- **ns.tcp.stream** - String like library for handling TCP data as a stream of bytes. The maximum size of TCP stream data on which these APIs can work is 128 KB. The ns.tcp.stream library functions can also be called in the usual extension object oriented style of calling. For example, `data:len()` is the same as `ns.tcp.stream.len(data)`
  - `ns.tcp.stream.len(data)` - Returns length of data in bytes, similar to Lua’s `string.len`
  - `ns.tcp.stream.find(data, pattern [, init])` - Function similar to Lua’s `string.find`. In addition, it also does partial matching at the end of data. Upon partial match, the start index is returned and the end index becomes nil.
  - `ns.tcp.stream.split(data, length)` - Splits the data into two chunks, the first chunk is of the specified length. After a successful split the original data is no longer usable as a TCP data stream. Any attempt to use it that way causes an error.
  - `ns.tcp.stream.byte(data[, i [, j]])` - Function similar to Lua’s `string.byte`. Returns the internal numerical codes of the characters `data[i]`, `data[i+1]`, …, `data[j]`.
  - `ns.tcp.stream.sub(data, i [, j])` - Function similar to Lua’s `string.sub`. Returns the substring of `s` that starts at `i` and continues until `j`.
  - `ns.tcp.stream.match(data, pattern, [, init])` - Function similar to Lua’s `string.match`. Looks for the first `match` of pattern in string `s`.

- **ns.send(processing_ctxt, event_name, event_data)** - Generic function to send events to a processing context. Event data is a Lua table that can have any content. The contents depend on the event. After the `ns.send()` API is called, the data reference is no longer usable. Any attempt to use it causes an error.

- **ns.pipe(src_ctxt, dest_ctxt)** - Using a call to `pipe()` API, extension code can connect source context to a destination context. After a call to `pipe`, all the events that are sent from source context to the next module in the pipeline go directly to the destination context. This API is typically used by the module that makes the `pipe()` call, to remove itself from the pipeline.

4. Citrix ADC Extensions
**Protocol extensions**

January 25, 2019

Contributed by: C

The Citrix ADC appliances have native support for protocols such as HTTP. In addition to this, you can use protocol extensions to add support for custom protocols. Presently only TCP-based custom protocols are supported, for example, Message Queuing Telemetry Transport (MQTT) protocol. For secure transactions, TCP over SSL is also supported.

The protocol extensions on the Citrix ADC appliance are part of the high-level scripting infrastructure available on the Citrix ADC appliance. The scripting language is based on the Lua 5.2 programming language. To add a custom protocol to a Citrix ADC appliance, the user has to write extension code to implement the applicable behaviors. For example, the ns.tcp.client and ns.tcp.server behaviors are applicable to TCP based protocols. To implement a behavior, implement only the callbacks that you want to customize. If callback is not implemented, its default takes effect. For more information about the scripting language, see Citrix ADC Extensions - Language Overview. For details on behaviors, see Citrix ADC Extensions API Reference.

The Citrix ADC protocol extensions can be used for the following:

- Add new protocol support on the Citrix ADC appliance programmatically, using extensions.
- Parse protocol traffic and do protocol-specific message based load balancing (MBLB).
- Configure user defined load balancing persistence.

3. Citrix ADC Extensions

**Protocol extensions - architecture**

January 25, 2019

Contributed by: C

To achieve traffic-level extensibility, the traffic processing on a Citrix ADC appliance is exposed as a pipeline of separate processing modules. Traffic flows through them as it processes it from ingress
These modules in the pipeline follow a shared nothing model. Message passing is used to send the traffic data from one module in the pipeline to the next module.

Certain points in the traffic processing pipeline are made extensible, so that you can add code to customize the Citrix ADC behavior.

By default, the traffic bypasses a programmable module to which you do not add any code.

**Behaviors**

The programmable interfaces for customizing the traffic handling are called behaviors. Behaviors are basically a formalization of common programmable patterns that are available on a Citrix ADC appliance. The behaviors consist of a pre-defined set of event callback functions. You can implement a behavior by providing callback functions conforming to the behavior.

For example, the TCP client behavior consists of a callback function (on_data) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

**Context:**

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

**Payload:**

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments.

So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

For Citrix ADC API extensions, see [Citrix ADC extension API reference](#).

The following code snippet shows a user defined function to handle TCP client data stream events. The context and payload are passed to the function by Citrix ADC code. This code simply forwards the TCP data received in every call to the next processing module context in the pipeline. In this case, the next module is the load balancing (LB) context, which is a Citrix ADC native module.

```
1 function client.on_data(ctxt, payload)
2     ns.send(ctxt.output, "DATA", {
3         data = payload.data 
4     })
5 end
```
Protocol extensions - traffic pipeline for user defined TCP client and server behaviors

January 25, 2019

Contributed by:
C

The following figure illustrates the sample protocol extension - traffic pipeline for user defined TCP client and server behaviors

Add a custom protocol by using protocol extensions

The command line interface (CLI) commands for custom protocol use the keyword “user” to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

The following example illustrates the user flow for adding support for a new protocol. The example adds MQTT protocol support to the system. MQTT is a machine-to-machine “Internet of Things” connectivity protocol. It is a lightweight publish/subscribe messaging transport. Useful for connections with remote locations, this protocol uses client and broker tools to publish messages to subscribers.

1. Import the MQTT protocol extension implementation file to Citrix ADC system. The code listing for mqtt.lua is given below. The example below imports the MQTT extension file hosted on a webserver.

2. Add a new user TCP based protocol to the system using the extension.

   add user protocol MQTT -transport TCP -extension mqtt_code

3. Add a user load balancing vserver and bind backend services to it.

   1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
   2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
   3 add lb vserver mqtt_lb USER_TCP -lbmethod USER_TOKEN
4. Add a user vserver for the newly added protocol. Set the defaultlb to the LB vserver configured above.

```bash
add user vserver mqtt_vs MQTT 10.217.24.28 8765 -defaultLb mqtt_lb
```

5. Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSSESSION.

```bash
set lb vserver mqtt_lb -persistenceType USERSSESSION
```

## Protocol extensions - use cases

January 25, 2019

Contributed by:

C

Protocol extensions can be used for the following use cases.

- Message based load balancing (MBLB)
- Streaming
- Token based load balancing
- Load balancing persistence
- TCP connection based load balancing
- Content based load balancing
- SSL
- Modify traffic
- Originate traffic to client or server

### Message based load balancing

Protocol extensions support Message Based Load Balancing (MBLB), which can parse any protocol on a Citrix ADC appliance and load balance the protocol messages arriving on one client connection,
that is, distribute the messages over multiple server connections. MBLB is achieved by user code that parses the client TCP data stream.

The TCP data stream is passed to the on_data callbacks for client and server behaviors. The TCP data stream is available to the extension functions through a Lua string like interface. You can use an API similar to the Lua string API to parse the TCP data stream.

Useful APIs include:

- `data:len()`
- `data:find()`
- `data:byte()`
- `data:sub()`
- `data:split()`

Once the TCP data stream has been parsed into a protocol message, the user code achieves load balancing by just sending the protocol message to the next context available from the context passed to the on_data callback for the client.

The `ns.send()` API is used to send messages to other processing modules. In addition to the destination context, the send API takes the event name and optional payload as arguments. There is one-to-one correspondence between the event name and the callback function names for the behaviors. The callbacks for events are called `on_<event_name>`. The callback names use only lowercase.

For example, the TCP client and server on_data callbacks are user-defined handlers for events named “DATA.” For sending the whole protocol message in one send call, the EOM event is used. EOM, which stands for end of message, signifies the end of protocol message to the LB context downstream, so a new load balancing decision is made for data that follows this message.

The extension code might sometimes not receive the whole protocol message in the on_data event. In such a case, the data can be held by using the `ctxt:hold()` API. The hold API is available for both TCP-client and server-callback contexts. When “hold with data” is called, the data is stored in the context. When more data is received in the same context, the newly received data is appended to the previously stored data and the on_data callback function is called again with the combined data.

**Note:** The load balancing method used depends on the configuration of the load balancing virtual server corresponding to the load balancing context.

The following code snippet shows the use of the send API to send the parsed protocol message.

**Example:**

```lua
function client.on_data(ctxt, payload)
    --
    -- code to parse payload.data into protocol message comes here
```
Streaming

In some scenarios, holding the TCP data stream until the whole protocol message is collected might not be necessary. In fact, it is not advised unless it is required. Holding the data increases memory usage on Citrix ADC appliance and can make the appliance susceptible to DDoS attacks by exhausting the memory on Citrix ADC appliance with incomplete protocol messages on many connections.

Users can achieve streaming of TCP data in the extension callback handlers by using the send API. Instead of holding the data until the whole message is collected, data can be sent in chunks. Sending data to ctxt.output by using the DATA event sends a partial protocol message. It can be followed by more DATA events. An EOM event must be sent to mark the end of the protocol message. The load balancing context downstream makes the load balancing decision on the first data received. A new load balancing decision is made after the receipt of the EOM message.

To stream protocol message data, send multiple DATA events followed by an EOM event. The contiguous DATA events and the following EOM event are sent to the same server connection selected by load balancing decision for the first DATA event in the sequence.

For a send to client context, EOM and DATA events are effectively the same, because there is no special handling by the client context downstream for EOM events.

Token based load balancing

For natively supported protocols, a Citrix ADC appliance supports a token based load balancing method that uses PI expressions to create the token. For extensions, the protocol is not known in
advance, so PI expressions cannot be used. For token based load balancing, you have to set the default load balancing vserver to use the USER_TOKEN load balancing method, and provide the token value from the extension code by calling the send API with a user_token field. If the token value is sent from the send API and the USER_TOKEN load balancing method is configured on the default load balancing vserver, the load balancing decision is made by calculating a hash based on the token value. The maximum length of token value is 64 bytes.

```
add lb vserver v\_mqttlb USER\_TCP -lbMethod USER\_TOKEN
```

The code snippet in the following example uses a send API to send an LB token value.

### Example:

```
1  -- send the message to lb
2
3  -- user_token is set to do LB based on clientID
4
5
6  ns.send(ctx.output, "$EOM" , {
7    data = message,
8      user_token = token_info 
9  })
```

### Load balancing persistence

Load balancing persistence is closely related to token based load balancing. Users have to be able to programmatically calculate the persistence session value and use it for load balancing persistence. The send API is used to send persistence parameters. To use load balancing persistence, you have to set the USERSESSION persistence type on the default load balancing virtual server and provide a persistence parameter from the extension code by calling the send API with a user_session field. The maximum length of the persistence parameter value is 64 bytes.

If you need multiple types of persistence for a custom protocol, you have to define user persistence types and configure them. The names of the parameters used to configure the virtual servers are decided by the protocol implementer. A parameter’s configured value is also available to the extension code.

The following CLI and code snippet shows the use of a send API to support load balancing persistence.
The code listing in the section Code Listing for mqtt.lua also illustrates the use of the user_session field.

For persistency, you have to specify the USERSESSION persistency type on the load balancing virtual server and pass the user_session value from the ns.send API.

```plaintext
add lb vserver v\\_mqttlb USER\\_TCP -persistencetype USERSESSION
```

Send the MQTT message to the load balancer, with the user_session field set to clientID in the payload.

**Example:**

```plaintext
1 -- send the data so far to lb
2 -- user_session is set to clientID as well (it will be used to persist session)
3 ns.send(ctxt.output, "DATA", {
4   data = data, user_session = clientID }
5 )
```

**TCP connection based load balancing**

For some protocols, MBLB might not be needed. Instead, you might need TCP connection based load balancing. For example, the MQTT protocol must parse the initial part of the TCP stream to determine the token for load balancing. And, all the MQTT messages on the same TCP connection must be sent to the same server connection.

TCP connection based load balancing can be achieved by using the send API with only DATA events and not sending any EOM. That way the downstream load balancing context bases the load balancing decision on the data received first, and sends all the subsequent data to the same server connection selected by the load balancing decision.

Also, some use cases might require the ability to bypass extension handling after the load balancing decision has been made. Bypassing the extension calls results in better performance, because the traffic is processed purely by native code. Bypass can be done by using the ns.pipe() API. A call to the pipe() API extension code can connect input context to an output context. After the call to pipe(), all the events coming from input context directly go to the output context. Effectively, the module from which the pipe() call is made is removed from the pipeline.

The following code snippet shows streaming and the use of the pipe() API to bypass a module. The code listing in the section Code Listing for mqtt.lua also illustrates how to do streaming and the use of pipe() API to bypass the module for rest of the traffic on the connection.

**Example:**
-- send the data so far to lb
ns.send(ctxt.output, "DATA", {
  data = data,
  user_token = clientID
})

-- pipe the subsequent traffic to the lb - to bypass the client
on_data handler
ns.pipe(ctxt.input, ctxt.output)

Content based load balancing

For native protocols, content switching like feature for protocol extensions is supported. With this feature, instead of sending the data to the default load balance, you can send the data to the selected load balancer.

Content switching feature for protocol extensions is achieved by using the ctxt:lb_connect(<lbname>) API. This API is available to the TCP client context. Using this API, the extension code can obtain a load balancing context corresponding to an already configured load balancing virtual server. You can then use the send API with the load balancing context thus obtained.

The lb context can be NULL sometimes:

- Virtual server does not exists
- Virtual server is not of user protocol type
- Virtual server’s state is not UP
- Virtual server is user vserver, not load balancing virtual server

If you remove the target load balancing virtual server when it is in use, then all connections associated with that load balancing virtual server is reset.

The following code snippet shows the use of lb_connect() API. The code maps the client ID to load balancing virtual server names (lbname) using the Lua table lb_map and then gets the LB context for lbname using lb_connect(). And finally sends to the LB context using send API.

```lua
local lb_map = {
  ["client1"] = "lb_1",
  ["client2"] = "lb_2",
  ["client3"] = "lb_3",
  ["client4"] = "lb_4"
}
```
SSL

SSL for protocols using extensions is supported in ways similar to how SSL for native protocols is supported. Using the same parsing code for creating custom protocols, you can create a protocol instance over TCP or over SSL which can then be used to configure the virtual servers. Similarly, you can add user services over TCP or SSL.

For more information, see Configuring SSL Offloading for MQTT and Configuring SSL Offloading for MQTT With End-To-End Encryption.

Server connection multiplexing

In some cases, the client sends one request at a time and sends the next request only after the response for the first request is received from the server. In such a case, server connection can be reused for other client connections, and for the next message on the same connection, after the response has been sent to the client. To allow reuse of server connection by other client connections, you must use the ctxt: reuse_server_connection() API on the server side context.

Note: This API is available in Citrix ADC 12.1 build 49.xx and later.
Modify traffic

To modify data in the request or response, you must use the native rewrite feature that uses an advanced policy PI expression. Because you cannot use PI expressions in extensions, you can use the following APIs to modify a TCP stream data.

```
data:replace(offset, length, new_string)
data:insert(offset, new_string)
data:delete(offset, length)
data:gsub(pattern, replace [,n])
```

The following code snippet shows the use of replace() API.

```
-- Get the offset of the pattern, we want to replace
local old_pattern = "pattern to replace"
local old_pattern_length = old_pattern:len()
local pat_off, pat_end = data:find(old_pattern)
-- pattern is not present
if (not pat_off) then
  goto send_data
end
-- If the data we want to modify is not completely present, then
-- wait for more data
if (not pat_end) then
ctxt:hold(data)
data = nil
  goto done
end
data:replace(pat_off, old_pattern_length, "new pattern")
::send_data::
ns.send(ctxt.output, "EOM", { data = data })
::done::
```

The following code snippet shows the use of insert() API.

```
data:insert(5, "pattern to insert")
```

The following code snippet shows the use of insert() API, when we want to insert after or before some pattern:

```
-- Get the offset of the pattern, after or before which we want to insert
local pattern = "pattern after/before which we need to insert"
```
local pattern_length = pattern:len()
local pat_off, pat_end = data:find(pattern)
-- pattern is not present
if (not pat_off) then
goto send_data
end
-- If the pattern after which we want to insert is not
-- completely present, then wait for more data
if (not pat_end) then
    ctxt:hold(data)
data = nil
    goto done
end
-- Insert after the pattern
data:insert(pat_end + 1, "pattern to insert")
-- Insert before the pattern
data:insert(pat_off, "pattern to insert")
::send_data::
ns.send(ctxt.output, "EOM", {
data = data }
)
::done::

The following code snippet shows the use of delete() API.

local delete_pattern = "pattern to delete"
local delete_pattern_length = delete_pattern:len()
local pat_off, pat_end = data:find(old_pattern)
-- pattern is not present
if (not pat_off) then
goto send_data
end
-- If the data we want to delete is not completely present,
-- then wait for more data
if (not pat_end) then
    ctxt:hold(data)
data = nil
    goto done
end
data:delete(pat_off, delete_pattern_length)
::send_data::
ns.send(ctxt.output, "EOM", {
data = data }
)
The following code snippet shows the use of gsub() API.

```plaintext
1 -- Replace all the instances of the pattern with the new string
data:gsub("old pattern", "new string")
2 -- Replace only 2 instances of "old pattern"
data:gsub("old pattern", "new string", 2)
3 -- Insert new_string before all instances of "http"
data:gsub("input data", "(http)", "new_string%1")
4 -- Insert new_string after all instances of "http"
data:gsub("input data", "(http)", "%1new_string")
5 -- Insert new_string before only 2 instances of "http"
data:gsub("input data", "(http)", "new_string%1", 2)
```

**Note:** This API is available in Citrix ADC 12.1 build 50.xx and later.

**Originates traffic to client or server**

You can use the ns.send() API to send data that originates from the extension code to a client and a back-end server. To send or receive response directly with a client, from client context, you must use ctxt.client as the target. To send or receive response directly with a back-end server from server context, you must use ctxt.server as the target. The data in the payload can be a TCP stream data or a Lua string.

To stop traffic processing on a connection, you can use ctxt:close() API from either the client or the server context. This API closes the client-side connection or any server connections linked to it.

When you call the ctxt:close() API, extension code sends TCP FIN packet to the client and server connections and if more data is received from the client or server on this connection, then the appliance resets the connection.

The following code snippet shows the use of ctxt.client and ctxt:close() APIs.

```plaintext
1 -- If the input packet is not MQTT CONNECT type, then
2 -- send some error response to the client.
3 function client.on_data(ctxt, payload)
4   local data = payload.data
5   local offset = 1
6   local msg_type = 0
7   local error_response = "Missing MQTT Connect packet."
8   byte = data:byte(offset)
9   msg_type = bit32.rshift(byte, 4)
10  if (msg_type ~= 1) then
11    -- Send the error response
```
The following code snippet shows the example when user can inject the data in the normal traffic flow.

```plaintext
12 ns.send(ctxt.client, "DATA", {
13    data = error_response
14  })
15  -- Since error response has been sent, so now close the connection
16  ctxt:close()
17 end
```

The following code snippet shows the use of ctxt.to_server API.

```plaintext
1  -- After sending request, send some log message to the server.
2  function client.on_data(ctxt, payload)
3      local data = payload.data
4      local log_message = "client id: ..data:sub(3, 7)..", "user name: ..data:sub(9, 15)"
5  end
6  -- Send the request we get from the client to backend server
7  ns.send(ctxt.output, "DATA", {
8      data = data
9  })  -- After sending the request, also send the log message
10 end
```

The following code snippet shows the use of ctxt.to_server API.

```plaintext
1  -- If the HTTP response status message is "Not Found",
2  -- then send another request to the server.
3  function server.on_data(ctxt, payload)
4      local data = payload.data
5      local request = "GET /default.html HTTP/1.1\r\n\r\n", ss
6          local start, end = data:find("Not Found")
7          if (start) then
8             -- Send the another request to server
9               ns.send(ctxt.server, "DATA", {
10              data = request
11          })
12 end
```

**Note:** This API is available in Citrix ADC 12.1 build 50.xx and later.

**Code listing for mqtt.lua**

January 23, 2019

Contributed by: C

The code listing below, mqtt.lua, gives the code to implement the MQTT protocol on Citrix ADC using protocol extensions. The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. For client data, the code parses the CONNECT MQTT protocol message and extracts the ClientID. It then uses the ClientID for user_token value, which is used to load balance all the client traffic for the connection based on the ClientID by setting LB method for the LB vserver as USER_TOKEN. It uses the ClientID also for user_session value, which can be used for LB persistence by setting persistence type for the LB vserver as USERSESSION. The code uses the ns.send() to do LB and send the initial data. It uses the ns.pipe() API to send the rest of the client traffic directly to server connection, bypassing calls to extension callback handler.
--[[
  MQTT event handler for TCP client data

cxt - TCP client side App processing context.
data - TCP Data stream received.

- parse the client ID from the connect message - the first message should be connect

- send the data to LB with ClientID as user token and session

- pipe the subsequent data to LB directly. This way the subsequent MQTT traffic will
  bypass the tcp client on_data handler

  - if a parse error is seen, throw an error so the connection is reset

  ]]--]

function client.on_data(ctxt, payload)
  local data = payload.data

Configure MQTT by using protocol extensions

January 25, 2019
Contributed by: C

The following steps add a MQTT protocol to the Citrix ADC appliance.

Import the extension file to the Citrix ADC appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see Import extensions.

import ns extension local:mqtt_generic_fs.lua mqtt_code

Add a new user TCP based protocol to the system by using the extension.

add user protocol MQTT -transport TCP -extension mqtt_code

Add a service of type USER_TCP to indicate that this is a user-defined protocol.

add service s1 10.102.90.112 USER_TCP 80

Add a user load balancing vserver and bind backend services to it.

add lb vs mysv USER_TCP
bind lb vs mys v1

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mys v

Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

set lb vserver mqtt_lb -persistenceType USERSESSION

**Configuring SSL offloading for MQTT**

January 25, 2019

Contributed by:

C

You can implement SSL offloading for user protocols by adding an SSL instance for the protocol. The example below shows how to do SSL offloading for a user protocol. The traffic to backend services is unencrypted with this configuration.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see [SSL certificates](#).

The following commands add the MQTT_SSL protocol by including mqtt.lua with transport value “SSL.”

```bash
1 import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
2 add user protocol MQTT_SSL -transport SSL -extension mqtt_code
```

The following commands add a user load balancing virtual server and bind backend services to it.

```bash
1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
3 add lb vserver mqtt_lb USER_TCP -lbMethod ROUNDROBIN
4 bind lb vserver mqtt_lb mqtt_svr1
5 bind lb vserver mqtt_lb mqtt_svr2
```
The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also sets the defaultLb to the load balancing virtual server configured in the previous step.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb mqtt_lb
```

For SSL offloading, you also need to enable the SSL feature and bind a certkey to the user virtual server. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

**Example:**

```
1 enable ns feature SSL
2 add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key
3 bind ssl vserver mqtt_vs -certkeyName mqtt_svr_cert_key
```

The following example shows how to do SSL offloading for MQTT with end-to-end encryption.

**Note:** This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see SSL certificates.

The following commands import the extension file and add the MQTT_SSL protocol with SSL transport.

```
1 import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
2 add user protocol MQTT_SSL -transport SSL -extension mqtt_code
```
The following commands add a user load balancing virtual server and bind backend services to it. Both the load balancing virtual server and the services are configured for the service type USER_SSL_TCP.

1. add service mqtt_svr1 10.217.24.48 USER_SSL_TCP 1501
2. add service mqtt_svr2 10.217.24.48 USER_SSL_TCP 1502
3. add lb vserver mqtt_lb USER_SSL_TCP -lbmethod RR
4. bind lb vserver mqtt_lb mqtt_svr1
5. bind lb vserver mqtt_lb mqtt_svr2

The following command adds a user virtual server for the newly added protocol MQTT_SSL. Using MQTT_SSL means the Citrix ADC appliance will do SSL offloading, because MQTT_SSL was configured with SSL transport. The command also makes the load balancing virtual server, configured in previous step, the default load balancer.

add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb mqtt_lb

For end-to-end encryption, you also need to enable the SSL feature and bind a certkey to the user and default load balancing virtual servers. For more information, see the following topics:

Add or update a certificate-key pair

Bind the certificate-key pair to the SSL virtual server

1. enable ns feature SSL
2. add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key
3. bind ssl vserver mqtt_lb -certKeyName mqtt_svr_cert_key
4. bind ssl vserver mqtt_vs -certKeyName mqtt_svr_cert_key

**Tutorial - load balancing syslog messages by using protocol extensions**

February 19, 2019

Contributed by:
C
Syslog protocol available on the Citrix ADC appliance works only for the messages generated on the Citrix ADC appliance. It does not load balance the messages coming from external nodes. To load balance such messages, you need to use the protocol extensions feature and write the syslog message parsing logic by using the Lua 5.2 programming language.

**Code for parsing syslog message**

The code only has the TCP client data callback function defined - client.on_data(). For server data, it does not add a callback function and the server to client takes the fast native path. The code identifies message boundary based on the trailing character. If the TCP packet contains more than one syslog messages, then we split the packet based on the trailing character and load balance each message.

```lua
---[]

Syslog event handler for TCP client data
ctxt - TCP client side App processing context.
data - TCP Data stream received.

function client.on_data(ctxt, payload)
    local message = nil
    local data_len
    local data = payload.data
    local trailing_character = ”\n”
    ::split_message::
        -- Get the offset of trailing character
        local new_line_character_offset = data:find(trailing_character)
        -- If trailing character is not found, then wait for more data.
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
if (not new_line_character_offset)
    goto need_more_data

end

-- Get the length of the current message

data_len = data:len()

-- Check whether we have more than one message

-- by comparing trailing character offset and current data length

if (data_len > new_line_character_offset) then
    -- If we have more than one message, then split
    -- the data into two parts such that first part
    -- message upto trailing character offset and
    -- will contain second part will contain
    -- remaining message.

    data:split(new_line_character_offset)
else
    message = data
data = nil

-- Send the data to the backend server.
ns.send(ctxt.output, "EOM", {
  data = message }
)

goto done

::need_more_data::

  -- Wait for more data
  ctxt:hold(data)
  data = nil
  goto done

::done::

  -- If we have more data to parse,
  -- then do
  if (data) then
    goto split_message
  end

end

1.
2. Citrix ADC
3. Citrix ADC 12.1
The following steps add an user SYSLOG protocol to the Citrix ADC appliance.

Import the extension file to the Citrix ADC appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see Importing Extensions.

```
import ns extension local:syslog_parser.lua syslog_parser_code
```

Add a new user TCP-based protocol to the system by using the extension.

```
add user protocol USER_SYSLOG -transport TCP -extension syslog_parser_code
```

Add a service of type USER_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

```
1 add lb vs mysv USER_TCP
2
3 bind lb vs mysv s1
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_syslog USER_SYSLOG 10.217.24.28 80 -defaultlb mysv
```

**Protocol extensions command reference**

January 23, 2019
The following table lists all the new commands added for custom protocols, and the existing commands that have been modified for custom protocols.

<table>
<thead>
<tr>
<th>CLI command</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>`add user protocol &lt;name&gt; -transport (TCP</td>
<td>SSL )-extension &lt;string&gt; -comment &lt;string&gt;`</td>
<td>Adds a new user protocol to the Citrix ADC appliance by using extensions. Currently only user protocols with transport value TCP or SSL are supported.</td>
</tr>
<tr>
<td><code>rm user protocol &lt;name&gt;</code></td>
<td>Removes a user protocol previously added to the Citrix ADC appliance.</td>
<td><code>rm user protocol mqtt</code></td>
</tr>
<tr>
<td><code>set user protocol &lt;name&gt; -comment &lt;string&gt;</code></td>
<td>Changes settings for a user protocol previously added to the Citrix ADC appliance.</td>
<td><code>set user protocol mqtt -comment “MQTT protocol implementation”</code></td>
</tr>
<tr>
<td><code>unset user protocol &lt;name&gt; -comment</code></td>
<td>Removes settings for a user protocol previously added to the Citrix ADC appliance.</td>
<td></td>
</tr>
</tbody>
</table>
Example:
unset user protocol mqtt -comment “MQTT protocol implementation”

• CLI command:

update ns extension <extension name>

• Description:

Updates the implementation for a previously added user protocol by using extensions.
You can update the protocol implementation only if the protocol is not being used by any user virtual server.

Example:
update ns extension my-extension

• CLI command:

add lb vserver <name> [USER_TCP | USER_SSL_TCP] [-lbmethod USER_TOKEN] [-persistencetype USERSESSION] [-timeout <value>]

• Description:

Adds a load balancing virtual server to the Citrix ADC appliance. This is an existing CLI command.
For load balancing user virtual servers, the service type to use is USER_TCP or USER_SSL_TCP.
The IP address and port are not allowed with user load balancing virtual servers.
For user load balancing virtual servers, only the ROUNDROBIN load balancing method is allowed, and the token value is provided by the extension code. Similarly, only USERSESSION persistence is allowed, and the persistence setting is provided by the extension code.

Example:
add lb vserver mysv USER_TCP –lbmethod ROUNDROBIN

• CLI command:

add user vserver <name> <userProtocol> <IPAddress> <port> -defaultLB <string> [-params <string>] [-comment <string>]

• Description:

Adds a virtual server for a user protocol by using extensions. The configured default user load balancing virtual server is available to the TCP client data extension handler as ctxt.output.
For a virtual server, extension parameters can be set by using the -params option with a name and a value pair. The corresponding parameter value is available to the extension handlers as ctxt.vserver.params.<paramName>.
Example:
add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv

• CLI command:
  rm user vserver <name>

• Description:
  Removes a user virtual server previously added to the Citrix ADC appliance.
  Example:
  rm user vserver v_mqtt

• CLI command:
  set user vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-defaultLB <string>] [-params <string>] [-comment <string>]

• Description:
  Changes settings for a user virtual server previously added to the Citrix ADC appliance. When an extension parameter is assigned a new value by the -params option, the old value is overwritten.
  Example:
  set user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

• CLI command:
  unset user vserver <name> [-params] [-comment]

• Description:
  Removes the settings for a user virtual server previously added to the Citrix ADC appliance. If you use the –params option to unset an extension parameter, the corresponding parameter value available to extension handlers is changed to nil.
  Example:
  unset user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment “MQTT protocol implementation”

• CLI command:
  show user protocol [name]

• Description:
  Displays information about a user protocol, such as extension and callbacks.
Example:
show user protocol mqtt

- **CLI command:**

  ```
  show user vserver [<name>]
  ```

- **Description:**

  Displays information about a user virtual server.

  ```
  Example:
  show user vserver vs_mqtt
  ```

- **CLI command:**

  ```
  stat user vserver [<name>]
  ```

- **Description:**

  Displays statistics about a user virtual server.

  ```
  Example:
  stat user vserver vs_mqtt
  ```

- **CLI command:**

  ```
  show lb persistentSessions [<vserv-name>]
  ```

- **Description:**

  Displays information about persistent sessions. This is an existing CLI. For user protocols, the persistence type is shown as USERSESSION.

- **CLI command:**

  ```
  rm lb vserver <name>
  ```

- **Description:**

  Removes a user LB vserver previously added to the Citrix ADC appliance.

  ```
  Example:
  rm lb vserver mysv
  ```

- **CLI command:**

  ```
  add service <name> <IPAddr> (USER_TCP | USER_SSL_TCP)<Port>
  ```

- **Description:**

  Adds a backend service to be used for a user protocol. This is an existing CLI command with new service types USER_TCP and USER_SSL_TCP.
Example:
add service mqtt_svr1 10.217.24.48 USER_TCP 1501

Note: The existing “set service and unset service” commands can be used to remove or change the settings of a previously added service for a user protocol.

• CLI command:

bind lb vserver <name> <serviceName>

• Description:

Binds a service to a user LB vserver. The service type should be USER_TCP/USER_SSL_TCP for binding to an LB vserver with type of USER_TCP/USER_SSL_TCP.

Example:
bind lb vserver mysv mqtt_svr1

• CLI command:

unbind lb vserver <name> <serviceName>

• Description:

Unbinds a previously bound service to a user LB vserver.

Example:
unbind lb vserver mysv mqtt_svr1

• CLI command:

rm service <name>

• Description:

Removes a service that is previously added for a user protocol.

Example:
rm service mqtt_svr1
If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

**Custom logging**

You can also add your own logging to your extension function. To do so, use the built-in `ns.logger:level()` function, where level is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C `printf()` function: a format string, and a variable number of arguments to supply values for the `%` specified in the format string. For example, you might add the following to the `COMBINE_HEADERS` function to log the result of a call:

```plaintext
1 local result\_str = table.concat(combined\_headers, "\r\n") .. "\r\n
2 ns.logger:info("Result: %s", result\_str)
3 return result\_str
```

The above function would log the following message to `/var/log/ns.log` for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^M
H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)libcurl
/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: */**^M H2: h2val1, h2val2,
h2val3^M ^^M
```

Policy extensions

January 23, 2019

Contributed by: C

The policy extension feature enables you to write extension functions for built-in policy types. The extensions can be used in policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated. This feature is useful for:

- Adding customized functions to existing Policies.
- Implementing logical constructs for complex customer requirements.

The policy extension feature addresses these limitations by enabling users to write extension functions for built in Policy types. The extensions can then be used in the policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated.

The following table lists the policy types that can be used when writing an extension, and their associated mappings.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Mapped Policy Type</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT_T</td>
<td>NSTEXT</td>
<td>String</td>
</tr>
<tr>
<td>BOOL_AT</td>
<td>NSBOOL</td>
<td>Boolean</td>
</tr>
<tr>
<td>NUM_AT</td>
<td>NSNUM</td>
<td>Number (double-precision floating point)</td>
</tr>
<tr>
<td>DOUBLE_AT</td>
<td>NSDOUBLE</td>
<td>Number (double-precision floating point)</td>
</tr>
</tbody>
</table>

Prerequisites for using policy extensions

The imported functions must conform to the existing policy standards. Therefore:

- The function name must start with a letter and may contain numbers or underscores.
- The function name is treated as case insensitive by Citrix ADC policies.
- The function must return a single value even if the extension language returns multiple values.
- Functions with a variable number of arguments are not supported.
How do policy extensions work?

The existing policies on a Citrix ADC appliance use an interpreter to evaluate the functions, which are imported in a policy extension file. When a user imports a new function in a policy extension file:

1. The extension file is validated for syntax and other conditions.
2. If the validation fails, the error is reported to the user.
3. If the validation succeeds, the extension file is imported to the Citrix ADC appliance and its contents can be used in policy expressions, just like any built-in policy function
   a) If the policy expression evaluation returns an error during runtime, it is reported as an undef event and the associated error counter is incremented.
      Note: If a policy undef event occurs and the policy rule contains one or more policy extension functions, the show ns extension <name> command displays the undef hits when applied to those policy extensions. If the extension function is aborted, the abort counter value is incremented.
   b) If the policy expression evaluation is successful, expression evaluation resumes until the entire expression is evaluated, or until it is aborted because of an error.

If the extension function takes too long to run, it is aborted, and the error counter pertaining to that extension function is incremented. The extension function is sandboxed, which prevents:

- Excessive CPU usage on the Citrix ADC appliance.
- Excessive memory usage on the Citrix ADC appliance.
- Usage of harmful built-in libraries or third-party libraries or binaries.
- Long-running scripts that could potentially cause the Citrix ADC appliance to reboot.

Configuring policy extensions

January 23, 2019

Contributed by:
C

When your policy extension file is ready, import it to the Citrix ADC appliance. The import process copies the extension file into a directory on the Citrix ADC appliance and checks for syntax errors.
After the import, you have to make the extension file available for use in the policy expressions.

**Note:** The import command is used to download the file content from an external source `<src>`, or an internal source, onto the Citrix ADC file system. To load this file content into the packet engine(s) for the first time, use the add command. If there is an update to the file content, the updated content can be downloaded to the Citrix ADC file system by issuing the import command with `-overwrite` argument. This updates the contents in the file system. To load the updated content to the packet engine(s), use the update command.

### Configure policy extensions by using the CLI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.
   a) HTTP Import
      
      If you have a web server available, you can store the extension file in the webserver directory and import it to the Citrix ADC appliance.
      
      ```
      import ns extension <src> <name> [-comment<string>] [-overwrite]
      ```
      
      **Example:**
      
      ```
      import ns extension http://myhost/path/to/extension myextension -comment "Custom crc calculation"
      ```
   b) Local Import
      
      You can use SSH client to copy the extension file from your workstation to the /var/tmp directory of the Citrix ADC appliance.
      
      ```
      scp extension-file-name <ns-userid@ns-ip-addr>:/var/tmp
      ```
      
      where
      
      - extension-file-name is the name of the extension file on your client machine.
      - ns-userid is the Citrix ADC appliance user with permission to write to /var/tmp.
      - ns-ip-addr is the Citrix ADC IP address.
      
      After copying the file to the Citrix ADC appliance, execute the import command on the Citrix ADC appliance.
      
      ```
      import ns extension local:<extension-file-name extension-name>
      ```
      
      **Note:** The CLI should be used to import a local extension file, by running the `import` command.

2. Add the policy extension to the packet engine for evaluation.
   
   ```
   add ns extension <name> [-comment <string>]
   ```
Example:

```
add ns extension myextension
```

After an extension file is imported, you can update it, if you included the -overwrite parameter in the import command, or remove it. You can also display the details of an imported extension file.

Update an extension file on the Citrix ADC appliance from the source

At the command prompt, type:

```
update ns extension <name>
```

**Note:** You can update the extension file only after importing the specified extension file to the Citrix ADC appliance with the -overwrite parameter.

**Example:**

```
update ns extension myextension
```

Remove an extension file from the Citrix ADC appliance

At the command prompt type:

```
rm ns extension <name>
```

**Example:**

```
rm ns extension myextension
```

Display the details of the specified extension function on the Citrix ADC appliance

At the command prompt, type:

```
show ns extension <name>
```

**Example:**

```
show ns extension myextension
```

Configure policy extensions by using the GUI

1. Import the policy extension file to the Citrix ADC Appliance, from either a web server (using HTTP) or your local workstation.
   a) Navigate to **AppExpert > Policy Extensions**, click **Policy Extension**, from the **Import From** drop-down list, select the URL for the location of the extension file that you want to import.
b) Navigate to AppExpert > Policy Extensions, click Policy Extension and import the extension file by selecting File in the Import From drop-down.

2. Add the policy extension to the packet engine for evaluation.
   Navigate to AppExpert > Policy Extensions and, on the Policy Extensions tab, add the extension file.

**Update an extension file on the Citrix ADC appliance from the source**

Navigate to AppExpert > Policy Extensions and, on the Policy Extensions tab, update the extension file.

**Remove an extension file from the Citrix ADC appliance**

Navigate to AppExpert > Policy Extensions and, on the Policy Extensions tab, remove the extension file.

**Display the details of the specified extension function on the Citrix ADC appliance**

Navigate to AppExpert > Policy Extensions and, on the Policy Extensions Functions tab, click the click drop-down arrow of the extension function that you want to see the details.

**Policy extensions - use cases**

January 23, 2019

Contributed by: C

Certain customer applications have requirements that cannot be addressed with existing policies and expressions. The policy extension feature enables customers to add customized functions to their applications to meet their requirement.

The following use cases illustrate the addition of new functions using the policy extension feature on the Citrix ADC appliance.
Case 1: Custom hash

The CUSTOM_HASH function provides a mechanism to insert any type of hash value in the responses sent to the client. In this use case, the hash function is used to compute the hash of the query string for a rewrite HTTP request and insert an HTTP header named CUSTOM_HASH with the computed value. The CUSTOM_HASH function implements the DJB2 hash algorithm.

Sample Usage of CUSTOM_HASH:

```
> add rewrite action test_custom_hash insert_http_header "CUSTOM_HASH" "HTTP.REQ.URL.QUERY.CUSTOM_HASH"
```

Sample Definition of CUSTOM_HASH():

```nsh
function NSTEXT:CUSTOM_HASH() : NSTEXT

local hash = 5381
local len = string.len(self)
for i = 1, len do
    hash = bit32.bxor((hash * 33), string.byte(self, i))
end
return tostring(hash)
end
```

Line-by-line description of the above sample:

```
function NSTEXT:CUSTOM_HASH() : NSTEXT
Defines the CUSTOM_HASH() function, with text input and a text return value.
```
local hash = 5381
local len = string.len(self)

Declares two local variables:

- hash. Accumulates the compute hash value and is seeded with the number 5381
- len. Sets to the length of the self input text string, using the built-in string.len() function.

for i = 1, len do
    hash = bit32.bxor((hash * 33), string.byte(self, i))
end

Iterates through each byte of the input string and adds the byte to the hash. It uses the built-in string.byte() function to get the byte and the built-in bit32.bxor() function to compute the XOR of the existing hash value (multiplied by 33) and the byte.

return tostring(hash)

Calls the built-in tostring() function to convert the numeric hash value to a string and returns the string as the value of the function.

Case 2: Collapse double slashes in URLs

Collapsing double slashes in URLs improves the website rendering time, because browsers parse the single slash URLs more efficiently. The single slash URLs also to maintain compatibility with applications that do not accept double slashes. The policy extension feature allows customers to add a function that replaces the double slashes with single slashes in the URLs. The following example illustrates the addition of a policy extension function that that collapses double slashes in URLs.

Sample Definition of COLLAPSE_DOUBLE_SLASHES():

-- Collapse double slashes in URL to a single slash and return the result
function NTEXT:COLLAPSE_DOUBLE_SLASHES() : NTEXT
    local result = string.gsub(self, "//", "/")
    return result
Line-by-line description of the above sample:

Line 1: function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
   Declares the COLLAPSE_DOUBLE_SLASHES() function with text input and return.
Line 2: local result = string.gsub(self, "//", "/")
   Declares a local variable named result and uses the built-in string.gsub() function to replace all double slashes with single slashes in the self input text.
Line 3: The second parameter of string.gsub() is actually a regular expression pattern, although here a simple string is used for the pattern.
Line 4: return result
   Returns the resulting string.

Case 3: Combine headers

Certain customer applications cannot handle multiple headers in a request. Also, parsing of duplicate headers with same header values, or multiple headers with same name but different values in a request, consumes time and network resources. The policy extension feature allows customers to add a function to combine these headers into single headers with a value combining the original values. For example, combining the values of the headers H1 and H2.

Original request:

```
GET /combine_headers HTTP/1.1
User-Agent: amigo unit test
Host: myhost
H2: h2val1
H1: abcd
Accept: */*
H2: h2val2
Content-Length: 0
H2: h2val3
H1: 1234
```

Modified request:

```
```
In general, this type of request modification is done using the Rewrite feature, using policy expressions to delineate the part of the request to be modified (the target) and the modification to be performed (the string builder expression). However, policy expressions do not have the ability to iterate over an arbitrary number of headers.

The solution to this problem requires an extension to the policy facility. To do this, we will define an extension function, called COMBINE_HEADERS. With this function, we can set up the following rewrite action:

```plaintext
> add rewrite action combine_headers_act replace 'HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn")' 'HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn").COMBINE_HEADERS'
```

Here, the rewrite target is HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn"). The AFTER_STR("HTTP/1.1rn") is required because FULL_HEADER includes the first line of the HTTP request (e.g. GET /combine_headers HTTP/1.1).

The string builder expression is HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1rn").COMBINE_HEADERS, where the headers (minus the first line) are fed into the COMBINE_HEADERS extension function, which combines and returns the values for headers.

**Sample Definition of COMBINE_HEADERS:**

```plaintext
-- Extension function to combine multiple headers of the same name into one header.

function NSTEXT:COMBINE_HEADERS(): NSTEXT

  local headers = {
  }
  -- headers

  local combined_headers = {
  }
  -- headers with final combined values
```
-- Iterate over each header (format "name:valuer\r\n")

-- and build a list of values for each unique header name.

for name, value in string.gmatch(self, "([\^:]*)\([\^\r\n]*\)\r\n") do

    if headers[name] then

        local next_value_index = #(headers[name]) + 1

        headers[name][next_value_index] = value

    else

        headers[name] = {
            name .. ":" .. value
        }

    end

end

-- iterate over the headers and concat the values with separator ",,"

for name, values in pairs(headers) do

    local next_header_index = #combined_headers + 1

    combined_headers[next_header_index] = table.concat(values, ",,"

end

-- Construct the result headers using table.concat()

local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"

return result_str
Line-by-line description of the above sample:

1. `function NSTEXT:COMBINE_HEADERS(): NSTEXT`
   - Defines the COMBINE_HEADERS extension function, with the text input into the function from the policy expression and a text `return` type to the policy expression.

2. `local headers = { }
   -- headers

3. `local combined_headers = { }
   -- headers with final combined values

4. `Declares local variables headers and combined_headers and initialize these variables to empty tables. headers will be a table of arrays of strings, where each array holds one or more values for a header. combined_headers will be an array of strings, where each array element is a header with its combined values.`

5. `for name, value in string.gmatch(self, "([^:]\+):([^\r\n]*)(\r\n)") do
   . . .
end`
   - This generic for loop parses each header in the input. The iterator is the built-in string.gmatch() function. This function takes two parameters: a string to search, and a pattern to use to match pieces of the string. The string to search is supplied by the implicit self parameter, which is the text for the headers input into the function.

   The pattern is expressed using a regular expression (regex for short). This regex matches the header name and value for each header, which the HTTP standard defines as `name:value\r\n`. The parentheses in the regex specify the matching parts to be extracted, so the regex schematic is `(match-name):(match-value)\r\n`. The `match-name` pattern needs to match all characters except the colon. This is written `[^:]++([^:]` is any character except : and + is one or more repetitions). Similarly, the `match-value` pattern has to match any characters except the \r\n, so it is written `[^\r\n]/[^\r\n] matches any character except \r and \n and` is zero or more repetitions). This makes the complete regex `([^:]++([^\r\n]*))\r\n`.

   The for statement uses a multiple assignment to set name and value to the two matches returned by the string.gmatch() iterator. These are implicitly declared as local variables within the body of the for
loop.

```plaintext
if headers[name] then
  local next_value_index = #(headers[name]) + 1
  headers[name][next_value_index] = value
else
  headers[name] = {
    name .. ":" .. value }
end
```

These statements within the for loop put the header names and values into the headers table. The first time a header name is parsed (say H2: h2val1 in the example input), there is no headers entry for the name and headers[name] is nil.

Since nil is treated as false, the else clause is executed. This sets the headers entry for name to an array with one string value name: value.

Note: The array constructor in the else loop is equivalent to {[1] = name .. ":" .. value}, which sets the first element of the array. For the first H2 header, it sets headers[“H2”] = (“H2:h2val1”).

On subsequent instances of a header, (say, H2: h2val2 in the example input). headers[name] is not nil, so the then clause is executed. This determines the next available index in the array value for headers[name], and puts the header value into that index. For the second H2 header, it sets headers[“H2”] = (“H2:h2val1”, “h2val2”).

```plaintext
for name, values in pairs(headers) do
  local next_header_index = #combined_headers + 1
  combined_headers[next_header_index] = table.concat(values, ",")
end
```

After the original headers have been parsed and the headers table filled in, this loop builds the combined_headers array. It uses the pairs() function as the for loop iterator.

Each call to pairs() returns the name and value of the next entry in the headers table.

The next line determines the next available index in the combined_headers array, and the next line sets that array element to the combined header. It uses the built-in table.concat() function, which takes as its arguments an array of strings and a string to use as a separator, and returns a string that is the concatenation of the array strings, separated by the separator.

For example, for values = (“H2:h2val1”, “h2val2”), this produces ”H2:h2val1, h2val2”

```plaintext
local result_str = table.concat(combined_headers, \r\n) .. \r\n```

After the combined_headers array are built, it concatenates the elements into one string, and adds a double \r\n that terminates the HTTP headers.
Returns a string as the result of the COMBINE_HEADERS extension function.

1. return result_str

Troubleshooting policy extensions

January 23, 2019
Contributed by: C

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the Citrix ADC appliance.

This topic provides information on:

- Extension tracing
- Custom logging

Extension tracing

To show what your extension function is doing, extension tracing functionality logs the execution of the function to the Citrix ADC system log (/var/log/ns.log). The trace logging uses the DEBUG log level, which normally is not enabled. Therefore, you have to enable ALL log levels. Then you can enable tracing by setting the -trace option of the set ns extension command. The available settings are:

- off turn off tracing (equivalent to unset ns extension -trace).
- calls trace function calls with arguments and function returns with the first return value.
- lines trace the above plus line numbers for executed lines.
- all trace the above plus local variables changed by executed lines.

Example:
Each trace message has the format

```
log-header : default NSEXEXTENSION Message message-number 0 : "TRACE function
-name CALL call-number: event"
```

Where,
- log-header supplies timestamps, the Citrix ADC IP address, and the Packet Engine ID.
- message-number is a sequential number identifying the log message.
- function-name is the extension function name.
- call-number is a sequential number for each extension function call. It can be used to group all
  the trace messages for an extension function call.
- event is one of the following:
  - CALL function-name ; parameter-values indicates that the function has been called with
    the specified parameters.
  - RETURN FROM function-name ; return = value indicates that a function has returned the
    specified (first) value. (Additional return values are not reported.)
  - LINE line-number ; variable-values indicates that a line has been executed and lists any
    variables with changed values.

Where,
- value or values is
  - a number, with or without a decimal point,
  - a string, enclosed in double quotes and with escaped characters as described earlier,
  - a boolean true or false,
  - nil,
  - a table constructor, of the format {[key1]=value1,[key2]=value2,...}.
- parameter-values is parameter1 = value1 ; parameter2 = value2 , ...
- variable-values is variable1 = value1 ; variable2 = value2 , ...

An example of abbreviated log messages:

```
> shell tail -f /var/log/ns.log | grep TRACE | more
...
NSEXEXTENSION Message 3035 0 : "TRACE combine_headers CALL 30 : CALL
COMBINE_HEADERS; self = "User-Agent: curl/7.24.0 (amd64-portbld-
freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r\nHost:
10.217.24.7\r\nAccept:*\r\nH2: h2val1\r\nH1: abcd\r\nH2: h2val2\r
\nH2: h2val3\r\n"
```
... NSEXTENSION Message 3036 0 : "TRACE combine_headers CALL 30 : LINE 4; headers = {
  }
"

... NSEXTENSION Message 3037 0 : "TRACE combine_headers CALL 30 : LINE 5; combined_headers = {
  }
"

... NSEXTENSION Message 3038 0 : "TRACE combine_headers CALL 30 : CALL gmatch"

... NSEXTENSION Message 3039 0 : "TRACE combine_headers CALL 30 :
RETURN FROM gmatch; return = function 0x2bee5a80"

... NSEXTENSION Message 3040 0 : "TRACE combine_headers CALL 30 :
for iterator"

... NSEXTENSION Message 3041 0 : "TRACE combine_headers CALL 30 :
RETURN FROM for iterator; return = "curl/7.24.0 (amd64-portbld-
freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3"
"

... NSEXTENSION Message 3042 0 : "TRACE combine_headers CALL 30 : LINE 9; name = "User-Agent"; value = " curl/7.24.0 (amd64-portbld-
freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3"
"

... NSEXTENSION Message 3043 0 : "TRACE combine_headers CALL 30 : LINE 10"

... NSEXTENSION Message 3044 0 : "TRACE combine_headers CALL 30 : LINE 14; headers = {
  ["User-Agent"]={
    [1]="User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4) libcurl/7.24.0
      OpenSSL/0.9.8y zlib/1.2.3" }
  }
"

...

... NSEXTENSION Message 3117 0 : "TRACE combine_headers CALL 30 :
for iterator"

... NSEXTENSION Message 3118 0 : "TRACE combine_headers CALL 30 :
RETURN FROM for iterator; return = nil"
Custom logging

You can also add your own logging to your extension function. To do so, use the built-in `ns.logger:level()` function, where `level` is `emergency`, `alert`, `critical`, `error`, `warning`, `notice`, `info`, or `debug`. The parameters are the same as the C `printf()` function: a format string, and a variable number of arguments to supply values for the `%` specified in the format string. For example, you might add the following to the COMBINE_HEADERS function to log the result of a call:

```plaintext
local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
ns.logger:info("Result: %s", result_str)
return result_str
```

The above function would log the following message to `/var/log/ns.log` for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above:

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^M H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4) libcurl
```

## Client Keep-Alive

January 23, 2019

Contributed by: C

The client keep-alive feature enables multiple client requests to be sent on a single client connection. This feature helps in a transaction management environment where typically the server closes the client connection after serving the response. The client then opens a new connection for each request and spends more time on the transaction.

Client keep-alive resolves this issue by keeping the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows sending multiple client requests using a single connection and saves the round trips associated with opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is also useful under either of the following conditions:

- When the server does not support client keep-alive.
- When the server supports client keep-alive but an application on the server does not support client keep-alive.

**Note**

Client keep-alive is applicable for HTTP and SSL traffic. Client-keep alive can be configured globally to be able to handle all traffic. It can also be configured to be active only on specific services.

In client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a “Connection: Close” header is present in the server response,
the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request; instead, the connection to the server is reopened.

**Note**
If a server sends back two “Connection: Close” headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is actually closed.

### Configure client keep-alive

Client keep-alive, by default, is disabled on the Citrix ADC, both globally and at service level. Therefore, you must enable the feature at the required scope.

**Note**
If you enable client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level. Additionally, if required, you can configure some HTTP parameters to specify the maximum number of HTTP connections retained in the connection reuse pool, enable connection multiplexing, and enable persistence Etag.

**Note**
When Persistent ETag is enabled, the ETag header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

To configure client keep-alive by using the command line interface:

At the command prompt, do the following:

1. Enable client keep-alive on the Citrix ADC.
   - At global level
     ```
     enable ns mode cka
     ```
   - At service level
     ```
     set service <name> -CKA YES
     ```

   **Note:**
   Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).

   ```
   set ns httpProfile <name> -maxReusePool <value> -conMultiplex ENABLED -persistentETag ENABLED
   ```
**Note:** Configure these parameters on the `nshttp_default_profile` HTTP profile, to make them available globally.

To configure client keep-alive by using the GUI:

1. Enable client keep-alive on the Citrix ADC.
   - At global level
     Navigate to **System > Settings**, click **Configure Modes** and select **Client side Keep Alive**.
   - At service level
     Navigate to **Traffic Management > Load Balancing > Services**, and select the required service. In the **Settings** grouping, enable **Client Keep-Alive**.

2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).
   Navigate to **System > Profiles**, and on **HTTP Profiles** tab, select the required profile and update the required HTTP parameters.

HTTP compression

April 12, 2019

Contributed by: C

For websites with compressible content, the HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve server performance by offloading the computationally intensive compression task from your servers to the Citrix ADC appliance.

The following table describes the capabilities of the HTTP compression feature:

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compression Ratio</td>
<td>Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing amount of data transmitted over the network.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Browser Awareness</strong></td>
<td>Citrix ADC serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.</td>
</tr>
<tr>
<td><strong>Compression blocking</strong></td>
<td>You can define content filters to selectively block compression by applying built-in actions.</td>
</tr>
<tr>
<td><strong>Compression Caching</strong></td>
<td>With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.</td>
</tr>
<tr>
<td><strong>HTTPS Support</strong></td>
<td>Compression is particularly useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the Citrix ADC appliance, and decrypted by the client.</td>
</tr>
<tr>
<td><strong>Intelligent Response Filtering</strong></td>
<td>The Citrix ADC compression engine intelligently filters server responses on the basis of defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression in conjunction with the Citrix ADC compression feature.</td>
</tr>
<tr>
<td><strong>Compression Switching</strong></td>
<td>The Citrix ADC appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.</td>
</tr>
</tbody>
</table>
How HTTP compression works

A Citrix ADC can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client’s browser and uncompressed as determined by the browser’s supported algorithm or algorithms (GZIP or DEFLATE).

Citrix ADC compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the Citrix ADC. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.
2. The ADC forwards the request to the server and receives the response.
3. The Citrix ADC compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser supports a compression algorithm specified by the action, the Citrix ADC applies the algorithm and sends the compressed response to the client browser.
5. The client applies the supported compression algorithm to decompress the response.

Configure HTTP compression

By default, compression is disabled on the Citrix ADC. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To enable HTTP compression by using the CLI

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- `enable ns feature cmp`
- `set service \<name\> -CMP YES`

To configure compression by using the GUI

Do one of the following:
To enable compression globally, navigate to System > Settings, click Configure Basic Features, and select HTTP Compression.

To enable compression for a specific service, navigate to Traffic Management > Load Balancing > Services, select the service, and click Edit. In the Settings group, click the pencil icon and enable Compression.

**Configuring a compression action**

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server’s response.

There are four built-in compression actions:

- **COMPRESS**: Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser’s response is not compressed.
- **NOCOMPRESS**: Does not compress data.
- **GZIP**: Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser’s response is not compressed.
- **DEFLATE**: Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, the browser’s response is not compressed. After creating an action, you associate the action with one or more compression policies.

At the command prompt, enter the following command to create a compression action:

```
add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -varyHeaderValue <string>]
```

To configure a compression policy by using the CLI

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

At the command prompt, enter the following command to create a compression policy:

```
add cmp policy <name> -rule <expression> -resAction <string>
```
To create a compression action by using the GUI

Navigate to Optimization > HTTP Compression > Actions, click Add, and create a compression action to specify the type of compression to be performed on the HTTP response.

**Configuring a compression policy**

A compression policy contains a rule, which is a logical expression that enables the Citrix ADC appliance to identify the traffic that should be compressed.

When the Citrix ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

<table>
<thead>
<tr>
<th>Built-in Classic or Default Syntax Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns_nocmp_mozilla_47, ns_adv_nocmp_mozilla_47</td>
<td>Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.</td>
</tr>
<tr>
<td>ns_cmp_mscss, ns_adv_cmp_mscss</td>
<td>Compresses CSS files when the request is sent from a Microsoft Internet Explorer browser.</td>
</tr>
<tr>
<td>ns_cmp_msapp, ns_adv_cmp_msapp</td>
<td>Compresses files that are generated by the following applications: Microsoft Office Word, Microsoft Office Excel, Microsoft Office PowerPoint.</td>
</tr>
<tr>
<td>ns_cmp_content_type, ns_adv_cmp_content_type</td>
<td>Compresses data when the response contains Content-Type header and contains text.</td>
</tr>
<tr>
<td>ns_nocmp_xml_ie, ns_adv_nocmp_xml_ie</td>
<td>Prevents compression when a request is sent, from a Microsoft Internet Explorer browser and the response contains a Content-Type header and contains text or xml.</td>
</tr>
</tbody>
</table>

**Binding a compression policy**

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to
requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

To bind a Compression Policy by using the CLI

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- `bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED|DISABLED)]`
- `bind lb vserver <vserverName> -policyName <policyName> -priority <positive_integer>`.

Repeat this command for each virtual server to which you want to bind the compression policy.

To bind a compression policy by using the GUI

Do one of the following:

At global level Navigate to Optimization > HTTP Compression > Policies, click Policy Manager and bind the required policies by specifying the relevant Bind Point and Connection Type (Request/Response).

At virtual server level

For load balancing virtual server, Navigate to Traffic Management > Load Balancing > Virtual Servers, select the required virtual server, click Policies, and bind the relevant policy.

For content switching virtual server, Navigate to Traffic Management > Content Switching > Virtual Servers, select the required virtual server, click Policies, and bind the relevant policy.

Set the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able to provide more effective compression by customizing these settings.

**Note**

After you configure the global compression parameters, you do not have to reboot your appliance. They get applied to the new flows immediately.

The following table describes the compression parameters that you can set on the Citrix ADC.
### Compression Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quantum size</td>
<td>Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the Citrix ADC compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344.</td>
</tr>
<tr>
<td>Compression level</td>
<td>Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.</td>
</tr>
<tr>
<td>Minimum HTTP response size</td>
<td>Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.</td>
</tr>
<tr>
<td>Bypass compression on CPU usage</td>
<td>Citrix ADC CPU usage, as a percentage, at or above which no compression is done. Default: 100.</td>
</tr>
<tr>
<td>Policy Type*</td>
<td>Type of policies used for compression. Possible values: Classic, Default Syntax. Default: Classic.</td>
</tr>
<tr>
<td>Allow Server-side compression</td>
<td>Allow servers to send compressed data to the Citrix ADC.</td>
</tr>
<tr>
<td>Compress push packet</td>
<td>Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.</td>
</tr>
<tr>
<td>External Cache</td>
<td>Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.</td>
</tr>
</tbody>
</table>

To configure HTTP compression by using the GUI

Do one of the following:

- To enable compression globally, navigate to System > Settings, click Configure Basic Features,
and select **HTTP Compression**.

- To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click **Edit**.
- In the **Settings** group, click the pencil icon and enable **Compression**.

To create a compression action by using the GUI

Navigate to **Optimization > HTTP Compression > Actions**, click **Add**, and create a compression action to specify the type of compression to be performed on the HTTP response.

To create a compression policy by using the GUI

Navigate to **Optimization > HTTP Compression > Policies**, click **Add**, and create a compression policy by specifying the condition and the corresponding action to be executed.

**Evaluate compression configuration**

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of hits that the policy counter increments during the policy based compression.

**Note**

- For more information about the statistics and charts, see the Dashboard help on the Citrix ADC appliance.
- For more information about SNMP, see **SNMP** topic.

To view compression statistics by using the CLI

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary.

   ```
   stat cmp
   ```

   **Note**

   The `stat cmp` command displays statistics for default syntax compression policies only.

2. To display compression policy hits and details

   ```
   show cmp policy <name>
   ```

3. To display detailed compression statistics

   ```
   stat cmp -detail
   ```

To view compression statistics by using the dashboard:

In the Dashboard utility, you can display the following types of compression statistics:
• Select Compression to display a summary of the compression statistics.
• To display detailed compression statistics by protocol type, click the Details tab.
• To display the rate of requests processed by the compression feature, click the Graphical View tab.

To view compression statistics by using SNMP

You can view the following compression statistics by using the SNMP network management application.

• Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
• Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
• Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
• Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
• Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
• Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
• Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

To view additional compression statistics by using the GUI

1. To display HTTP compression statistics:
   Navigate to Optimization > HTTP Compression and click Statistics.
2. To display statistics of a compression policy.
   Navigate to Optimization > HTTP Compression > Policies > select the policy, and click Statistics.
3. To display statistics of a compression policy label
4. Navigate to Optimization > HTTP Compression > Policies > select a policy label, and click Statistics.

**Offloading HTTP compression**

Performing compression on a server can affect the server’s performance. A Citrix ADC placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

Disable compression on the web servers, enable the Citrix ADC Compression feature at a global level, and configure services for compression.

Leave the compression feature enabled on the web servers and configure the Citrix ADC appliance to remove the “Accept Encoding” header from all HTTP client requests. The servers then send uncompressed responses. The Citrix ADC compresses the server responses before sending them to the clients.
The second option does not work if the servers automatically compress all responses. The Citrix ADC does not attempt to compress a response that is already compressed.

The Servercmp parameter enables the Citrix ADC appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the Citrix ADC appliance. To offload HTTP compression, you need to set the servercmp parameter to OFF. At the command prompt, enter the following commands:

```
set service <service name> -CMP YES
```

Repeat this command for each service for which you want to enable compression.

```
show service <service name>
```

Repeat this command for each service, to verify that compression is enabled.

```
Save config
```

```
set cmp parameter -serverCmp OFF
```

**Note:**

When Servercmp parameter is turned on and if the appliance receives compressed response from the server, the appliance does not further compress the data. Instead, it forwards the compressed response to the client.

**Integrated caching**

January 25, 2019

Contributed by: C

The integrated cache provides in-memory storage on the Citrix ADC appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of Citrix ADC appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple Web pages and image files. You can also configure the integrated cache to store and serve dynamic content that is usually marked as non-cacheable by Web and application servers (for example, database records and stock quotes).
**Note:** The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created, the Citrix ADC appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the Default content group, but you can create your own content groups for different types of content.

To enable the Citrix ADC appliance to find cached objects in a content group, you can configure selectors, which match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors (which Citrix recommends), configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server, or to a label that can be called from other policy banks.

You can tune the performance of the integrated cache, using methods such as pre-loading cached objects before they are scheduled to expire. To manage the handling of cached data once it leaves the Citrix ADC appliance, you can configure caching-related headers that are inserted into responses. The integrated cache can also act as a forward proxy for other cache servers.

**Note:** Integrated caching requires some familiarity with HTTP requests and responses. For information about the structure of HTTP data, see Live HTTP Headers at "<http://livehttpheaders.mozdev.org/>."

### How integration cache works

The integrated cache monitors HTTP and SQL requests that flow through the Citrix ADC appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, the integrated cache feature can also serve partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data can be compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a cache hit, and data served from the origin is a cache miss, as described in the following table.
### Transaction Type Specification

<table>
<thead>
<tr>
<th>Transaction Type</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache Hit</td>
<td>Responses that the Citrix ADC appliance serves from the cache, including: Static objects, for example, image files and static Web pages, 200 OK pages, 203 Non-Authoritative Response pages, 300 Multiple Choices pages, 301 Moved Permanently pages, 302 Found pages, 304 Not Modified pages. These responses are known as positive responses. The Citrix ADC appliance also caches the following negative responses: 307 Temporary Redirect pages, 403 Forbidden pages, 404 Not Found pages, 410 Gone pages. To further improve performance, you can configure the Citrix ADC appliance to cache additional types of content.</td>
</tr>
<tr>
<td>Storable Cache Miss</td>
<td>For a storable cache miss, the Citrix ADC appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.</td>
</tr>
<tr>
<td>Non-Storable Cache Miss</td>
<td>A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss: 201, 202, 204, 205, 206 status codes, All 4xx codes, except 403, 404 and 410, 5xx status codes.</td>
</tr>
</tbody>
</table>

**Note**

To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.

To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the Citrix ADC appliance receives a request that matches an expired response, it refreshes the response from the origin server.

**Note**

Citrix recommends that you synchronize the times on the Citrix ADC appliance and the back-end server(s).
How dynamic cache works

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
1 GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
2 Host: mycompany.net
3 User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
   Gecko/2008052906 Firefox/3.0
4 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
5 Accept-Language: en-us,en;q=0.5
6 . . .
```

In this example, GET requests for this bug reporting application always contain the following parameters:
- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:
- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a hit selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

**Note:** that a browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
1 GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
2 GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbtns&RecordId=31231&TableId=1000
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To fulfill these requests, multiple responses are sent to the user’s browser, and the Web page that the
user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache should be refreshed with
data from the origin server. The bug reporting application issues HTTP POST requests when a user
updates a bug report. In this example, you configure the following to ensure that POST requests trig-
ger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST
  HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based
  on the RecordID parameter. This parameter appears in all of the responses, so the invalidation
  selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```plaintext
POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\r\nUser-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0 Opera 7.23 [en]\r\nHost: mybugreportingsystem\r\nCookie: ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23
       unowned%3Afalse%23submitter%3Afalse%23incsub%3Atrue;
Cookie2: $Version=1\r\n...\r\n\r\nProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=Update&
CopyProjectId=0&ReloadForm=0&State=&RecordLockId=49873+issues+in+
HTTP&F43. ...
```

When the Citrix ADC appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the Citrix ADC appliance goes to the origin server for updated copies of all the responses that are associated with the report instance, stores the responses in the content group, and serves them to the user’s browser, which reassembles the report and displays it.

**Configure integrated cache**

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix® Citrix ADC® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of Citrix ADC appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see “Displaying Cached Objects and Cache Statistics.”

**Note**
The Citrix ADC cache is an in-memory store that is purged when you restart the appliance.

To install integrated cache license

An integrated cache license is required. For information about licenses, see information about obtaining licenses topic.

Obtain a license code from Citrix, go to the command line interface, and log in.

At the command line interface, copy the license file to the /nsconfig/license folder.

Reboot the Citrix ADC appliance by using the following command:

reboot

**To enable integrated caching:**

When you enable integrated caching, the Citrix ADC appliance begins caching server responses. If you have not configured any policies or content groups, the built in policies store cached objects in the Default content group.

At the command prompt, type one of the following commands to enable or disable integrated caching:

‘enable ns feature IC’

To configure global attributes for caching
Global attributes apply to all cached data. You can specify the amount of Citrix ADC memory allocated to the integrated cache, Via header insertion, a criterion for verifying that a cached object should be served, the maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (the central distribution hub of all incoming TCP requests) in the nCore Citrix ADC appliance is aware of objects cached by other packet engines in the nCore Citrix ADC appliance.

**Note:**

When the default global memory limit is set as 0 and the Integrated Caching (IC) feature is enabled, the appliance does not cache any objects. For caching, you must explicitly configure the global memory limit. However, if you enable “set aaa parameter enableStaticPageCaching” option, there will be some default memory configured in the appliance. This memory is insufficient for caching large Objects and so it is necessary to assign a higher memory limit for IC. You can perform this by configuring the “set cache parameter –memLimit” command. The new setting is applied only after you save the configuration and reboot the appliance.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), if a higher amount of memory (greater than 4 GB) is already being used to cache objects, the Citrix ADC continues using that amount of memory.

This means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (memory Usage limit) and the actual value being used (memory usage limit (active value)).

At the command prompt, type:

```
```

**To enable integrated caching by using the GUI:**

Navigate to **System > Settings**, click **Configure Basic Features**, and select **Integrated Caching**.

**To configure global settings for caching by using the GUI:**

Navigate to **Optimization > Integrated Caching**, click **Change Cache Settings**, and configure the global settings for caching.

**To set up built-in content group, pattern set, and policies for Integrated Cache:**
The Citrix ADC appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called ctx_cg_poc, a pattern set called ctx_file_extensions, and a set of integrated cache policies. In the content group ctx_cg_poc, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common file extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind them to a bind point if you want the Citrix ADC appliance to evaluate traffic against the policies. The policies cache objects in the ctx_cg_poc content group.

<table>
<thead>
<tr>
<th>Integrated caching policy name</th>
<th>Policy rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>_cacheVPNStaticObjects</td>
<td>HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_INDEX(ctx_file_extensions).BETWEEN(101,150)</td>
</tr>
<tr>
<td>_cacheTCPVPNStaticObjects</td>
<td>HTTP.REQ.URL.ENDSWITH(&quot;.css&quot;)</td>
</tr>
<tr>
<td>_cacheOCVPNStaticObjects</td>
<td>HTTP.REQ.URL.ENDSWITH(&quot;.pdf&quot;)</td>
</tr>
<tr>
<td>_cacheWFStaticObjects</td>
<td>HTTP.REQ.URL.ENDSWITH(&quot;.js&quot;)</td>
</tr>
<tr>
<td>_mayNoCacheReq</td>

## Configure selectors and basic content groups

March 22, 2019

Contributed by: C

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache hits or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use hit parameters and invalidation parameters. However, Citrix recommends that you configure selectors.
After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in “Improving Cache Performance” and “Configuring Cookies, Headers, and Polling”, but you might first want to configure caching policies.

Note
Content group parameters and selectors are used only at request time, and you typically associate them with policies that use MAY_CACHE or MAY_NOCACHE actions.

Advantages of selectors

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix ADC appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for host1.domain.com\mypage.htm, host2.domain.com\mypage.htm, and host3.domain.com\mypage.htm. In contrast, a selector can match just the URL (mypage.html, using the expression http.req.url) and the domain (.com, using the expression http.req.hostname.domain), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see “Policies and Expressions.”

Use parameters Instead of selectors

Although Citrix recommends the use of selectors with a content group, you can instead configure hit parameters and invalidation parameters. For example, suppose that you configure three hit parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the Citrix ADC appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is an invalidation parameter and a user issues a POST request to update a bug report. An invalidation
policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the Citrix ADC appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a hit parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

**Configure a selector**

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an advanced expression.

For more information about advanced expressions, see “Policies and Expressions.”

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the CLI

At the command prompt, type:

```bash
add cache selector <selectorName> (<rule> …)
```

For information about configuring the expression or expressions, see “To configure a selector expression by using the command line interface.”

```
> add cache selector product_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
```
To configure a selector by using the GUI

Navigate to Optimization > Integrated Caching > Cache Selectors, and add the cache selector.

**Content groups**

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create new content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups.** Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.

- **Dynamic content groups.** Looks for objects that contains particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

Serve a hit from a content group

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the Citrix ADC appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, usually based on criteria that you configure in a selector.

For example, the content group can retrieve responses that match NameField=username and BugID=ID.

1. If it finds matching objects, the Citrix ADC appliance can serve them to the user’s browser, where they are assembled into a complete response (for example, a bug report).

Invalidate an object in a content group

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The Citrix ADC appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the Citrix ADC appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

For example, an invalidation selector can find responses that match NameField=username and BugID=ID.

1. The next time the Citrix ADC appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user’s browser, where they are assembled into a complete bug report.

Set up a basic content group

By default, all cached data is stored in the default content group. You can configure additional content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

To set up a basic content group by using the command line interface

At the command prompt, type:

```plaintext
add cache contentgroup <name> (-hitSelector <hitSelectorName> -invalSelector <invalidationSelectorName> | -hitParams <hitParamName> -invalParams <invalidationParamName>)-type <type> [-relExpiry <sec> | -relExpiryMilliSec <msec>][-heurExpiryParam <positiveInteger>]
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To set up a basic content group by using the GUI

Navigate to Optimization > Integrated Caching > Content Groups, and create the content group.

**Expire or flush cached objects**

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see “Configuring Policies for Caching and Invalidation.”
- Expire the content group or objects within it manually.

After a cached response expires, the Citrix ADC appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the Citrix ADC appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual.** Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based.** Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry.** For responses that have a Last-Modified header, heuristic expiry is a percentage of the time since the response was modified (calculated as current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses need to be expired more often.
- **Absolute or relative.** Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time or GMT. Local time may not work in all time zones.

Relative expiration specifies a number of seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.
Absolute and relative expiration override any expiration information in the response itself.

- **On download.** The option Expire After Complete Response Received expires a response as soon as it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.

Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the Citrix ADC appliance fetches only one response for a block of simultaneous requests.

- **Pinned.** By default, when the cache is full the Citrix ADC appliance replaces the least recently used response first. The Citrix ADC appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are additional options for expiring objects in the group:

- Configure a policy with an INVAL action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVAL action.

**How expiration methods are applied**

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the Citrix ADC appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration cause the Citrix ADC appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and “Weak Positive” and “Weak Negative” expiration (labeled as **Default** values in the configuration utility) cause the Citrix ADC appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the Citrix ADC appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, Citrix ADC appliance uses the “weak positive” value.
  - For negative responses that lack an Expires or Cache-Control header, Citrix ADC appliance uses the “weak negative” value.
The following table describes how these methods are applied.

<table>
<thead>
<tr>
<th>Response Type</th>
<th>Expiration Header Type</th>
<th>Content Group Setting</th>
<th>Period the Object Remains in the Cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>Any header</td>
<td>Expire Content After (relExpiry) with no other settings</td>
<td>Use the value of the Expire Content After setting.</td>
</tr>
<tr>
<td>Positive</td>
<td>Last-Modified (with any other headers)</td>
<td>Heuristic (heurExpiry Param) with any other setting</td>
<td>Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.</td>
</tr>
<tr>
<td>Positive</td>
<td>Expires or Cache-Control: Max-Age header is present</td>
<td>Last-Modified header is absent</td>
<td>Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both</td>
</tr>
</tbody>
</table>
Subtract the current date from the Expires or the Cache-Control:Max-Age date.

Positive

no caching headers

Default (positive) (weakPosRel Expiry) and any other expiration setting

Use the value of the Default (positive) setting.

Positive

no caching headers

Heuristic (heurExpiry Param) is present

Default (positive) (weakPosRel Expiry) setting is absent

If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status.

If the Last-Modified header is present, use the heuristic expiry value.

Negative

Expires or Cache-Control:Max-Age

Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings

Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.

Negative

Expires or Cache-Control headers are absent

Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings

Response is not cached, or is cached with an Already Expired status.

Negative

Expires or Cache-Control:Max-Age

Any setting

Subtract the current date from the Expires or Cache-Control:Max-Age date.

Negative

Expires and Cache-Control:Max-Age headers are absent

Default (negative) (weakNegRel Expiry)

Use the value of the Default (negative) setting.

Negative
Expires and Cache-Control:Max-Age headers are absent

Any setting other than Default (negative) (weakNegRel Expiry)

Object is not cached or is cached with an Already Expired status.

**Expire a content group by manual method**

You can manually expire all of the entries in a content group.

To manually expire all responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache contentGroup <name>
```

To manually expire all responses in a content group by using the GUI

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and click Invalidate to expire all the responses in a content group.

To manually expire all responses in the cache by using the GUI

Navigate to Optimization > Integrated Caching > Content Groups, and click Invalidate All to expire all the responses in cache.

**Configure periodic expiration of a content group**

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

To configure content group expiration by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> (-relExpiry|-relExpiryMilliSec|-absExpiry|-absExpiryGMT| -heurExpiryParam|-
weakPosRelExpiry|-weakNegRelExpiry| -expireAtLastBye) <expirationValue>
```

To configure content group expiration by using the GUI

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and specify expiry method.

**Expire individual responses**

Expiring a response forces the Citrix ADC appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, ETag or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.
To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name as well as the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:
```
expire cache object -url <URL> -host <hostName> [-port <port>] [-groupName<contentGroupName>] [-httpMethod GET|POST]
```

To expire individual responses in a content group by using the CLI

At the command prompt, type the following command:
```
expire cache object -locator <positiveInteger>
```

To expire a cached response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, select the cached response, and expire.

To expire a response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, click **Search** and, set the search criteria to find the required cached response and expire.

**Flush responses in a content group**

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing a cached response frees up memory for new cached responses.

Note: To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:
```
flush cache contentGroup <name> [-query <queryString> | [-selectorValue <selectorExpressionIDList> -host <hostName>]]
```

To flush responses from a content group by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**.
2. In details pane, flush the responses as follows:
   - To flush all responses in all content groups, click **Invalidate All**, and flush all the responses.
   - To flush responses in a particular content group, select the content group, click **Invalidate**, and flush all the responses.
Note:
If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click **Flush and OK**. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the Query field.

If the content group uses an invalidation parameter and Invalidate objects belonging to target host is configured, enter strings in the Query and Host fields.

To flush a cached response by using the command line interface

At the command prompt, type:
```
flush cache object -locator <positiveInteger> | -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET|POST]
```

To flush a cached response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, select the cached object, and flush.

**Deleting a content group**

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltajs group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:
```
rm cache contentgroup <name>
```

To delete a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and delete.
Configure policies for caching and invalidation

January 30, 2019
Contributed by:
C

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The NetScaler appliance provides built-in policies for integrated caching, and you can configure additional policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache’s Policies node in the configuration utility. The built-in policy names begin with an underscore (_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions.** Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions.** Policies that you associate with the INVAL action immediately expire cached responses and refresh them from the origin server. Note that for Web-based applications, invalidation policies often evaluate POST requests.
- **“Do not cache” actions.** Policies that you associate with a NOCACHE action never store objects in the cache.
- **Provisionally cache actions.** Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of additional policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a LOCK request. For invalidation policies only, you can specify LOCK as a method by using the expression http.req.method.eq("lock"). Unlike policies for GET and POST requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you should understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks.
In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

**Actions to associate with integrated caching policies**

The following table describes actions for integrated caching policies.

<table>
<thead>
<tr>
<th>Action</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>CACHE</td>
<td>Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.</td>
</tr>
<tr>
<td>NOCACHE</td>
<td>Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.</td>
</tr>
</tbody>
</table>
## MAY_CACHE

Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible:

1. If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy.
2. If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy.
3. If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied.
4. If a matching response-time policy has a NOCACHE action, perform a NOCACHE action.
5. If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.
### MAY_NOCACHE

For a request-time policy, this setting provisionally prevents caching the response. At response time, one of following actions is taken:  
- If no response-time policy matches the request, the final action is NOCACHE.  
- If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy.  
- If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE.  
- If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.

### INVAL

Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. Note: You can specify INVAL actions in request-time policies only.

## Bind points for a policy

You can bind the policy to one of the following bind points:

- **A global policy bank.** These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in “Order of Policy Evaluation.”
- **A virtual server.** Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in “Order of Policy Evaluation.” Note that when binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label.** A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:  
  - _reqBuiltinDefaults. This policy label, by default, is invoked from the request-time default policy bank.
Citrix ADC 12.1

- _resBuiltinDefaults. This policy label, by default, is invoked from the response-time default policy bank.

You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points.

**Important:**
You should bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

**Order of policy evaluation**

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance’s processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override.** If a request matches a request-time override policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.

- **Request-time load balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.

- **Request-time content switching virtual server.** Policies that are bound to this bind point are evaluated after request-time policies that are bound to load balancing virtual servers.

- **Request-time default.** If policy evaluation cannot be completed after all request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes request-time default policies. If the request matches a request-time default policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.

- **Response-time override.** Similar to request-time override policy evaluation.

- **Response-time load balancing virtual server.** Similar to request-time virtual server policy evaluation.

- **Response-time content switching virtual server.** Similar to request-time virtual server policy evaluation.

- **Response-time default.** Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.
After all integrated caching policies have been evaluated, if there are conflicting actions specified in request-time and response-time policies.”

**Note:**
Request-time policies for POST data or cookie headers must be invoked during request-time over-ride evaluation, because the built-in request-time policies in the integrated cache return a NO-CACHE action for POST requests and a MAY_NOCACHE action for requests with cookies. Note that you would associate MAY_CACHE or MAY_NOCACHE actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

**Configure a policy in the integrated cache**

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- **Rule:** A logical expression that evaluates an HTTP request or response.
- **Action:** You associate a policy with an action to determine what to do with a request or response that matches the policy rule.

**Content groups:** You associate the policy with one or more content groups to identify where the action is to be performed.

To configure a policy for caching by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action CACHE|MAY_CACHE|MAY_NOCACHE[-storeInGroup <contentGroupName>][-undefAction NOCACHE|RESET]
```

```
> add cache policy image_cache -rule "http.req.url.contains("jpg")||http.req.url.contains("jpeg")"-action CACHE -storeInGroup myImages_group-undefaction NOCACHE
```

```
```

```
> add cache policy my_form_policy -rule "http.req.header(\"Host\")contains(\"my.company.com\")&&http.req.method.eq(\"GET\")&&http.req.url.query.contains(\"v=7\")"-action CACHE -storeInGroup my_form_event
```

```
> add cache policy viewproducts_policy -rule "http.req.url.contains("viewproducts.aspx")"-action CACHE -storeInGroup Product_Details
```

To configure a policy for invalidation by using the command line interface

```
At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -action INVAL [-invalObjects "<contentGroupName1>,<selectorName1>"[..]] | [-invalGroup <contentGroupName1>[..]] [-undefAction NOCACHE|RESET]
```

- `add cache policy invalidation_events_policy -rule "http.req.header("Host")contains("my.company.com")&& http.req.method.eq("GET")&& http.req.url.query.contains("v=8")"-action INVAL -invalObjects my_form_event -undefaction NOCACHE`
- `add cache policy inval_all -rule "http.req.method.eq("POST")&& http.req.url.contains("jpeg")"-action INVAL -invalGroups myImages_group myApps_group PDF_group`
- `add cache policy bugReportInvalidationPolicy -rule "http.req.url.query.contains("TransitionForm")"-action INVAL -invalObjects bugReport`
- `add cache policy editproducts_policy -rule "http.req.url.contains("editproducts.aspx")"-action INVAL -invalObjects "Product_Details,batchnum_sel" "Products_In_Depots,batchid_sel"
```

To configure a policy for caching or invalidation by using the GUI

Navigate to **Optimization > Integrated Caching > Policies**, and create the new policy.

**Globally binding an integrated caching policy**

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

To bind an integrated caching policy globally by using the command line interface

At the command prompt, type:

```
bind cache global <policy> -priority <positiveInteger> [-typeREQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] [-gotoPriorityExpression <expression>] [-invoke <labelType> <labelName>]
```

- `bind cache global myCachePolicy -priority 100 -type req_default`

**Note**

The type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and
response time parameters, it is bound to RES_DEFAULT. Following is an example of a binding that omits the type.

Following is an example of a binding that omits the type.

```plaintext
> bind cache global myCache Policy 200
```

To bind an integrated caching policy globally by using the configuration utility

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager** and bind policies by specifying the relevant bind point and connection type (Request/Response).

### Bind an integrated caching policy to a virtual server

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the configuration utility, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all NetScaler modules that are bound to this virtual server. You can also use the Policy Manager configuration dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

To bind an integrated caching policy to a virtual server by using the command line interface

At the command prompt, type:

```plaintext
> bind lb vserver <name>@ -policyName <policyName> -priority <positiveInteger>
> -type(REQUEST|RESPONSE)
> bind cs vserver <name>@ -policyName <policyName> -priority <positiveInteger>
> -type(REQUEST|RESPONSE)
```

To bind an integrated caching policy to a virtual server by using the configuration utility (virtual server method)

- CS Virtual Server - Navigate to Traffic Management > Content Switching > Virtual Servers, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate to Traffic Management > Load Balancing > Virtual Servers, select the virtual server, and bind relevant cache policies.

To bind an integrated caching policy to a virtual server by using the configuration utility (Policy Manager method)

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager**, and bind cache policies by specifying the relevant bind point and connection type.

**Note**

You can bind cache policies to both LB virtual server and CS virtual server by selecting the appro-
How to cache compressed and uncompressed versions of a file

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an Accept-Encoding:compression format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a cached .gzip file cannot be served in response to a request with an Accept-Encoding:deflate header. A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.req.header("Host")"
add cache contentGroup uncompressed_group -hitSelector uncompressed_response_selector
 -invalSelector uncomp_resp_sel
add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS("xyz")&&
 !HTTP.REQ.HEADER("Accept-Encoding").EXISTS"-action CACHE -storeInGroup uncompressed_group
bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression
END -type REQ_OVERRIDE

add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.REQ.
 HEADER("Host")""HTTP.REQ.HEADER("Accept-Encoding")"
add cache contentGroup compressed_group -hitSelector compressed_response_selector
add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS("xyz")&&
 HTTP.REQ.HEADER("Accept-Encoding").EXISTS"-action CACHE -storeInGroup compressed_group
bind cache global cache_compressed -priority 200 -gotoPriorityExpression
END -type REQ_OVERRIDE
```
Configure a policy bank for caching

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation order in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling order of policy evaluation by binding the policy and assigning a priority level, as described in “Binding Policies”, you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed.

The following table summarizes the entries to control evaluation in a policy bank.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.</td>
</tr>
<tr>
<td>Priority</td>
<td>An integer. The lower the integer, the higher the priority.</td>
</tr>
</tbody>
</table>
Attribute | Specifies
--- | ---
**Goto Expression** | Determines the next policy or policy bank to evaluate. You can provide one of the following values: 1. NEXT: Go to the policy with the next higher priority. 2. END: Stop evaluation. 3. USE_INVOCATION_RESULT: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. 4. Positive number: Priority number of the next policy to be evaluated. 5. Numeric expression: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.

**Invocation Type** | Designates a policy bank type. The value can be one of the following - 1. Request Vserver: Invokes request-time policies that are associated with a virtual server. 2. Response Vserver: Invokes response-time policies that are associated with a virtual server. 3. Policy label: Invokes another policy bank, as identified by the policy label for the bank.

**Invocation Name** | Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure additional policy labels:

- `_reqBuiltInDefaults`: This policy label is invoked from the request-time default bind point.
- `_resBuiltInDefaults`: This policy label is invoked from the response-time default bind point.

To invoke a policy label in a caching policy bank by using the command line interface

At the command prompt, type:

```
bind cache policylabel <labelName> -policyname<policyName> -priority<priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke <labelType>]
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
labelName>]

To invoke a policy label in a caching policy bank by using the GUI

1. Navigate to **Optimization > Integrated Caching**, click **Cache policy manager**, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.

2. If you want to invoke a policy label without evaluating a policy, click **NOPOLICY**.

**Note:**

To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

To invoke a caching policy label in a virtual server policy bank by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> @ -policyName <policyName>|<NOPOLICY-CACHE> -priority<positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke<labelType> <labelName>
bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -priority<positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke<labelType> <labelName>
```

To invoke a caching policy label in a virtual server policy bank by using the GUI

1. Navigate to **Traffic Management > Load Balancing/Content Switching > Virtual Servers**, select the virtual server, and click **Policies**.

2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy” NOPOLICY entry, click **Add** and do one of the following:
   - To configure a new policy, click **Cache** and configure the new policy as described in “Configuring a Policy in the Integrated Cache.”
   - To invoke a policy bank without processing a policy a rule, select the NOPOLICY-CACHE option.

**Note**

To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.
Configure a policy label in an integrated cache

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the Integrated Caching details pane (request override, request default, response override, or response default) or the built-in policy labels_resBuiltinDefaults. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The configuration utility provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

**Note:**

You can use the NOPOLICY “dummy” policy to invoke any policy label from another policy bank. The NOPOLICY entry is a placeholder that does not process a rule.

To configure a policy label for caching by using the command line interface

At the command prompt, type the following command to create a policy label and verify the configuration:

```
• add cache policylabel <labelName> -evaluates (REQ|RES)
• show cache policylabel <labelName>
```

Invoke this policy label from a policy bank.

To configure a policy label for caching by using the GUI

Navigate to Optimization > Integrated Caching > Policy Labels, add a policy label, and bind the cached policies.

**Note:**

To ensure that the NetScaler processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points.

To rename a policy label by using the GUI

Navigate to Optimization > Integrated Caching > Policy Labels select the policy label, and rename.

Unbind and delete an integrated caching policy and policy label

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).
To unbind a global caching policy by using the command line interface
At the command prompt, type:

```
unbind cache global <policy>
```

To unbind a virtual server-specific caching policy by using the command line interface
At the command prompt, type:

```
(unbind lb vserver|unbind cs vserver)<vservername> -policyName <policyName> -type(REQUEST|RESPONSE)
```

To delete a caching policy by using the command line interface
At the command prompt, type:

```
rm cache policy <policyName>
```

To unbind a caching policy by using the configuration utility

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

To delete a policy label invocation by using the configuration utility

1. Navigate to Optimization > Integrated Caching, click Cache policy manager, and specify the relevant bind point (LB virtual server or CS virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

**Cache support for database protocols**

January 25, 2019

Contributed by:

C

The integrated cache monitors database requests that flow through the Citrix® ADC appliance and caches them as determined by the cache policies. Users have to configure the cache polices for MYSQL and MSSQL protocols, because the appliance does not provide any default policies for these protocols. When configuring the protocols, remember that request based policies currently support CACHE and
INVAL actions, while response based policies currently support only NOCACHE action. After configuring the policies, bind them to virtual servers. MYSQL and MSSQL policies, both request and response, can be bound only to virtual servers.

Before creating a cache policy, create a cache content group of type MYSQL or MSSQL. When you create a MYSQL or MSSQL cache content group, associate at least one hit selector with it. See “Setting Up a Basic Content Group” for setting up cache content groups.

The following example illustrates the procedure for configuring and verifying cache support for SQL protocols.

```
1> enable feature IC
2> set cache parameter -memlimit 100
3> add cache selector sel1 mssql.req.query.text
4> add cache contentgroup cg1 -type "MSSQL" -hitselector "sel1" -invalselector "inval_sel" -relExpiry "500" -maxResSize "100"
5> add cache policy cp1 -rule "mssql.req.query.command.contains("select")" -action "CACHE" -storeInGroup "cg1"
6> add cache policy cp2 -invalObjects "cg1" -rule "mssql.req.query.text.contains("insert")" -action "INVAL"
7> add db user user1 -password "Pass1"
8> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -downstateflush "ENABLED"
9> add lb vserver lb_mssql1 mssql 10.102.147.77 1433 -lbmethod "roundrobin"
10> bind lb vserver lb_mssql1 svc_sql_1
11> bind lb vserver lb_mssql1 -policyName cp1 -type "REQUEST" -priority "2"
12> bind lb vserver lb_mssql1 -policyName cp2 -type "REQUEST" -priority "1"

13> show cache selector sel1
   Name: sel1
   Expressions:
   1)mssql.req.query.text

14> show cache policy cp1
   Name: cp1
   Rule: mssql.req.query.command.contains("select")
   CacheAction: CACHE
   Stored in group: cg1
   UndefAction: Use Global
   Hits: 2
```
Configure expressions for caching policies and selectors

January 25, 2019

Contributed by:
C

A request-time expression examines data in request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix ADC appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers http://livehttpheaders.mozdev.org/)or HTTPFox https://addons.mozilla.org/en-US/firefox/addon/6647 can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
1  GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi &selected=CTXS&random=0.00792039478975548 HTTP/1.1
2  
3  Host: quotes.mystockquotes.com
```

Note

The methods for reducing flash crowds, as explained in “Reducing Flash Crowds”, are not supported for MYSQL and MSSQL protocols.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
When configuring an expression, note the following limitations:

<table>
<thead>
<tr>
<th>Expression Type</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request</td>
<td>Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.</td>
</tr>
<tr>
<td>Response</td>
<td>Configure response-time expressions in caching policies only. Selectors can use only request-time expressions. Do not configure response-time expressions in a policy with an INVAL action. Note: Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.</td>
</tr>
</tbody>
</table>

**Note**

For a comprehensive discussion of advanced expressions, see “Policies and Expression.”

**Expression syntax**

Following are basic components of the syntax:

- Separate keywords with periods (.), as follows:

  ```text
  http.req.url
  ```

- Enclose string values in parentheses and quotes, as follows:

  ```text
  http.req.url.query.contains("this")
  ```
When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit values in the expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:

\"abc\"

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

**Configure an expression in a caching policy or a selector**

**Note**
The syntax for a policy expression is somewhat different from a selector expression. For a comprehensive discussion of advanced expressions, see “Policies and Expressions.”

To configure a policy expression by using the command line interface

1. Start the policy definition as described in “Globally Binding an Integrated Caching Policy.”
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains("jpg")"
```

To add Boolean values, insert `&&`, `, or ! operators.

1. The following are examples:

```
"http.req.url.contains("jpg")|| http.req.url.contains("jpeg")"
"http.req.url.query.contains("IssuePage")"
"http.req.header("Host")contains("my.company.com")&& http.req.method.eq("GET")&& http.req.url.query.contains("v=7")"
```

1. To configure an order of evaluation for the constituent parts of a compound

```
"http.req.url.contains("jpg")|| (http.req.url.contains("jpeg")& http.req.method.eq("GET"))"
```

To configure a selector expression by using the command line interface

1. Start the selector definition as described in “About Content Groups.”

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3255
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

"http.req.url.contains("jpg")"

You cannot add Boolean values, insert &&, , or ! operators. Enter each expression element delimited in quotes. Multiple expressions in the definition are treated as a compound expression joined by logical ANDs.

1. The following are examples:

To configure a policy or selector expression by using the GUI

1. Start the policy or selector definition as described in “To configure a policy for caching or invalidation by using the configuration utility” or “To configure a selector by using the configuration utility.”

2. In the Expression field, you can either manually type the default syntax by clicking Switch to Classic Syntax or create new expression using Expression Editor.

To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars, |

3.

4. Click Frequently Used Expressions drop-down to insert the commonly used expressions.
5. To test the expression, click the **Evaluate**. In the **Expression Evaluator** dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click **Evaluate**.

**Display cached objects and cache statistics**

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

**View cached objects**

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response size (bytes)</td>
<td>The size of the response header and body.</td>
</tr>
<tr>
<td>Response header size (bytes)</td>
<td>The size of the header portion of the response.</td>
</tr>
<tr>
<td>Response status code</td>
<td>The status code sent with the response.</td>
</tr>
<tr>
<td>Properties</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ETag</td>
<td>The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.</td>
</tr>
<tr>
<td>Last-Modified</td>
<td>The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.</td>
</tr>
<tr>
<td>Cache-Control</td>
<td>The Cache-Control header inserted in the response.</td>
</tr>
<tr>
<td>Date</td>
<td>The Date header that indicates when the response was sent.</td>
</tr>
<tr>
<td>Contentgroup</td>
<td>The content group where the response is stored.</td>
</tr>
<tr>
<td>Complex match</td>
<td>If this object was cached on the basis of parameterized values, this field value is YES.</td>
</tr>
<tr>
<td>Host</td>
<td>The host specified in the URL that requested this response.</td>
</tr>
<tr>
<td>Host port</td>
<td>The listen port for the host specified in the URL that requested this response.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL issued for the stored response.</td>
</tr>
<tr>
<td>Destination IP</td>
<td>The IP address of the server from which this response was fetched.</td>
</tr>
<tr>
<td>Destination port</td>
<td>The listen port for the destination server.</td>
</tr>
<tr>
<td>Hit parameters</td>
<td>If the content group that stores the response uses hit parameters, they are listed in this field.</td>
</tr>
<tr>
<td>Hit selector</td>
<td>If this content group uses a hit selector, it is listed in this field.</td>
</tr>
<tr>
<td>Inval selector</td>
<td>If this content group uses an invalidation selector, it is listed in this field.</td>
</tr>
<tr>
<td>Selector Expressions</td>
<td>If this content group uses a selector, this field displays the expression that defines the selection rule.</td>
</tr>
<tr>
<td>Request time</td>
<td>The time in milliseconds since the request was issued.</td>
</tr>
<tr>
<td>Properties</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Response time</td>
<td>The time in milliseconds since the cache started to receive the response.</td>
</tr>
<tr>
<td>Age</td>
<td>Amount of time the object has been in the cache.</td>
</tr>
<tr>
<td>Expiry</td>
<td>Amount of time after which the object is marked as expired.</td>
</tr>
<tr>
<td>Flushed</td>
<td>Whether the response has been flushed after expiry.</td>
</tr>
<tr>
<td>Prefetch</td>
<td>If Prefetch has been configured for this content group, the amount of time</td>
</tr>
<tr>
<td></td>
<td>before expiry during which the object is fetched from the origin.</td>
</tr>
<tr>
<td></td>
<td>Prefetch does not apply to negative objects (for example, 404 “object not</td>
</tr>
<tr>
<td></td>
<td>found” responses).</td>
</tr>
<tr>
<td>Current readers</td>
<td>Approximately the current number of hits being served. When a response with</td>
</tr>
<tr>
<td></td>
<td>a Content-Length header object is being downloaded, the current misses and</td>
</tr>
<tr>
<td></td>
<td>the current readers values are each typically 1.</td>
</tr>
<tr>
<td></td>
<td>When a chunked response object is being downloaded, the current misses</td>
</tr>
<tr>
<td></td>
<td>value is typically 1, but the current readers value is typically 0,</td>
</tr>
<tr>
<td></td>
<td>because the chunked response that is served to the client does not come</td>
</tr>
<tr>
<td></td>
<td>from the integrated caching buffers.</td>
</tr>
<tr>
<td>Current misses</td>
<td>The current number of requests that resulted in a cache miss and fetching</td>
</tr>
<tr>
<td></td>
<td>from the origin server. This value is typically 0 or 1. If Poll Every Time</td>
</tr>
<tr>
<td></td>
<td>is enabled for a content group, the count can be greater than 1.</td>
</tr>
<tr>
<td>Hits</td>
<td>The number of cache hits for this object.</td>
</tr>
<tr>
<td>Misses</td>
<td>The number of cache misses for this object.</td>
</tr>
<tr>
<td>Compression format</td>
<td>The type of compression applied to this object. Compression formats include</td>
</tr>
<tr>
<td></td>
<td>gzip, deflate, compress, and pack200-gzip.</td>
</tr>
<tr>
<td>Properties</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HTTP version in response</td>
<td>The version of HTTP that was used to send the response.</td>
</tr>
<tr>
<td>Weak etag present in response</td>
<td>Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a “W.”</td>
</tr>
<tr>
<td>Negative marker cell</td>
<td>A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.</td>
</tr>
<tr>
<td>Reason marker created</td>
<td>The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).</td>
</tr>
<tr>
<td>Auto poll every time</td>
<td>If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).</td>
</tr>
<tr>
<td>Citrix ADC Etag inserted in response</td>
<td>A variation of the ETag header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an Etag in the response.</td>
</tr>
<tr>
<td>Full response present in cache</td>
<td>Indicates whether this is a complete response.</td>
</tr>
<tr>
<td>Destination IP verified by DNS</td>
<td>Indicates whether DNS resolution was performed when storing the object.</td>
</tr>
<tr>
<td>Object stored through a cache forward proxy</td>
<td>Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.</td>
</tr>
<tr>
<td>Object is a Delta basefile</td>
<td>A response that is delta-compressed.</td>
</tr>
<tr>
<td>Properties</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Waiting for minhits</td>
<td>Indicates whether this content group requires a minimum number of origin server hits before caching a response.</td>
</tr>
<tr>
<td>Minhit count</td>
<td>If this content group requires a minimum number of origin server hits before caching an object, this field displays a count of the number of hits received so far.</td>
</tr>
<tr>
<td>HTTP Request Method</td>
<td>The method, GET or POST, used in the request that obtained this object.</td>
</tr>
<tr>
<td>Stored by policy</td>
<td>The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.</td>
</tr>
<tr>
<td>Application firewall metadata exists</td>
<td>This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request’s session.</td>
</tr>
<tr>
<td>HTTP callout object, name, type, response</td>
<td>These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see “HTTP Callouts”.</td>
</tr>
</tbody>
</table>

To view cached objects by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**. You can view all the cached objects and sort them accordingly as per your requirement.
Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name, and so on.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select Copy. For more information about selectors, see “Configuring Selectors and Basic Content Groups.”

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST]])| [-httpStatus <positive integer>] | -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF)] -includeNotReadyObjects (ON | OFF)
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects ( ON | OFF )| -includeNotReadyObjects ( ON | OFF)| [-httpStatus<positive integer>]
```

To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the configuration utility:

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the selector search criteria to view the required cached response.
The following table summarizes the detailed cache statistics that you can view.

<table>
<thead>
<tr>
<th>Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Hits</td>
<td>Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action.</td>
</tr>
<tr>
<td>Misses</td>
<td>Intercepted HTTP requests where the response was ultimately fetched from origin server.</td>
</tr>
<tr>
<td>Requests</td>
<td>Total cache hits plus total cache misses.</td>
</tr>
<tr>
<td>Non-304 hits</td>
<td>If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object. This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.</td>
</tr>
<tr>
<td>304 hits</td>
<td>Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.</td>
</tr>
<tr>
<td>304 hit ratio (%)</td>
<td>Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.</td>
</tr>
<tr>
<td>Hit ratio (%)</td>
<td>Percentage of responses that the Citrix ADC appliance served from the cache (cache hits) relative to responses that could not be served from the cache.</td>
</tr>
<tr>
<td>Origin bandwidth saved (%)</td>
<td>An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.</td>
</tr>
<tr>
<td>Bytes served by the Citrix ADC</td>
<td>Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.</td>
</tr>
<tr>
<td>Bytes served by cache</td>
<td>Total number of bytes that the Citrix ADC appliance served from the cache.</td>
</tr>
<tr>
<td>Byte hit ratio (%)</td>
<td>Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.</td>
</tr>
<tr>
<td>Compressed bytes from cache</td>
<td>Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.</td>
</tr>
<tr>
<td>Storable misses</td>
<td>If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.</td>
</tr>
<tr>
<td>Non-storable misses</td>
<td>A non-storable cache miss cannot be stored in the cache.</td>
</tr>
<tr>
<td>Misses</td>
<td>All cache misses.</td>
</tr>
<tr>
<td>Revalidations</td>
<td>Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see “Inserting a Cache-Control Header.”</td>
</tr>
<tr>
<td>Successful revalidations</td>
<td>Number of revalidations that have been performed.</td>
</tr>
</tbody>
</table>
For more information, see “Inserting a Cache-Control Header.”

Conversions to conditional req: A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server.

For more information, see “Polling the Origin Server Every Time a Request Is Received.”

Storable miss ratio (%): Storable cache misses as a percentage of non-storable cache misses.

Successful reval ratio (%): Successful revalidations as a percentage of all revalidation attempts.

Poll every time requests: If Poll Every Time is enabled, the Citrix ADC appliance always consults the origin server before serving a stored object.

For more information, see “Polling the Origin Server Every Time a Request Is Received.”

Expire at last byte: Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.”

For more information, see “Example of Performance Optimization.”

Flashcache misses: If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses.

For more information, “Queuing Requests to the Cache.”

Flashcache hits: Number of Flash Cache requests that were cache hits.

For more information, see “Queuing Requests to the Cache.”

Parameterized inval requests: Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.

Full inval requests: Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.

Inval requests: Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.

Parameterized requests: Number of cache requests that were processed using a policy with a parameterized content group.

Parameterized non-304 hits: Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.

Parameterized 304 hits: Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.

Total parameterized hits: Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.

Parameterized 304 hit ratio (%): Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.

Poll every time hits: Number of times a cache hit was found using the Poll Every Time method.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”

- **Poll every time hit ratio (%)**: Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”

- **Maximum memory (KB)**: Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”

- **Maximum memory active value (KB)**: Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios.”

- **Utilized memory (KB)**: Amount of memory that is actually being used.

- **Memory allocation failures**: Number of failed attempts to utilize memory for the purpose of storing a response in the cache.

- **Largest response so far**: Largest response in bytes found in either the cache or the origin server and sent to the client.

- **Cached objects**: Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.

- **Marker objects**: Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.

- **Hits being served**: Number of hits that have been served from the cache.

- **Misses being handled**: Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

**To view summary cache statistics by using the command line interface:**

At the command prompt, type:

```
stat cache
```

**To view specific cache statistics by using the command line interface:**

At the command prompt, type:

```

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the **Integrated Caching** section of the window.
3. To see detailed statistics, click the More… link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the **Reporting** tab at the top of the page.
2. Under Built-In Reports, expand **Integrated Cache**, and then click the report with the statistics you want to view.
3. To save the report as a template, click **Save As** and name the report. The saved report appears under **Custom** Reports.

### Display cached objects and cache statistics

January 23, 2019

Contributed by:
C

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics
**View cached objects**

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

<table>
<thead>
<tr>
<th>Properties</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response size (bytes)</td>
<td>The size of the response header and body.</td>
</tr>
<tr>
<td>Response header size (bytes)</td>
<td>The size of the header portion of the response.</td>
</tr>
<tr>
<td>Response status code</td>
<td>The status code sent with the response.</td>
</tr>
<tr>
<td>ETag</td>
<td>The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.</td>
</tr>
<tr>
<td>Last-Modified</td>
<td>The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.</td>
</tr>
<tr>
<td>Cache-Control</td>
<td>The Cache-Control header inserted in the response.</td>
</tr>
<tr>
<td>Date</td>
<td>The Date header that indicates when the response was sent.</td>
</tr>
<tr>
<td>Contentgroup</td>
<td>The content group where the response is stored.</td>
</tr>
<tr>
<td>Complex match</td>
<td>If this object was cached on the basis of parameterized values, this field value is YES.</td>
</tr>
<tr>
<td>Host</td>
<td>The host specified in the URL that requested this response.</td>
</tr>
<tr>
<td>Properties</td>
<td>Specification</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Host port</td>
<td>The listen port for the host specified in the URL that requested this response</td>
</tr>
<tr>
<td>URL</td>
<td>The URL issued for the stored response.</td>
</tr>
<tr>
<td>Destination IP</td>
<td>The IP address of the server from which this response was fetched.</td>
</tr>
<tr>
<td>Destination port</td>
<td>The listen port for the destination server.</td>
</tr>
<tr>
<td>Hit parameters</td>
<td>If the content group that stores the response uses hit parameters, they are listed in this field.</td>
</tr>
<tr>
<td>Hit selector</td>
<td>If this content group uses a hit selector, it is listed in this field.</td>
</tr>
<tr>
<td>Inval selector</td>
<td>If this content group uses an invalidation selector, it is listed in this field.</td>
</tr>
<tr>
<td>Selector Expressions</td>
<td>If this content group uses a selector, this field displays the expression that defines the selection rule.</td>
</tr>
<tr>
<td>Request time</td>
<td>The time in milliseconds since the request was issued.</td>
</tr>
<tr>
<td>Response time</td>
<td>The time in milliseconds since the cache started to receive the response.</td>
</tr>
<tr>
<td>Age</td>
<td>Amount of time the object has been in the cache.</td>
</tr>
<tr>
<td>Expiry</td>
<td>Amount of time after which the object is marked as expired.</td>
</tr>
<tr>
<td>Flushed</td>
<td>Whether the response has been flushed after expiry.</td>
</tr>
<tr>
<td>Prefetch</td>
<td>If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found” responses).</td>
</tr>
<tr>
<td>Properties</td>
<td>Specification</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Current readers</td>
<td>Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.</td>
</tr>
<tr>
<td>Current misses</td>
<td>The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.</td>
</tr>
<tr>
<td>Hits</td>
<td>The number of cache hits for this object.</td>
</tr>
<tr>
<td>Misses</td>
<td>The number of cache misses for this object.</td>
</tr>
<tr>
<td>Compression format</td>
<td>The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.</td>
</tr>
<tr>
<td>HTTP version in response</td>
<td>The version of HTTP that was used to send the response.</td>
</tr>
<tr>
<td>Weak etag present in response</td>
<td>Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a “W.”</td>
</tr>
<tr>
<td>Negative marker cell</td>
<td>A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.</td>
</tr>
<tr>
<td>Properties</td>
<td>Specification</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Reason marker created</td>
<td>The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).</td>
</tr>
<tr>
<td>Auto poll every time</td>
<td>If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).</td>
</tr>
<tr>
<td>Citrix ADC Etag inserted in response</td>
<td>A variation of the ETag header generated by the Citrix ADC appliance. A value of YES appears if the Citrix ADC inserts an Etag in the response.</td>
</tr>
<tr>
<td>Full response present in cache</td>
<td>Indicates whether this is a complete response.</td>
</tr>
<tr>
<td>Destination IP verified by DNS</td>
<td>Indicates whether DNS resolution was performed when storing the object.</td>
</tr>
<tr>
<td>Object stored through a cache forward proxy</td>
<td>Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.</td>
</tr>
<tr>
<td>Object is a Delta basefile</td>
<td>A response that is delta-compressed.</td>
</tr>
<tr>
<td>Waiting for minhits</td>
<td>Indicates whether this content group requires a minimum number of origin server hits before caching a response.</td>
</tr>
<tr>
<td>Minhit count</td>
<td>If this content group requires a minimum number of origin server hits before caching an object, this field displays a count of the number of hits received so far.</td>
</tr>
<tr>
<td>HTTP Request Method</td>
<td>The method, GET or POST, used in the request that obtained this object.</td>
</tr>
<tr>
<td>Stored by policy</td>
<td>The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.</td>
</tr>
</tbody>
</table>
Application firewall metadata exists

This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request’s session.

HTTP callout object, name, type, response

These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see “HTTP Callouts”.

Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.

If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name, and so on.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select Copy. For more information about selectors, see “Configuring Selectors and Basic Content Groups.”

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:
To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```bash
show cache object [-locator <positiveInteger>] [-url <URL>] [-host <hostName>] [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET POST] [-httpStatus<positiveInteger>] [-group <contentGroupName>] [ignoreMarkerObjects (ON OFF)] [includeNotReadyObjects (ON OFF)]
```

To display cached responses in content groups that do not have a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**, click **Search**, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**, click **Search**, and set the selector search criteria to view the required cached response.

**View cache statistics**

The following table summarizes the cache statistics.

<table>
<thead>
<tr>
<th>Counter</th>
</tr>
</thead>
</table>
### Viewing cache statistics

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

<table>
<thead>
<tr>
<th>Counter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hits</td>
<td>Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action.</td>
</tr>
<tr>
<td>Misses</td>
<td>Intercepted HTTP requests where the response was ultimately fetched from origin server.</td>
</tr>
<tr>
<td>Requests</td>
<td>Total cache hits plus total cache misses.</td>
</tr>
<tr>
<td>Non-304 hits</td>
<td>If the user requests an item more than once, and the item in the cache is unchanged since the last time the Citrix ADC appliance served it, the Citrix ADC appliance serves a 304 response instead of the cached object. This statistic indicates how many items the Citrix ADC appliance served from the cache, excluding 304 responses.</td>
</tr>
<tr>
<td>304 hits</td>
<td>Number of 304 (object not modified) responses the Citrix ADC appliance served from the cache.</td>
</tr>
<tr>
<td>304 hit ratio (%)</td>
<td>Percentage of 304 responses that the Citrix ADC appliance served, relative to other responses.</td>
</tr>
<tr>
<td>Hit ratio (%)</td>
<td>Percentage of responses that the Citrix ADC appliance served from the cache (cache hits) relative to responses that could not be served from the cache.</td>
</tr>
<tr>
<td>Origin bandwidth saved (%)</td>
<td>An estimate of the processing capacity that the Citrix ADC appliance saved on the origin server due to serving responses from the cache.</td>
</tr>
<tr>
<td>Bytes served by the Citrix ADC</td>
<td>Total number of bytes that the Citrix ADC appliance served from the origin server and the cache.</td>
</tr>
<tr>
<td>Bytes served by cache</td>
<td>Total number of bytes that the Citrix ADC appliance served from the cache.</td>
</tr>
<tr>
<td>Byte hit ratio (%)</td>
<td>Percentage of data that the Citrix ADC appliance served from the cache, relative to all of the data in all served responses.</td>
</tr>
<tr>
<td>Compressed bytes from cache</td>
<td>Amount of data, in bytes, that the Citrix ADC appliance served in compressed form.</td>
</tr>
<tr>
<td>Storable misses</td>
<td>If the Citrix ADC appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.</td>
</tr>
<tr>
<td>Non-storable misses</td>
<td>A non-storable cache miss cannot be stored in the cache.</td>
</tr>
<tr>
<td>Misses</td>
<td>All cache misses.</td>
</tr>
</tbody>
</table>
| Revalidations | Max-Age setting in a Cache-Control header determines, in number of seconds, when...
an intervening cache must revalidate the content with the integrated cache before serving it to the
user. For more information, see “Inserting a Cache-Control Header.”
|Successful revalidations|Number of re-validations that have been performed. For more information, see “Inserting a Cache-Control Header.”|
|Conversions to conditional req|A user-agent request for a cached PET object is always converted
to a conditional request and sent to the origin server. For more information, see “Polling the Origin Server Every Time a Request Is Received.”|
|Storable miss ratio (%)|Storable cache misses as a percentage of non-storable cache misses.|
|Successful reval ratio (%)|Successful revalidations as a percentage of all revalidation attempts. For more information, see “Inserting a Cache-Control Header.”|
|Expire at last byte|Number of times that the cache expired content immediately after receiving the
last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.” For more information, see “Example of Performance Optimization.”|
|Flashcache misses|If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, “Queuing Requests to the Cache.”|
|Flashcache hits|Number of Flash Cache requests that were cache hits. For more information, see “Queuing Requests to the Cache.”|
|Parameterized inval requests|Requests that match a policy with an invalidation (INVAL) action and a
content group that uses an invalidation selector or parameters to selectively expire cached objects in
the group.|
|Full inval requests|Requests that match an invalidation policy where the invalGroups parameter is
configured and expires one or more content groups.|
|Inval requests|Requests that match an invalidation policy and result in expiration of specific cached
responses or entire content groups.|
|Parameterized requests|Number of cache requests that were processed using a policy with a parameterized content group.|
|Parameterized non-304 hits|Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.|
|Parameterized 304 hits|Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.|
|Total parameterized hits|Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.|
|Parameterized 304 hit ratio (%)|Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.|
|Poll every time requests|If Poll Every Time is enabled, the Citrix ADC appliance always consults the
origin server before serving a stored object. For more information, see “Polling the Origin Server
Every Time a Request Is Received.

- Poll every time hits: Number of times a cache hit was found using the Poll Every Time method. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
- Poll every time hit ratio (%): Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
- Maximum memory (KB): Maximum amount of memory in the Citrix ADC appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”
- Maximum memory active value (KB): Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a Citrix ADC Appliance for various Scenarios.”
- Utilized memory (KB): Amount of memory that is actually being used.
- Memory allocation failures: Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
- Largest response so far: Largest response in bytes found in either the cache or the origin server and sent to the client.
- Cached objects: Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
- Marker objects: Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
- Hits being served: Number of hits that have been served from the cache.
- Misses being handled: Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the GUI

1. Click the Dashboard tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More… link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears underCustom Reports.
Improve cache performance

January 23, 2019

Contributed by:
C

You can improve the performance of integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

Reduce flash crowds

Flash crowds occur when many users simultaneously request the same data. All of the requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

• **PREFETCH**: Refreshes a positive response before it expires to ensure that it never becomes stale or inactive. For more information, see “Refreshing a Response Prior to Expiration” section.

• **Cache buffering**: Starts serving a response to multiple clients as soon as it receives the response header from the origin server, rather than waiting for the entire response to be downloaded. The only limit on the number of clients that can download a response simultaneously is the available system resources. The Citrix ADC appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the size of the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.

• **Flash Cache**: Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.

For more information, see “Queuing Requests to the Cache” section.

Refresh a response before expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the
first client request. From that point onward, the Citrix ADC appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -prefetchPeriodMilliSec <milliseconds>] [-prefetchMaxPending <positiveInteger>]
```

*To configure prefetch for a content group by using the GUI

Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.

On Others tab, in the Flash Crowd and Prefetch group, select Prefetch option, and specify the values in Interval and Maximum number of pending prefetches text boxes.

Queue requests to the cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the Citrix ADC appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

**Note:**

If Flash Cache is enabled, in some situations the Citrix ADC appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The Citrix ADC appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

```
set cache contentgroup <contentGroupName> -flashcache yes
```
To enable Flash Cache by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option.

**Cache a response after a client halts a download**

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the Citrix ADC appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -quickAbortSize <integerInKBytes>
```

To configure quick abort size by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in **Quick Abort: Continue caching if more than** text box.

**Requiring a minimum number of server hits before caching**

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You should consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -minhits <positiveInteger>
```

To configure the minimum number of hits that are required before caching by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in **Do not cache, if hits are less than** text box.
Example for performance optimization

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to all of the clients, and the next request for a quote for the same stock is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Configure caching for a stock quote application

Create a content group for stock quotes

For more information, see “About Content Groups.”

Configure the following for this content group:

1. On the Expiry Method tab, select the Expire after complete response received check box.
2. On the Others tab, select the Flash Cache check box, and click Create.
3. Add a cache policy to cache the stock quotes.

For more information, see “Configuring a Policy in the Integrated Cache.”

Configure the following for the policy

1. In the Action and Store in Group lists, select CACHE and select the group that you defined in the previous step.
2. Click Add, and in the Add Expression dialog box configure an expression that identifies stock quote requests, for example: http.req.url.contains("cgi-bin/stock-quote.pl")
3. Activate the policy.

For more information, see “Globally Binding an Integrated Caching Policy.” In this example, you bind this policy to request-time override processing and set the priority to a low value.

1. Citrix ADC
2. Citrix ADC 12.1

Configure cookies, headers, and polling

January 25, 2019

Contributed by:
C
This topic describes the procedures to configure how the cache manages cookies, HTTP headers, and origin server polling, including modifying default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content under specialized circumstances.

Divergence of cache behavior from the standards

By default, the integrated cache conforms to the following standards:

- RFC 2616, “Hypertext Transfer Protocol HTTP/1.1”
- The caching behaviors described in RFC 2617, “HTTP Authentication: Basic and Digest Access Authentication”
- The caching behavior described in RFC 2965, “HTTP State Management Mechanism”

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specifications as follows:

- There is limited support for the Vary header. By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains Content-Encoding: gzip, Content-Encoding: deflate, or Content-Encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-Encoding header.
- The integrated cache ignores the values of the headers Cache-Control: no-cache and Cache-Control: private. For example, a response that contains Cache-Control: no-cache=”Set-Cookie” is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.
- An image (Content-Type = image/*) is always considered cacheable even if an image response contains Set-Cookie or Set-Cookie2 headers, or if an image request contains a Cookie header. The integrated cache removes Set-Cookie and Set-Cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

```
1  add cache policy rfc_compliant_images_policy -rule "http.res.header.set
   cookie2.exists || http.res.header.set-cookie.exists" -action
   NOCACHE
2
3
4  bind cache global rfc_compliant_images_policy -priority 100 -type REQ\_OVERRIDE
```
• The following Cache-Control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

  Cache-control: max-age=0
  
  Cache-control: no-cache
  
  To guard against Denial of Service attacks, this behavior is not the default. For more information, see “Inserting a Cache-Control Header” section.

  • By default, the caching module considers a response to be cacheable unless a response header states otherwise. To make this behavior RFC 2616 compliant, set -weakPosRelExppiry and -weakNegResExpiry to 0 for all content groups.

Remove cookies from a response

Cookies are often personalized for a user, and typically should not be cached. The Remove Response Cookies parameter removes Set-Cookie and Set-Cookie2 headers before caching a response. By default, the Remove Response Cookies option for a content group prevents caching of responses with Set-Cookie or Set-Cookie2 headers.

  Note:
  When images are cached, the built-in behavior is to remove the Set-Cookie and Set-Cookie2 headers before caching, no matter how the content group is configured.

  Note:
  Citrix recommends that you accept the default Remove Response Cookies for every content group that stores embedded responses, for example, images.

To configure Remove Response Cookies for a content group by using the command line interface:

At the command prompt, type:

  set cache contentgroup <name> -removeCookies YES

To configure Remove Response Cookies for a content group by using the configuration utility:

  1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
  2. On Others tab, in the Settings group, select Remove response cookies option.

Inserting HTTP headers at response time

The integrated cache can insert HTTP headers in responses that result from cache hits. The Citrix® Citrix ADC® appliance does not alter headers in responses that result from cache misses.
The following table describes headers that you can insert in a response.

<table>
<thead>
<tr>
<th>Header</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
<td>Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.</td>
</tr>
<tr>
<td>via</td>
<td>Lists protocols and recipients between the start and end points for a request or a response. The Citrix ADC appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is “NS-CACHE-9.2:last octet of the Citrix ADC IP address.” For more information, see “Configuring Global Attributes for Caching.”</td>
</tr>
<tr>
<td>ETag</td>
<td>The cache supports response validation using Last-Modified and ETag headers to determine if a response is stale. The cache inserts an ETag in a response only if it caches the response and the origin server has not inserted its own ETag header. The ETag value is an arbitrary unique number. The ETag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With ETag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an ETag header and replace the origin-provided Cache-Control header.</td>
</tr>
<tr>
<td>Cache-Control</td>
<td>The Citrix ADC appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the Citrix ADC appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache. For more information, see “Inserting a Cache-Control Header” section.</td>
</tr>
</tbody>
</table>

**Insert an age, via, or ETag header**

The following procedures describe how to insert Age, Via, and ETag headers.

**To insert an Age, Via, or ETag header by using the command line interface:**

At the command prompt, type:

```
set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag YES
```

**To insert an Age, Via, or ETag header by using the GUI**

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the **content group**.
2. On **Others** tab, in the HTTP Header Insertions group, select the **Via**, **Age**, or **ETag** options, as appropriate.
3. The values for the other header types are calculated automatically. Note that you configure the Via value in the main settings for the cache.

**Insert a cache-control header**

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

**To insert a cache-control header by using the command line interface**

At the command prompt, type:

```
set cache contentgroup <name> -cacheControl <value>
```

**To insert a cache-control header by using the configuration utility**

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and
   a) Click **Expiry Method** tab, clear the heuristic and default expiry settings and set the relevant value in Expire content after text box.
   b) Click **Others** tab and type the header you want to insert in the Cache-Control text box. Alternatively, click **Configure** to set the Cache-Control directives in cached responses.

**Ignoring cache-control and pragma headers in requests**

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the Citrix ADC appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.
The following table summarizes the implications of various settings for these headers and the Ignore Browser’s Reload Request setting.

<table>
<thead>
<tr>
<th>Setting for Ignore Cache-Control and Pragma Headers</th>
<th>Setting for Ignore Browser’s Reload Request</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Yes or No</td>
<td>Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.</td>
</tr>
<tr>
<td>No</td>
<td>Yes</td>
<td>The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.</td>
</tr>
<tr>
<td>No</td>
<td>No</td>
<td>A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.</td>
</tr>
</tbody>
</table>

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReqCachingHdrs YES
```

To ignore browser reload requests by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReloadReq NO
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>By default, the -ignoreReloadReq parameter is set to YES.</td>
</tr>
</tbody>
</table>

To ignore Cache-Control and Pragma headers in a request by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Others** tab, in the **Settings** group, select **Ignore Cache-control and Pragma Headers** in **Requests** option.
Example of a policy to ignore Cache-Control headers

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/* regardless of the Cache-Control header in the response.

To configure a request-time override policy to cache all responses with image/*
Flush the cache using the Invalidate All option.
For more information, see “Flushing Responses in a Content Group.”

Configure a new cache policy, and direct the policy to a particular content group. For more information, see “Configuring a Policy in the Integrated Cache.”

Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in “Ignoring Cache-Control and Pragma Headers in Requests.”

Bind the policy to the request-time override policy bank.
For more information, see Globally Binding an Integrated Caching Policy topic.

Polling the origin server every time a request is received

You can configure the Citrix ADC appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the Citrix ADC appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the Citrix ADC appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:
For a cached response that has validators in the form of an ETag or a Last-Modified header, if the response expires it is automatically marked PET and cached.

You can configure PET for a content group.

If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- Conditional Requests: A client issues a conditional request to ensure that the response that it has is the most recent copy. A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time
from the Last-Modified header. An If-None-Match header contains the response’s ETag header value. If the client’s copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.

- Non-Conditional Requests: A non-conditional request can only generate a 200 OK that contains the entire response.

### Origin Server Response | Action
--- | ---
Send the full response | The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.

<table>
<thead>
<tr>
<th>Origin Server Response</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>304 Not Modified</td>
<td>The following header values in the 304 response are merged with the cached response and the cached response is served to the client: Date, Expires, Age, Cache-Control header Max-Age, and S-Maxage tokens.</td>
</tr>
<tr>
<td>401 Unauthorized; 400 Bad Request; 405 Method Not Allowed; 406 Not Acceptable; 407 Proxy Authentication Required</td>
<td>The origin’s response is served as-is to the client. The cached response is not changed.</td>
</tr>
<tr>
<td>Any other error response, for example, 404 Not Found</td>
<td>The origin’s response is served as-is to the client. The cached response is removed.</td>
</tr>
</tbody>
</table>

**Note**

The Poll Every Time parameter treats the affected responses as non-storable.

To configure poll every time by using the command line interface

At the command prompt, type:

```
add cache contentgroup <contentGroupName> -pollEveryTime YES
```

To configure poll every time by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Others** tab, in the Settings group, select Poll every time (validate cached content with origin for every request) option.

**PET and client-specific content**

The PET function can ensure that content is customized for a client. For example, a Web site that serves content in multiple languages examines the Accept-Language request header to select the lan-
guage for the content that it is serving. For a multi-language Web site where English is the predomi-
nant language, all English language content can be cached in a PET content group. This ensures that
every request goes to the origin server to determine the language for the response. If the response is
English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, config-
ure a named expression that identifies English responses in the cache, and configure a policy that uses
this content group and named expression. Bold is used for emphasis:

```
1. add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
2. add expression containsENExpression -rule "http.res.header("Content-Language")\.contains("en")"
3. add cache policy englishPolicy -rule containsENExpression -action CACHE
   -storeInGroup englishLanguageGroup
4. bind cache policy englishPolicy -priority 100 -precedeDefRules NO
```

PET and authentication, authorization, and auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from
PET. All mail responses (*.EML objects) have an ETag validator that enables them to be stored as PET
responses.

Every request for a mail response travels to the origin server, even if the response is cached. The
origin server determines whether the requestor is authenticated and authorized. It also verifies that
the response exists in the origin server. If all results are positive, the origin server sends a 304 Not
Modified response.

Configure integrated cache as a forward proxy

January 23, 2019

Contributed by:

C

The integrated cache can service as a forward proxy device that passes requests to other Citrix ADC
appliances or to other types of cache servers. You configure the integrated cache as a forward proxy
by identifying the IP addresses of the cache server or servers. After configuring the forward proxy,
the Citrix ADC appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the Citrix ADC as a forward cache proxy by using the command line interface

At the command prompt, type:

```
add cache forwardProxy <IPAddress> <port>
```

To configure the Citrix ADC as a forward cache proxy by using the GUI

1. Navigate to **Optimization > Integrated Caching > Forward Proxy**, and add a forward proxy by specifying the IP address and port number.

2. **Citrix ADC**

3. **Citrix ADC 12.1**

**Default settings for the integrated cache**

February 19, 2019

Contributed by: C

The Citrix ADC integrated cache feature provides built-in policies with default settings as well as initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

**Default caching policies**

The integrated cache has built-in policies. The Citrix ADC appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

**Note**

If you configured policies prior to release 9.0 and specified the -precedeDefRules parameter when binding the policies, they are automatically assigned to override-time bind points during migration.
View default policies

The built-in policy names start with an underscore (_). You can view the built-in policies from the command line and the administrative console using the show cache policy command.

Default request policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the MAY_NOCACHE action stipulates that the transaction is cached only when there is a user-configured or built-in CACHE directive at response time.

The following policies are bound to the _reqBuiltinDefaults policy label. They are listed in priority order.

Do not cache a response for a request that uses any method other than GET.

The policy name is _nonGetReq. The following is the policy rule:

\[
!\text{HTTP.REQ.METHOD.eq(GET)}
\]

Set a NOCACHE action for a request with header value that contains If-Match or If-Unmodified-Since.

The policy name is _advancedConditionalReq. The following is the policy rule:

\[
\text{HTTP.REQ.HEADER("If-Match")\ .EXISTS} \ || \ \text{HTTP.REQ.HEADER("If-Unmodified-Since")\ .EXISTS}
\]

Set a MAY_NOCACHE action for a request with the following header values: Cookie, Authorization, Proxy-authorization or a request which contains the NTLM or Negotiate header.

The policy name is _personalizedReq. The following is the policy rule:

\[
\text{HTTP.REQ.HEADER("Cookie")\ .EXISTS} \ || \ \text{HTTP.REQ.HEADER("Authorization")\ .EXISTS} \\
|| \ \text{HTTP.REQ.HEADER("Proxy-Authorization")\ .EXISTS} || \ \text{HTTP.REQ.IS_NTLM_OR_NEGOTIATE}
\]

Default response policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the _resBuiltinDefaults policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.
The policy name is \_uncacheableStatusRes. The following is the policy rule:

!((HTTP.RES.STATUS.EQ(200)) || (HTTP.RES.STATUS.EQ(304)) || (HTTP.RES.
STATUS.BETWEEN(400, 499)) || (HTTP.RES.STATUS.BETWEEN(300, 302)) || (HTTP.
RES.STATUS.EQ(307)) || (HTTP.RES.STATUS.EQ(203)))

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

The compression module inserts the Vary: Accept-Encoding header. The name of this expression is \_uncacheableVaryRes. The following is the policy rule:

(((HTTP.RES.HEADER("Vary").EXISTS) && ((HTTP.RES.HEADER("Vary").INSTANCE
(1).LENGTH > 0)) || ((HTTP.RES.HEADER("Vary").STRIP_END\WS.SET_TEXT_MODE
(IGNORECASE).eq("Accept-Encoding"))))

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

The policy name is \_uncacheableCacheControlRes. The following is the policy rule:

(((HTTP.RES.CACHE\_CONTROL.IS\_PRIVATE) || (HTTP.RES.CACHE\_CONTROL.IS
\_NO\_CACHE) || (HTTP.RES.CACHE\_CONTROL.IS\_NO\_STORE) || (HTTP.RES.
CACHE\_CONTROL.IS\_INVALID))

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

The policy name is \_cacheableCacheControlRes. The following is the policy rule:

(((HTTP.RES.CACHE\_CONTROL.IS\_PUBLIC) || (HTTP.RES.CACHE\_CONTROL.IS\_MAX\_AGE
)) || (HTTP.RES.CACHE\_CONTROL.IS\_MUST\_REVALIDATE) || (HTTP.RES.CACHE\_CONTROL
.IS\_PROXY\_REVALIDATE) || (HTTP.RES.CACHE\_CONTROL.IS\_S\_MAXAGE))

5. Do not cache responses that contain a Pragma header.

The name of the policy is \_uncacheablePragmaRes. The following is the policy rule:

HTTP.RES.HEADER("Pragma").EXISTS

6. Cache responses that contain an Expires header.

The name of the policy is \_cacheableExpiryRes. The following is the policy rule:

HTTP.RES.HEADER("Expires").EXISTS

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

The name of the policy is \_imageRes. The following is the policy rule:
HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH("image/
")

You could configure the following content group to work with this policy:
add cache contentgroup nocookie -group -removeCookies YES

8. Do not cache a response that contains a Set-Cookie header.

The name of the policy is _personalizedRes. The following is the policy rule:

| HTTP.RES.HEADER("Set-Cookie").EXISTS | HTTP.RES.HEADER("Set-Cookie2").EXISTS |

Restrictions on default policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 byes.
3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.

Note
This is different from the If-Modified-Since header.

5. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

Initial settings for the default content group

When you first enable integrated caching, the Citrix ADC appliance provides one predefined content group named the Default content group. For detailed information, see Default content group settings

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3298
If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

**Resources for troubleshooting**

For best results, use the following resources to troubleshoot an integrated cache issue on a Citrix ADC appliance:

- The relevant trace files
- The ns.conf file
- The RFC 2616 document
- A copy of the object, if possible

In addition to the above resources, the following tools expedite troubleshooting:

- The ihttpheaders or a similar utility
- The Wireshark application customized for the Citrix ADC trace files

**Troubleshooting integrated caching issues**

The following are effective steps to troubleshoot the objects that are not cached:

1. **Verify that the Integrated Caching feature is enabled.**

   Run the following command to verify the feature is enabled:

   ```
   show ns feature
   ```

   Following is sample output of the above command:
<table>

The entry highlighted in boldface (for reference) in the above output indicates that the integrated caching feature is enabled. If the feature is not enabled, run the following command to enable it:

```
enable ns feature IC
```

2. **Make sure that sufficient memory is available on the Citrix ADC appliance.**

Depending on the size of the object to be cached, memory available to store the cacheable object might be insufficient. You can set the memory limit for the integrated cache either globally or for individual content groups.

Run the following command to verify the memory allocated to integrated cache globally:

```
show cache parameter
```

Following is sample output of the above command:

```
show cache parameter

Integrated cache global configuration: Memory usage limit: 256 MBytes
Via header: NS-CACHE-6.1: 101 Verify cached object using: HOSTNAME_AND_IP
Max POST body size to accumulate: 32768 Current outstanding prefetches
```
Max outstanding prefetches: 4294967294 Treat NOCACHE policies as BYPASS policies: YES

The entry highlighted in boldface (for reference) in the preceding output indicates the amount of memory allocated to the integrated cache globally.

Run the following command to verify the memory allocated to an individual content group:

```
show cache contentGroup <Content_Group_Name>
```

Following is sample output of the above command:

```
show cache contentgroup content1

Name: content1 Heuristic expiry time parameter: 10 percent Weak relative expiry time - Positive responses: 3600 secs Weak relative expiry time - Negative responses: 600 secs Hit parameters: NONE Invalidation Parameters: NONE Invalidation restricted to host: NO Ignore parameter value case: NO Match Request Cookies: NO Poll Every Time: NO Ignore reload request: YES Remove Response Cookies: YES Prefetch: YES Prefetch period: heuristic Current outstanding prefetches: 0 Max outstanding prefetches: 4294967294 Flashcache: NO Expire at last byte: NO Insert Via header: YES Insert Age header: YES Insert ETag header: YES Cache-control header: NONE Quick abort size: 4194303 KBytes (MAXIMUM)Minimum Response Size: 0 KBytes Maximum Response Size: 80 KBytes Memory usage: 0 Bytes Memory usage limit: 64 MBytes Ignore caching headers in request : YES Non-304 hits: 0 304 hits: 0 Cached objects: 0 Number of times expired/flushed: 1 MinHits configured: 0 Always evaluate policies: NO Pinned: NO
```

The entry highlighted in boldface (for reference) in the above output indicates the amount of memory allocated to the content group.

3. **Verify that cacheable object is small enough to be stored within the configured memory limits.**

Complete the following procedure to make space for the object to be cached:

- Run the following command to flush the cache for the content group to which the object belongs:

  ```
  flush cache contentGroup <Content_Group_Name>
  ```

- Verify that the object is cached. If the object is cached successfully, increase the memory allocated for the content group. Otherwise, run the following command to flush the cache globally:

  ```
  flush cache contentGroup ALL
  ```
• Verify that the object is cached. If the object is cached successfully, consider increasing the global memory limit. If the object is still not cached, something else is causing the failure to cache the object.

The memory allocated to the integrated cache depends on the Citrix ADC appliance model. You can allocate approximately half the available memory to the integrated cache. Similarly, the maximum amount of memory you can allocate for a content group cannot be more than the memory allocated for global cache.

To increase the global memory limit for the integrated cache, run the following command:

```bash
set cache parameter -memLimit <Integer>
```

To increase the memory limit for a content group, run the following command:

```bash
set cache contentgroup <contentgroup name> -memLimit <Integer>
```

4. **Verify that the cache policy is bound to an appropriate bind point, an appropriate priority is set for the policy, and an appropriate precedeDefRules switch is configured.**

You must activate a caching policy by binding it globally. To verify that the policy is active, run the following command:

```bash
show cache global
```

Following is sample output of the above command:

```
1) Name: red_pol State: ACTIVE Priority: 1
Rule: URL CONTAINS red
Action: NOCACHE
Precede default HTTP rules: YES
Hits : 10
Done
In the output, verify the following settings:

- **The policy is bound**: The output should contain all the active cache policies. If the cache policy for the object to be cached is not listed in the output, the policy is not yet bound. Run the following command to bind the policy globally:

```bash
bind cache global <Policy_Name> -priority <Integer> [-precedeDefRules YES|NO]
```

- **The policy is Active**: If the policy is bound, verify that the state of the policy is displayed as Active. The entry indicating that the policy in the preceding output is active is the first
highlighted entry in the sample output of the show cache global command, above. The policy is active if it is bound globally and an appropriate priority is set. Otherwise, the status of the policy is showed as Passive.

- **An appropriate priority is assigned to the policy**: The first highlighted entry in the sample output above displays the priority of the policy. If the priority is not set, you can use the bind command to set the priority of the policy. Note that the higher the priority number, the lower the priority. The priority assigned to the policy enables the Citrix ADC appliance to determine the order in which the policy should be evaluated.

If evaluation of a particular policy fails, increase the priority of the policy so that it is evaluated before other policies. Caching policies, due to their high granularity, can be very complicated to configure. Therefore, two policies might be contradictory. As a result, only the higher-priority policy takes effect.

- **The precedeDefRules switch setting is correct**: The second highlighted entry in the sample output of the show cache global command, above, indicates the precedeDefRules switch setting. This setting enables the Citrix ADC appliance to determine whether the policy should be evaluated before the default built-in policies, which implement the standard HTTP caching behavior, such as basing caching decisions on HTTP header fields (for example, the If-Modified-Since and no-cache fields). You can set this switch when binding the policy.

For certain types of HTTP(S) transactions, you might have to make sure that the policy precedes default HTTP rules, to force objects to be cached. Especially if requests include header fields, such as If-Modified-Since, or responses contain the No-Cache header field, you might have to make sure that the cache policy overrides the default in order for objects from these transactions to be cached. Force the policy to override default HTTP rules by rebinding the cache policy with the -precedeDefRules YES switch.

1. **Verify the size of the object to be cached.**

   You can configure a content group with minimum, which by default is 0 KB, and maximum, which by default is 80 KB, response sizes for the objects to be cached. The object does not get cached if its size is not within the configured range. Additionally, verify that the cache expiry
times are set to an appropriate value. For example, check for a very small time limit, such as one second.

Run the following command from the command line interface of the appliance to display the size limits and expiry times for a specific content group:

```
show cache contentGroup <Content_Group_Name>
```

Following is an example of this command’s output:

```
show cache contentGroup content1
Name: content1
Heuristic expiry time parameter: 10 percent
Weak relative expiry time - Positive responses: 3600 secs
Weak relative expiry time - Negative responses: 600 secs
Hit parameters: NONE
Invalidation Parameters: NONE
Invalidation restricted to host: NO
Ignore parameter value case: NO
Match Request Cookies: NO
Poll Every Time: NO
Ignore reload request: YES
Remove Response Cookies: YES
Prefetch: YES
Prefetch period: heuristic
Current outstanding prefetches: 0
Max outstanding prefetches: 4294967294
Flashcache: NO
Expire at last byte: NO
Insert Via header: YES
Insert Age header: YES
Insert ETag header: YES
Cache-control header: NONE
Quick abort size: 4194303 KBytes (MAXIMUM)
Minimum Response Size: 0 KBytes
Maximum Response Size: 80 KBytes
Memory usage: 0 Bytes
Memory usage limit: UNLIMITED
Ignore caching headers in request: YES
Non-304 hits: 0
304 hits: 0
Cached objects: 0
Number of times expired/flushed: 0
MinHits configured: 0
Always evaluate policies: NO
Pinned: NO
Done

In addition to the above steps for troubleshooting integrated caching issues, you can consider using the following troubleshooting techniques:

• Depending on the configuration of a policy, there are virtually an unlimited number of reasons for the policy not getting evaluated. If you have completed the preceding steps to troubleshoot the issue, consider completing the following procedure to troubleshoot the issue further:
  a) Flush the cache.
  b) Verify the value of the hit parameter for the policy by running the following command:
     
     show cache global

     Name: home_pol_1 State: ACTIVE Priority: 99
     Rule: URL CONTAINS home
     Action: NOCACHE
     Precede default HTTP rules: NO
     Hits : 2
     a) Send an HTTP request for the related object from a Web browser.
     b) Run the show cache global command again and verify that the value for the hit parameter has incremented.

     Depending on the policy receiving hits or not, you can determine whether the issue is due to the policy have not been configured correctly or to a more global cache setting.

Front end optimization

January 25, 2019

Contributed by:
C
The HTTP protocols that underlie web applications were originally developed to support transmission and rendering of simple web pages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The Citrix ADC front end optimization (FEO) feature addresses such issues and reduces the load time and render time of web pages by:

- Reducing the number of requests.
- Required for rendering each page.
- Reducing the number of bytes in page responses.

Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. Citrix ADCs support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

### Optimizations performed by the FEO feature

<table>
<thead>
<tr>
<th>Web Optimization</th>
<th>Problem</th>
<th>What Citrix ADC FEO feature does</th>
<th>Benefits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inlining</td>
<td>Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the web page.</td>
<td>CSS inline, JavaScript inline, CSS combine</td>
<td>Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that will be viewed only once, and for mobile devices that have limited cache sizes.</td>
</tr>
<tr>
<td>Web Optimization</td>
<td>Problem</td>
<td>What Citrix ADC FEO feature does</td>

</tr>
<tr>
<td>Minification</td>
<td>Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency.</td>
<td>CSS minification, JavaScript minification, Removal of HTML comments</td>
<td>Minified files consume less bandwidth and avoid the latency caused by special processing.</td>
</tr>
<tr>
<td>Image optimization</td>
<td>Mobile browsers often have slow connection speeds and limited cache memory. Downloading images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in website latency.</td>
<td>JPEG optimization, CSS image inlining, Image shrink-to attributes, GIF to PNG conversion, HTML image inlining, WebP image conversion, JPEG, GIF, PNG to JPEG-XR image conversion</td>
<td>Reduces the image to the size indicated in image tag by Citrix ADC, enabling client browsers to load images faster.</td>
</tr>
<tr>
<td>Repositioning</td>
<td>Inefficient processing of external CSS, images, and JavaScript increases page-load time.</td>
<td>Image lazy loading, CSS move to Head, JavaScript move to end</td>
<td>Repositions HTML elements, to reduce rendering time for web pages and enable client browsers to load the objects faster.</td>
</tr>
</tbody>
</table>
Web Optimization Problem

What Citrix ADC FEO feature does Benefits

Connection Management Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time. Domain sharding Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel.

Web Optimizations performed on different file types:

The following table lists the web optimizations that the Citrix ADC performs on CSS, Images, JavaScript, and HTML.

<table>
<thead>
<tr>
<th>Object</th>
<th>Optimization</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSS</td>
<td>Minify linked CSS files, Combine multiple linked CSS files that are present within the head tag into a single CSS file, Convert linked CSS files to inline CSS files, Convert CSS import rule to linked CSS. Note: This optimization works if you have not defined the scope and media attributes for the import tag and when the import tag immediately follows the style tag, Within a linked CSS file, convert linked images to inline images, Move a CSS present within the body tag of an HTML page to the head tag. Note: The head tag must already be present within the HTML script.</td>
</tr>
<tr>
<td>Images</td>
<td>1. Optimize JPEG images by removing extraneous bytes. 2. Reduce image size by weakening the image quality to a value specified in FEO parameters. 3. Image shrink to attributes. 4. Convert linked images to inline images. Note: For animated images in GIF format, only this optimization is supported. 5. Convert non-animated images in GIF format to PNG format. 6. Reduce the image size to that specified on the web page, if the size specified on the web page is smaller. 7. Convert images in GIF, PNG, JPEG format to WebP format. 8. Convert images in JPEG format to JPEG-XR format. 9. Lazy loading.</td>
</tr>
<tr>
<td>JavaScript</td>
<td>1. Minify linked JavaScript. 2. Convert linked JavaScript to inline JavaScript. 3. Move JavaScript present in the body tag to the end of the body tag. Note: The size of the body tag must be lesser than 64 Kbytes. 5. Extend cache expiry period.*</td>
</tr>
<tr>
<td>HTML</td>
<td>Remove Comments from HTML (Removes comments within the HTML files)</td>
</tr>
</tbody>
</table>
Note:
The front end optimization feature supports ASCII characters only. It does not support the unicode character set.

How front end optimization works

After the Citrix ADC receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy.
   
   For example, a Citrix ADC can apply the following optimization rules:
   
   • Remove white spaces or comments present within a CSS or JavaScript.
   • Combine one or more CSS files to one file.
   • Convert GIF image format to PNG format.

2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.

3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

Remove extraneous information such as white spaces and comments.

Configure front end optimization

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

Note: The Citrix ADC evaluates front end optimization policies at request time only, not at response time.

To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the Citrix ADC, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority.
lower priority number indicates a higher value. The Citrix ADC applies the policies in the order of their priorities.

**Prerequisites**

Front end optimization requires the Citrix ADC integrated caching feature to be enabled. Additionally, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see [Integrated Caching](#).

**Note:** The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

To configure front end optimization by using the command line interface

At the command prompt, do the following:

1. Enable the front end optimization feature.

   ```
   enable ns feature FEO
   ```

2. Create one or more front end optimization actions.

   ```
   add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...
   ```

   **Example:** To add a front end optimization action for converting images in GIF format to PNG format and to extend cache expiry period:

   ```
   add feo action allact -imgGifToPng -pageExtendCache
   ```

3. [Optional] Specify non-default values for front end optimization global settings.

   ```
   ```

   **Example:** To specify the cache maximum expiry period:

   ```
   set feo parameter -cacheMaxage 10
   ```

4. Create one or more front end optimization policy.

   ```
   add feo policy <name> <rule> <action>
   ```

   **Example:** To add a front end optimization policy and associate it with the above specified allact action:

   ```
   add feo policy pol1 TRUE allact
   ```
add feo policy pol1 "(HTTP.REQ.URL.CONTAINS("testsite"))" allact!

5. Bind the policy to a load balancing or content switching virtual server, or bind it globally.

```
1 bind lb vserver <name> -policyName <string> -priority <num>
2 bind cs vserver <name> -policyName <string> -priority <num>
3 bind feo global <policyName> <priority> -type <type> <
goToPriorityExpression>
```

Example: To apply the front end optimization policy to a virtual server named “abc”:

```
> bind lb vserver abc -policyName pol1 -priority 1 -type NONE
```

Example: To apply the front end optimization policy for all the traffic reaching the ADC:

```
> bind feo global pol1 100 -type REQ_DEFAULT
```

1. Save the configuration. save ns config

Configure front end optimization by using the GUI

1. Navigate to Optimization > Front End Optimization > Actions, click Add and create a front end optimization action by specifying the relevant details.
2. [Optional] Specify the front end optimization global settings.
3. Navigate to Optimization > Front End Optimization, and on the right-pane, under Settings, click Change Front End Optimization settings and specify the front end optimization global settings.
4. Create a front end optimization policy.
5. Navigate to Optimization > Front End Optimization > Policies, click Add and create a front end optimization policy by specifying the relevant details.
6. Bind the policy to a load balancing or content switching virtual server.
   a) Navigate to Optimization > Front End ptimization > Policies.
   b) Select a front end optimization policy and click Policy Manager.
   c) Under Front End Optimization Policy Manager, bind the front end optimization policy to a load balancing or content switching virtual server.

**Verify front end optimization configuration**

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of hits that the policy counter increments during policy based FEO.
Note

For more information about statistics and charts, see the Dashboard help on the Citrix ADC appliance.

View FEO statistics by using the command line interface

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy hits and details, and detailed FEO statistics, respectively:

- `stat feo` (Note: The `stat feo policy` command displays statistics only for advanced FEO policies.)
- `show feo policy name`
- `stat feo -detail`

View FEO statistics on Citrix ADC dashboard

In the dashboard GUI, you can:

- Select Front End Optimization to display a summary of FEO statistics.
- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

Sample optimization:

Refer to the **Sample** pdf for some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

Content accelerator

January 30, 2019

Contributed by:

C

Important

The content accelerator feature is no longer supported on the Citrix ADC appliance.

Content accelerator is a Citrix ADC feature that you can use in a Citrix ByteMobile T1100 deployment, to store data on a Citrix ByteMobile T2100 appliance.

Storing data on a T2100 appliance saves bandwidth and provides faster response times, because the Citrix ADC does not have to connect to the server for repeated requests of the same data.
Note: Content accelerator works with a Citrix ByteMobile platinum license. Contact customer support for more information and for obtaining the license.

How content accelerator works

When a load balancing or content switching virtual server receives a client request, the Citrix ADC appliance evaluates a content accelerator policy that you have bound to the virtual server. The policy filters the requests to identify the ones to which to apply the content accelerator feature.

Note: For HTTP requests, the content accelerator feature can serve partial content in response to single byte-range requests.

The following figure illustrates the operations that the appliance performs when a client request arrives at a virtual server configured to use the content accelerator feature:

The process flow is as follows:

1. Client sends request.
2. Citrix ADC forwards the request to the server.
3. Server responds with the predefined size of the response (specified by the accumResSize parameter of the add ca action command).
4. Citrix ADC computes a hash of the response sent by the server.
5. Citrix ADC looks up the hash on the T2100 appliance.
6. A successful lookup indicates that the data is available and the T2100 appliance sends the data to the Citrix ADC.

   Note:
   When a lookup does not succeed, the Citrix ADC fetches all of the requested data from the server, and simultaneously serves the data to the client and updates the data on the T2100 appliance.
   The T2100 appliance can be configured to specify the number of requests after which to cache the data.
7. Citrix ADC sends the response to the client.

Configure content accelerator

Before configuring the content accelerator feature, you must enable it on the Citrix ADC appliance.

You can configure the content accelerator feature to use one or multiple T2100 appliances. You must add each T2100 appliance as a service and bind these services to a load balancing virtual server that is dedicated to distributing the load between the configured T2100 appliances.
You must also configure a content accelerator action to lookup the data on the T2100 appliance. The action must also specify the T2100 load balancing virtual server and the size of data (in KB) to be fetched from the server to calculate the hash.

The action must be bound to a content accelerator policy that defines the traffic on which to perform content acceleration. The content accelerator policy must be bound to a content switching or load balancing virtual server that receives client traffic. Alternatively, you can bind the policy globally to be applicable to all virtual servers.

To configure content accelerator by using the command line interface

At the command prompt, do the following:

1. Enable the content accelerator feature.
   
   enable ns feature ca

2. Identify the T2100 appliances and add each as a service on the Citrix ADC appliance.
   
   add service <name> <IPAddress> <serviceType> <port>

   **Example:**
   
   1 > add service T2100-A 10.102.29.61 HTTP 30
   2 > add service T2100-B 10.102.29.62 HTTP 40
   3 > add service T2100-C 10.102.29.63 HTTP 50

   **Note:**
   
   The services must be of type HTTP only.

3. Create a load balancing virtual server for the T2100 appliances. Specify the token load balancing method and the rule shown in the following syntax.

   
   1 add lb vserver <name> <serviceType> <IPAddress> <port> -lbMethod TOKEN -rule "http.req.url.after_str("/lookup") alt http.req.url.path.SKIP(1).PREFIX(64)"

   **Example:**

   1 add lb vserver T2100-lbvserver HTTP 10.102.29.64 99 -lbMethod TOKEN -rule "http.req.url.after_str("/lookup") alt http.req.url.path.SKIP(1).PREFIX(64)"

4. Bind the T2100 services to the load balancing virtual server that you created for them.

   bind lb vserver <name> <serviceName>

   **Example:**
5. Define a content accelerator action.

```
add ca action <name> accumResSize <KBytes> -lbvserver <string> -type lookup
```

**Example:**
```
> add ca action ca_action1 -type lookup -lbvserver T2100-lbvserver - accumResSize 60
```

6. Define a content accelerator policy.

```
add ca policy <name> -rule <expression> -action <name>
```

**Example:** To create a content accelerator policy that caches all video formats.
```
> add ca policy ca_mp4_pol -rule ns_video -action ca_action1
```

where `ns_video` is a built-in expression.

7. Bind the content accelerator policy to either a virtual server that receives traffic or globally to the Citrix ADC system.

```
bind lb vserver <name> -policyName <string>
bind cs vserver <name> -policyName <string>
bind ca global -policyName <string> -priority <num> -type <type>
```

**Example:** To apply the content accelerator policy to a virtual server named “traf_rec”
```
> bind lb vserver traf_rec -policyName ca_mp4_pol
```

**Example:** To apply the content accelerator policy for all traffic reaching the Citrix ADC.
```
> bind ca global -policyName ca_mp4_pol -priority 100 -type RES_DEFAULT
```

8. Save the configuration.

```
save ns config
```

Configuring content accelerator by using the GUI

1. Navigate to **System > Settings > Configure Advanced Features** and select **Content Accelerator**.

2. Create a service for each of the T2100 appliances.
   a) Navigate to **Traffic Management > Load Balancing > Services**.
b) Click Add and specify the relevant details. In the Server field, make sure you specify the IP address of the T2100 appliance. In the Protocol field select HTTP.

3. Create a virtual server and bind the T2100 services to it.
   a) Navigate to Traffic Management > Load Balancing > Virtual Servers.
   b) Click Add and specify the relevant details.
   c) In the Method and Persistence tab, specify the Method as Token.
   d) In the Policies tab, specify the rule as http.req.url.after_str("/lookup/") alt http.req.url.path.SKIP(1).PREFIX(64).
   e) In the Services tab, select the T2100 services that you want to bind to the virtual server.

4. Create a content accelerator action.
   a) Navigate to Optimization > Content Accelerator > Actions.
   b) Specify the relevant details.

5. Create a content accelerator policy.
   a) Navigate to Optimization > Content Accelerator > Policies.
   b) Click Add, specify the policy rule, and associate the content accelerator action.

6. Bind the content accelerator policy globally or to a virtual server.
   a) Navigate to Optimization > Content Accelerator.
   b) Under the Content Accelerator Policy Manager [REQUEST] or Content Accelerator Policy Manager [RESPONSE] sections, bind the content accelerator policy globally or to a virtual server.

Media classification

January 23, 2019

Contributed by: C

Understanding the type of traffic in the network helps network administrators to manage bandwidth consumption for optimal network performance. The media classification mode monitors and displays the statistics of media traffic going through the Citrix ADC appliance.

With this mode enabled, a network administrators can collect stats showing the amount of data accessed, and the types of devices from which the media files have been accessed. The Citrix ADC appliance also supports byte-range requests in this mode.

Currently the Citrix ADC appliance can monitor and display statistics for the following media file types:
Media File type
Microsoft Smooth Streaming Video
Apple Live Streaming Video
Audio Data Transport Stream (ADTS) Audio
Advanced Audio Coding (AAC) Audio
Flash Video (FLV) Audio and Video
3GP Audio and Video

The appliance can display stats for the following devices:

Device Platform Device Type
iOS iPad and iPod
Android Mobiles and tablets
Laptop or Desktop Windows laptop and desktop computers
Others Other mobile devices (mobiles and tablets)

The network administrators can check the following stats counters to know the amount of data accessed through the Citrix ADC appliance for various media traffic types.

Media File Name Stats Counter
Microsoft Smooth Streaming mcmsmthstrmvid—This counter records the total number of Microsoft Smooth Streaming videos served by the Citrix ADC appliance; Mcmsmthstrvidpl—This counter records the total number of Microsoft Smooth Streaming video playlists served by the Citrix ADC appliance; Mcmsmthstrmvidbytes—This counter records the total number of data bytes served for Microsoft Smooth Streaming media traffic on the Citrix ADC appliance; Mcmsmthstrmplvidbytespl—This counter records the total number of Microsoft Smooth Streaming playlist bytes served by the Citrix ADC appliance.

<tr>
<td>3GP</td>
<td>mc3gpvidbytes—This counter records the total number of data bytes served for 3GP media traffic on the Citrix ADC appliance.</td>
</tr>
</tbody>
</table>
The Citrix ADC appliance detects media file types by their signatures in the initial body bytes of the responses. For example, the initial body bytes for an mp4 file has the following signature in the response:

```
**....ftypmp42** ....isommp42...moov...lmvhd.....c.!c.!.
```

The Citrix ADC appliance detects the client device type by the user agent string that the client device includes in the HTTP GET request. For example, a windows phone using a UC browser will have the following user agent string in the HTTP GET request:

```
User-Agent: **UCWEB**/2.0 (**Windows**; U; wds 8.10; en-US; HTC; 8X by HTC) U2/1.0.0
```

**Enable media classification**

By default, media classification is disabled on the Citrix ADC appliance. You have to enable the mode before using it.

To enable media classification by using the command line interface

At the command prompt, type:

```
enable ns mode Mediaclassification
```

To enable media classification by using the GUI

Enable media classification on Citrix ADC appliance

Navigate to **System > Settings > Configure Modes** and select **Media Classification**.

To view media traffic statistics on the Citrix ADC appliance

Navigate to **Optimization** and click **Media Classification** to view the media traffic statistics.

**Verify media classification statistics**

You can view the media traffic statistics in the dashboard utility or using the command line interface. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

**Note**

For more information about statistics and charts, see the Dashboard help on your Citrix ADC appliance.

To view media classification statistics by using the command line interface

At the command prompt, type one of the following commands to display a summary of media classification statistics, display detailed statistics, or clear the display:

```
stat Mediaclassification
```
To view Media Classification statistics on the Dashboard

In the Dashboard utility, you can display the following types of media classification statistics:

1. Select Media Classification to display a summary of the media traffic statistics.
2. To display detailed media traffic statistics, click the Details.
3. To clear the media traffic statistics, click Clear.

Reputation

January 25, 2019

Contributed by: C

Citrix offers reputation based security. Using reputation assessment to determine the risk of processing requests, you can take actions such as blocking or dropping certain requests to improve the performance of your application.

The Citrix ADC IP reputation feature uses IP reputation checks to prevent Zero day attacks and provide protection against malicious sources associated with web attacks, phishing activity, or web scanning.

For additional details, see IP Reputation.

IP Reputation

March 26, 2019

Contributed by: C

stat Mediaclassification -detail
stat Mediaclassification -clearstats
IP reputation is an extremely effective tool in identifying the IP address that is sending unwanted requests. You can use the IP reputation list to preemptively reject requests that are coming from the IP with the bad reputation. For example, you can use this feature to optimize application firewall performance by filtering out the requests that you do not want to process. You can reset or drop the connection, or you can configure a responder policy to take a specific responder action.

Following are some examples of attacks that you can prevent by using IP Reputation:

- **Virus Infected personal computers** (home PCs) are the single biggest source of Spam on the internet. IP Reputation can identify the IP address that is sending unwanted requests. IP reputation can be especially useful for blocking large scale DDoS, DoS, or anomalous syn flood attacks from known infected sources.
- **Centrally managed and automated botnet** attacks have gained popularity for stealing passwords, because it doesn’t take long when hundreds of computers work together to crack your password. It is easy to launch botnet attacks to figure out passwords that use commonly used dictionary words.
- **Compromised web-server** attacks are not as common as they used to be, because awareness and server security have increased, so hackers and spammers look for easier targets. There are still web servers and online forms that hackers can compromise and use to send spam (often the more vicious types, such as viruses and porn) but usually this type of activity is easier to detect and and quickly shut down, or block with a reputation list such as SpamRats.
- **Windows Exploits** (such as Active IPs offering/distributing malware, shell code, rootkits, worms or viruses).
- **Known spammers and hackers**.
- **Mass e-mail marketing campaigns**.
- **Phishing Proxies** (IP addresses hosting phishing sites, and other fraud such as ad click fraud or gaming fraud).
- **Anonymous proxies** (IPs providing proxy and anonymization services including The Onion Router aka TOR).

A Citrix ADC appliance uses **Webroot** as the service provider for the dynamically generated malicious IP database and the metadata for those IP addresses. Metadata might include geolocation details, threat category, threat count, and so on. The Webroot threat Intelligence engine receives real-time data from millions of sensors. It automatically and continuously captures, scans, analyses and scores the data, using advanced machine learning and behavioral analysis. Intelligence about a threat is continually updated.

As soon as a threat is detected anywhere in the network, the IP address is flagged as malicious and all appliances connected to the network are immediately protected. The dynamic changes in the IP addresses are processed with high speed and accuracy by leveraging advanced machine learning.

As stated in the datasheet from Webroot, the Webroot’s sensor network identifies many key IP threat types, including spam sources, Windows exploits, botnets, scanners, and others. (See the flow dia-
gram on the datasheet)

The Citrix ADC appliance uses an iprep client process to get the database from Webroot. The iprep client uses the HTTP GET method to get the absolute IP list from Webroot for the first time. Subsequently, it checks delta changes once every 5 minutes.

Important

- Make sure the Citrix ADC appliance has Internet access and DNS is configured before you use the IP Reputation feature.

- To access the webroot database, the Citrix ADC appliance should be able to connect to api.bcti.brightcloud.com on port 443. Each node in the High Availability (HA) or Cluster deployment gets the database directly from the webroot and should be able to access this Fully Qualified Domain Name (FQDN).

- Webroot hosts it’s reputation database in AWS currently. Therefore, Citrix ADC should be able to resolve AWS domains for downloading the reputation db. Also, firewall should be open for AWS domains.

- Citrix ADC appliance should be able to connect to wiprep-rtu.s3-us-west-2.amazonaws.com on port 443 to obtain IP data from AWS.

Note

- NSPPE might fail with high CPU and insufficient memory due to the MEM_NETWORK and MEM_IPREPUTATION modules. These modules consume high CPU and memory. When this happens, it is recommended to test the Citrix ADC appliance by disabling IP reputation feature using the following command: disable ns feature Rep

Note

Each packet engine requires at least 4GB to function properly when IP Reputation feature is enabled.

PI Expressions. The IP Reputation feature can be configured by using PI expressions (Citrix ADC default syntax expressions) in the policies bound to supported modules such as application firewall and responder. Following are two examples showing expressions that can be used to detect whether the client IP address is malicious

1. CLIENT.IP.SRC.IPREP_IS_MALICIOUS: This expression evaluates to TRUE if the client is included in the malicious IP list.

2. CLIENT.IP.SRC.IPREP_THREAT_CATEGORY(CATEGORY): This expression evaluates to TRUE if the client IP is malicious IP and is in the specified threat category.

Following are the possible values for the threat category:

SPAM_SOURCES, WINDOWS_EXPLOITS, WEB_ATTACKS, BOTNETS, SCANNERS, DOS, REPUTATION, PHISHING, PROXY, NETWORK,
CLOUD_PROVIDERS, MOBILE_THREATS.

Note
The IP reputation feature can check both source and destination IP addresses. It can also detect malicious IPs in the header. If the PI Expression in a policy can identify the IP address, the IP reputation check can determine whether it is malicious.

IPRep log message. The /var/log/iprep.log file contains useful messages that capture information about communication with the Webroot database. The information can be about the credentials used during Webroot communication, failure to connect with Webroot, what is included in an update (such as number of IP addresses in the database), and so on.

Creating a blacklist or whitelist of IPs using policy data set. You can maintain a whitelist to allow access to specific IP addresses that are blacklisted in the Webroot database. You can also create a customized blacklist of IP addresses to supplement the Webroot reputation check. These lists can be created by using policy data set. A data set is a specialized form of pattern set that is ideally suited for IPv4 address matching. To use data sets, first create the data set and bind IPv4 addresses to it. Then, when you configure a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

To use the dataset to create a customized whitelist of addresses to treat as exceptions during IP reputation evaluation, configure the policy so that the PI expression evaluates to False even if an address in the whitelist is listed as malicious by Webroot (or any service provider).

Enabling or disabling IP reputation. IP reputation is a part of the general reputation feature, which is license based. When you enable or disable the reputation feature, it enables or disables IP Reputation.

General procedure. Deploying IP reputation involves the following tasks

- Verify that the license installed on the Citrix ADC appliance has IP reputation support. Platinum and standalone application firewall licenses support the IP reputation feature.
- Enable the IP reputation and application firewall features.
- Add an application firewall profile.
- Add an application firewall policy using the PI expressions to identify the malicious IP addresses in the IP Reputation database.
- Bind the application firewall policy to an appropriate bind point.
- Verify that any request received from a malicious address gets logged in the ns.log file to show that the request was processed as specified in the profile.

Using the Command Line to Configure the IP Reputation Feature

To enable or disable IP reputation using CLI, you can use the following commands:

- enable feature reputation
The following examples show how you can add an application firewall policy using the PI expression to identify malicious addresses. You can use the built-in profiles, or add a new profile, or configure an existing profile to invoke the desired action when a request matches a policy match.

Examples 3 and 4 show how to create a policy dataset to generate a Black (to be blocked) or White (to be allowed) list of IP addresses.

**Example 1:**
The following command creates a policy that identifies malicious IP addresses and block the request if a match is triggered:

```
add appfw policy pol1 CLIENT.IP.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
```

**Example 2:**
The following command creates a policy that uses the reputation service to check the client IP address in a specific header (X-Forwarded-For) and reset the connection if a match is triggered:

```
> add appfw policy pol1 "HTTP.REQ.HEADER("X-Forwarded-For")\.TYPECAST_IP_ADDRESS_AT .IPREP_IS_MALICIOUS\"APPFW_RESET"
```

**Example 3:**
The following example shows how to add a list to add exceptions that allow specified IP addresses:

```
> add policy dataset Allow_list ipv4
> bind policy dataset Allow_list 10.217.25.17 -index 1
> bind policy dataset Allow_list 10.217.25.18 -index 2
```

**Example 4:**
The following example shows how to add the customized list to flag specified IP addresses as malicious:

```
> add policy dataset Block_List ipv4
> bind policy dataset Block_List 10.217.31.48 -index 1
> bind policy dataset Block_List 10.217.25.19 -index 2
```

**Example 5:**
The following example shows a policy expression to block the client IP if it matches an IP address configured in the customized Block_list (example 4) or if it matches an IP address listed in the Webroot database unless relaxed by inclusion in the Allow_list (example 3).
Using Proxy server:

If the Citrix ADC appliance does not have direct access to the Internet and is connected to proxy, use the following command to configure the iprep client to send requests to the proxy.

```
set reputation settings -proxyServer <proxy server ip> -proxyPort <proxy server port>
```

**Example:**

```
> set reputation settings proxyServer 10.102.30.112 proxyPort 3128
> set reputation settings -proxyServer testproxy.citrite.net -proxyPort 3128
> unset reputation settings -proxyserver -proxyport
> sh reputation settings
```

**Note**
The Proxy Server IP can be an IP address or a fully qualified domain name (FQDN).

Using the GUI to Configure the IP Reputation Feature

To enable reputation (which enables IP reputation) feature in GUI:

Navigate to the System > Settings. In the Modes and Features section, click the link to access the Configure Advanced Features pane and enable the Reputation check box. Click OK.

To configure a proxy server by using the configuration utility:

1. On the configuration tab, navigate to Security > Reputation. Under Settings, click Change Reputation Settings to configure a proxy server. You can also enable or disable the reputation feature. Proxy Server can be an IP address or a fully qualified domain name (FQDN). Proxy port accepts values between [1 – 65535].

To use a dataset to create a whitelist (list of safe IPs) and blacklist (list of unsafe IPs) of Client IP addresses:

- On the Configuration tab, navigate to AppExpert > Data Sets.
- Click Add.
• In the **Create Data Set** (or **Configure Data set**), provide a meaningful name for the list of the IP addresses. The name should reflect the purpose of the list. For example, you could use a name such as *whitelist* or *Allow_list* when creating a list of IP addresses you would like to exempt from the action taken when the IP Reputation check determines that the source IP matches an IP address designated as a malicious IP in the webroot database. Similarly, use names such as *Block_list* or *Malicious_ip_list* if you are adding a list of IP addresses you want to flag as malicious to supplement the webroot database.

• Select **Type** as *IPv4*.
• Click **Insert** to add a new entry.

• In the Configure Policy dataset binding pane, add an IPv4 format IP address in the Value input box.
• Provide an index.
• Add a comment that explains the purpose of the list. This step is optional, but is recommended because a descriptive comment is quite helpful in managing the list.

Similarly, you can create a *Block_list* and add the IP addresses that are to be considered malicious.

Also see, **Pattern sets and data sets** for additional details regarding using data sets and configuring default syntax policy expressions.

**To configure an application firewall policy by using the configuration utility:**

1. On the **Configuration** tab, navigate to **Security > Application Firewall > Policies > Firewall**. Click **Add** to add a new policy using the PI expressions to use IP reputation.

You can also use the Expression editor to build your own policy expression. The drop-down menu shows preconfigured options that are quite useful for configuring an expression using the threat categories.

**Highlights**

• Quickly and accurately stop bad traffic at the network’s edge from known malicious IP addresses posing different types of threats. You can block the request without parsing the body.
• Dynamically configure IP reputation functionality for multiple applications.
• Secure your network against data breach without a performance penalty, and consolidate protections onto a single services fabric using fast and easy deployments.
• You can do IP Reputation checks on source as well as destination IPs.
• You can also inspect the headers to detect malicious IPs.
• IP reputation check is supported in both forward proxy and reverse proxy deployments.
• The iprep process connects with Webroot and updates the database every 5 minutes.
• Each node in the High Availability (HA) or Cluster deployment gets the database from Webroot.
• The IP reputation data is shared across all partitions in admin-partition deployments.
• You can use an AppExpert data set to create lists of IP addresses to add exceptions for IPs blacklisted in the Webroot database. You can also create your own customized blacklist to designate specific IPs as malicious.
• The iprep.db file is created in the /var/nslog/iprep folder. Once created, it is not deleted even if the feature is disabled.
• When the reputation feature is enabled, the Citrix ADC Webroot database is downloaded. After that, it is updated every 5 minutes.
• The Webroot database major version is currently version: 1.
• The minor version gets updated every day. The update version is incremented after every 5 minutes and is reset back to 1 when the minor version is incremented.
• PI expressions enable you to use IP reputation with other features, such as responder and rewrite.
• The IP addresses in the database are in decimal notation.

Debugging Tips

- If you cannot see the reputation feature in GUI, verify that you have the right license
- Monitor the messages in /var/log/iprep.log for debugging.
- **Webroot connectivity:** If you see the “ns iprep: Not able to connect/resolve WebRoot” message, make sure that the appliance has internet access and DNS is configured.
- **Proxy server:** If you see the “ns iprep: iprep_curl_download:88 curl_easy_perform failed. Error code: 5 Err msg:couldnt resolve proxy name” message, make sure that the proxy server configuration is accurate.
- **IP Reputation feature not working:** The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.
- **Database download:** If the IP DB data download is failing after enabling IP Reputation feature, the following error is seen in logs.

```
iprep: iprep_curl_download:86 curl_easy_perform failed. Error code:7 Err msg:Couldn't connect to server
```

**Solution:** Allow the out-bound traffic to the following URLs or configure a proxy to resolve the issue.

https://api.bcti.brightcloud.com (port 443)

https://wiprep-rtu.s3-us-west-2.amazonaws.com (port 443)

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration
SSL offload and acceleration

January 23, 2019
Contributed by: C

A Citrix ADC appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A Citrix ADC configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS Citrix ADC appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM).

All Citrix ADC appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect and SafeNet external HSMs. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled Citrix ADC appliance.

SSL offloading configuration

January 25, 2019
Contributed by: C
To configure SSL offloading, you must enable SSL processing on the Citrix ADC appliance and configure an SSL based virtual server that will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

**Enable SSL**

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing, but they will not work until SSL processing is enabled.

**Enable SSL processing by using the CLI**

At the command prompt, type:

1. `enable ns feature ssl`
2. `show ns feature`

**Example:**

```
1  enable ns feature SSL
2       Done
3  show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>9) SSL Offloading</td>
<td>SSL</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Done
```
**Enable SSL processing by using the GUI**

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select SSL Offloading.

**Configure services**

On the Citrix ADC appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

**Add a service by using the CLI**

At the command prompt, type the following commands to add a service and verify the configuration:

```
1 add service <name> (<IP> | <serverName>) <serviceType> <port>
2 show service <serviceName>
```

**Example:**

```
1 add service sslsvc 198.51.100.225 SSL 443
2
3 Done
4
5 sh ssl service sslsvc
6
7 Advanced SSL configuration for Back-end SSL Service sslsvc:
8   DH: DISABLED
9   DH Private-Key Exponent Size Limit: DISABLED  Ephemeral RSA: DISABLED
10   Session Reuse: ENABLED                       Timeout: 300 seconds
11   Cipher Redirect: DISABLED
12   SSLv2 Redirect: DISABLED
13   ClearText Port: 0
14   Server Auth: DISABLED
15   SSL Redirect: DISABLED
16   Non FIPS Ciphers: DISABLED
17   SNI: DISABLED
18   OCSP Stapling: DISABLED
20   Send Close-Notify: YES
21   Strict Sig-Digest Check: DISABLED
```
Modify or remove a service by using the CLI

To modify a service, use the `set service` command, which is just like using the `add service` command, except that you enter the name of an existing service. To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

Configure a service by using the GUI

Navigate to Traffic Management > Load Balancing > Services, create a service, and specify the protocol as SSL.

SSL virtual server configuration

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the Citrix ADC appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

**Note:** The SSL virtual server is marked as down on the Citrix ADC appliance until a valid certificate/key pair and at least one service are bound to it. An SSL-based virtual server is a load balancing virtual server of protocol type SSL or SSL_TCP. The load balancing feature must be enabled on the Citrix ADC appliance.

Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

```
1  add lb vserver <name> (serviceType) <IPAddress> <port>
2  show ssl vserver <name>
```
Example:

```plaintext
1 add lb vserver sslvs SSL 192.0.2.240 443
2 Done
3
4 sh ssl vserver sslvs
5
6   Advanced SSL configuration for VServer sslvs:
7   DH: DISABLED
8   DH Private-Key Exponent Size Limit: DISABLED   Ephemeral
9   RSA: ENABLED      Refresh Count: 0
10  Session Reuse: ENABLED   Timeout: 120 seconds
11  Cipher Redirect: DISABLED
12  SSLv2 Redirect: DISABLED
13  ClearText Port: 0
14  Client Auth: DISABLED
15  SSL Redirect: DISABLED
16  Non FIPS Ciphers: DISABLED
17  SNI: DISABLED
18  OCSP Stapling: DISABLED
19  HSTS: DISABLED
20  HSTS IncludeSubDomains: NO
21  HSTS Max-Age: 0
22  SSLv2: DISABLED   SSLv3: ENABLED   TLSv1.0: ENABLED   TLSv1.1: ENABLED   TLSv1.2: ENABLED   TLSv1.3: DISABLED
23  Push Encryption Trigger: Always
24  Send Close-Notify: YES
25  Strict Sig-Digest Check: DISABLED
26  Zero RTT Early Data: DISABLED
27  DHE Key Exchange With PSK: NO
28  Tickets Per Authentication Context: 1
29  ECC Curve: P_256, P_384, P_224, P_521
30
31  1) Cipher Name: DEFAULT
32      Description: Default cipher list with encryption strength >= 128bit
33
34 Done
```

**Modify or remove an SSL-based virtual server by using the CLI**

To modify the load balancing properties of an SSL virtual server, use the `set lb vserver` command, which is just like using the `add lb vserver` command, except that you enter the name of an existing vserver. To modify the SSL properties of an SSL-based virtual server, use the `set ssl vserver` command.
For more information, see the “SSL virtual server parameters” section later in this page.

To remove an SSL virtual server, use the rm lb vserver command, which accepts only the <name> argument.

**Configure an SSL-based virtual server by using the GUI**

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

**Bind services to the SSL virtual server**

For the Citrix ADC appliance to forward decrypted SSL data to servers in the network, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Because the link between the Citrix ADC appliance and the physical server is typically secure, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to-end encryption by encrypting data transfer between the appliance and the server. For details, see Configure SSL offloading with end-to-end encryption.

**Note:** The load balancing feature should be enabled on the Citrix ADC appliance before you bind services to the SSL based virtual server.

**Bind a service to a virtual server by using the CLI**

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

```
1 bind lb vserver <name> <serviceName>
2 show lb vserver <name>
```

**Example:**

```
1 bind lb vserver sslvs sslsvc
2   Done
3
4 sh lb vserver sslvs
5
6   sslvs (192.0.2.240:443) - SSL     Type: ADDRESS
7   State: DOWN[Certkey not bound]

Done

Unbind a service from a virtual server by using the CLI

At the command prompt, type the following command:

```plaintext
unbind lb vserver <name> <serviceName>
```

Example:

1 unbind lb vserver sslvs sslsvc
2 Done

Bind a service to a virtual server by using the GUI

2. Open a virtual server, and click in the Services section to bind a service to the virtual server.

Configure an SNI virtual server for secure hosting of multiple sites

Virtual hosting is used by Web servers to host more than one domain name with the same IP address. The appliance supports hosting of multiple secure domains by offloading SSL processing from the Web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple Web sites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the appliance cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling Server Name Indication (SNI) on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. The Citrix ADC appliance compares this host name to the common name and, if it does not match, compares it to the subject alternative name (SAN). If the name matches, the appliance presents the corresponding certificate to the client.

A wildcard SSL Certificate helps enable SSL encryption on multiple subdomains if the domains are controlled by the same organization and share the same second-level domain name. For example, a wildcard certificate issued to a sports network using the common name “*.sports.net” can be used to secure domains, such as “login.sports.net” and “help.sports.net” but not “login.ftp.sports.net.”

Note:
On a Citrix ADC appliance, only domain name, URL, and email ID DNS entries in the SAN field are compared.

You can bind multiple server certificates to a single SSL virtual server or transparent service using the -SNICert option. These certificates are issued by the virtual server or service if SNI is enabled on the virtual server or service. You can enable SNI at any time.

Bind multiple server certificates to a single SSL virtual server by using the CLI

At the command prompt, type the following commands to configure SNI and verify the configuration:

```
1  set ssl vserver <vServerName>@ [-SNIEnable ( ENABLED | DISABLED )]
2
3  bind ssl vserver <vServerName>@ -certkeyName <string> -SNICert
4
5  show ssl vserver <vServerName>
```

To bind multiple server certificates to a transparent service by using the CLI, replace vserver with service and vservename with servicename in the above commands.

Note: The SSL service should be created with -clearTextPort 80 option.
Bind multiple server certificates to a single SSL virtual server by using the GUI

2. Open an SSL virtual server and, in Certificates, click Server Certificate.
3. Add a new certificate or select a certificate from the list, and select Server Certificate for SNI.
4. In Advanced Settings, click SSL Parameters.
5. Select SNI Enable.

Support for SNI on the back-end service

**Note:** SNI is not supported on a DTLS back-end service.

The Citrix ADC appliance supports Server Name Indication (SNI) at the back end. That is, the common name is sent as the server name in the client hello to the back-end server for successful completion of the handshake. In addition to helping meet federal system integrator customer security requirements, this enhancement provides the advantage of using only one port instead of opening hundreds of different IP addresses and ports on a firewall.

Federal system integrator customer security requirements include support for Active Directory Federation Services (ADFS) 3.0 in 2012R2 and WAP servers. This requires supporting SNI at the back end on a Citrix ADC appliance.

**Note:**

For SNI to work, the server name in the client hello must match the host name configured on the back-end service that is bound to an SSL virtual server. For example, if the host name of the backend server is www.mail.example.com, the SNI-enabled back-end service must be configured with the server name as `https://www.mail.example.com`, and this host name must match the server name in the client hello.

Configure SNI on the back-end service by using the CLI

At the command prompt, type:

```bash
1 add service <name> <IP> <serviceType> <port>
2 add lb vserver <name> <IPAddress> <serviceType> <port>
3 bind lb vserver <name> <serviceName>
4 set ssl service <serviceName> -SNIEnable ENABLED -commonName <string>
```

Example:
Configure SNI on the back-end service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select an SSL service, and in **Advanced Settings**, select **SSL Parameters**.
3. Select **SNI Enable**.

Bind a secure monitor to an SNI-enabled back-end service

You can also bind secure monitors of type HTTP-ECV or TCP-ECV to the back-end services that support SNI. To do this, the custom header in the monitor must be set to the server name that is sent as the SNI extension in the client hello.

Configure and bind a secure monitor to an SNI-enabled back-end service by using the CLI

At the command prompt, type:

```bash
add lb monitor <monitorName> <type>
set lb monitor <monitorName> <type> -customHeaders <string>
bind service <name> -monitorName <string>
```

**Example:**

```bash
add monitor https-ecv-mon http-ecv
Done
set monitor https-ecv-mon HTTP-ECV -customHeaders "Host: example.com\n"
Done
bind service ssl_service -monitorName https-ecv
```
Configure and bind a secure monitor to an SNI-enabled back-end service by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitor**.
2. Add a monitor of type **HTTP-ECV** or **TCP-ECV**, and specify a **Custom Header**.
3. Click **Create**.
4. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
5. Select an SSL service and click **Edit**.
6. In **Monitors**, click **Add Binding**, select the monitor created in step 3, and click **Bind**.

Add or update a certificate-key pair

**Note:**

If you don’t have an existing certificate and key, see [Create a certificate](#).

To create an ECDSA certificate-key pair, click [Create an ECDSA certificate-key pair](#).

From release 12.1 build 50.x, the password of the private key used while adding an SSL certificate-key pair is now saved using a unique encryption key for each Citrix ADC appliance.

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server’s public key, which is available through the server’s certificate. Decryption requires the corresponding private key.

Because the Citrix ADC appliance offloads SSL transactions from the server, the server’s certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must then be bound to the virtual server that processes the SSL transactions.

**Note:** From release 11.0, the default certificate on a Citrix ADC appliance is 2048-bits. In earlier builds, the default certificate was 512-bits or 1024-bits. After upgrading to release 11.0, you must delete all your old certificate-key pairs starting with “ns-“, and then restart the appliance to automatically generate a 2048-bit default certificate.

Both the certificate and the key must be in local storage on the Citrix ADC appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

**Important:** Certificates and keys are stored in the /nsconfig/ssl directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the Citrix ADC appliance. The Citrix ADC FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

On a Citrix ADC MPX appliance and a Citrix ADC FIPS appliance, only RSA private keys are supported. On a VPX virtual appliance, both RSA and DSA private keys are supported. On an SDX appliance if SSL
chips are assigned to an instance, then only RSA private keys are supported. However, if SSL chips are not assigned to an instance, then both RSA and DSA private keys are supported. In all the cases, you can bind a CA certificate with either RSA or DSA keys.

Set the notification period and enable the expiry monitor to issue a prompt before the certificate expires.

The Citrix ADC appliance supports the following input formats of the certificate and the private-key files:

- PEM - Privacy Enhanced Mail
- DER - Distinguished Encoding Rule
- PFX - Personal Information Exchange

The format is automatically detected by the software. Therefore, you are no longer required to specify the format in the inform parameter. If you do specify the format (correct or incorrect), it is ignored by the software. The format of the certificate and the key file must be the same.

**Note:** A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384 (supported only on the front end)
- SHA-512 (supported only on the front end)

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

**Note**

A Citrix ADC SDX appliance supports certificates of 512 or more bits. Each Citrix ADC VPX instance hosted on the appliance supports the certificate sizes listed above for a VPX virtual appliance.
However, if an SSL chip is assigned to an instance, that instance supports the certificate sizes supported by an MPX appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

```plaintext
1  add ssl certKey <certkeyName> -cert <string>[-key <string> [-password <string>] | -fipsKey <string>] [-inform ( DER | PEM )] [-fipsKey <string>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod < positive_integer>]]
2 3
2  show ssl certKey [<<certkeyName>]
```

Example:

```plaintext
1  add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -password ssl -expiryMonitor ENABLED -notificationPeriod 30
2  Done
3  Note: For FIPS appliances, replace -key with -fipskey
4 5
5  show ssl certKey sslckey
6  Name: sslckey  Status: Valid,  Days to expiration : 8418
7  Version: 3
8  Serial Number: 01
9  Signature Algorithm: md5WithRSAEncryption
10  Issuer:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
11  Validity
12  Not Before: Jul 15 02:25:01 2005 GMT
13  Not After : Nov 30 02:25:01 2032 GMT
14  Subject:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSSL,CN=www.server.com
15  Public Key Algorithm: rsaEncryption
16  Public Key size: 2048
17  Done
```

Update or remove a certificate-key pair by using the CLI

To modify the expiry monitor or notification period in a certificate-key pair, use the set ssl certkey command. To replace the certificate or key in a certificate-key pair, use the update ssl certkey command. The update ssl certkey command has an additional parameter for overriding the domain check. For
both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the rm ssl certkey command, which accepts only the <certkeyName> argument.

Example:

```
1  set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) ]
2             [-notificationPeriod <positive_integer>] ]
3
4  update ssl certKey <certkeyName> [-cert <string> [-password]] [-key
5              <string> | -fipsKey <string>] [-inform <inform>] [-noDomainCheck

Add or update a certificate-key pair by using the GUI

Navigate to Traffic Management > SSL > Certificates, and configure a certificate-key pair.

Bind the certificate-key pair to the SSL virtual server

An SSL certificate is an integral element of the SSL encryption and decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

You can use a valid, existing SSL certificate that you have uploaded to the Citrix ADC appliance. As an alternative for testing purposes, you can create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the appliance cannot be bound to an SSL virtual server.

As a part of the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DNs) of all the certificate authorities (CAs) bound to the server from which it will accept a client certificate. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the skipCA flag. This setting indicates that the particular CA certificate’s distinguished name should not be sent to the SSL client.

For details on how to create your own certificate, see Managing Certificates.

Note: Citrix recommends that you use only valid SSL certificates that have been issued by a trusted certificate authority.
Bind an SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

```
1 - bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
2 - show ssl vserver <vServerName>
```

Example:

```
bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
Done
sh ssl vs vs1

Advanced SSL configuration for VServer vs1:

DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
IncludeSubDomains: NO
HSTS Max-Age: 0
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1: DISABLED  TLSv1.2: DISABLED

Push Encryption Trigger: Always
Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED

1) CertKey Name: cert1 CA Certificate OCSPCheck: Optional  CA_Name Sent
2) CertKey Name: cert2 CA Certificate OCSPCheck: Optional  CA_Name Skipped
1) Cipher Name: DEFAULT
Description: Default cipher list with encryption strength >= 128bit

Unbind an SSL certificate-key pair from a virtual server by using the CLI

If you try to unbind a certificate-key pair from a virtual server by using the unbind ssl certKey <certkeyName> command, an error message appears because the syntax of the command has changed. At the command prompt, type the following command:

```
unbind ssl vserver <vServerName> -certkeyName <string>
```

Example:

```
unbind ssl vserver vssl -certkeyName sslckey
```

Bind an SSL certificate-key pair to a virtual server by using the GUI

2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate or CA certificate to the virtual server. To add a server certificate as an SNI certificate, select Server Certificate for SNI.
SSL virtual server parameters

You can set the advanced SSL configuration for an SSL virtual server. Many of these parameters can also be set in an SSL profile. For information about the parameters that can be set in an SSL profile, see SSL profile parameters.

Set SSL virtual server parameters by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName>@ [-clearTextPort <port>] [-dh ( ENABLED | DISABLED ) -dhFile <string>] [-dhCount <positive_integer>] [-dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED | DISABLED )] [-eRSACount <positive_integer>] [-sessReuse ( ENABLED | DISABLED )] [-sessTimeout <positive_integer>] [-cipherRedirect ( ENABLED | DISABLED )] [-cipherURL <URL>] [-sslv2Redirect ( ENABLED | DISABLED )] [-sslv2URL <URL>] [-clientAuth ( ENABLED | DISABLED )] [-clientCert ( Mandatory | Optional )]] [-sslRedirect ( ENABLED | DISABLED )] [-redirectPortRewrite ( ENABLED | DISABLED )] [-ssl2 ( ENABLED | DISABLED )] [-ssl3 ( ENABLED | DISABLED )] [-tls1 ( ENABLED | DISABLED )] [-tls11 ( ENABLED | DISABLED )] [-tls12 ( ENABLED | DISABLED )] [-tls13 ( ENABLED | DISABLED )] [-SNIEnable ( ENABLED | DISABLED )] [-ocspStapling ( ENABLED | DISABLED )] [-pushEncTrigger <pushEncTrigger>] [-sendCloseNotify ( YES | NO )] [-dtlsProfileName <string>] [-sslProfile <string>] [-HSTS ( ENABLED | DISABLED )] [-maxage <positive_integer>] [-IncludeSubdomains ( YES | NO )] [-strictSigDigestCheck ( ENABLED | DISABLED )] [-zeroRttEarlyData ( ENABLED | DISABLED )] [-tls13SessionTicketsPerAuthContext <positive_integer>] [-dheKeyExchangeWithPsk ( YES | NO )]
```

Diffe-Hellman (DH) parameters

If you are using ciphers on the appliance that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the appliance and configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the CLI, type: sh cipher DH.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to Traffic Management > SSL > Cipher Groups, and double-click DH.

For details on how to enable DH key exchange, see Generate a Diffie-Hellman (DH) key.
Citrix ADC 12.1

Configure DH parameters by using the CLI

At the command prompt, type the following commands to configure DH parameters and verify the configuration:

```
1 - 'set ssl vserver <vservername> -dh <Option> -dhCount <RefreshCountValue> -filepath <string>
2 - show ssl vserver <vservername>'
```

Example:

```
1 set ssl vserver vs-server -dh ENABLED -dhFile /nsconfig/ssl/ns-server.cert -dhCount 1000
2 Done
3
4 show ssl vserver vs-server
5
6 Advanced SSL configuration for VServer vs-server:
7         DH: ENABLED
8       Ephemeral RSA: ENABLED Refresh Count: 1000
9     Session Reuse: ENABLED Timeout: 120 seconds
10   Cipher Redirect: DISABLED
11 SSLv2 Redirect: DISABLED
12  ClearText Port: 0
13    Client Auth: DISABLED
14   SSL Redirect: DISABLED
15  Non FIPS Ciphers: DISABLED
16      SNI: DISABLED
17    OCSP Stapling: DISABLED
18      HSTS: DISABLED
19  HSTS IncludeSubDomains: NO
20   HSTS Max-Age: 0
21 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2: ENABLED
22
23  1) Cipher Name: DEFAULT
24     Description: Predefined Cipher Alias
25 Done
```

Configure DH Parameters by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable DH Param, and specify a refresh count and file path.
Ephemeral RSA

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object and/or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the Citrix ADC appliance, with the refresh count set to zero (infinite use).

Note:
The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted but reused at a later date when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

Configure Ephemeral RSA by using the CLI

At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

```
1 set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <positive_integer>
2 show ssl vserver <vServerName>
```

Example:

```
1 set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
2 Done
3
4 show ssl vserver vs-server
5
6  Advanced SSL configuration for VServer vs-server:
7  DH: DISABLED
8  Ephemeral RSA: ENABLED Refresh Count: 1000
9  Session Reuse: ENABLED Timeout: 120 seconds
10  Cipher Redirect: DISABLED
11  SSLv2 Redirect: DISABLED
12  Cleartext Port: 0
13  Client Auth: DISABLED
14  SSL Redirect: DISABLED
15  Non FIPS Ciphers: DISABLED
16  SN1: DISABLED
17  OCSP Stapling: DISABLED
18  HSTS: DISABLED
```
Configure Ephemeral RSA by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.  
2. In the SSL Parameters section, select Enable Ephemereal RSA, and specify a refresh count.

Session reuse

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the Citrix ADC appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that can be supported by the server.

Configure session reuse by using the CLI

At the command prompt, type the following commands to configure session reuse and verify the configuration:

```
set ssl vserver <vServerName> -sessReuse ( ENABLED | DISABLED ) -sessTimeout <positive_integer>
show ssl vserver <vServerName>
```

Example:

```
set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
Done
show ssl vserver vs-ssl
Advanced SSL configuration for VServer vs-ssl:
```

**Configure session reuse by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Session Reuse, and specify a time for which to keep the session active.

**SSL protocol settings**

The Citrix ADC appliance supports the SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these can be set on the appliance as required by your deployment and the type of clients that will connect to the appliance.

TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the Citrix ADC appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that...
attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A “man in the middle” (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol, and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS_FALLBACK_SCSV) in the client request.

A TLS_FALLBACK_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. If a TLS_FALLBACK_SCSV is not included in the client hello message, or if the protocol version in the client hello is the highest protocol version supported by the virtual server, the handshake succeeds.

Configure SSL protocol support by using the CLI

At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

```
1 set ssl vserver <vServerName> -ssl2 ( ENABLED | DISABLED ) -ssl3 ( ENABLED | DISABLED ) -tls1 ( ENABLED | DISABLED ) -tls11 ( ENABLED | DISABLED ) -tls12 ( ENABLED | DISABLED )
2
3 show ssl vserver <vServerName>
```

Example:

```
1 set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
2 Done
3
4 sh ssl vs vs-ssl
5
6 Advanced SSL configuration for VServer vs-ssl:
7         DH: DISABLED
8         Ephemeral RSA: ENABLED  Refresh
9         Count: 0
10         Session Reuse: ENABLED  Timeout: 120 seconds
11         Cipher Redirect: DISABLED
12         SSLv2 Redirect: DISABLED
13         ClearText Port: 0
14         Client Auth: DISABLED
15         SSL Redirect: DISABLED
16         Non FIPS Ciphers: DISABLED
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Configure SSL protocol support by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select a protocol to enable.

Close-notify

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see the Global SSL parameters section later in this page.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unseting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

Configure close-notify at the entity level by using the CLI

At the command prompt, type any of the following commands to configure close-notify and verify the configuration:

1. To configure close-notify at the virtual server level, type:

   ```
   set ssl vserver <vServerName> -sendCloseNotify ( YES | NO )
   ```

2. To configure close-notify at the service level, type:
set ssl service <serviceName> -sendCloseNotify ( YES | NO )
show ssl service <serviceName>

3. To configure close-notify at the service group level, type:

set ssl serviceGroup <serviceGroupName> -sendCloseNotify ( YES | NO )
show ssl serviceGroup <serviceGroupName>

Example:

set ssl vserver sslvsvr -sendCloseNotify YES
Done

Configure close-notify at the entity level by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Send Close-Notify.

Global SSL parameters

Advanced customization of your SSL configuration addresses specific issues. You can use the set ssl parameter command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.
  Note: The time that you specify applies only if you use the set ssl vserver command or the configuration utility to set timer-based encryption.

Configure global SSL parameters by using the CLI

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:
set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout <positive_integer>] [-sendCloseNotify (YES | NO)] [-encryptTriggerPktCount <positive_integer>] [-denySSLReneg <denySSLReneg>] [-insertionEncoding (Unicode | UTF-8)] [-ocspCacheSize <positive_integer>] [-pushFlag <positive_integer>] [-dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <positive_integer>]

show ssl parameter

Example:

set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks no -ssltriggerTimeout 100 -sendClosenotify no -encryptTriggerPktCount 45 -denySSLReneg no -insertionEncoding unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES -pushEncTriggerTimeout 100 ms

Done

show ssl parameter

Advanced SSL Parameters
-----------------------
SSL quantum size: 8 kB
Max CRL memory size: 256 MB
Strict CA checks: NO
Encryption trigger timeout: 100 mS
Send Close-Notify: NO
Encryption trigger packet count: 45
Deny SSL Renegotiation: NO
Subject/Issuer Name Insertion Format: Unicode
OCSP cache size: 10 MB
Push flag: 0x3 (On every decrypted and encrypted record )
Strict Host Header check for SNI enabled SSL sessions: YES
PUSH encryption trigger timeout: 100 ms

Done

Configure global SSL parameters by using the GUI

Navigate to Traffic Management > SSL and, in the Settings group, select Change advanced SSL settings.
**PUSH flag based encryption trigger mechanism**

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the set ssl parameter -pushEncTriggerTimeout command.

**Configure PUSH flag-based encryption by using the CLI**

At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

```
1  set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]
2
3  show ssl vserver
```

**Example:**

```
1  set ssl vserver vserver1 -pushEncTrigger always
2
3  Done
4
5  sh ssl vserver vserver1

  Advanced SSL configuration for VServer vserver1:
  DH: DISABLED
  DH Private-Key Exponent Size Limit: DISABLED  Ephemeral RSA: ENABLED
  Refresh Count: 0
  Session Reuse: ENABLED  Timeout: 120 seconds
  Cipher Redirect: DISABLED
  SSLv2 Redirect: DISABLED
  ClearText Port: 0
  Client Auth: DISABLED
  SSL Redirect: DISABLED
  Non FIPS Ciphers: DISABLED
  SNI: DISABLED
  OCSP Stapling: DISABLED
  HSTS: DISABLED
  HSTS IncludeSubDomains: NO
  HSTS Max-Age: 0
```
Configure PUSH flag-based encryption by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual servers and open an SSL virtual server.
2. In the SSL Parameters section, from the PUSH Encryption Trigger list, select a value.

Support for TLS1.2 signature hash algorithm

The Citrix ADC appliance is completely TLS1.2 signature hash extension compliant.

In an SSL handshake, a client sends a list of supported signature hash (sighash) algorithms. The client uses the “signature_algorithms” extension to indicate to the server which sighash algorithm pairs may be used in the SSL handshake messages (SKE and CCV). The “extension_data” field of this extension contains a “supported_signature_algorithms” value in the Client Hello message. The SSL handshake proceeds if the server supports one of these sighash algorithms. If the server does not support any of these algorithms, the connection is dropped.

Similarly, if a client certificate is requested by the server for client authentication, the Certificate Request message contains a “supported_signature_algorithms” value. The client certificate is selected based on this sighash algorithm.

Note:

The Citrix ADC appliance acts as a server to a client and as a client to the back-end server.

Previously, the appliance supported only RSA-SHA1 and RSA-SHA256 on the frontend, and RSA-MD5, RSA-SHA1, and RSA-SHA256 on the backend. In addition, the VPX appliance supported DSA-SHA1 on the frontend and backend.
Now, the MPX/SDX/VPX appliance supports the following sighash combinations. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

- On a VPX instance:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
  - DSA-SHA1
  - DSA-SHA224
  - DSA-SHA256
  - DSA-SHA384
  - DSA-SHA512

- On an MPX/SDX appliance with N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
  - ECDSA-SHA1
  - ECDSA-SHA224
  - ECDSA-SHA256
  - ECDSA-SHA384
  - ECDSA-SHA512

- On an MPX/SDX appliance without N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512

By default, all the sighash algorithms are enabled. However, you can enable only a few sighash algorithms by using the following command:

```bash
set ssl parameter -sigDigestType <sigDigestType>
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
sigDigestType

Signature digest algorithms supported by the appliance. The platform determines the list of algorithms supported by default.

On VPX: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384 RSA-

SHA512 RSA-SHA1 DSA-SHA224 DSA-SHA256 DSA-SHA384 DSA-

SHA512

On MPX with N3 cards: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-

SHA256 RSA-SHA384 RSA-SHA512 ECDSA-SHA1 ECDSA-SHA224 ECDSA-

SHA256 ECDSA-SHA384 ECDSA-SHA512

Other MPX Platforms: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-

SHA256 RSA-SHA384 RSA-

SHA512.

set ssl parameter -sigDigestType RSA-SHA224 RSA-SHA256 RSA-SHA384 RSA-SHA512

Validate the peer certificate

According to RFC 5246, the peer certificate must be signed using one of the sighash algorithms included in the Client Hello extension. To do this, use the strictSigDigestCheck parameter. Depending on the sighash list sent by the client, if you enable strictSigDigestCheck, the appliance returns a certificate signed by one of the sighash algorithms mentioned in the Client Hello extension. If the peer does not have a proper certificate, the connection is dropped. If this parameter is disabled, sighash is not checked in the peer certificate.

You can configure strict signature digest check on an SSL virtual server and service. If you enable this parameter on an SSL virtual server, the server certificate sent by the server must be signed by one of the sighash algorithms listed in the Client Hello extension. If client authentication is enabled, then the client certificate received by the server must be signed using one of the sighash algorithms listed in the certificate request sent by the server.

If you enable this parameter on an SSL service, the server certificate received by the client must be signed by one of the sighash algorithms listed in the Client Hello extension. The client certificate must
be signed using one of the sighash algorithms listed in the certificate request message.

If default profile is enabled, you can use it to configure strict signature digest check on an SSL virtual server, SSL service, and SSL profile.

Configure strict signature digest check on an SSL virtual server, service, or profile by using the CLI

At the command prompt, type:

```
set ssl vserver <vServerName> -strictSigDigestCheck ( ENABLED | DISABLED )
set ssl service <serviceName> -strictSigDigestCheck ( ENABLED | DISABLED )
set ssl profile <name>-strictSigDigestCheck ( ENABLED | DISABLED )
```

Parameters

strictSigDigestCheck

Check whether peer entity certificate is signed using one of the signature-hash algorithms supported by the Citrix ADC appliance.

Possible values: ENABLED, DISABLED

Default: DISABLED

Example:

```
set ssl vserver v1 -strictSigDigestCheck Enabled
set ssl service s1 -strictSigDigestCheck Enabled
set ssl profile p1 -strictSigDigestCheck Enabled
```

Important:

If DH, ECDHE, or ECDSA ciphers are configured on the appliance, the SKE message must be signed using one of the sighash common to the client list and the list configured on the appliance. If there is no common sighash, the connection is dropped.

**TLSv1.3 protocol support as defined in RFC 8446**

March 18, 2019

Contributed by: C

The Citrix ADC VPX and Citrix ADC MPX appliances now support the TLSv1.3 protocol, specified in RFC 8446.

**Note:**

Software-only support for TLSv1.3 protocol is available on all Citrix ADC MPX appliances except Citrix ADC FIPS appliances.

To use TLS1.3, you must use a client that conforms to the RFC 8446 specification.

**Supported Citrix ADC features**

The following SSL features are supported:

1. TLSv1.3 cipher suites:
   - TLS1.3-AES256-GCM-SHA384 (0x1302)
   - TLS1.3_CHACHA20_POLY1305_SHA256 (0x1303) (supported only on VPX, and VPX instance on SDX without SSL chip assigned)
   - TLS1.3-AES128_GCM-SHA256 (0x1301)

2. ECC curves for ephemeral Diffie-Hellman key exchange:
   - P_256
   - P_384
   - P_521

3. Abbreviated handshakes when ticket-based session resumption is enabled

4. 0-RTT early application data

5. Optional or mandatory certificate-based client authentication, with support for OCSP and/or CRL validation of client certificates

6. Server name extension: server certificate selection by using SNI

7. Application protocol negotiation (ALPN) by using the application_level_protocol_negotiation extension.
8. OCSP stapling

9. Log messages and AppFlow records are produced for TLSv1.3 handshakes.

10. Optional logging of TLS 1.3 traffic secrets by the nstrace packet capture utility.

11. Interoperability with TLS clients implementing RFC 8446. For example, Mozilla Firefox, Google Chrome, and OpenSSL.

Configuration

TLSv1.3 is disabled by default on an SSL profile.

Add an SSL profile by using the CLI

At the command prompt, type:

```
add ssl profile <tls13-profile-name>
```

Example:

```
add ssl profile tls13profile
sh ssl profile tls13profile
1) Name: tls13profile (Front-End)
   SSLv3: DISABLED   TLSv1.0: ENABLED   TLSv1.1: ENABLED
   TLSv1.2: ENABLED   TLSv1.3: DISABLED
   Client Auth: DISABLED
   Use only bound CA certificates: DISABLED
   Strict CA checks: NO
   Session Reuse: ENABLED   Timeout: 120 seconds
   DH: DISABLED
   DH Private-Key Exponent Size Limit: DISABLED   Ephemeral RSA: ENABLED
   Refresh Count: 0
   Deny SSL Renegotiation: ALL
   Non FIPS Ciphers: DISABLED
   Cipher Redirect: DISABLED
   SSL Redirect: DISABLED
   Send Close-Notify: YES
   Strict Sig-Digest Check: DISABLED
   Zero RTT Early Data: DISABLED
   DHE Key Exchange With PSK: NO
   Tickets Per Authentication Context: 1
   Push Encryption Trigger: Always
   PUSH encryption trigger timeout: 1 ms
```
SSL profile parameters for TLSv1.3 protocol

1. Enable or disable TLS1.3 parameters in an SSL profile.

   **tls13**: State of TLSv1.3 protocol support for the SSL profile.

   Possible values: ENABLED, DISABLED

   Default value: DISABLED

   ```
   set ssl profile tls13profile -tls13 enable
   ```

   ```
   set ssl profile tls13profile -tls13 disable
   ```

2. Set number of session tickets issued.

   **tls13SessionTicketsPerAuthContext**: Number of tickets the SSL virtual server issues when TLS1.3 is negotiated, ticket-based resumption is enabled, and either (1) a handshake completes or (2) client authentication completes after the handshake.

   This value can be increased to enable clients to open multiple sessions.
parallel connections using a fresh ticket for each connection.
No tickets are sent if resumption is disabled.
Default value: 1
Minimum value: 1
Maximum value: 10

```
1 set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 1
2 set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 10
```

3. Set DH key exchange
dheKeyExchangeWithPsk: Specifies whether an SSL virtual server requires a DHE key exchange to occur when a pre-shared key is accepted during a TLS 1.3 session resumption handshake. A DHE key exchange ensures forward secrecy, even if ticket keys are compromised, at the expense of extra resources required to carry out the DHE key exchange.

Available settings work as follows, if session ticket is enabled:

**YES:** DHE key exchange is required when a pre-shared key is accepted, regardless of whether the client supports the key exchange. The handshake is aborted with a fatal alert, if the client does not support DHE key exchange when offering a pre-shared key.

**NO:** DHE key exchange is performed when a pre-shared key is accepted, only if requested by the client.

Possible values: YES, NO
Default value: NO

```
1 set ssl profile tls13profile dheKeyExchangeWithPsk yes
2 set ssl profile tls13profile dheKeyExchangeWithPsk no
```

4. Enable or disable 0-RTT early data acceptance
zeroRttEarlyData: State of TLS 1.3 early application data. Applicable settings work as follows:
ENABLED: Early application data might be processed before the handshake is complete.
DISABLED: Early application data is ignored.
Possible values: ENABLED, DISABLED
Default value: DISABLED

```
1 set ssl profile tls13profile -zeroRttEarlyData ENABLED
2 set ssl profile tls13profile -zeroRttEarlyData DISABLED
```
Default cipher group

The default cipher group includes TLS1.3 ciphers.

<table>
<thead>
<tr>
<th>Cipher Name</th>
<th>Priority</th>

Mac=AEAD  
HexCode=0x1301 |

Limitations

- On the Citrix ADC MPX platform, TLSv1.3 processing is not offloaded to crypto hardware.
- TLSv1.3 is not supported on the back end.
- TLSv1.3 is not supported on a Citrix Secure Web Gateway appliance and on a Citrix ADC FIPS appliance.
- This release provides limited protection against early data replay attacks when the virtual server is configured to accept early data. You can enable or disable this feature at configuration time.

Operational considerations

**TLS 1.3 draft version compatibility note:** A Citrix ADC appliance implements the RFC 8446 variant of the TLS 1.3 protocol (as opposed to earlier draft versions of the protocol). Use a TLS 1.3 client that supports RFC 8446 (or an interoperable draft # - 26, 27 or 28) to complete a TLS 1.3 handshake with a
Citrix ADC appliance. Clients and servers that implement different draft versions of the TLS 1.3 protocol might not interoperate with each other.

**Security restrictions**

TLSv1.3 server operators should keep in mind the following security restrictions for backward compatibility outlined in RFC 8446. The default configuration on a NetScaler appliance is compliant with these restrictions. However, a NetScaler appliance does not enforce that these rules are adhered to.

- The security of RC4 cipher suites is considered insufficient as described in RFC7465. Implementations must not offer or negotiate RC4 cipher suites for any version of TLS.
- Old versions of TLS allowed the use of low strength ciphers. Ciphers with a strength less than 112 bits must not be offered or negotiated for any version of TLS.
- The security of SSL 3.0 [SSLv3] is considered insufficient as described in RFC7568, and must not be negotiated. Disable SSLv3 when TLSv1.3 is enabled (SSLv3 is disabled by default.)
- The security of SSL 2.0 [SSLv2] is considered insufficient as described in RFC6176, and must not be negotiated. Disable SSLv2 when TLS 1.3 is enabled (SSLv2 is disabled by default.)
- Application data sent in 0-RTT early data is susceptible to replay attacks.

**Note:**

For information about troubleshooting protocols that run over TLS1.3, see Decrypting TLS1.3 traffic from packet trace.

SSL certificates

January 23, 2019
Contributed by: C

An SSL certificate, which is an integral part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding
private key, which resides securely on the Citrix ADC appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as VeriSign
- By generating a new SSL certificate and key on the Citrix ADC appliance

Alternately, you can use an existing SSL certificate on the appliance.

Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as VeriSign, for all your SSL transactions. Certificates generated on the Citrix ADC appliance should be used for testing purposes only, not in any live deployment.

Create a certificate

January 30, 2019
Contributed by: C

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Certificates issued or signed by a CA are automatically trusted by applications, such as web browsers, that conduct SSL transactions. These applications maintain a list of the CAs that they trust. If the certificate being used for the secure transaction is signed by any of the trusted CAs, the application proceeds with the transaction.

To obtain an SSL certificate from an authorized CA, you must create a private key, use that key to create a certificate signing request (CSR), and submit the CSR to the CA. The only special characters allowed in the file names are underscore and dot.

To import an existing certificate and key, see Import a Certificate.

Create a private key

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and should be kept securely on the Citrix ADC appliance. Any data encrypted with the public key can be decrypted only by using the private key.
The appliance supports two encryption algorithms, RSA and DSA, for creating private keys. You can submit either type of private key to the CA. The certificate that you receive from the CA is valid only with the private key that was used to create the CSR, and the key is required for adding the certificate to the Citrix ADC appliance.

**Caution:** Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.

- From release 12.1 build 49.x, you can use AES256 algorithm with PEM key format to encrypt a private key on the appliance. AES with 256-bit key is more mathematically efficient and secure compared to the 56-bit key of DES.
- From release 12.1 build 50.x, you can create an RSA or DSA key in PKCS#8 format.

All SSL certificates and keys are stored in the /nsconfig/ssl folder on the appliance. For added security, you can use the Data Encryption Standard (DES) or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

**Note:**

The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

---

### Create an RSA private key by using the CLI

At the command prompt, type:

```bash
create ssl rsakey <keyFile> <bits> [-exponent ( 3 | F4 )] [-keyform ( DER | PEM )] [-des | -des3 | -aes256] { -password } [-pkcs8]
```

**Example:**

```bash
create rsakey testkey 2048 -aes256 -password 123456 -pkcs8
```

### Create an RSA private key by using the GUI

Navigate to Traffic Management > SSL and, in the SSL Keys group, select Create RSA Key, and create an RSA key.

To select AES256 encoding algorithm in an RSA key by using the GUI:

1. Navigate to Traffic Management > SSL > SSL Files > Create RSA Key.
2. In **Key Format**, select **PEM**.
3. In **PEM Encoding Algorithm**, select **AES256**.
4. Select **PKCS8**.

**Create a DSA private key by using the CLI**

At the command prompt, type:

```bash
create ssl dsakey <keyfile> <bits> [-keyform (DER | PEM)] [-pkcs8]
```

**Example:**

```bash
create ssl dsakey Key-DSA-1 2048 -keyform PEM
```

**Create a DSA private key by using the GUI**

1. Navigate to **Traffic Management > SSL** and, in the **SSL Keys** group, select **Create DSA Key**, and create a DSA key.
2. To create a key in PKCS#8 format, select **PKCS8**.

**Support for SHA 256 digest algorithm in a certificate signing request**

The certificate signing request (CSR) is a collection of information, including the domain name, other important company details, and the private key to be used to create the certificate. To avoid generating an invalid certificate, make sure that the details you provide are accurate.

The Citrix ADC appliance supports creating a CSR signed with the SHA1 digest algorithm by default. In earlier releases, to create a CSR signed with the SHA256 digest algorithm, you had to use OpenSSL.

The appliance supports creating a CSR signed with the SHA256 digest algorithm. The encryption hash algorithm used in SHA256 makes it stronger than SHA1.

**Create a certificate signing request by using the CLI**

At the command prompt, type:

```bash
create ssl certreq <reqFile> -keyFile <input_filename> | -fipsKeyName <string>) [-keyForm (DER | PEM) { -PEMPassPhrase }
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Create a certificate signing request by using the GUI

1. Navigate to Traffic Management > SSL.
2. In SSL Certificate, click Create Certificate Signing Request (CSR).
3. In Digest Method, select SHA256.

Support for subject alternative name in a certificate signing request

The subject alternative name (SAN) field in a certificate allows you to associate multiple values, such as domain names and IP addresses, with a single certificate. In other words, you can secure multiple domains, such as www.example.com, www.example1.com, www.example2.com, with a single certificate.

Some browsers, such as Google Chrome, no longer support common name in a certificate signing request (CSR). They enforce SAN in all publicly trusted certificates.

The Citrix ADC appliance supports adding SAN values when creating a CSR. You can send a CSR with a SAN entry to a certificate authority to obtain a signed certificate with the SAN entry. When the appliance receives a request, it checks for a matching domain name in the SAN entries in the server certificate. If a match is found, it sends the certificate to the client and completes the SSL handshake.

You can use the CLI or the GUI to create a CSR with SAN values.

Note:

The Citrix ADC appliance processes only DNS based SAN values.

Create a CSR with the subject alternative name by using the CLI

```bash
create ssl certreq priv_csr_sha256 -keyfile priv_2048_2 -keyform PEM -countryName IN -stateName Karnataka -localityName Bangalore -organizationName Citrix -organizationUnitName NS -digestMethod SHA256
```
create ssl certReq <reqFile> [-keyFile <input_filename> | -fipsKeyName <string>] [-subjectAltName <string>] [-subjectAltName <string>] [keyform ( DER | PEM ) { -PEMPassPhrase } ] [-countryName <string> | -stateName <string> | -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] { -challengePassword } [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]

Parameters:

subjectAltName: The subject alternative name (SAN) is an extension to X.509 that allows various values to be associated with a security certificate using a subjectAltName field. These values are called “Subject Alternative Names” (SAN). Names include:

1. IP addresses (Prefix with “IP:” Example: IP:198.51.10.5 IP:192.0.2.100)
2. DNS names (Prefix with “DNS:” Example: DNS:www.example.com DNS:www.example.org DNS:www.example.net)

On the CLI, enter values within quotation marks. Separate two values with a space. Quotation marks are not required in the GUI.

Maximum Length: 127

Example:

create certReq test1.csr -keyFile test1.ky -countryName IN -stateName Kar -organizationName citrix -commonName ctx.com -subjectAltName "DNS:*.*.example.com DNS:www.example.org DNS:www.example.net"

Note:

On a FIPS appliance, you must replace the key file name with the FIPS key name if you create the FIPS key directly on the appliance.

create certReq <csrname> -fipsKeyName fipskey.ky -countryName IN -stateName Kar -organizationName citrix -commonName ctx.com -subjectAltName "DNS:www.example.com DNS:www.example.org DNS:www.example.net"

Create a CSR by using the GUI

1. Navigate to Traffic Management > SSL > SSL Files.
2. In the CSR tab, click Create Certificate Signing Request (CSR).
3. Enter the values and click Create.
Limitations

To use SAN when creating an SSL certificate, you must explicitly specify the SAN values. The values are not read automatically from the CSR file.

Submitting the CSR to the CA

Most CAs accept certificate submissions by email. The CA will return a valid certificate to the email address from which you submit the CSR.

Generate a test certificate

Note:

To generate a server test certificate, see Generating a Server Test Certificate.

The Citrix ADC appliance has a built-in CA tools suite that you can use to create self-signed certificates for testing purposes.

Caution: Because these certificates are signed by the Citrix ADC appliance itself, not by an actual CA, you must not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users receive a “certificate invalid” warning each time the virtual server is accessed.

The appliance supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the Citrix ADC CA Tools to generate a certificate.

Create a certificate by using a wizard

1. Navigate to Traffic Management > SSL.
2. In the details pane, under Getting Started, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.
Create a root-CA certificate by using the CLI

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>]
```

In the following example, csreq1 is the CSR and rsa1 is the private key that was created earlier.

**Example:**

```
create ssl cert cert1 csreq1 ROOT_CERT -keyFile rsa1 -keyForm PEM -days 365
```

Create an intermediate-CA certificate by using the CLI

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>]
[-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)]
[-CAkey <input_filename>] [-CAkeyForm (DER | PEM)]
[-CAserial <output_filename>]
```

In the following example, csr1 is the CSR created earlier. Cert1 and rsakey1 are the certificate and corresponding key of the self-signed (root-CA) certificate, and pvtkey1 is the private key of the intermediate-CA certificate.

**Example:**

```
create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -CAserial 23
```

Create a root-CA certificate by using the GUI

Navigate to Traffic Management > SSL and, in the Getting Started group, select Root-CA Certificate Wizard, and configure a root CA certificate.
Create an intermediate-CA certificate by using the GUI

Navigate to Traffic Management > SSL and, in the Getting Started group, select Intermediate-CA Certificate Wizard, and configure an intermediate CA certificate.

Create an end-user certificate

An end-user certificate can be a client certificate or a server certificate. To create a test end-user certificate, specify the Intermediate CA certificate or the self-signed root-CA certificate.

Note:
To create an end-user certificate for production use, specify a trusted CA certificate and send the CSR to a certificate authority (CA).

Create a test end-user certificate by using the command line interface

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM )] [-days<positive_integer>] [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm ( DER | PEM )] [-CAkey<input_filename>] [-CAkeyForm ( DER | PEM )] [-CAserial <output_filename>]
```

If there is no intermediate certificate, use the certificate (cert1) and private key (rsakey1) values of the root-CA certificate in CAcert and CAkey.

Example:
```
1 create ssl cert cert12 csr1 SRVR_CERT -CAcert cert1 -CAkey rsakey1 -CAserial 23
2
3 Done
```

If there is an intermediate certificate, use the certificate (certsy) and private key (pvtkey1) values of the intermediate certificate in CAcert and CAkey.

Example:
```
1 create ssl cert cert12 csr1 SRVR_CERT -CAcert certsy -CAkey pvtkey1 -CAserial 23
2
3 Done
```
Install, link, and update certificates

January 25, 2019
Contributed by: C

To install a certificate, see Add or update a certificate-key pair.

Link certificates

Many server certificates are signed by multiple hierarchical Certificate Authorities (CAs). This means that the certificates form a chain like the following:

Sometimes, the Intermediate CA is split into a primary and secondary intermediate CA. Then the certificates form a chain like the following:

Client machines usually contain the root CA certificate in their local certificate store, but not the intermediate CA certificate(s). The ADC appliance must send the intermediate CA certificate(s) to the clients.

**Note:** The appliance must not send the root CA certificate to the client. The Public Key Infrastructure (PKI) trust relationship model requires root CA certificates to be installed on clients through an out-of-band method (For example, the certificates are included with the operating system or web browser). The client ignores a root CA certificate sent by the appliance.

If an intermediate CA that is not recognized by standard web browsers as a trusted CA, issues the server certificate, the CA certificate(s) must be sent to the client with the server’s own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

There are two ways to add the server and intermediate certificates:

- Create a certificate set that contains the chain of certificates.
- Create a chain of certificates manually by adding and linking the certificates individually.
Add and link a certificate set

Note: This feature is not supported on the Citrix ADC FIPS platform and in a cluster setup.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file. You can specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (should be the first certificate in the file)
  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on
  Note: Intermediate certificate files are created for each intermediate certificate with the name “<certificatebundlename>.pem_ic<n>” where n is between 1 and 9. For example, bundle.pem_ic1, where bundle is the name of the certificate set and ic1 is the first intermediate certificate in the set.
- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not in placed in the file in the same order as they are created.
- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

Add a certificate set by using the CLI

At the command prompt, type the following commands to create a certificate set and verify the configuration:

```bash
1 add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES | NO)
2
3 show ssl certKey
```
In the following example, the certificate set (bundle.pem) contains the following files:

1. Server certificate (bundle) linked to bundle_ic1
2. First intermediate certificate (bundle_ic1) linked to bundle_ic2
3. Second intermediate certificate (bundle_ic2) linked to bundle_ic3
4. Third intermediate certificate (bundle_ic3)

```
add ssl certKey bundle -cert bundle.pem -key bundle.pem -bundle yes
sh ssl certkey

Add a certificate set by using the GUI

1. Navigate to Traffic Management > SSL > Certificates > CA Certificates.
2. In the details pane, click Install.
3. In the Install Certificate dialog box, type the details, such as the certificate and key file name, and then select Certificate Bundle.
4. Click Install, and then click Close.

Create a chain of certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). For this approach to work, the intermediate CA certificate file must already be installed on the Citrix ADC appliance, and the client application must trust one of the certificates in the chain. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.
**Note:** The appliance supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

### Create a certificate chain by using the CLI

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

```plaintext
1 link ssl certkey <certKeyName> <linkCertKeyName>
2 show ssl certlink
```

**Example:**

```
1 link ssl certkey siteAcertkey CAcertkey
2 Done
3
4 show ssl certlink
5
6 linked certificate:
7 1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
8 Done
```

### Create a certificate chain by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**.
2. Select a server certificate, and in the **Action** list, select **Link**, and specify a CA certificate name.

### Update an existing server certificate

To avoid downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

When you remove or unbind a certificate from a configured SSL virtual server, or an SSL service, the virtual server or service becomes inactive until a new valid certificate is bound to it. To avoid downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service, without first unbinding the existing certificate.

Overview diagram of how to update an SSL certificate on the Citrix ADC appliance.
Update an existing certificate-key pair by using the CLI

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

```
1. update ssl certkey <certkeyName> -cert <string> -key <string>
2. show ssl certKey <certkeyName>
```

Example:

```
1. update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /nsconfig/ssl/pkey.pem
2. Done
3. show ssl certkey siteAcertkey
4. Name: siteAcertkey  Status: Valid
   Version: 3
   Serial Number: 02
   Signature Algorithm: md5WithRSAEncryption
   Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
   Validity
   Not Before: Nov 11 14:58:18 2001 GMT
   Not After: Aug 7 14:58:18 2004 GMT
   Subject: /C=US/ST=CA/L=San Jose/O=CA/OU=Security
   Public Key Algorithm: rsaEncryption
   Public Key size: 2048
5. Done
```

Update an existing certificate-key pair by using the GUI

1. Navigate to Traffic Management > SSL > Certificates > Server Certificates.
2. Select the certificate that you want to update, and click Update.
3. Select Update the certificate and key.
4. In Certificate File Name, click Choose File > Local, and browse to the updated .pfx file or certificate PEM file.
• If you upload a .pfx file, you are prompted to specify the .pfx file password.

• If you upload a certificate pem file, you must also upload a certificate key file. If the key is encrypted, you must specify the encryption password.

5. If the common name of the new certificate does not match the old certificate, then select **No Domain Check**.

6. Click **OK**. All the SSL virtual servers to which this certificate is bound are automatically updated.

7. After replacing the certificate, you might have to update the certificate link to a new intermediate certificate. For more information about updating an intermediate certificate without breaking the links, see Update an intermediate certificate without breaking the links.

   • Right-click the updated certificate, and click **Cert Links**, to see if it is linked to an intermediate certificate.

   • If the certificate is not linked, then right-click the updated certificate, and click **Link** to link it to an intermediate certificate. If you don’t see an option to link, then you must first have to install a new intermediate certificate on the appliance under the **CA Certificates** node.

### Update an existing CA certificate

The steps to update an existing CA certificate are the same as updating an existing server certificate. The only difference is that you do not need a key in the case of CA certificates.

### Disable domain checks

When an SSL certificate is replaced on the appliance, the domain name mentioned on the new certificate should match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to now host a new domain, you can disable the domain check before updating its certificate.

### Disable the domain check for a certificate by using the CLI

At the command prompt, type the following commands to disable the domain check and verify the configuration:

```
1 update ssl certKey <certkeyName> -noDomainCheck
2
```
Disable the domain check for a certificate by using the GUI

1. Navigate to Traffic Management > SSL > Certificates, select a certificate, and click Update.
2. Select No Domain Check.

Enable the expiry monitor

An SSL certificate is valid for a specific period. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the appliance creates entries in the appliance's syslog and ns audit logs when a certificate configured is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

Enable an expiry monitor for a certificate by using the CLI

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

```
set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]]
show ssl certKey <certkeyName>
```
Example:

```
1 set ssl certKey sv -expiryMonitor ENABLED -notificationPeriod 60
2 Done
```

Enable an expiry monitor for a certificate by using the GUI

1. Navigate to Traffic Management > SSL > Certificates, select a certificate, and click Update.
2. Select Notify When Expires, and optionally specify a notification period.

Update an intermediate certificate without breaking the links

You can now update an intermediate certificate without breaking any existing links. You can do this if the optional ‘AuthorityKeyIdentifier’ extension, in the linked certificate issued by the certificate to be replaced, does not contain an authority certificate serial number (‘authorityCertSerialNumber’) field. If the ‘AuthorityKeyIdentifier’ extension contains a serial number field, then the certificate serial numbers of the old and new certificate must be the same. You can update any number of certificates in the link, one at a time, if the preceding condition is met. Previously, the links broke if an intermediate certificate was updated.

For example, there are four certificates: CertA, CertB, CertC, and CertD. CertA is the issuer for CertB, CertB is the issuer for CertC, and so on. To replace intermediate certificate CertB with CertB_new, without breaking the link, the following condition must be met:

The certificate serial number of CertB should match the certificate serial number of CertB_new if both of the following conditions are met:

- The AuthorityKeyIdentifier extension is present in CertC.
- This extension contains a serial number field.

If the common name in a certificate changes, while updating the certificate specify nodomaincheck.

In the preceding example, to change “www.example.com” in CertD to “*.example.com”, select the ‘No Domain Check” parameter.

Update the certificate by using the CLI

At the command prompt, type:

```
1 update ssl certKey <certkeyName> -cert <string> [-password] -key <string> [-noDomainCheck]
```

Example:
Display a certificate chain

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain until you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the appliance presents a certificate and the chain of issuer certificates that are present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

View the certificate chain for the certificates present on the appliance by using the CLI

At the command prompt, type:

```
1 show ssl certchain <cert_name>
```

Examples

There are 3 certificates: c1, c2, and c3. Certificate c1 is signed by c2, c2 is signed by c3, and c3 is the root CA certificate. The following examples illustrate the output of the `show ssl certchain c1` command in different scenarios.

Scenario 1:

Certificate c2 is linked to c1, and c3 is linked to c2.

Certificate c3 is a root CA certificate.

If you run the following command, the certificate links up to the root CA certificate are displayed.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4  1) Certificate name: c2 linked; not a root certificate
5  2) Certificate name: c3 linked; root certificate
6 Done
```
Scenario 2:

Certificate c2 is linked to c1.

Certificate c2 is not a root CA certificate.

If you run the following command, information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4  1) Certificate Name: c2 linked; not a root certificate
5  2) Certificate Name: c3 not linked; root certificate
6 Done
```

Scenario 3:

Certificate c1, c2, and c3 are not linked but are present on the appliance.

If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed and it is specified that the certificates are not linked.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4  1) Certificate Name: c2 not linked; not a root certificate
5  2) Certificate Name: c3 not linked; root certificate
6 Done
```

Scenario 4:

Certificate c2 is linked to c1.

Certificate c3 is not present on the appliance.

If you run the following command, information about the certificate linked to c1 is displayed and you are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4  1) Certificate Name: c2 linked; not a root certificate
6
```
Scenario 5:
A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.
If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

```
sh ssl certchain c1
```

Certificate chain details of certificate name c1 are:

```
1) Certificate Name: /ST=KA/C=IN
   Action: Add a certificate with this subject name.
```

Generate a server test certificate

January 23, 2019
Contributed by: C

The Citrix ADC appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. A server certificate is generally issued by a trusted CA and is sent out by the server to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a CA. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. It should not be used in a production environment.

You can install the server test certificate on any virtual server that uses the SSL or the SSL_TCP protocol.
Generate a server test certificate by using the GUI

Navigate to Traffic Management > SSL and, in the SSL Certificates group, select Create and Install a Server Test Certificate.

1.
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

Import and convert SSL files

January 25, 2019
Contributed by: C

You can now import SSL resources, such as certificates, private keys, CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in /nsconfig/ssl as follows:

- For certificate files: /nsconfig/ssl/certfile
- For private keys: the /nsconfig/ssl/keyfile
- For CRLs: /var/netscaler/ssl/crlfile
- For DH keys: /nsconfig/ssl/dhfile

Imports from both HTTP and HTTPS servers are supported. However, the import fails if the file is on an HTTPS server that requires client certificate authentication for access.

Note:
The import command is not stored in the configuration (ns.conf) file, because reimporting the file after a restart might cause an error.

Import a certificate file

You can use the CLI and GUI to import a file (resource) from a remote host.

Import a certificate file from a remote host by using the CLI

At the command prompt, type:
**Import a certificate file from a remote host by using the CLI**

At the command prompt, type:

```
import ssl certFile [name] [src]
```

**Example:**

```
import ssl certfile my-certfile http://www.example.com/file_1
```

To remove a certificate file, use the `rm ssl certFile` command, which accepts only the `name` argument.

**Import a key file from a remote host by using the CLI**

At the command prompt, type:

```
import ssl keyFile [name] [src]
```

**Example:**

```
import ssl keyfile my-keyfile http://www.example.com/key_file
```

To remove a key file, use the `rm ssl keyFile` command, which accepts only the `name` argument.

**Import a CRL file from a remote host by using the CLI**

At the command prompt, type:

```
import ssl crlFile [name] [src]
```

To remove a CRL file, use the `rm ssl crlFile` command, which accepts only the `<name>` argument.

**Example:**

```
import ssl crlfile my-crlfile http://www.example.com/crl_file
```
Import a DH file from a remote host by using the CLI

At the command prompt, type:

```
import ssl dhFile [<name>] [<src>]
```

Example:

```
import ssl dhfile my-dhfile http://www.example.com/dh_file
show ssl dhfile
  Name : my-dhfile
  URL : http://www.example.com/dh_file
```

To remove a DH file, use the rm ssl dhFile command, which accepts only the <name> argument.

Import an SSL resource by using the GUI

Navigate to Traffic Management > SSL > Imports, and then select the appropriate tab.

Import PKCS#8 and PKCS#12 certificates

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the Citrix ADC appliance. You might have to convert exported certificates and keys before you can import them to the Citrix ADC appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

**Note:**

For installation on the Citrix ADC appliance, key and certificate names cannot contain spaces or special characters other than those supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.

A certificate and private key pair is commonly sent in the PKCS#12 format. The appliance supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see the “Convert SSL certificates for import or export” section later in this page.

The Citrix ADC appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the CLI.
or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
leuSSZQZKgrgUQ==
-----END ENCRYPTED PRIVATE KEY-----
```

**Open the OpenSSL interface from the CLI**

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type `shell`.
4. At the shell prompt type `openssl`.

**Open the OpenSSL interface from the GUI**

Navigate to Traffic Management > SSL and, in the Tools group, select OpenSSL interface.

**Convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface**

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type rsa or dsa:

```
1 OpenSSL> rsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>
2
3 OpenSSL> dsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>
```

**Parameters for converting an unsupported key format to a supported key format**

- **PKCS#8 Key Filename**: The input file name of the incompatible PKCS#8 private key.
- **encrypted Key Filename**: The output file name of the compatible encrypted private key in PEM format.
- **unencrypted Key Filename**: The output file name of the compatible unencrypted private key in PEM format.

**Convert SSL certificates for import or export**

A Citrix ADC appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The Citrix ADC appliance can convert the PKCS#12 format (the personal information exchange syntax standard) to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For additional security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

**Note:**

If you use the GUI to import a PKCS#12 certificate, and the password contains a dollar sign ($), backquote (’), or escape (\) character, the import may fail. If it does, the ERROR: Invalid password message appears. If you must use a special character in the password, be sure to prefix it with an escape character (\) unless all imports are performed by using the CLI.

**Convert the format of a certificate by using the CLI**

At the command prompt, type the following command:

```bash
```

During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.

**Example:**

1. `convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.pfx -des`
2. `convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -keyFile Key-Client-1`
Convert the format of a certificate by using the GUI

1. Navigate to Traffic Management > SSL and, in the Tools group, select Import PKCS#12.
2. Specify the PEM certificate name in the Output File Name field.
3. Browse to the location of the PFX certificate on your local computer or the appliance.
4. Click OK.
5. Click Manage Certificates / Keys / CSRs to view the converted PEM file.
6. You can view the uploaded PFX file and the converted PEM file.
7. Navigate to SSL > Certificates > Server Certificates and click Install.
8. Specify a Certificate-Key Pair Name.
9. Browse to the location of the PEM file.
10. Specify the password when prompted.
11. Click Install.
12. Bind the certificate-key pair to an SSL virtual server.

SSS profiles

January 23, 2019
Contributed by: C

An SSL profile is a collection of settings for SSL entities. It offers ease of configuration and flexibility. Instead of configuring the settings on each entity, you can configure them in a profile and bind the profile to all the entities that the settings apply to.

The SSL profile infrastructure has been enhanced to use the latest ciphers and protocols. Differences between the legacy profile (old profile) and the enhanced SSL profile (new profile) are highlighted.

Differences between the old and the new SSL profile infrastructure
<table>
<thead>
<tr>
<th>Differences</th>
<th>Old Profile</th>
<th>New Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ciphers and ECC Curves included in the profile</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Inserting a cipher or cipher group in the middle of an existing list</td>
<td>Unbind all the ciphers and bind again in the order of the required priority.</td>
<td>Add a cipher and assign it a priority. If a priority is not specified, the cipher is assigned the lowest priority in the list.</td>
</tr>
<tr>
<td>Unbinding all the ciphers</td>
<td>&gt; unbind ssl vserver &lt;name&gt; ciphername –ALL</td>
<td>unbind ssl profile –cipherName FlushAllCiphers (Release 11.0 build 64.x or later includes the FlushAllCiphers parameter for unbinding all the ciphers or cipher groups from a profile, because ALL is treated like a cipher group.)</td>
</tr>
<tr>
<td>State of SSLv3</td>
<td>n/a</td>
<td>Disabled on the default front-end profile (ns_default_ssl_profile_frontend). Note: Before you enable this profile, SSLv3 is enabled globally. After enabling the profile, SSLv3 is disabled on the front-end default profile.</td>
</tr>
</tbody>
</table>

**SSL profile infrastructure**

January 25, 2019
Contributed by: C
Vulnerabilities in SSLv3 and RC4 implementation have emphasized the need to use the latest ciphers and protocols to negotiate the security settings for a network connection. Implementing any changes to the configuration, such as disabling SSLv3 across thousands of SSL end points, is a cumbersome process. Therefore, settings that were part of the SSL end points configuration have been moved to the SSL profiles, along with the default ciphers. To implement changes in the configuration, including cipher support, you need only modify the profile that is bound to the entities.

The default SSL profiles (default front-end and default back-end) contain all the default ciphers and ECC curves, in addition to the settings that were part of the old profiles. Sample outputs for the default profiles are provided in the appendix. The Enable Default Profile operation automatically binds the default front-end profile to all front-end entities, and the default back-end profile to all back-end entities. You can modify a default profile to suit your deployment. You can also create custom profiles and bind them to SSL entities.

**Important:**

After the upgrade, if you enable the default profiles, you cannot undo the changes. That is, the profiles cannot be disabled. Save the configuration and create a copy of the configuration file (ns.conf) before enabling the profiles. However, if you do not wish to use the features in the default profile, you can continue to use the old SSL profiles. For more information about these profiles, see Legacy SSL profile.

From release 11.1 51.x, in the GUI and CLI, a confirmation prompt is added when you enable the default profile so that it is not enabled by mistake.

**Command:**

1. `set ssl parameter -defaultProfile ENABLED`
2. Save your configuration before enabling the Default profile. You cannot undo the changes. Are you sure you want to enable the Default profile? [Y/N]Y
3. Done

**Note:**

However, if you are using a script, you can bypass the prompt by adding the following command to your script:

1. `set ssl parameter -defaultProfile ENABLED -force`

By default, some SSL parameters, called *global parameters*, apply to all the SSL end points. However, if a profile is bound to an SSL end point, the global parameters do not apply. The settings specified in the profile apply instead.
Points to note

1. A profile can be bound to multiple virtual servers, but a virtual server can have only one profile bound to it.
2. You cannot delete a profile that is bound to a virtual server without first unbinding the profile.
3. A cipher or cipher group can be bound to multiple profiles at different priorities.
4. A profile can have multiple ciphers and cipher groups bound at different priorities.
5. Changes to a cipher group are immediately reflected in all the profiles and in all the virtual servers that one of the profiles is bound to.
6. If a cipher suite is part of a cipher group, you cannot remove the cipher suite from the profile without first editing the cipher group to remove the specific cipher suite.
7. If you do not assign a priority to a cipher suite or cipher group that you attach to a profile, it is assigned the lowest priority within the profile.
8. You can create a custom cipher group (also called a user-defined cipher group) from existing cipher groups and cipher suites. If you create cipher group A and add existing cipher groups X and Y to it, in that order, cipher group Y is assigned at a lower priority than cipher group X. That is, the group that is added first has a higher priority.
9. If a cipher suite is already part of a cipher group that is attached to a profile, and the same cipher suite is part of another cipher group that is also attached to the same profile, the cipher suite is not added again as part of the second cipher group. The cipher suite at the higher priority is in effect when traffic is processed.
10. Cipher groups are not expanded in the profile. As a result, the number of lines in the configuration file (ns.conf) is greatly reduced. For example, if there are a thousand SSL virtual servers to which two cipher groups are bound, and each cipher group contains 15 ciphers, expansion would result in 30*1000 entries related to ciphers in the configuration file. With the new profile, it would have only two entries: one for each cipher group that is bound to a profile.
11. Creating a user defined cipher group from existing ciphers and cipher groups is a copy-paste operation. Any changes in the original group are not reflected in the new group.
12. A user-defined cipher group lists all the profiles that it is a part of.
13. A profile lists all the SSL virtual server, services, and service groups that it is bound to.
14. If the default SSL profile feature is enabled, you must use the profile to set or change any of the attributes of a virtual server, service, service group, or an internal service.

Enable the default profile

Important:

Save your configuration before you upgrade the software and enable the default profiles.

From release 11.1 build 51.x, in the GUI and CLI, a confirmation prompt appears when you enable
the default profile so that it is not enabled by mistake.

Command:

1. set ssl parameter -defaultProfile ENABLED
2. Save your configuration before enabling the Default profile. You cannot undo the changes. Are you sure you want to enable the Default profile? [Y/N] Y
3. Done

Note:
However, if you are using a script, you can bypass the prompt by adding the following command to your script:

1. set ssl parameter -defaultProfile ENABLED -force

Upgrade the software to a build that supports the enhanced profile infrastructure, and then enable the default profiles. You can take one of two approaches depending on your specific deployment. If your deployment has a common SSL configuration across end points, see Use Case 1. If your deployment has a large SSL configuration and the SSL parameters and ciphers are not common among end points, see Use Case 2.

Note:
A single operation (Enable Default Profile or set ssl parameter -defaultProfile ENABLED) enables (binds) both the default front-end profile and the default back-end profile.

Save the configuration by using the CLI

At the command prompt, type:

1. save config
2. shell
3. root@ns# cd /nsconfig
4. root@ns# cp ns.conf ns.conf.NS<currentreleasenumber><currentbuildnumber>

Example:

1. save config
2. shell
3. root@ns# cd /nsconfig
Use case 1

After you enable the default profiles, they are bound to all the SSL end points. The default profiles are editable. If your deployment uses most of the default settings and changes only a few parameters, you can edit the default profiles. The changes are immediately reflected across all the end points.

The following flowchart explains the steps that you must perform:

1. For information about upgrading the software, see Upgrading the System Software.
2. Enable the default profiles by using the CLI or GUI.
   - At the command line, type: `set ssl parameter -defaultProfile ENABLED`
   - If you prefer to use the GUI, navigate to Traffic Management > SSL > Change advanced SSL settings, scroll down, and select Enable Default Profile.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

3. (Optional) Manually change any settings in the default profile.
   - At the command line, type: `set ssl profile <name>` followed by the parameters to modify.
   - If you prefer to use the GUI, navigate to System > Profiles. In SSL Profiles, select a profile and click Edit.

Use Case 2

If your deployment uses specific settings for most of the SSL entities, you can run a script that automatically creates custom profiles for each end point and binds them to the end point. Use the procedure detailed in this section to retain the SSL settings for all the SSL end points in your deployment. After upgrading the software, download and run a migration script to capture the SSL-specific changes. The output of running this script is a batch file. Enable the default profiles and then apply the commands in the batch file. See the appendix for a sample migration of the SSL configuration after upgrade.

The following flowchart explains the steps that you must perform:

1. For information about upgrading the software, see Upgrading the System Software.
2. Download and run a script to capture the SSL-specific changes. In addition to other migration activities, the script analyzes the old ns.conf file and moves any special settings (settings other than the default) from an SSL end point configuration to a custom profile. You must enable the default profiles after the upgrade for the configuration changes to apply.
To download the script, log on to https://www.citrix.com/. On the Downloads tab, select Citrix ADC, and then select the release (for example, Release 12.0). Within the release, in Firmware, select a build (for example, 41.16). The SSL Default Profile Script is available in Additional Components.

Note:
When running the migration script, you can choose to automatically generate the profile names, or you can prompt the user for the profile names interactively. The migration script checks the following and creates profiles accordingly.

- End points with the default settings and similar ciphers and cipher group settings: The script creates one profile.
- End points with the default settings and with different cipher groups or different priorities for the ciphers/cipher groups: In each case, the script creates a user-defined cipher group, binds it to a profile, and binds each profile to the appropriate end points.
- End points with the default settings and default ciphers: A default profile is bound to the end point.

To run the script, at the command prompt, type:

```
1 ./default_profile_script /nsconfig/ns.conf -b > <output file name>
```

Note:
You must run this command from the folder in which you store the script.

3. Enable the default profiles by using the CLI or GUI.

- At the command line, type: `set ssl parameter -defaultProfile ENABLED`
- If you prefer to use the GUI, navigate to Traffic Management > SSL > Change advanced SSL settings, scroll down, and select Enable Default Profile.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

4. Apply the commands in the text file (output of running the migration script) to the configuration. After you apply the commands in the text file, custom profiles are created for end points for which default parameters and ciphers have been changed, and the custom profiles are automatically bound to the end points.

**SSL profile parameters**

You can set the following SSL parameters in an SSL profile. You can set some of these parameters in an SSL virtual server. For more information about SSL virtual server parameters, see SSL virtual server parameters.
Set SSL profile parameters by using the CLI

At the command prompt, type:

```plaintext
set ssl profile <name> [-ssllogProfile <string>] [-dh ( ENABLED | DISABLED ) -dhFile <string>] [-dhCount <positive_integer>] [-dhKeyExpSizeLimit ( ENABLED | DISABLED )] [-eRSA ( ENABLED | DISABLED )] [-sessReuse ( ENABLED | DISABLED )] [-ssl3 ( ENABLED | DISABLED )] [-tls1 ( ENABLED | DISABLED )] [-tls11 ( ENABLED | DISABLED )] [-tls12 ( ENABLED | DISABLED )] [-tls13 ( ENABLED | DISABLED )] [-SNIEnable ( ENABLED | DISABLED )] [-ocspStapling ( ENABLED | DISABLED )] [-serverAuth ( ENABLED | DISABLED )] [-commonName <string>] [-pushEncTrigger <pushEncTrigger>] [-sendCloseNotify ( YES | NO )] [-clearTextPort <port[*]>] [-insertionEncoding ( Unicode | UTF-8 )] [-denySSLReneg <denySSLReneg>] [-quantumSize <quantumSize>] [-strictCAChecks ( YES | NO )] [-encryptTriggerPktCount <positive_integer>] [-dropReqWithNoHostHeader ( YES | NO )] [-pushEncTriggerTimeout <positive_integer>] [-sslTriggerTimeout <positive_integer>] [-clientAuthUseBoundCAChain ( ENABLED | DISABLED )] [-sslInterception ( ENABLED | DISABLED )] [-sslReneg ( ENABLED | DISABLED )] [-sslOCSPCheck ( ENABLED | DISABLED )] [-sslMaxSessPerServer <positive_integer>] [-HSTS ( ENABLED | DISABLED )] [-maxage <positive_integer>] [-IncludeSubdomains ( YES | NO )] [-sessionTicket ( ENABLED | DISABLED )] [-sessionTicketLifeTime <positive_integer>] [-sessionTicketKeyRefresh ( ENABLED | DISABLED )] { -sessionTicketKeyData }
```
TLS session ticket extension

An SSL handshake is a CPU-intensive operation. If session reuse is enabled, the server/client key exchange operation is skipped for existing clients. They are allowed to resume their sessions. This improves the response time and increases the number of SSL transactions per second that a server can support. However, the server must store details of each session state, which consumes memory and is difficult to share among multiple servers if requests are load balanced across servers.

Citrix ADC appliances support the SessionTicket TLS extension. Use of this extension indicates that the session details are stored on the client instead of on the server. The client must indicate that it supports this mechanism by including the session ticket TLS extension in the client Hello message. For new clients, this extension is empty. The server sends a new session ticket in the NewSessionTicket handshake message. The session ticket is encrypted by using a key-pair known only to the server. If a server cannot issue a new ticket at this time, it completes a regular handshake.

This feature is available only in front-end SSL profiles, and only at the front end of communication in which the Citrix ADC appliance acts as a server and generates session tickets.

Limitations

- This feature is not supported on a FIPS platform.
- This feature is supported only with TLS versions 1.1 and 1.2.
- SSL session ID persistency is not supported with session tickets.

Enable TLS session ticket extension by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket (ENABLED | DISABLED ) [-
  sessionTicketLifeTime <positive_integer>]
```

Arguments:
**sessionTicket**: State of TLS session ticket extension. Use of this extension indicates that the session details are stored on the client instead of on the server, as defined in RFC 5077.

Possible values: ENABLED, DISABLED

Default value: DISABLED

**sessionTicketLifeTime**: Specify a time, in seconds, after which the session ticket expires and a new SSL handshake must be initiated.

Default value: 300

Minimum value: 0

Maximum value: 172800

**Example:**

```
1 add ssl profile profile1 -sessionTicket ENABLED -sessionTicketlifeTime 300
2 Done
```

**Enable TLS session ticket extension by using the GUI**

1. Navigate to **System > Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. Select **Session ticket**.
4. Optionally, specify **Session Ticket Lifetime (secs)**.

**Secure implementation of session tickets**

By using TLS session tickets, clients can use abbreviated handshakes for faster reconnection to servers. However, if session tickets aren’t encrypted or changed for long periods of time, they can pose a security risk. You can secure session tickets by encrypting them with a symmetric key. To achieve forward secrecy, you can specify a time interval at which the session-ticket key is refreshed.

Session ticket keys are generated by the appliance by default. However, if multiple appliances in a deployment need to decrypt each other’s session tickets, they must all use the same session-ticket key. Therefore, you must set (add or load) the same session-ticket key data manually on all the appliances.

Session-ticket key data includes the following information:

- Session ticket name.
- Session AES key used to encrypt or decrypt the ticket.
- Session HMAC key used to compute the digest of the ticket.

You can now configure session ticket key data of length 64 bytes to support 256-bit HMAC keys as recommended in RFC 5077. Key lengths of 48 bytes are also supported for backward compatibility.
Note:
If you are typing the session-ticket key data manually, ensure that the configuration across all the Citrix ADC appliances in an HA setup or in a cluster setup is the same.

The sessionTicketKeyLifeTime parameter specifies how often a session-ticket key is refreshed. In addition, you can set the prevSessionTicketKeyLifeTime parameter to specify how long the previous session-ticket key will be maintained for decrypting tickets using that key, after a new key is generated. The prevSessionTicketKeyLifeTime setting extends the time for which a client can use an abbreviated handshake to reconnect. For example, if sessionTicketKeyLifeTime is set to 10 minutes and prevSessionTicketKeyLifeTime to 5 minutes, a new key is generated after 10 minutes and used for all new sessions. However, previously connected clients have another 5 minutes for which previously issued tickets will be honored for an abbreviated handshake.

Configure SSL session-ticket data by using the CLI

At the command prompt, type:

```
set ssl profile <name> -sessionTicket ENABLED -sessionTicketLifeTime <positive_integer> -sessionTicketKeyRefresh ( ENABLED | DISABLED )] -sessionTicketKeyLifeTime <positive_integer> [prevSessionTicketKeyLifeTime <positive_integer>]
```

Arguments:

**sessionTicket**: Use session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

**sessionTicketLifeTime**: Lifetime, in seconds, of the session ticket. After this time expires, clients cannot use this ticket to resume their sessions.

**sessionTicketKeyRefresh**: When the time specified by the session-ticket key lifetime parameter expires, regenerate the session-ticket key used to encrypt or decrypt the session tickets. Automatically enabled if sessionTicket is enabled. Disabled if the session-ticket data is entered by an administrator.

Possible values: ENABLED, DISABLED. Default: ENABLED

**sessionIdKeyLifeTime**: Lifetime, in seconds, of a symmetric key used to encrypt the session tickets issued by a Citrix ADC appliance.

**prevSessionKeyLifeTime**: Time, in seconds, for which the previous symmetric key used to encrypt session tickets remains valid for existing clients after the session-ticket key lifetime expires. Within this time, existing clients can resume their sessions by using the previous session ticket key. Session tickets for new clients are encrypted by using the new key.

Maximum value: 172800. Minimum value: 0. Default: 0

**Example:**

```
1  set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED
2     -sessionTicketlifeTime 120 -sessionTicketKeyRefresh ENABLED -
3     sessionTicketKeyLifeTime 100 -prevSessionTicketKeyLifeTime 60

Done

5  show ssl profile ns_default_ssl_profile_frontend

7    Session Ticket: ENABLED
8    Session Ticket Lifetime: 120 (secs)
9    Session Key Auto Refresh: ENABLED
10   Session Key Lifetime: 100 (secs)
11   Previous Session Key Lifetime: 60 (secs)
```

**Configure SSL session-ticket data by using the GUI**

1. Navigate to **System > Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. In the **Basic Settings** section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Lifetime (secs)
   - Session Ticket Key Auto Refresh
   - Session Ticket Key Lifetime (secs)
   - Previous Session Ticket Key Lifetime (secs)
4. Click **OK**.

**Type SSL session ticket data manually by using the CLI**

At the command prompt, type:

```
1  set ssl profile <name> -sessionTicket ENABLED
2
3  set ssl profile <name> -sessionTicketKeyData
```
show ssl profile ns_default_ssl_profile_frontend

**Arguments:**

**sessionTicket**: Use of session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

**sessionTicketKeyData**: Contains the session ticket name (0-15 bytes), the session AES key used to encrypt or decrypt the session ticket (16-31 bytes), and the session HMAC key used to compute the digest of the ticket (32-63 bytes). Externally generated by an administrator and added to a Citrix ADC appliance.

Maximum length: 64 bytes

**Example:**

```bash
1  set ssl profile ns_default_ssl_profile_frontend -sessionticket ENABLED
2  Done
4
5  set ssl profile ns_default_ssl_profile_frontend -sessionticketkey
111111111111111111111111111111111111111111111111111111111111
6  Done
9
10  show ssl profile ns_default_ssl_profile_frontend
11   1) Name: ns_default_ssl_profile_frontend (Front-End)
12   SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED
13   Client Auth: DISABLED
14   Use only bound CA certificates: DISABLED
15   Strict CA checks: NO
16   Session Reuse: ENABLED Timeout: 120 seconds
17   DH: DISABLED
18   DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA: ENABLED
19   Refresh Count: 0
20   Deny SSL Renegotiation ALL
21   Non FIPS Ciphers: DISABLED
22   Cipher Redirect: DISABLED
23   SSL Redirect: DISABLED
24   Send Close-Notify: YES
25   Push Encryption Trigger: Always
26   PUSH encryption trigger timeout: 1 ms
```
Type SSL session ticket data manually by using the GUI

1. Navigate to **System > Profiles**, and select **SSL Profile**.

2. Select **ns_default_ssl_profile_frontend** and click **Edit**.

3. In the **Basic Settings** section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Key Data
Load an old configuration

Enabling the default profiles is not reversible. However, if you decide that your deployment does not require the default profiles, you can load an older configuration that you saved before you enabled the default profiles. The changes are effective after you restart the appliance.

Load an old configuration by using the CLI

At the command prompt, type:

```bash
1 shell
2 root@ns# clear config
3 root@ns# cd /nsconfig
4 root@ns# cp ns.conf NS.11.0.jun.16 ns.conf
5 root@ns# reboot
```

Secure front-end profile

In addition to a default front-end and a default back-end profile, a new default secure front-end profile is available from release 12.1. The settings required for an A+ rating (as of May 2018) from Qualys SSL Labs are preloaded into this profile. Earlier, you had to explicitly set each of the parameters required for an A+ rating on an SSL front-end profile or an SSL virtual server. Now you can bind the
ns_default_ssl_profile_secure_frontend profile to your SSL virtual server and the required parameters are automatically set on your SSL virtual server.

**Note:**
The secure front-end profile is not editable.

When you enable the default profile, the default front-end profile is automatically bound to all the SSL virtual servers. To get an A+ rating, you must explicitly bind the ns_default_ssl_profile_secure_frontend profile and also bind an SHA2/SHA256 server certificate to your SSL virtual server.

**Secure front-end profile parameters**

The parameters with their default settings are listed below:

```
1 SSLv3: DISABLED  TLSv1.0: DISABLED  TLSv1.1: DISABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED
2 Deny SSL Renegotiation: NONSECURE
3 HSTS: ENABLED
4 HSTS IncludeSubDomains: YES
5 HSTS Max-Age: 15552000
6 Cipher Name: SECURE  Priority : 1
```

**Secure cipher alias**

A new secure cipher alias is added and bound to the secure front-end profile. To list the ciphers that are part of this alias, at the command prompt type: show cipher SECURE

```
1 show cipher SECURE
2 1) Cipher Name: TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 Priority : 1
   Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(256)
   Mac=AEAD  HexCode=0xc030
3 2) Cipher Name: TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 Priority : 2
   Description: TLSv1.2 Kx=ECC-DHE  Au=RSA  Enc=AES-GCM(128)
   Mac=AEAD  HexCode=0xc02f
5 3) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
**Configuration**

Perform the following steps:

1. Add a load balancing virtual server of type SSL.
2. Bind a SHA2/SHA256 certificate.
3. Enable the default profile.
4. Bind the secure front-end profile to the SSL virtual server.

**Get an A+ rating for an SSL virtual server by using the CLI**

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <IPAddress> <port>
2 bind ssl vserver <vServerName> -certkeyName <string>
3 set ssl parameter -defaultProfile ENABLED
4 set ssl vserver <vServerName> -
   sslProfile ns_default_ssl_profile_secure_frontend
5 show ssl vserver [<<vServerName>]
```

**Example:**

```
1 add lb vserver ssl-vsvr SSL 192.0.2.240 443
2 bind ssl vserver ssl-vsvr -certkeyName let_rsa
3 set ssl parameter -defaultProfile ENABLED
4 set ssl vserver ssl-vsvr -sslProfile
   ns_default_ssl_profile_secure_frontend
```

Appendix A: Sample migration of the SSL configuration after upgrade

January 23, 2019
Contributed by:
C

Sample settings on an SSL virtual server, service, and service group are shown below. On the virtual server, client authentication is ENABLED (default is DISABLED), and the AES cipher group is bound to the virtual server. On the service, server authentication is ENABLED (default is DISABLED), and the AES cipher group is bound to the service. The service group has the default settings.

```
1  sh ssl vserver v1
2
3  Advanced SSL configuration for VServer v1:
4  DH: DISABLED
5  Ephemeral RSA: ENABLED            Refresh Count: 0
6  Session Reuse: ENABLED            Timeout: 120 seconds
```
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED
Push Encryption Trigger: Always
Send Close-Notify: YES
ECC Curve: P_256, P_384, P_224, P_521
1) CertKey Name: mycertkey Server Certificate
1) Cipher Name: AES
Description: Predefined Cipher Alias
Done

sh ssl service svc1
Advanced SSL configuration for Back-end SSL Service svc1:
DH: DISABLED
Ephemeral RSA: DISABLED
Session Reuse: ENABLED Timeout: 300 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Server Auth: ENABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED
Send Close-Notify: YES
1) Cipher Name: AES
Description: Predefined Cipher Alias
Done

sh ssl serviceGroup
1) Service Group Name: sg1
Session Reuse: ENABLED Timeout: 300 seconds
Server Auth: DISABLED
Non FIPS Ciphers: DISABLED
The following procedure migrates the above configuration.

1. Save your configuration.

2. Run the migration script. You can redirect the output to a text file if you use the default names for the profiles. Type:

   ```
   ./default_profile_script /nsconfig/ns.conf -b > ssl_config.txt
   ```

   Use an editor, such as vi, to view the changes. The output cannot be redirected if you provide the profile names interactively. The output is displayed on the console and you must copy and paste it into a text file to apply it to your configuration after the upgrade.

3. After the upgrade, enable the profile.

   - At the CLI, type: `set ssl parameter -defaultProfile ENABLED`
   - In the GUI, navigate to **Traffic Management > SSL > Change advanced SSL settings**, scroll down and select **Enable Default Profile**.

The interim output for the three new profiles that are created for the virtual server, service, and service group, respectively, is shown below. The default profiles are bound to the end points until you apply the changes in the text file that was created after running the migration script.

```
1 sh ssl vserver v1
2
3 Advanced SSL configuration for VServer v1:
4 Profile Name :ns_default_ssl_profile_frontend
5 1) CertKey Name: mycertkey Server Certificate
6 Done

1 sh ssl service svc1
2
3 Advanced SSL configuration for Back-end SSL Service svc1:
4 Profile Name :ns_default_ssl_profile_backend
5 Done

1 sh ssl serviceGroup sg1
2
3 Advanced SSL configuration for Back-end SSL Service Group sg1:
4 Profile Name :ns_default_ssl_profile_backend
5 Done
```
4. You must now apply the configuration in ssl_config.txt to the current configuration, so that your non-default settings are applied after the upgrade.

   batch -f /<path to the batch file>/ssl_config.txt

5. After applying the configuration, the output changes as follows:

   show ssl vserver v1
   Advanced SSL configuration for VServer v1:
   Profile Name :profile-002
   1) CertKey Name: mycertkey Server Certificate
   Done

   show ssl service svc1

**Legacy SSL profile**

January 25, 2019

Contributed by:
C

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Note:
Citrix recommends using the enhanced profiles instead of legacy profiles. For information about the enhanced profile infrastructure, see SSL profile infrastructure.

Important:
You must bind an SSL profile to an SSL virtual server. Do not bind a DTLS profile to an SSL virtual server. For information about DTLS profiles, see DTLS Profiles.

You can use an SSL profile to specify how a Citrix ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.
- Backend profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiples entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

<table>
<thead>
<tr>
<th>Front end profile</th>
<th>Backend profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>cipherRedirect, cipherURL</td>
<td>denySSLReneg</td>
</tr>
<tr>
<td>clearTextPort*</td>
<td>encryptTriggerPktCount</td>
</tr>
<tr>
<td>clientAuth, clientCert</td>
<td>nonFipsCiphers</td>
</tr>
<tr>
<td>denySSLReneg</td>
<td>pushEncTrigger</td>
</tr>
<tr>
<td>dh, dhFile, dhCount</td>
<td>pushEncTriggerTimeout</td>
</tr>
<tr>
<td>dropReqWithNoHostHeader</td>
<td>pushFlag</td>
</tr>
<tr>
<td>encryptTriggerPktCount</td>
<td>quantumSize</td>
</tr>
<tr>
<td>eRSA, eRSACount</td>
<td>serverAuth</td>
</tr>
<tr>
<td>insertionEncoding</td>
<td>commonName</td>
</tr>
<tr>
<td>nonFipsCiphers</td>
<td>sessReuse, sessTimeout</td>
</tr>
<tr>
<td>pushEncTrigger</td>
<td>SNIEnable</td>
</tr>
<tr>
<td>pushEncTriggerTimeout</td>
<td>ssl3</td>
</tr>
</tbody>
</table>
The clearTextPort parameter applies only to an SSL virtual server.

An error message appears if you try to set a parameter that is not part of the profile (for example, if you try to set the clientAuth parameter in a backend profile).

Some SSL parameters, such as CRL memory size, OCSP cache size, UndefinedAction Control, and UndefinedAction Data, are not part of any of the above profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- **Add**—Creates an SSL profile on the Citrix ADC. Specify whether the profile is front end or back-end. Front end is the default.
- **Set**—Modifies the settings of an existing profile.
- **Unset**—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- **Remove**—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- **Show**—Displays all the profiles that are available on the Citrix ADC. If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.
Create an SSL profile by using the CLI

- To add an SSL profile, type:

```bash
add ssl profile <name> [-sslProfileType (BackEnd | FrontEnd )]
```

- To modify an existing profile, type:

```bash
set ssl profile <name>
```

- To unset an existing profile, type:

```bash
unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA]…
```

- To unset an existing profile from an entity, type:

```bash
unset ssl vserver <vServerName> -sslProfile
```

- To remove an existing profile, type:

```bash
rm ssl profile <name>
```

- To display an existing profile, type:

```bash
sh ssl profile <name>
```

Create an SSL profile by using the GUI

Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile.

Enable stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by
one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCAChain setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the Citrix ADC appliance.

**Enable stricter control on client certificate validation by using the CLI**

At the command prompt, type: `set ssl profile <name> -ClientAuthUseBoundCAChain Enabled`

**Enable stricter control on client certificate validation by using the GUI**

1. Navigate to **System > Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

**Certificate revocation lists**

January 23, 2019

Contributed by: C

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA may revoke the issued certificate before the expiration date (for example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes).

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.
Certificate authorities issue CRLs on a regular basis. You can configure the Citrix ADC appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the Citrix ADC appliance. You can configure refresh options. You can also configure the Citrix ADC to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The appliance supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the Citrix ADC appliance.

If you have used the Citrix ADC as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the Citrix ADC are not used either in a production environment or beyond a particular date.

Note:
By default, CRLs are stored in the /var/netscaler/ssl directory on the Citrix ADC appliance.

Create a CRL on the ADC

Since you can use the Citrix ADC appliance to act as a certificate authority and create self-signed certificates, you can also revoke certificates that you have created and certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

Revoke a certificate or create a CRL by using the CLI

At the command prompt, type the following command:

```
create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>)
```

Example:

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```
Revoke a certificate or create a CRL by using the GUI

1. Navigate to Traffic Management > SSL and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the Choose Operation list, select Revoke Certificate or Generate CRL.

Add an existing CRL to the ADC

Before you configure the CRL on the Citrix ADC appliance, make sure that the CRL file is stored locally on the Citrix ADC appliance. In the case of an HA setup, the CRL file must be present on both Citrix ADC appliances, and the directory path to the file must be the same on both appliances.

Add a CRL on the Citrix ADC by using the CLI

At the command prompt, type the following commands to add a CRL on the Citrix ADC and verify the configuration:

```
add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]
show ssl crl [<crlName>]
```

Example:

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM
Done
> show ssl crl crl-one
Name: crl-one   Status: Valid,  Days to expiration: 29
CRL Path: /var/netscaler/ssl/CRL-one
Format: PEM   CAcert: samplecertkey
Refresh: DISABLED
Version: 1
Signature Algorithm: sha1WithRSAEncryption
Issuer: C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,OU=SSL Acceleration,CN=www.ns.com/emailAddress=support@Citrix ADC appliance.com
Last_update: Jun 15 10:53:53 2010 GMT
Next_update: Jul 15 10:53:53 2010 GMT
1) Serial Number: 00
```
Add a CRL on the Citrix ADC by using the GUI

Navigate to Traffic Management > SSL > CRL, and add a CRL.

Configure CRL refresh parameters

A CRL is generated and published by a Certificate Authority periodically or, in some cases, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the Citrix ADC appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The Citrix ADC appliance can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you execute the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. You must explicitly specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

Configure CRL autorefresh by using the CLI

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration the following commands to configure CRL auto refresh and verify the configuration:

```
1 set ssl crl <crlName> [-refresh ( ENABLED | DISABLED ))] [-CAcert <
 string>] [-url <URL | -server <ip_addr|ipv6_addr>] [-method HTTP | ( 
 LDAP [-baseDN <string>] [-bindDN <string>] [-scope ( Base | One )]
 [-password <string>] [-binary ( YES | NO )])] [-port <port>] [-
 interval <interval>]
2
3 show ssl crl [<<crlNameName>]
```

Example:

```
1 set CRL crl1 -refresh enabled -method ldap -inform DER -CAcert cal
-sever 10.102.192.192 -port 389 -scope base -baseDN "cn=
clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01
2
```
Configure CRL autorefresh using LDAP or HTTP by using the GUI

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, and select Enable CRL Auto Refresh.

Note: If the new CRL has been refreshed in the external repository before its actual update time as specified by the Last Update time field of the CRL, you should immediately refresh the CRL on the Citrix ADC appliance.

To view the last update time, select the CRL, and click Details.

Synchronize CRLs

The Citrix ADC appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the Citrix ADC appliance needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the appliance to update CRLs automatically at a specified refresh interval.

The appliance maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated, connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.
**Note:** If CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, all client-authentication connections with the same issuer as the CRL are rejected as REVOKED until the CRL is successfully refreshed.

You can specify the interval at which the CRL refresh should be carried out. You can also specify the exact time.

**Synchronize CRL autorefresh by using the CLI**

At the command prompt, type the following command:

```
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <HH:MM>]
```

**Example:**

```
set ssl crl CRL-1 -refresh ENABLE -interval MONTHLY -days 10 -time 12:00
```

**Synchronize CRL refresh by using the GUI**

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, select enable CRL Auto Refresh, and specify the interval.

**Perform client authentication by using a certificate revocation list**

If a certificate revocation list (CRL) is present on a Citrix ADC appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional.

The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

**Table 1. Result of a Handshake with a Client Using a Revoked Certificate**
### Rule for CRL Check

<table>

**Note:**

- The CRL check is optional by default. To change from optional to mandatory or vice-versa, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.
- In the output of the `sh ssl vserver` command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the `sh ssl vserver` command only if CRL check is set to mandatory. If CRL check is set to optional, the CRL check details do not appear.

### To configure CRL check by using the CLI

At the command prompt, type the following command:

```bash
bind ssl vserver <vServerName> -certkeyName <string> [(-CA -crlCheck (Mandatory | Optional))]  
sh ssl vserver
```

**Example:**

```bash
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory  
> sh ssl vs v1

Monitor certificate status with OCSP

January 23, 2019
Contributed by:
C

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. Citrix ADC appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. Citrix ADC implementation of OCSP includes request batching and response caching.

**OCSP implementation**

OCSP validation on a Citrix ADC appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the appliance creates an OCSP request and forwards it to the OCSP responder. To do so, the appliance uses a locally configured URL. The transaction is in a suspended state until the appliance evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the appliance will allow the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The appliance supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

**OCSP request batching**

Each time the appliance receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the appliance can query the status of more than one client certificate in the same request. For this to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

**OCSP response caching**

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the appliance caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the appliance first checks its local cache
for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the appliance sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

**Note:** From release 12.1 build 49.x, the cache timeout limit is now increased to a maximum of 43200 minutes (30 days). Earlier the limit was 1440 minutes (one day). The increased limit helps reduce the lookups on the OCSP server and avoid any SSL/TLS connection failures in case the OCSP server is not reachable due to network or other problems.

**OCSP responder configuration**

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

**Add an OCSP responder by using the CLI**

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```plaintext
1 add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED ) [-cacheTimeout <positive_integer>]] [-batchingDepth <positive_integer>][ -batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce ( YES | NO )][ -insertClientCert( YES | NO )]
```

```plaintext
1 bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
```

```plaintext
1 bind ssl vserver <vServerName>@ (-certkeyName <string> ( CA [-ocspCheck ( Mandatory | Optional )]))
```

```plaintext
1 show ssl ocspResponder [<name>]
```

**Example:**
```
add ssl ocspResponder ocsp_responder1 -url "http://www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -batchingDelay 100 -resptimeout 100 -responderCert responder_cert -producedAtTimeSkew 300 -signingCert sign_cert -insertClientCert YES

bind ssl certKey ca_cert -ocspResponder ocsp_responder1 -priority 1

bind ssl vserver vs1 -certkeyName ca_cert -CA -ocspCheck Mandatory

sh ocspResponder ocsp_responder1
1) Name: ocsp_responder1
Caching: Enabled Timeout: 30 minutes
Batching: 8 Timeout: 100 mS
HTTP Request Timeout: 100mS
Request Signing Certificate: sign_cert
Response Verification: Full, Certificate: responder_cert
Produced At Time Skew: 300 s
Nonce Extension: Enabled
Client Cert Insertion: Enabled
Done

show certkey ca_cert
1) Name: ca_cert 
Status: Valid, Days to expiration: 8907
Version: 3
... 
1) VServer name: vs1 CA Certificate
1) OCSP Responder name: ocsp_responder1 Priority: 1
Done

sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
DH: DISABLED
... 
1) CertKey Name: ca_cert CA Certificate OCSPCheck: Mandatory
1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias
Done
```
Modify an OCSP responder by using the CLI

You cannot modify the responder name. All other parameters can be changed using the set ssl ocspResponder command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
2 unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
3 bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
4 show ssl ocspResponder [<name>]
```

Configure an OCSP responder by using the GUI

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select OCSP Mandatory.

1. Citrix ADC
2. Citrix ADC 12.1
3. SSL offload and acceleration

OCSP stapling

January 23, 2019
Contributed by: C

The Citrix ADC implementation of CRL and OCSP reports the revocation status of client certificates only. To check the revocation status of a server certificate received during an SSL handshake, a client must send a request to a certificate authority.

For web sites with heavy traffic, many clients receive the same server certificate. If each client sent a query for the revocation status of the server certificate, the certificate authority would be inundated with OCSP requests to check the validity of the certificate.

**OCSP stapling solution**

To avoid unnecessary congestion, the Citrix ADC appliance now supports OCSP stapling. That is, the appliance can now send the revocation status of a server certificate to a client, at the time of the SSL handshake, after validating the certificate status from an OCSP responder. The revocation status of a server certificate is “stapled” to the response the appliance sends to the client as part of the SSL handshake. To use the OCSP stapling feature, you must enable it on an SSL virtual server and add an OCSP responder on the appliance.

**Note:**

- Citrix ADC appliances support OCSP stapling as defined in RFC 6066.
- OCSP stapling is supported only on the front-end of Citrix ADC appliances.

**Important:**

Citrix ADC support for OCSP stapling is limited to handshakes using TLS protocol version 1.0 or higher.

**OCSP response caching of server certificates**

During the SSL handshake, when a client requests the revocation status of the server certificate, the appliance first checks its local cache for an entry for this certificate. If a valid entry is found, it is evaluated and the server certificate and its status are presented to the client. If a revocation status entry is not found, the appliance sends a request for the revocation status of the server certificate to the OCSP responder. If it receives a response, it sends the certificate and the revocation status to the client. If the next update field is present in the OCSP response, the response is cached for the configured length of time (value specified in timeout field.)

**Note:** From release 12.1 build 49.x, you can clear the cached response, of the server certificate,
from the OCSP responder even before the timeout expires. Earlier, you could not discard the cached status in the certificate-key pair until the configured timeout was over.

To clear the cached status by using the CLI, at the command prompt, type:

```
clear ssl certKey <certkey name> -ocsp staplingCache
```

**Example:**

```
clear ssl certKey s1 -ocsp staplingCache
```

To clear the cached status by using the GUI

1. In the GUI, navigate to Traffic Management > SSL > Certificates > CA Certificates.
2. In the details pane, select a certificate.
3. In the Select Action list, select Clear. If prompted to confirm, click Yes.

**OCSP stapling configuration**

Configuring OCSP stapling involves enabling the feature and configuring OCSP. To configure OCSP, you must add an OCSP responder, bind the OCSP responder to a CA certificate, and bind the certificate to an SSL virtual server.

**Note:**

OCSP responders with only HTTP based URL are supported.

**Enable OCSP stapling by using the CLI**

At the command prompt, type:

```
set ssl vserver <name> -ocsp stapling [ENABLED | DISABLED]
```

**Example:**

```
set ssl vserver vip1 -ocspStapling ENABLED
```

Done

```
sh ssl vserver vip1
```

Advanced SSL configuration for VServer vip1:

```
DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED
Ephemeral RSA: ENABLED
Refresh Count: 0
Session Reuse: ENABLED
Timeout: 120 seconds
```
Enable OCSP stapling by using the GUI

1. Navigate to Traffic Management > SSL > Virtual Server.
2. Open a virtual server and, in SSL Parameters, select OCSP Stapling.

OCSP configuration

An OCSP responder is added dynamically or manually to send OCSP stapling requests. An internal responder is dynamically added when you add a server certificate and its issuer certificate based on the OCSP URL in the server certificate. A manual OCSP responder is added from the CLI or GUI. To send an OCSP request for a server certificate, the Citrix ADC appliance selects an OCSP responder based on the priority assigned to it when binding it to an issuer certificate. If a responder fails to send an OCSP stapling request, the responder with the next highest priority is selected for sending the request. For example, if only one responder is manually configured and it fails and a dynamically bound responder exists, it is selected for sending the OCSP request.

If the OCSP URL is other than HTTP, an internal OCSP responder is not created.
Note
A manually added OCSP responder takes precedence over a dynamically added responder.

Difference between a manually created OCSP responder and an internally created OCSP responder

<table>
<thead>
<tr>
<th>Manually created OCSP responder</th>
<th>Internally (dynamically) created OCSP responder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created manually and explicitly bound to the issuer certificate with a priority.</td>
<td>Created and bound by default, while adding a server certificate and its issuer certificate (CA certificate). Name starts with “ns_internal_”.</td>
</tr>
<tr>
<td>Priority between 1 and 127 is reserved for configured responder.</td>
<td>Priority is automatically assigned from 128 onwards.</td>
</tr>
<tr>
<td>URL and batching depth can be changed.</td>
<td>URL and batching depth cannot be changed.</td>
</tr>
<tr>
<td>Deleted directly.</td>
<td>Deleted only when you delete the server certificate or the CA certificate.</td>
</tr>
<tr>
<td>Can be bound to any CA certificate.</td>
<td>Bound by default to one CA certificate. Cannot be bound to any other CA certificate.</td>
</tr>
<tr>
<td>Saved in the configuration (ns.conf).</td>
<td>Add commands are not saved in the configuration; only set commands are saved.</td>
</tr>
<tr>
<td>If you bind three OCSP responders to the same issuer certificate with priorities 1, 2, and 3 respectively, and later unbind priority 2, the other priorities are not affected.</td>
<td>Three OCSP responders are automatically bound to an issuer certificate with priorities 128, 129, and 130 respectively. If you remove the server certificate that was used to create a responder bound with priority 129, then that responder is deleted. Also, the priority for the next responder (priority 130) is automatically changed to 129.</td>
</tr>
</tbody>
</table>

Example of request handling:

1. Add a virtual server (VIP1).
2. Add issuer certificate (CA1) and bind it to VIP1.
3. Add three certificates S1, S2, and S3. Internal responders resp1, resp2, and resp3 respectively are created by default.
4. Bind S3 to VIP1.
5. A request comes to VIP1. Responder resp3 is selected.

To create an internal OCSP responder dynamically, the appliance needs the following:

- Certificate of the issuer of the server certificate (usually the CA certificate).
- Certificate-key pair of the server certificate. This certificate must contain the OCSP URL provided by the CA. The URL is used as the name of the dynamically added internal responder.

An internal OCSP responder has the same default values as a manually configured responder.

**Note:**
Caching is disabled by default on an internal responder. Use the “set ssl ocspResponder” command to enable caching.

**Configure OCSP by using the CLI**

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]
add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED ) [-cacheTimeout <positive_integer>]] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce ( YES | NO )] [-insertClientCert ( YES | NO )]
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
show ssl ocspResponder [ <name> ]
```

**Parameters:**

**httpMethod:**
HTTP method used to send OCSP requests. For requests, less than 255 bytes long, you can configure the HTTP GET method for queries to an OCSP server. If you specify the GET method but the length is greater than 255 bytes, the appliance uses the default method (POST).

Possible values: GET, POST
ocspUrlResolveTimeout:

Time, in milliseconds, to wait for an OCSP URL resolution. After this time elapses, the responder with the next higher priority is selected. If all the responders fail, an error message appears or the connection is dropped, depending on the settings on the virtual server.

Minimum value: 100

Maximum value: 2000

Example:

```
1  add ssl certkey root_ca1 -cert root_cacert.pem
3  bind ssl certKey root_ca1 -ocspResponder ocsp_responder1 -priority 1
4  sh ocspResponder ocsp_responder1
5   1) Name: ocsp_responder1
7   Caching: Enabled  Timeout: 30 minutes
8   Batching: 8  Timeout: 100 mS
9   HTTP Request Timeout: 100mS
10  Request Signing Certificate: sign_cert
11  Response Verification: Full, Certificate: responder_cert
12  ProducedAt Time Skew: 300 s
13  Nonce Extension: Enabled
14  Client Cert Insertion: Enabled
15  Done
16
17  show certkey root_ca1
18   Name: root_ca1  Status: Valid,  Days to expiration:8907
19   Version: 3
20   ...
21   1)  OCSP Responder name: ocsp_responder1  Priority: 1
22   Done
```

Modify OCSP by using the CLI

You cannot modify the name of an OCSP responder, but you can use the set ssl ocspResponder command to change any of the other parameters.
At the command prompt, type the following commands to set the parameters and verify the configuration:

```plaintext
```

1. `unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]`
2. `bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]`
3. `show ssl ocspResponder [<name>]`

**Configure OCSP by using the GUI**

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select OCSP Mandatory.

**Note:**

The insert client certificate parameter in the “add ssl ocspResponder” and the “set ssl ocspResponder” commands is no longer valid. That is, the parameter is ignored during configuration.

**Ciphers available on the Citrix ADC appliances**

January 25, 2019

Contributed by: C
Your Citrix ADC appliance ships with a predefined set of cipher groups. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see Configure user-defined cipher groups on the ADC appliance.

- To display information about the cipher suites bound by default at the front end (to a virtual server), type: `sh cipher DEFAULT`
- To display information about the cipher suites bound by default at the back end (to a service), type: `sh cipher DEFAULT_BACKEND`
- To display information about all the cipher groups (aliases) defined on the appliance, type: `sh cipher`
- To display information about all the cipher suites that are part of a specific cipher group, type: `sh cipher <alias name>`. For example, `sh cipher ECDHE`.

The following links list the cipher suites supported on different Citrix ADC platforms and on external hardware security modules (HSMs):

- **Citrix ADC MPX/SDX (N3) appliance**: Cipher support on a Citrix ADC MPX/SDX (N3) appliance
- **Citrix ADC MPX/SDX Intel Coleta appliance**: Cipher support on a Citrix ADC MPX/SDX Intel Coleta SSL chip based appliance
- **Citrix ADC VPX appliance**: Cipher support on a Citrix ADC VPX appliance
- **Citrix ADC MPX/SDX 14000 FIPS appliance**: Cipher support on a Citrix ADC MPX/SDX 14000 FIPS appliance
- **External HSM (Thales/Safenet)**: Cipher supported on an External HSM (Thales/Safenet)
- **Citrix ADC MPX/SDX (N2) appliance**: Cipher support on a Citrix ADC MPX/SDX (N2) appliance
- **Citrix ADC MPX 9700 FIPS appliance**: Cipher support on a Citrix ADC MPX 9700 FIPS with firmware 2.2

**Note:**
For DTLS cipher support, see DTLS cipher support on Citrix ADC VPX, MPX, and SDX appliances.

For the detailed list of ECDSA ciphers supported, see [ECDSA Cipher Suites support](#).

Note

- TLS-Fallback_SCSV cipher suite is supported on all appliances from release 10.5 build 57.x
- HTTP Strict Transport Security (HSTS) support is policy-based.
- All SHA-2 signed-certificates (SHA256, SHA384, SHA512) are supported on the front end of all appliances. In release 11.1 build 54.x and later, these certificates are also supported on the back-end of all appliances. In release 11.0 and earlier, only SHA256 signed-certificates are supported on the back end of all appliances.
- In release 11.1 build 52.x and earlier, the following ciphers are supported only on the front-end of the MPX 9700 and MPX/SDX 14000 FIPS appliances:
  - TLS1.2-ECDHE-RSA-AES-256-SHA384
  - TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 From release 11.1 build 53.x, and in release 12.0, these ciphers are also supported on the back end.
- All ChaCha20-Poly1305 ciphers use a TLS pseudo random function (PSF) with the SHA-256 hash function.
All Citrix ADC appliances support the ECDHE cipher group on the front end and the back end. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

For more information about the builds and platforms that support these ciphers, see Ciphers available on the Citrix ADC appliances.

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A Citrix ADC appliance supports the following ECC curves:

- P_256
- P_384
- P_224
- P_521

Note: If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers or front end services. The curves are bound by default to any virtual servers or front end services that you create after the upgrade.

You can bind an ECC curve to SSL front-end entities only. By default all four curves are bound, in the following order: P_256, P_384, P_224, P_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.

### Unbind and bind ECC curves to an SSL virtual server by using the CLI

At the command prompt, type:

```
1 unbind ssl vserver <vServerName> -eccCurveName ALL
2 bind ssl vserver <vServerName> -eccCurveName <eccCurveName>
```

Example:

```
1 unbind ssl vs v1 -eccCurveName ALL
2 bind ssl vserver v1 -eccCurveName P_224
3 sh ssl vserver v1
4 Advanced SSL configuration for VServer v1:
5 DH: DISABLED
```

**Diffie-Hellman parameters generation and achieving PFS with DHE**

March 11, 2019

Contributed by: C

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction to agree upon a shared secret over an insecure channel. These parties have no prior knowledge about each other. This secret can be converted into cryptographic keying material for symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default. Configured the feature to support ciphers that use DH as the key exchange algorithm.

**Note:**
Generating 2048-bit DH parameters might take a long time (up to 30 minutes).
### Generate DH parameters by using the CLI

At the command prompt, type the following command:

```
create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]
```

**Example:**

```
create ssl dhparam Key-DH-1 512 -gen 2
```

### Generate DH parameters by using the GUI

Navigate to Traffic Management > SSL and, in the Tools group, select Create Diffie-Hellman (DH) key, and Configure SSL DH Param.

**Note:**
For information about DH parameters, see Diffie-Hellman parameters.

### Achieve perfect forward secrecy with DHE

Generating DH parameters is a CPU-intensive operation. In earlier releases, parameter generation, on a VPX appliance, took a long time because it was done in the software. Parameter generation is optimized by setting the `dhKeyExpSizeLimit` parameter. You can set this parameter for an SSL virtual server or an SSL profile and then bind the profile to a virtual server.

You can maintain perfect forward secrecy (PFS) on Citrix ADC MPX appliances by setting DH count equal to zero. As a result, DH parameters are generated for each transaction (minimum `DHcount` is 0) on Citrix ADC MPX appliances. The parameters are generated without a significant drop in performance, because the operation is optimized. Earlier, the minimum DH count allowed was 500. That is, you could not regenerate the key for up to 500 transactions.

On a Citrix ADC VPX appliance, you can generate DH parameters for every 500 transaction at the minimum (`DHcount = 500`). If you set `DHcount` equal to 0, then the DH parameters are not regenerated.

**Limitation:**
You cannot achieve PFS in VPX today with DH ciphers.

### Optimize DH parameters generation by using the CLI

At the command prompt, type commands 1 and 2, or type command 3:
1. Add SSL profile `<name> [ -sslProfileType ( BackEnd | FrontEnd ) ] [ -dhCount <positive_integer> ] [ -dh ( ENABLED | DISABLED ) -dhFile < string> ] [ -dhKeyExpSizeLimit ( ENABLED | DISABLED ) ]`

2. Set SSL vserver `<vServerName> [ -sslProfile <string> ]`

3. Set SSL vserver `<vServerName> [ -dh ( ENABLED | DISABLED ) -dhFile < string> ] [ -dhCount <positive_integer> ] [ -dhKeyExpSizeLimit ( ENABLED | DISABLED ) ]`

**Optimize DH parameters generation by using the GUI**

2. In the **SSL Parameters** section, select **Enable DH Key Expire Size Limit**.

**Cipher redirection**

February 28, 2019

Contributed by: C

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client do not match those configured on the SSL server, the SSL handshake fails, and the failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When SSL handshake fails, the Citrix ADC appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.
**Configure cipher redirection by using the CLI**

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

```plaintext
1 - set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED> -cipherURL < URL>
2 - show ssl vserver <vServerName>
```

**Example:**

```plaintext
1 set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://redirectURL
2 Done
3 show ssl vserver vs-ssl
4 Advanced SSL configuration for VServer vs-ssl:
5 DH: DISABLED
6 Ephemeral RSA: ENABLED          Refresh Count: 1000
7 Session Reuse: ENABLED          Timeout: 600 seconds
8 Cipher Redirect: ENABLED        Redirect URL: http://redirectURL
9 SSLv2 Redirect: DISABLED
10 ClearText Port: 0
11 Client Auth: DISABLED
12 SSL Redirect: DISABLED
13 Non FIPS Ciphers: DISABLED
14 SNI: DISABLED
15 OCSP Stapling: DISABLED
16 HSTS: DISABLED
17 HSTS IncludeSubDomains: NO
18 HSTS Max-Age: 0
19 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2: ENABLED
20 1) CertKey Name: Auth-Cert-1 Server Certificate
21 1) Cipher Name: DEFAULT
22 1) Description: Predefined Cipher Alias
23 Done
```

**Configure cipher redirection by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Cipher Redirect, and specify a redirect URL.

Leverage hardware and software to improve ECDHE and ECDSA cipher performance

January 23, 2019

Contributed by:

C

Note:
This enhancement is applicable only to the following platforms:

- MPX/SDX 11542
- MPX/SDX 14000
- MPX 22000, MPX 24000, and MPX 25000
- MPX/SDX 14000 FIPS

Previously, ECDHE and ECDSA computation on a Citrix ADC appliance was performed only on the hardware (Cavium chips), which limited the number of SSL sessions at any given time. With this enhancement, some operations are also performed in the software. That is, processing is done both on the Cavium chips and on the CPU cores to improve ECDHE and ECDSA cipher performance.

The processing is first performed in software, up to the configured software crypto threshold. After this threshold is reached, the operations are offloaded to the hardware. Therefore, this hybrid model leverages both hardware and software to improve SSL performance. You can enable the hybrid model by setting the “softwareCryptoThreshold” parameter to suit your requirement. To disable the hybrid model, set this parameter to 0.

Benefits are greatest if the current CPU utilization is not too high, because the CPU threshold is not exclusive to ECDHE and ECDSA computation. For example, if the current workload on the Citrix ADC appliance consumes 50% of the CPU cycles, and the threshold is set to 80%, ECDHE and ECDSA computation can use an additional 30% of the cycles. After the configured software crypto threshold of 80% is reached, further ECDHE and ECDSA computation is offloaded to the hardware. In that case, actual CPU utilization might exceed 80%, because performing ECDHE and ECDSA computations in hardware consumes some CPU cycles.
Enable the hybrid model by using the CLI

At the command prompt, type:

```bash
set ssl parameter -softwareCryptoThreshold <positive_integer>
```

**Synopsis:**

softwareCryptoThreshold:

Citrix ADC CPU utilization threshold (as a percentage) beyond which crypto operations are not done in software. A value of zero implies that CPU is not utilized for doing crypto in software.

Default = 0
Min = 0
Max = 100

**Example:**

```bash
> set ssl parameter -softwareCryptoThreshold 80
Done
> show ssl parameter
Advanced SSL Parameters

SSL quantum size : 8 KB
Max CRL memory size : 256 MB
Strict CA checks : NO
Encryption trigger timeout : 100 ms
Send Close-Notify : YES
Encryption trigger packet c : 45
Deny SSL Renegotiation : ALL
Subject/Issuer Name Insertion Format : Unicode
OCSP cache size : 10 MB
Push flag : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout : 1 ms
Crypto Device Disable Limit : 0
Global undef action for control policies : CLIENTAUTH
Global undef action for data policies : NOOP
Default profile : DISABLED
Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors : NO
```
Disable TLS 1.1/1.2 for dynamic and VPN services: NO
Software Crypto acceleration CPU Threshold: 80
Signature and Hash Algorithms supported by TLS1.2: ALL

Enable the hybrid model by using the GUI

1. Navigate to Traffic Management > SSL > Change advanced SSL settings.
2. Enter a value for Software Crypto Threshold (%).

1.

Citrix ADC

Citrix ADC 12.1

ECDSA cipher suites support

January 30, 2019
Contributed by:
C

ECDSA cipher suites use elliptical curve cryptography (ECC). Because of its smaller size, it is particularly helpful in environments where processing power, storage space, bandwidth, and power consumption are constrained.

The following Citrix ADC appliances now support the elliptical curve digital signature algorithm (ECDSA) cipher group:

- Citrix ADC MPX and SDX appliances with N3 chips
- Citrix ADC MPX 5900/8900
- Citrix ADC SDX 8900
- Citrix ADC VPX appliances

To support ECDSA cipher suites on a Citrix ADC SDX appliance, an SSL core must be assigned to the VPX instance.

When the ECDHE_ECDSA cipher group is used, the server’s certificate must contain an ECDSA-capable public key.

Note: From release 12.1 build 50.x, you can create an ECDSA key in PKCS#8 format.

Example:
The following table lists the ECDSA ciphers that are supported on the Citrix ADC MPX and SDX appliances with N3 chips, MPX 5900, and MPX/SDX 8900 appliances.
<table>

**Important**

Use the `show ns hardware` command to find out if your appliance has N3 chips.

**Example:**

```
1  sh ns hardware
2  Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100
3  Manufactured on: 8/19/2013
4  CPU: 2900MHZ
5  Host Id: 1006665862
6  Serial no: ENUK6298FT
7  Encoded serial no: ENUK6298FT
8  Done
```
ECDSA/RSA cipher and certificate selection

You can bind both ECDSA and RSA server certificates at the same time to an SSL virtual server. When both ECDSA and RSA certificates are bound to the virtual server, it automatically selects the appropriate server certificate to present to the client. If the client cipher list includes RSA ciphers, but does not include ECDSA ciphers, the virtual server presents the RSA server certificate. If both ciphers are present in the client’s list, then the server certificate presented depends on the cipher priority set on the virtual server. That is, if RSA has a higher priority, the RSA certificate is presented. If ECDSA has a higher priority, the ECDSA certificate is presented to the client.

Client authentication by using an ECDSA or an RSA certificate

For client authentication, the CA certificate bound to the virtual server can be ECDSA or RSA signed. The appliance supports a mixed certificate chain. For example, the following certificate chain is supported.

Client certificate (ECDSA) <-> CA certificate (RSA) <-> Intermediate certificate (RSA) <-> Root certificate (RSA)

Note

ECDSA certificates with only the following curves are supported:
- prime256v1
- secp384r1
- secp521r1 (VPX only)
- secp224r1 (VPX only)

Create an ECDSA certificate-key pair

You can create an ECDSA certificate-key pair directly on a Citrix ADC appliance by using the CLI or the GUI. Earlier, you could install and bind an ECC certificate-key pair on the appliance, but you had to use OpenSSL to create a certificate-key pair.

Only P_256 and P_384 curves are supported.

Note

This support is available on all platforms except MPX 9700/1050/12500/15500.

To create an ECDSA certificate-key pair by using the CLI:

At the command prompt, type:
To create an ECDSA certificate-key pair by using the GUI:

1. Navigate to Traffic Management > SSL > SSL Files > Keys and click Create ECDSA Key.
2. To create a key in PKCS#8 format, select PKCS8.

To create a user-defined cipher group on the ADC appliance

April 3, 2019
Contributed by: C

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the Citrix ADC appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create an SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher...
alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

Binding a cipher group to an SSL virtual server, service, or service group, appends the ciphers to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity. Then bind the specific cipher group to the entity. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.

   ```
   unbind ssl service <service name> -cipherName ALL
   ```

2. Bind the AES cipher group to the service

   ```
   bind ssl service <Service name> -cipherName AE
   ```

   If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

   ```
   bind ssl service <service name> -cipherName DES
   ```

**Note:** The free Citrix ADC virtual appliance supports only the DH cipher group.

### Configure a user-defined cipher group by using the CLI

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

```
1 add ssl cipher <cipherGroupName>
2 bind ssl cipher <cipherGroupName> -cipherName <string>
3 show ssl cipher <cipherGroupName>
```

**Example:**

1. `add ssl cipher test`
2. `Done`
3. `bind ssl cipher test -cipherName ECDHE`
4. `Done`
1) Cipher Name: TLS1-ECDHE-RSA-AES256-SHA Priority: 1
Description: SSLv3 Kx=ECC-DHE Au=RSA Enc=AES(256) Mac=SHA1 HexCode =0xc014
2) Cipher Name: TLS1-ECDHE-RSA-AES128-SHA Priority: 2
Description: SSLv3 Kx=ECC-DHE Au=RSA Enc=AES(128) Mac=SHA1 HexCode =0xc013
3) Cipher Name: TLS1.2-ECDHE-RSA-AES-256-SHA384 Priority: 3
Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES(256) Mac=SHA-384 HexCode=0xc028
4) Cipher Name: TLS1.2-ECDHE-RSA-AES-128-SHA256 Priority: 4
Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES(128) Mac=SHA-256 HexCode=0xc02f
5) Cipher Name: TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 Priority: 5
Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES-GCM(256) Mac=AEAD HexCode=0xc030
6) Cipher Name: TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 Priority: 6
Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES-GCM(128) Mac=AEAD HexCode=0xc027
7) Cipher Name: TLS1-ECDHE-ECDSA-AES256-SHA Priority: 7
Description: SSLv3 Kx=ECC-DHE Au=ECDSA Enc=AES(256) Mac=SHA1 HexCode=0xc00a
8) Cipher Name: TLS1-ECDHE-ECDSA-AES128-SHA Priority: 8
Description: SSLv3 Kx=ECC-DHE Au=ECDSA Enc=AES(128) Mac=SHA1 HexCode=0xc009
9) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-SHA384 Priority: 9
Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES(256) Mac=SHA-384 HexCode=0xc024
10) Cipher Name: TLS1.2-ECDHE-ECDSA-AES128-SHA256 Priority: 10
Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES(128) Mac=SHA-256 HexCode=0xc023
11) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384 Priority: 11
Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES-GCM(256) Mac=AEAD HexCode=0xc02c
12) Cipher Name: TLS1.2-ECDHE-ECDSA-AES128-GCM-SHA256 Priority: 12
Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES-GCM(128) Mac=AEAD HexCode=0xc02b
13) Cipher Name: TLS1-ECDHE-RSA-DES-CBC3-SHA Priority: 13
Description: SSLv3 Kx=ECC-DHE Au=RSA Enc=3DES(168) Mac=SHA1 HexCode =0xc012
14) Cipher Name: TLS1-ECDHE-ECDSA-DES-CBC3-SHA Priority: 14
Description: SSLv3 Kx=ECC-DHE Au=ECDSA Enc=3DES(168) Mac=SHA1
Unbind ciphers from a cipher group by using the CLI

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

```bash
1  show ssl cipher <cipherGroupName>
2  unbind ssl cipher <cipherGroupName> -cipherName <string>
3  show ssl cipher <cipherGroupName>
```

Remove a cipher group by using the CLI

**Note:** You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

```bash
1  rm ssl cipher <userDefCipherGroupName> [<cipherName> ...]
2  show ssl cipher <cipherGroupName>
```

**Example:**

```bash
1  rm ssl cipher test Done
2
3  sh ssl cipher test ERROR: No such resource [cipherGroupName, test]
```
Configure a user-defined cipher group by using the GUI

Navigate to Traffic Management > SSL > Cipher Groups, and configure a cipher group.

To bind a cipher group to an SSL virtual server, service, or service group by using the CLI:

At the command prompt, type one of the following:

```
bind ssl vserver <vServerName> -cipherName <string>
bind ssl service <serviceName> -cipherName <string>
bind ssl serviceGroup <serviceGroupName> -cipherName <string>
```

Example:

```
bind ssl vserver ssl_vserver_test -cipherName test
Done
bind ssl service nshttps -cipherName test
Done
bind ssl serviceGroup ssl_svc -cipherName test
Done
```

To bind a cipher group to an SSL virtual server, service, or service group by using the GUI:

   - For service, replace virtual servers with services. For service groups, replace virtual servers with service groups.
   - Open the virtual server, service, or service group.
2. In Advanced Settings, select SSL Ciphers.
3. Bind a cipher group to the virtual server, service, or service group.

Binding individual ciphers to an SSL virtual server or service

You can also bind individual ciphers, instead of a cipher group, to a virtual server or service.

To bind a cipher by using the CLI:

At the command prompt, type:

```
bind ssl vserver <vServerName> -cipherName <string>
bind ssl service <serviceName> -cipherName <string>
```
Example:

```bash
1 bind ssl vserver v1 -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
2 Done
3
4 bind ssl service sslsvc -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
5 Done
```

To bind a cipher to an SSL virtual server by using the GUI:

2. Select an SSL virtual server and click Edit.
3. In Advanced Settings, select SSL Ciphers.
4. In Cipher Suites, select Add.
5. Search for the cipher in the available list and click the arrow to add it to the configured list.
6. Click OK.
7. Click Done.

To bind a cipher to an SSL service, repeat the preceding steps after replacing virtual server with service.

```
1
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration
```

Server certificate support matrix on the ADC appliance

January 23, 2019

Contributed by: C

The Citrix ADC appliance supports the following server certificates.

Table 1: Support on Frontend (FE) and Backend (BE) Service

<table>

</tbody>
</table>

### Note:
- In release 11.1 and earlier, a Citrix ADC appliance supports the following “signature algorithms” extensions in the back end client hello message: RSA-MD5, RSA-SHA1, and RSA-SHA256. Because SHA 384 and SHA 512 signature algorithms extensions are not supported by the Citrix ADC appliance, some servers, such as Windows IIS servers, reset the connection.
Client authentication

January 25, 2019
Contributed by: C

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server by checking the server’s certificate before initiating the SSL transaction. In some cases, however, you might want to configure the server to authenticate the client that is connecting to it.

With client authentication enabled on an SSL virtual server, the Citrix ADC appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

**Note:** For the appliance to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the appliance and bound to the virtual server that the client is transacting with.

If the certificate is valid, the appliance allows the client to access all secure resources. But if the certificate is invalid, the appliance drops the client request during the SSL handshake.

The appliance verifies the client certificate by first forming a chain of certificates, starting with the client certificate and ending with the root CA certificate for the client (for example, VeriSign). The root CA certificate may contain one or more intermediate CA certificates (if the client certificate is not directly issued by the root CA).

Before you enable client authentication on the Citrix ADC appliance, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that will handle the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the appliance.

**Note:** A Citrix ADC MPX appliance supports a certificate-key pair size from 512 to 4096 bits. The certificate must be signed by using one of the following hash algorithms:
On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A Citrix ADC virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 4096-bit certificate on the physical server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

**Provide the client certificate**

Before you configure client authentication, a valid client certificate must installed on the client. A client certificate includes details about the specific client system that will create secure sessions with the Citrix ADC appliance. Each client certificate is unique and should be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the Citrix ADC appliance, you must convert the certificate to the correct format. On the Citrix ADC appliance, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client system, make sure that it is installed on that system and configured for the client application that will be part of the SSL transactions (for example, the web browser).

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Import and convert SSL files.

For instructions on how to generate a client certificate, see Create a certificate.

**Enable client-certificate based authentication**

By default, client authentication is disabled on the Citrix ADC appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional
or mandatory as part of the SSL handshake.

If client authentication is optional, the appliance requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the appliance terminates the SSL handshake if the SSL client does not provide a valid certificate.

**Caution:** Citrix recommends that you define proper access control policies before changing client-certificate-based authentication check to optional.

**Note:** Client authentication is configured for individual SSL virtual servers, not globally.

### Enable client-certificate based authentication by using the CLI

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

```
1 set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-clientCert (MANDATORY | OPTIONAL)]
2 show ssl vserver <vServerName>
```

**Example:**

```
1 set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
2 Done
3 show ssl vserver vssl

5 Advanced SSL configuration for VServer vssl:
6 DH: DISABLED
7 Ephemeral RSA: ENABLED Refresh Count: 0
8 Session Reuse: ENABLED Timeout: 120 seconds
9 Cipher Redirect: DISABLED
10 SSLv2 Redirect: DISABLED
11 ClearText Port: 0
12 Client Auth: ENABLED Client Cert Required: Mandatory
13 SSL Redirect: DISABLED
14 Non FIPS Ciphers: DISABLED
15 SNI: DISABLED
16 OCSP Stapling: DISABLED
17 HSTS: DISABLED
18 HSTS IncludeSubDomains: NO
19 HSTS Max-Age: 0
20 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2: ENABLED TLSv1.3: ENABLED
21
22 1) CertKey Name: sslckey Server Certificate
```
Enable client-certificate based authentication by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

Note:
If client authentication is set to mandatory and if the client certificate contains policy extensions, certificate validation fails. From release 12.0-56.x, you can set a parameter in the front-end SSL profile to skip this check. The parameter is disabled by default. That is, the check is performed by default.

Skip the policy extension check during client authentication by using the CLI

At the command prompt, type:

```plaintext
set ssl profile ns_default_ssl_profile_frontend -clientauth ENABLED -skipClientCertPolicyCheck ENABLED
```

Parameter

```plaintext
skipClientCertPolicyCheck
```

Control policy extension check, if present inside the X509 certificate chain. Applicable only if client authentication is enabled and client certificate is set to mandatory. Possible values functions as follows:

- **ENABLED**: Skip the policy check during client authentication.
- **DISABLED**: Perform policy check during client authentication.

Possible values: ENABLED, DISABLED

Default: DISABLED
Skip the policy extension check during client authentication by using the GUI

1. Navigate to System > Profiles > SSL Profiles.
2. Create a new front-end profile or edit an existing front-end profile.
3. Verify that client authentication is enabled and client certificate is set to mandatory.

Bind CA certificates to the virtual server

A CA whose certificate is present on the Citrix ADC appliance must issue the client certificate used for client authentication. You must bind this certificate to the Citrix ADC virtual server that will carry out client authentication.

You must bind the CA certificate to the SSL virtual server in such a way that the appliance can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The appliance forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by CA_A, where CA_A is an intermediate CA whose certificate is issued by CA_B, whose certificate is in turn issued by a trusted root CA, Root_CA, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the Citrix ADC appliance.

For instructions on binding one or more certificates to the virtual server, see Bind the certificate-key pair to the SSL virtual server.

For instructions on creating a chain of certificates, see Create a chain of certificates.

Stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by
one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCAChain setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the Citrix ADC appliance.

**Enable stricter control on client certificate validation by using the CLI**

At the command prompt, type:

```
set ssl profile <name> -ClientAuthUseBoundCAChain Enabled
```

**Enable stricter control on client certificate validation by using the GUI**

1. Navigate to **System > Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

**Server authentication**

January 23, 2019

Contributed by:

C

Since the Citrix ADC appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server’s certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the appliance becomes the SSL client, carries out a secure transaction with the SSL server, verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.
To authenticate the server, you must first enable server authentication and then bind the certificate of the CA that signed the server’s certificate to the SSL service on the Citrix ADC appliance. When binding the certificate, you must specify the bind as CA option.

**Enable (or disable) server certificate authentication**

You can use the CLI and the GUI to enable and disable server certificate authentication.

**Enable (or disable) server certificate authentication using the CLI**

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

```
1 set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
2 show ssl service <serviceName>
```

**Example:**

```
1 set ssl service ssl-service-1 -serverAuth ENABLED
```

```
1 show ssl service ssl-service-1
2
3      Advanced SSL configuration for Back-end SSL Service ssl-service-1:
4        DH: DISABLED
5        Ephemeral RSA: DISABLED
6        Session Reuse: ENABLED       Timeout: 300 seconds
7        Cipher Redirect: DISABLED
8        SSLv2 Redirect: DISABLED
9        Server Auth: ENABLED
10       SSL Redirect: DISABLED
11       Non FIPS Ciphers: DISABLED
12       SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
13 1)      Cipher Name: ALL
14      Description: Predefined Cipher Alias
15       Done
```

**Enable (or disable) server certificate authentication by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

**Bind the CA certificate to the service by using the CLI**

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

```bash
bind ssl service <serviceName> -certkeyName <string> -CA
show ssl service <serviceName>
```

Example:

```bash
bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
```

```bash
show ssl service ssl-service-1
Advanced SSL configuration for Back-end SSL Service ssl-service-1:
  DH: DISABLED
  Ephemeral RSA: DISABLED
  Session Reuse: ENABLED Timeout: 300 seconds
  Cipher Redirect: DISABLED
  SSLv2 Redirect: DISABLED
  Server Auth: ENABLED
  SSL Redirect: DISABLED
  Non FIPS Ciphers: DISABLED
  SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
  1) CertKey Name: samplecertkey CA Certificate CRLCheck: Optional
     1) Cipher Name: ALL
     Description: Predefined Cipher Alias
Done
```

**Configure a common name for server certificate authentication**

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful.
If the common names do not match, the common name specified for the service or service group is compared to values in the subject alternative name (SAN) field in the certificate. If it matches one of those values, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

**Note:** Only domain name, URL, and email ID DNS entries in the SAN field are compared.

**Configure common-name verification for an SSL service or service group by using the CLI**

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure common name in a service, type:

   ```
   1 set ssl service <serviceName> -commonName <string> -serverAuth ENABLED
   2 show ssl service <serviceName>
   ```

2. To configure common name in a service group, type:

   ```
   1 set ssl serviceGroup <serviceGroupName> -commonName <string> -serverAuth ENABLED
   2 show ssl serviceGroup <serviceGroupName>
   ```

**Example:**

```
1 > set ssl service svc1 -commonName xyz.com -serverAuth ENABLED

1 show ssl service svc
2
3 Advanced SSL configuration for Back-end SSL Service svc1:
4 DH: DISABLED
5 Ephemeral RSA: DISABLED
6 Session Reuse: ENABLED Timeout: 300 seconds
7 Cipher Redirect: DISABLED
8 SSLv2 Redirect: DISABLED
9 Server Auth: ENABLED Common Name: www.xyz.com
10 SSL Redirect: DISABLED
11 Non FIPS Ciphers: DISABLED
12 SNI: DISABLED
13 SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
14 1) CertKey Name: cacert CA Certificate OCSPCheck: Optional
```
Configure common-name verification for an SSL service or service group by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services or Navigate to Traffic Management > Load Balancing > Service Groups, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

SSL actions and policies

January 23, 2019

Contributed by: C

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.

**Note:** Users who are not experienced in configuring policies at the CLI usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.
Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the Citrix ADC appliance.

2. Citrix ADC 12.1
3. SSL offload and acceleration

SSL policies

January 25, 2019
Contributed by: C

Policies on the Citrix ADC appliance help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through any virtual server configured on the Citrix ADC appliance.

The Citrix ADC appliance SSL feature supports default syntax (advanced) policies. For a complete description of default syntax expressions, how they work, and how to configure them manually, see Policies and Expressions.

**Note:**

Users who are not experienced in configuring policies at the CLI will usually find using the configuration utility considerably easier.

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies.
In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see SSL built-in actions and user-defined actions.

SSL default syntax policies

An SSL default syntax policy, also known as advanced policy, defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy.** A control policy uses a control action, such as forcing client authentication.
  
  **Note:** In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL.
However, control policies, such as CLERAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReNeg to NO.

- **Data policy.** A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed.

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an additional action, called an UNDEF action, to be performed in the event that applying the expression to a request has an undefined result.

**SSL policy configuration**

You can configure an SSL default syntax policy by using the CLI and the GUI.

**Configure an SSL policy by using the CLI**

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -Action <string> [-undefAction <string>] [-comment <string>]
```

**Configure an SSL policy by using the GUI**

Navigate to Traffic Management > SSL > Policies and, on the Policies tab, click Add.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

**SSL built-in actions and user-defined actions**

January 25, 2019

Contributed by:
C

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies, so that you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- CLIENTAUTH—Perform client certificate authentication.
- NOCLIENTAUTH—Do not perform client certificate authentication.

The built-in data actions are:

- RESET—Close the connection by sending a RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

You can create user-defined data actions. For example, if you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying CLIENTAUTH or NOCLIENTAUTH.

**Examples of built-in actions in a policy**

In the following example, if the client sends a cipher other than an EXPORT category cipher, the Citrix ADC appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction CLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction NOOP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction DROP
```
If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```bash
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction RESET
```

**User-defined SSL actions**

In addition to built-in actions, you can also configure other SSL actions depending on your deployment. These are called user-defined actions.

**Configure a user-defined SSL action by using the CLI**

At the command prompt, type the following commands to configure an action and verify the configuration:

```bash
1 add SSL action <name> -clientAuth(DOCIENTAUTH | NOCLIENTAUTH) -clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <string> -clientCertSerialNumber (ENABLED | DISABLED) -certSerialHeader <string> -clientCertSubject (ENABLED | DISABLED) -certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader <string> -clientCertNotBefore (ENABLED | DISABLED) -certNotBeforeHeader <string> -clientCertNotAfter (ENABLED | DISABLED) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
```

```bash
1 show ssl action [<name>]
```

**Example:**

```bash
1 add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X-Client-Cert"
```

```bash
1 show ssl action Action-SSL-ClientCert
2 3 1) Name: Action-SSL-ClientCert
4 Data Insertion Action:
5  Cert Header: ENABLED                Cert Tag: X-Client-Cert
6 Done
```
Configure a user-defined SSL action by using the GUI

Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.

Configure an SSL action to forward client traffic to another virtual server

Note: This feature is available in release 12.1 build 49.x and later.

Admins can configure an SSL action to forward the client traffic received on an SSL virtual server to another virtual server to avoid SSL offloading or terminating the connection on the ADC appliance. For example, if the appliance does not have a certificate or it does not support a specific cipher, instead of terminating the connection, admins can choose to forward the request to another virtual server for further action. This virtual server can be of type: SSL, TCP, or SSL_BRIDGE.

To achieve the above, a new bind point ‘CLIENTHELLO_REQ’ is added to evaluate client traffic when a client hello is received. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, the traffic is forwarded to another virtual server. If this virtual server is of type SSL, it performs the handshake. If this virtual server is of type TCP or SSL_BRIDGE, the backend server performs the handshake.

In release 12.1-49.x, only the forward and reset actions are supported for CLIENTHELLO_REQ bind point. The following expression prefixes are available:

- CLIENT.SSL.CLIENT_HELLO.CIPHERS.HAS_HEXCODE
- CLIENT.SSL.CLIENT_HELLO.CLIENT_VERSION
- CLIENT.SSL.CLIENT_HELLO.IS_RENEGOTIATE
- CLIENT.SSL.CLIENT_HELLO.IS_REUSE
- CLIENT.SSL.CLIENT_HELLO.IS_SCSV
- CLIENT.SSL.CLIENT_HELLO.IS_SESSION_TICKET
- CLIENT.SSL.CLIENT_HELLO.LENGTH
- CLIENT.SSL.CLIENT_HELLO.SNI

For a description of these prefixes, see Advanced policy expressions: parsing SSL

A new parameter ‘forward’ is added to the ‘add SSL action’ command and new bind point ‘CLIENTHELLO_REQ’ is added to the ‘bind ssl vserver’ command.

Configuration using the CLI

At the command prompt, type:

```
1 add ssl action <name> -forward <virtual server name>
2
3 add ssl policy <name> -rule <expression> -action <string>
```
4
5 bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>

EXAMPLE:

1 add ssl action act1 -forward v2
2
3 add ssl policy poll -rule client.ssl.client_hello.ciphers.has_hexcode(0x002f) -action act1
4
5 bind ssl vserver v1 -policyName poll -priority 1 -type CLIENTHELLO_REQ

Configuration using the GUI

Navigate to Traffic Management > SSL > Policies.

Create SSL action:

1. In SSL Actions, click Add.
2. In Create SSL Action, specify a name for the action.
3. In Forward Action Virtual Server, select an existing virtual server or add a new virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click Create.

Create SSL policy:

1. In SSL Policies, click Add.
2. In Create SSL Policy, specify a name for the policy.
3. In Action, select the action that you created above.
4. In Expression Editor, enter the rule to evaluate.
5. Click Create.

Create or add a virtual server and bind policy:

2. Add or select a virtual server.
3. In Advanced Settings, click SSL Policies.
4. Click in the SSL Policy section.
5. In Select Policy, select the policy that you created earlier.
7. In Type, select CLIENTHELLO_REQ.
8. Click Bind.
9. Click **Done**.

For the end-to-end configuration for the most popular use cases, see Configure SSL action to forward client traffic if the appliance does not have a domain specific (SNI) certificate and Configure SSL action to forward client traffic if a cipher is not supported on the ADC.

**SS...**

Starting Citrix ADC release 12.1 build 50.x, you can send only the list of CAs based on SNI (domain) in the client certificate request rather than the list of all the CAs bound to an SSL virtual server. For example, when a client hello is received, only the CA certificates based on the SSL policy expression (for example, SNI) are sent. To send a specific set of certificates, you must create a CA certificates group, bind this group to an SSL action, and bind the action to an SSL policy. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, only a specific CA certificates group is sent in the client request certificate.

Earlier, you had to bind CA certificates to an SSL virtual server. With this enhancement, you can simply add CA certificate groups and associate them to an SSL action.

**Note:** Client authentication and SNI must be enabled on the SSL virtual server, and the correct SNI certificates must be bound to the virtual server.

Perform the following steps:

1. Add a CA certificate group.
2. Add certificate-key pairs.
3. Bind the certificate-key pairs to this group.
4. Add an SSL action.
5. Add an SSL policy. Specify the action in the policy.
6. Bind the policy to an SSL virtual server. Specify the bind point as CLIENTHELLO_REQ.

**Configuration using the CLI**

At the command prompt, type the following commands in a sequence:

```
1. add ssl caCertGroup <caCertGroupName>
2. add ssl certkey <certkey_name> -cert <cert> -key <key>
3. bind ssl caCertGroup <caCertGroupName> <certkey_name>
4. add ssl action <name> -caCertGrpName <string>
5. add ssl policy <name> -rule <expression> -action <string>
6. bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type CLIENTHELLO_REQ
```
Example:

```
1  add ssl cacertGroup ca_cert_group
2  add ssl certkey ca_certkey1 -cert cacert1 -key cakey1
3  add ssl certkey ca_certkey2 -cert cacert2 -key cakey2
4  add ssl certkey snicert -cert snicert -key snikey
5  bind ssl cacertGroup ca_cert_group ca_certkey1
6  bind ssl caCertGroup ca_cert_group ca_certkey2

1  sh ssl caCertGroup ca_cert_group
2  CA GROUP NAME:   ca_cert_group
3  ACTIONS REFERRING:  1
4
5  1)   CertKey Name: ca_certkey1  CA Certificate  CRLCheck: Optional
6      CA_Name Sent
7  2)   CertKey Name: ca_certkey2  CA Certificate  CRLCheck: Optional
8      CA_Name Sent

1  add ssl action pick_ca_group -cacertGrpName ca_cert_group

1  sh ssl action pick_ca_group
2  1)   Name:   sniaction
3      Type:  Data Insertion
4      PickCaCertGroup:  ca_cert_group
5      Hits:  0
6      Undef Hits:  0
7      Action Reference Count:  1

1  add ssl policy snipolicy -rule client.ssl.client_hello.sni.contains("abc") -action pick_ca_group
2  bind ssl vserver v_SSL -policyName snipolicy -type CLIENTHELLO_REQ -priority 10

1  sh ssl policy snipolicy
2    Name:  poll
3    Rule:  client.ssl.client_hello.sni.contains("abc")
4    Action:  pick_ca_group
5    UndefAction:  Use Global
6    Hits:  0
7    Undef Hits:  0
```
Policy is bound to following entities

1)  Bound to: CLIENTHELLO_REQ VSERVER v_SSL
    Priority: 10

set ssl vserver v_SSL -clientauth ENABLED -SNIEnable ENABLED
bind ssl vserver v_SSL -certkeyName snicert -sniCert

sh ssl vserver v_SSL

Advanced SSL configuration for VServer v_SSL:
DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED     Ephemeral RSA: ENABLED   Refresh Count: 0
Session Reuse: ENABLED   Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED   Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: ENABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
SSLv2: DISABLED  SSLv3: ENABLED  TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2: ENABLED  TLSv1.3: DISABLED

Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED
Zero RTT Early Data: DISABLED
DHE Key Exchange With PSK: NO
Tickets Per Authentication Context: 1
ECC Curve: P_256, P_384, P_224, P_521

1)  CertKey Name: snicert  Server Certificate for SNI

Data policy

1)  Policy Name: snipolicy  Priority: 10
Configuration using the GUI

Create CA certificates group and bind certificates to the group:

1. Navigate to Traffic Management > SSL > CA Certificates Group.
2. Click Add and specify a name for the group.
3. Click Create.
4. Select the CA certificate group and then click Show Bindings.
5. Click Bind.
6. In the CA Certificate Binding page, select an existing certificate or click Add to add a new certificate.
7. Click Select and then click Bind.
8. To bind another certificate, repeat steps 5 through 7.
9. Click Close.

Navigate to Traffic Management > SSL > Policies.

Create SSL action:

1. In SSL Actions, click Add.
2. In Create SSL Action, specify a name for the action.
3. In Forward Action Virtual Server, select an existing virtual server or add a new virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click Create.

Create SSL policy:

1. In SSL Policies, click Add.
2. In Create SSL Policy, specify a name for the policy.
3. In Action, select the action that you created above.
4. In Expression Editor, enter the rule to evaluate.
5. Click Create.

Create or add a virtual server and bind policy:

2. Add or select a virtual server.
3. In Advanced Settings, click SSL Policies.
4. Click in the SSL Policy section.
5. In Select Policy, select the policy that you created earlier.
7. In Type, select CLIENTHELLO_REQ.
8. Click Bind.
9. Click Done.

Unbind a CA certificate group by using the GUI

1. Navigate to Traffic Management > SSL > CA Certificates Group.
2. Select a certificate group and click Show Bindings.
3. Select the certificate to remove from the group and click Unbind.
4. If prompted for confirmation, click Yes.
5. Click Close.

Remove a CA certificate group by using the GUI

1. Navigate to Traffic Management > SSL > CA Certificates Group.
2. Select a certificate group and click Delete.
3. If prompted for confirmation, click Yes.
• REQUEST (Default bind point. Policy evaluation is done in the HTTP layer after the SSL handshake is completed.)
• INTERCEPT_REQ (This option applies to a Citrix Secure Web Gateway setup. For more information, see https://docs.citrix.com/en-us/netscaler-secure-web-gateway/12-1/ssl-interception/policy.html)
• CLIENTHELLO_REQ (supported in release 12.1-49.x and later)

Similarly, when unbinding a policy from a virtual server, you must specify the bind point.

If you specify CLIENTHELLO_REQ as the bind point, the policy is evaluated when a client hello message is received. The allowed actions are RESET and FORWARD. The reset action terminates the connection. The forward action forwards the request to a load balancing virtual server for processing. For more information about the forward action, see Configure an SSL action to forward client traffic to another virtual server.

**Bind an SSL policy globally by using the CLI**

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

```
bind ssl global -policyName <string> [- priority <positive_integer>]
show ssl global
```

**Example:**

```
bind ssl global -policyName Policy-SSL-2 -priority 90
Done
sh ssl global
1) Name: Policy-SSL-2 Priority: 90
2) Name: Policy-SSL-1 Priority: 100
Done
```

**Bind an SSL policy globally by using the GUI**

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind SSL Policies to Global dialog box, click Insert Policy.
4. In the Policy Name drop-down list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click **OK**. A message appears in the status bar, stating that the policy has been bound successfully.

**Bind or unbind an SSL policy to a virtual server by using the CLI**

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

```plaintext
1. bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>
2. unbind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>
```

**Example:**

```plaintext
1. bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
2. unbind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
```

```plaintext
1. show ssl vserver vs-server
2. Advanced SSL configuration for VServer vs-server:
3. DH: DISABLED
4. Ephemeral RSA: ENABLED Refresh Count: 1000
5. Session Reuse: ENABLED Timeout: 120 seconds
6. Cipher Redirect: DISABLED
7. SSLv2 Redirect: DISABLED
8. ClearText Port: 80
9. Client Auth: DISABLED
10. SSL Redirect: ENABLED
11. SSL-REDIRECT Port Rewrite: ENABLED
```
Bind an SSL policy to a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. In Advanced Settings, select SSL Policy. Click in the SSL policy section to bind a policy to the virtual server.
3. In the Policy Binding page, select an existing policy or add a new policy.
4. Specify priority and type (bind point) for the policy.
5. Select Bind.
6. Select Done.

SSL policy labels

January 23, 2019
Contributed by:
C

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, you bind policies to the label and specify the order of evaluation of each policy relative to others...
in the bank of policies for the policy label. At the CLI, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

**Create an SSL policy label and bind policies to the label by using the CLI**

At the command prompt, type:

```
1 add ssl policylabel <labelName> -type ( CONTROL | DATA )
2 bind ssl policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]
```

**Example:**

```
1 add ssl policylabel cpl1 -type CONTROL
2 add ssl policylabel dpl1 -type DATA
3 bind ssl policylabel cpl1 -policyName ctrlpol -priority 1
4 bind ssl policylabel dpl1 -policyName datapol -priority 1
```

**Configure an SSL policy label and bind policies to the label by using the GUI**

Navigate to Traffic Management > SSL > Policy Labels, and configure an SSL policy label.

1. Citrix ADC
2. Citrix ADC 12.1
3. SSL offload and acceleration

**Selective SSL logging**

January 23, 2019

Contributed by: C

In a large deployment comprising thousands of virtual servers, all SSL-related information is logged. Earlier, filtering the client authentication and SSL handshake successes and failures for a few critical virtual servers was not easy. Perusing through the entire log to get this information was a time-
consuming and tedious task because the infrastructure did not offer the control to filter the logs. Now, you can log SSL-related information in `ns.log`, for a specific virtual server or for a group of virtual servers. This information is especially helpful in debugging failures. To log this information, you must add an SSL log profile.

See sample `ns.log` output for successful client authentication at the end of this page.

### SSL log profile

An SSL log profile provides control over logging the following events for a virtual server or a group of virtual servers:

- Client authentication success and failures, or only failures.
- SSL handshake success and failures, or only failures.

By default, all the parameters are disabled.

An SSL log profile can be set on an SSL profile, or on an SSL action. If set to an SSL profile, you can log both client authentication and SSL handshake success and failure information. If set to an SSL action, you can only log client authentication success and failure information because the handshake is complete before the policy is evaluated.

Client authentication and SSL handshake success and failures are logged even if you do not configure an SSL log profile. However, selective logging is possible only if SSL log profile is used.

**Note:**

SSL log profile is supported in high availability and cluster setups.

### Add an SSL log profile by using the CLI

At the command prompt, type:

```
1  add ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )] [-sslLogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED | DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
```

**Parameters:**

**Name:**

Name for the SSL log profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

Name is a mandatory argument. Maximum Length: 127
sslLogClAuth:
Log all client authentication events. Includes both success and failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

ssllogClAuthFailures:
Log all client authentication failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

sslLogHS:
Log all SSL handshake related events. Includes both success and failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

sslLogHSfailures:
Log all SSL handshake related failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

Example:

```bash
1     > add ssl logprofile ssllog10 -sslLogClAuth ENABLED -sslLogHS ENABLED
2          Done
3
4     sh ssllogprofile ssllog10
5
6      1)      Name: ssllog10
7          SSL log ClientAuth [Success/Failures] : ENABLED
8          SSL log ClientAuth [Failures] : DISABLED
9          SSL log Handshake [Success/Failures] : ENABLED
10         SSL log Handshake [Failures] : DISABLED
11          Done
```
Add an SSL log profile by using the **GUI**

Navigate to System > Profiles > SSL Log Profile and add a profile.

Modify an SSL log profile by using the **CLI**

At the command prompt type:

```
set ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )][-ssllogClAuthFailures ( ENABLED | DISABLED )] [-ssllogHS ( ENABLED | DISABLED )] [-ssllogHSfailures ( ENABLED | DISABLED )]
```

Example:

```
set ssllogprofile ssllog10 -ssllogClAuth en -ssllogClAuthFailures en -ssllogHS en -ssllogHSfailures en
Done
sh ssllogprofile ssllog10
1) Name: ssllog10
SSL log ClientAuth [Success/Failures] : ENABLED
SSL log ClientAuth [Failures] : ENABLED
SSL log Handshake [Success/Failures] : ENABLED
SSL log Handshake [Failures] : ENABLED
Done
```

Modify an SSL log profile by using the **GUI**

1. Navigate to System > Profiles > SSL Log Profile, select a profile, and click **Edit**.
2. Make changes and click **OK**.

View all the SSL log profiles by using the **CLI**

At the command prompt, type:

```
sh ssl logprofile
```

Example:
```
sh ssl logprofile

1) Name: ssllogp1
   SSL log ClientAuth [Success/Failures] : ENABLED
   SSL log ClientAuth [Failures] : ENABLED
   SSL log Handshake [Success/Failures] : DISABLED
   SSL log Handshake [Failures] : ENABLED

2) Name: ssllogp2
   SSL log ClientAuth [Success/Failures] : DISABLED
   SSL log ClientAuth [Failures] : DISABLED
   SSL log Handshake [Success/Failures] : DISABLED
   SSL log Handshake [Failures] : DISABLED

3) Name: ssllogp3
   SSL log ClientAuth [Success/Failures] : DISABLED
   SSL log ClientAuth [Failures] : DISABLED
   SSL log Handshake [Success/Failures] : DISABLED
   SSL log Handshake [Failures] : DISABLED

4) Name: ssllog10
   SSL log ClientAuth [Success/Failures] : ENABLED
   SSL log ClientAuth [Failures] : ENABLED
   SSL log Handshake [Success/Failures] : ENABLED
   SSL log Handshake [Failures] : ENABLED

Done
```

View all the SSL log profiles by using the GUI

Navigate to System > Profiles > SSL Log Profile. All the profiles are listed.

Attach an SSL log profile to an SSL profile

You can attach (set) an SSL log profile on an SSL profile when you are creating an SSL profile, or later by editing the SSL profile. You can log both client authentication and handshake successes and failures.

**Important:**

The default SSL profile must be enabled before you can attach an SSL log profile.
**Attach an SSL log profile on an SSL profile by using the CLI**

At the command prompt, type:

```
1 set ssl profile <name> [-ssllogProfile <string>]
```

**Example:**

```
1 set ssl profile fron_1 -ssllogProfile ssllog10
```

**Attach an SSL log profile to an SSL profile by using the GUI**

1. Navigate to System > Profiles > SSL Profile.
2. Click Edit and in SSL Log Profile, specify a profile.

**Attach an SSL log profile to an SSL action**

You can set an SSL log profile only while creating an SSL action. You cannot modify an SSL action to set the log profile. Associate the action to a policy. You can only log client authentication successes and failures.

**Attach an SSL log profile to an SSL action by using the CLI**

At the command prompt, type:

```
1 add ssl action <name> -clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) -ssllogProfile <string>
```

**Example:**

```
> add ssl action act1 -clientAuth DoCLIENTAUTH -ssllogProfile ssllog10
Done
> sh ssl action act1
1) Name: act1
   Type: Client Authentication (DOCLIENTAUTH)
   Hits: 0
   Undef Hits: 0
   Action Reference Count: 0
   SSLlogProfile: ssllog10
```
Attach an SSL log profile to an SSL action by using the GUI

1. Navigate to Traffic Management > SSL > Policies and click SSL Actions.
2. Click Add.
3. In Client Authentication, select ENABLED.
4. In SSL Log Profile, select a profile from the list, or click “+” to create a profile.
5. Click Create.

Sample output from the log file

The following is a sample log output from ns.log for successful client authentication.

```
1 Jan 24 16:24:25 <local0.debug> 10.102.57.80 01/24/2019:10:54:25 GMT 0-PPE-0 : default SSLLOG SSL_HANDSHAKE_SUCCESS 158 0 : SPCBId 671 - ClientIP 10.102.1.98 - ClientPort 49451 - VserverServiceIP 10.102.57.82 - VserverServicePort 443 - ClientVersion TLSv1.2 - CipherSuite "AES-256-CBC-SHA TLSv1.2 Non-Export 256-bit" - Session New - CLIENT_AUTHENTICATED -SerialNumber "2A" - SignatureAlgorithm "sha1WithRSAEncryption" - ValidFrom "Sep 22 09:15:20 2008 GMT" - ValidTo "Feb 8 09:15:20 2036 GMT" - HandshakeTime 10 ms

Support for DTLSv1.0 protocol

February 7, 2019

Contributed by:

Notes:

- DTLSv1.0 protocol is supported on Citrix ADC MPX/SDX (N2 and N3 based), VPX, and MPX 14000 FIPS appliances. It is not supported on external HSMs.
- Citrix ADC MPX 14000 FIPS platform is supported in build 12.1-49.x and later.
- Support for Intel Coleto based appliances is added in build 12.1-50.x and later. The following appliances ship with Intel Coleto chips:
  - MPX 5901/5905/5910
  - MPX 8905/8910/8920/8930
  - MPX/SDX 26100-100G/26160-100G/26100-200G

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is slow. In addition, TLS cannot handle lost or reordered packets. UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

Create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (nsdtls_default_profile) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4 ciphers are not supported on a DTLS virtual server.
DTLS configuration

You can use the command line (CLI) or the configuration utility (GUI) to configure DTLS on your ADC appliance.

Create a DTLS configuration by using the CLI

At the command prompt, type:

```
1 add lb vserver <vserver_name> DTLS <IPAddress> <port>
2 add service <service_name> <IPAddress> UDP 443
3 bind lb vserver <vserver_name> <udp_service_name>
```

The following steps are optional:

```
1 add dtlsProfile dtls1 -maxretryTime <positive_integer>
2 set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
```

Create a DTLS configuration by using the GUI

2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a profile, click the plus (+) next to DTLS Profile.

Support for SNI on a DTLS virtual server

From release 12.1 build 49.x, SNI is supported on a DTLS virtual server. For information about SNI, see Configure an SNI virtual server for secure hosting of multiple sites.

Configure SNI on a DTLS virtual server by using the CLI

At the command prompt, type:

```
1 set dtls vserver <vServerName> -SNIEnable ENABLED
2 bind dtls vserver <vServerName> -certkeyName <string> -SNICert
3 show dtls vserver <vServerName>
```

Example:
set ssl vserver v1 -sniEnable ENABLED
bind ssl vserver v1 -certkeyName san2 -sniCert
bind ssl vserver v1 -certkeyName san13 -sniCert
bind ssl vserver v1 -certkeyName san17 -sniCert

sh ssl vserver v1

Advanced SSL configuration for VServer v1:
DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED
Ephemeral RSA: ENABLED
Refresh Count: 0
Session Reuse: ENABLED
Timeout: 1800 seconds
Cipher Redirect: DISABLED

ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: ENABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
DTLSv1: ENABLED
Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED
Zero RTT Early Data: DISABLED
DHE Key Exchange With PSK: NO
Tickets Per Authentication Context: 1

DTLS profile name: nsdtls_default_profile

ECC Curve: P_256, P_384, P_224, P_521

1) CertKey Name: ca
CA Certificate OCSPCheck: OptionalCA_Name Sent
2) CertKey Name: san2 Server Certificate for SNI
3) CertKey Name: san17 Server Certificate for SNI
4) CertKey Name: san13 Server Certificate for SNI

1) Cipher Name: DEFAULT
Configure SNI on a DTLS virtual server by using the GUI

2. Open a DTLS virtual server and, in Certificates, click Server Certificate.
3. Add a certificate or select a certificate from the list and select Server Certificate for SNI.
4. In Advanced Settings, click SSL Parameters.
5. Select SNI Enable.

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- Secure renegotiation

Parameters not used by a DTLS virtual server

A DTLS virtual server ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

Configure renegotiation on a DTLS service

From build 49.x, non-secure renegotiation is supported on a DTLS service. You can use the CLI or the GUI to configure this setting.
**Configure renegotiation on a DTLS service by using the CLI**

At the command prompt, type:

```
1 set ssl parameter -denysslreneg NONSECURE
```

**Example:**

```
1 set ssl parameter -denysslreneg NONSECURE
```

```
1 sh ssl parameter
2 Advanced SSL Parameters
3 -----------------------
4 SSL quantum size : 8 KB
5 Max CRL memory size : 256 MB
6 Strict CA checks : NO
7 Encryption trigger timeout : 100 ms
8 Send Close-Notify : YES
9 Encryption trigger packet count: 45
10 Deny SSL Renegotiation : NONSECURE
11 Subject/I ssuer Name Insertion Format : Unicode
12 OCSP cache size : 10 MB
13 Push flag : 0x0 (Auto)
14 Strict Host Header check for SNI enabled SSL sessions : NO
15 PUSH encryption trigger timeout : 1 ms
16 Crypto Device Disable Limit : 0
17 Global undef action for control policies : CLIENTAUTH
18 Global undef action for data policies : NOOP
19 Default profile : DISABLED
20 SSL Insert Space in Certificate Header : YES
21 Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors : NO
22 Disable TLS 1.1/1.2 for dynamic and VPN services : NO
23 Software Crypto acceleration CPU Threshold : 0
24 Hybrid FIPS Mode : DISABLED
25 Signature and Hash Algorithms supported by TLS1.2 : ALL
26 SSL Interception Error Learning and Caching : DISABLED
27 SSL Interception Maximum Error Cache Memory : 0 Bytes
28 Done
```

**Configure renegotiation on a DTLS service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Select a DTLS service and click Edit.
3. Navigate to SSL > Advanced Settings.
4. Select Deny SSL Renegotiation.

Features not supported by a DTLS service

The following options cannot be enabled on a DTLS service:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation

Parameters not used by a DTLS service

A DTLS service ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

Note:
SSL session reuse handshake fails on a DTLS service because session reuse is not currently supported on DTLS services.

Workaround: Manually disable session reuse on a DTLS service. At the CLI, type:

```
set ssl service <dtls-service-name> -sessReuse DISABLED
```

DTLS profile

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a DTLS profile with specific settings to suit your requirement.

Use a DTLS profile with a DTLS virtual server or a VPN DTLS virtual server. You cannot use an SSL profile with a DTLS virtual server.
Create a DTLS profile by using the CLI

```plaintext
1 add ssl dtlsProfile <name>
2 show ssl dtlsProfile <name>
```

Example:

```plaintext
1 add dtlsProfile dtls1 -helloVerifyRequest ENABLED -maxretryTime 4
2 Done
3 show dtlsProfile dtls1
4 1) Name: dtls1
5     PMTU Discovery: DISABLED
6     Max Record Size: 1460 bytes
7     Max Retry Time: 4 sec
8     Hello Verify Request: ENABLED
9     Terminate Session: DISABLED
10    Max Packet Count: 120 bytes
11 Done
```

Create a DTLS profile by using the GUI

Navigate to System > Profiles > DTLS Profiles and configure a new profile.

Example for an end-to-end DTLS configuration

```plaintext
1 enable ns feature SSL LB
2 add server s1 198.51.100.2
3 en ns mode usnip
4 add service svc_dtls s1 DTLS 443
5 add lb vserver v1 DTLS 10.102.59.244 443
6 bind ssl vserver v1 -ciphername ALL
```
add ssl certkey servercert -cert servercert_aia_valid.pem -key serverkey_aia.pem
bind ssl vserver v1 -certkeyname servercert
bind lb vserver lb1 svc_dtls

sh lb vserver v1

**DTLS cipher support**

**Note:**
From release 12.1 build 49.x, ADH ciphers are no longer supported with the DTLS protocol.

**How to read the tables:**
Unless a build number is specified, a cipher suite is supported for all builds in a release.

**Example:**
- **10.5, 11.0, 11.1, 12.0, 12.1:** All builds of 10.5, 11.0, 11.1, 12.0, 12.1 releases.
- **NA:** not applicable.

**DTLS cipher support on Citrix ADC VPX, MPX/SDX (N2 and N3 based) appliances**

**DTLS cipher support on the Citrix ADC MPX 14000 FIPS platform**

**Note:** Enlightened Data Support (EDT) is supported on the FIPS platform in build 49.x and later if all of the following conditions are met:

- UDT MSS value set on StoreFront is 900.
- Windows client version is 4.12 or later.
- DTLS enabled VDA version is 7.17 or later.
- Non-DTLS VDA version is 7.15 LTSR CU3 or later.

Support for Intel Coleto SSL chip based platforms

January 23, 2019
Contributed by: C

The following appliances ship with Intel Coleto chips:

- MPX 5901/5905/5910
- MPX 8905/8910/8920/8930
- MPX/SDX 26100-100G/26160-100G/26100-200G

Use the 'show hardware' command to identify whether your appliance has Coleto (COL) chips.

```
> sh hardware
Platform: NSMPX-8900 8*CPU+4*F1X+6*E1K+1*E1K+1*COL 8955 30010
Manufactured on: 10/18/2016
CPU: 2100MHZ
Host Id: 0
Serial no: CRAC5CR8UA
```
Limitations:

- DH 512 cipher is not supported.
- SSLv3 protocol is not supported.
- GnuTLS is not supported.
- ECDSA certificates with ECC curves P_224 and P521 are not supported (Not supported on platforms with Cavium chips also.)
- DNSSEC offload is not supported. (DNSSEC is supported in software but offload to hardware is not supported.)

1. 
   2. Citrix ADC 
   3. Citrix ADC 12.1 
   4. SSL offload and acceleration 

MPX 9700/10500/12500/15500 FIPS appliances 

January 25, 2019

Contributed by:
C

The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The Citrix ADC FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—and a Cavium CN1620-NFBE3-2.0-G on the MPX 9700/10500/12500/15500 FIPS appliances—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.
The following table summarizes the differences between standard Citrix ADC and Citrix ADC FIPS appliances.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Citrix ADC appliance</th>
<th>Citrix ADC FIPS appliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key storage</td>
<td>On the hard disk</td>
<td>On the FIPS card</td>
</tr>
<tr>
<td>Cipher support</td>
<td>All ciphers</td>
<td>FIPS approved ciphers</td>
</tr>
<tr>
<td>Accessing keys</td>
<td>From the hard disk</td>
<td>Not accessible</td>
</tr>
</tbody>
</table>

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you should export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability (HA) setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard HA setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1, and you can reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a Citrix ADC FIPS appliance.

**HSM configuration**

Before you can configure the HSM of your Citrix ADC FIPS appliance, you must complete the initial hardware configuration. For more information about MPX appliances, see Initial Configuration. For information about SDX appliances, click here.

Configuring the HSM of your Citrix ADC FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser (nsroot account). The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM. The maximum length allowed for the password is 14 alphanumeric characters. Symbols are not allowed.

**Important:** Do not perform the set ssl fips command without first resetting the FIPS card and restarting the MPX FIPS appliance. Although the FIPS appliance can be used with the default password values, you should modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

**Important:** Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. Should you need to reinitialize the HSM, you will need to specify this password as the old SO password.
Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see Upgrading or Downgrading the System Software.

After upgrading, verify that the /nsconfig/fips directory has been successfully created on the appliance.

**Configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the CLI**

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

```
1  show ssl fips
2  reset ssl fips
3  reboot
4  set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <userPassword> [-hsmLabel <string>]
5  save ns config
6  reboot
7  show ssl fips
```

**Example:**

```
1  show fips
2  FIPS Card is not configured
3  Done
4  reset fips
5  reboot
6  Are you sure you want to restart NetScaler (Y/N)? [N]:y
7  set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel cavium
8  This command will erase all data on the FIPS card. You must save the configuration
9  (saveconfig) after executing this command.
10
```
Do you want to continue? (Y/N) y

Done

save ns config
reboot

Are you sure you want to restart NetScaler (Y/N)? [N]: y

show fips

FIPS HSM Info:
HSM Label : Citrix ADC FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 2.1G1008-IC000021
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Firmware Version : 1.1
Firmware Release Date : Jun04,2010
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3994
Total SRAM Memory : 467348
Free SRAM Memory : 62564
Total Crypto Cores : 3
Enabled Crypto Cores : 1
Done

Note: If you upgrade the firmware to version 2.2, the firmware release date is replaced with the firmware build.

> show fips

FIPS HSM Info:
HSM Label : Citrix ADC FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 3.0G1235-ICM000264
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Hardware Version : 2.0-G
Firmware Version : 2.2
Firmware Build : NFBE-FW-2.2-130009
Configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the GUI

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Infotab, click Reset FIPS.
3. In the navigation pane, click System.
4. In the details pane, click Reboot.
5. In the details pane, on the FIPS Info tab, click Initialize HSM.
6. In the Initialize HSM dialog box, specify values for the following parameters:
   - Security Officer (SO) Password*—new SO password
   - Old SO Password*—old SO password
   - User Password*—user password
   - Level—initHSM (Currently set to Level2 and cannot be changed)
   - HSM Label—hsmLabel
   *A required parameter

7. Click OK.
8. In the details pane, click Save.
9. In the navigation pane, click System.
10. In the details pane, click Reboot.
11. Under FIPS HSM Info, verify that the information displayed for the FIPS HSM that you just configured is correct.

Create and transfer FIPS keys

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance’s HSM. You can then export the FIPS key to the appliance’s CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance. You must enable SIM between
two standalone nodes before you export and transfer the keys. In an HA setup, if one of the nodes is replaced with a new appliance, you must enable SIM between this new appliance and the existing appliance of the HA setup before you export or import FIPS keys.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

**Note:** If you are planning an HA setup, make sure that the FIPS appliances are configured in an HA setup before creating a FIPS key.

### Create FIPS keys

Before creating a FIPS key, make sure that the HSM is configured.

You must specify the key type (RSA or ECDSA) and specify the curve for ECDSA keys.

**Create a FIPS key by using the GUI**

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Keys tab, click Add.
3. In the Create FIPS Key dialog box, specify values for the following parameters:
   - **FIPS Key Name**—fipsKeyName
   - **Modulus**—modulus
   - **Exponent**—exponent
   
   *A required parameter*
4. Click Create, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just created are correct.

**Create a FIPS key by using the CLI**

At the command prompt, type the following commands to create a FIPS key and verify the settings:

```
1 create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent ( 3 | F4 )]
2
3 show ssl fipsKey [<fipsKeyName>]
```

**Example:**
Export FIPS keys

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the /nsconfig/ssl folder on the appliance’s CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

Export a FIPS key by using the CLI

At the command prompt, type:

```
export ssl fipsKey <fipsKeyName> -key <string>
```

Example:

```
export fipskey Key-FIPS-1 -key Key-FIPS-1.key
```

Export a FIPS key by using the GUI

1. Navigate to Traffic Management > SSL > FIPS

2. In the details pane, on the FIPS Keys tab, click Export.

3. In the Export FIPS key to a file dialog box, specify values for the following parameters:

   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

   *A required parameter

4. Click Export, and then click Close.
Import an existing FIPS key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

**Note:** To avoid errors when importing a FIPS key, make sure that the name of the key imported is the same as the original key name when it was created.

Import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the CLI

At the command prompt, type the following commands to import a FIPS key and verify the settings:

```bash
1 - import ssl fipsKey <fipsKeyName> -key <string> -inform SIM -exponent (F4 | 3)
2 - show ssl fipskey <fipsKeyName>
```

**Example:**

```bash
1 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
2 show ssl fipskey key-FIPS-2
3 FIPS Key Name: Key-FIPS-2 Modulus: 2048 Public Exponent: F4 (Hex value 0x10001)
```

Import a FIPS key by using the GUI

1. Navigate to Traffic Management > SSL > FIPS

2. In the details pane, on the FIPS Keys tab, click Import.

3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
   - Exponent*

   *A required parameter

4. Click Import, and then click Close.

5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.
Import an external key

In addition to transferring FIPS keys that are created within the Citrix ADC appliance’s HSM, you can transfer external private keys (such as those created on a standard Citrix ADC, Apache, or IIS) to a FIPS Citrix ADC appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance’s flash drive under /nsconfig/ssl.

On the MPX 9700/10500/12500/15500 FIPS appliances, the -exponent parameter in the import ssl fipskey command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The Citrix ADC FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```
openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
```

**Note:** If you import an RSA key as a FIPS key, Citrix recommends that you delete the RSA key from the appliance for security purposes.

Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the CLI

1. Copy the external key to the appliance’s flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:

```
convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx file name> -password <password>
```

3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:

```
import ssl fipsKey <fipsKeyName> -key <string> -informPEM
2 show ssl fipskey<fipsKeyName>
```

**Example:**

```
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx
```
**Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the GUI**

1. If the key is in .pfx format, you must first convert it to PEM format.
   a) Navigate to Traffic Management > SSL.
   b) In the details pane, under Tools, click Import PKCS#12.
   c) In the Import PKCS12 File dialog box, set the following parameters:
      - Output File Name*
      - PKCS12 File Name*—Specify the .pfx file name.
      - Import Password*
      - Encoding Format
      *A required parameter

2. Navigate to Traffic Management > SSL > FIPS

3. In the details pane, on the FIPS Keys tab, click Import.

4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify
     the complete path or click Browse and navigate to a location.
   *A required parameter

5. Click Import, and then click Close.

6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported
   are correct.

---

```bash
import fipskey Key-FIPS-2 -key iis.pem -inform PEM
show ssl fipskey key-FIPS-2
FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0x10001)
```
Configure FIPS appliances in a high availability setup

January 25, 2019
Contributed by: C

You can configure two appliances in a high availability (HA) pair as FIPS appliances. For information about configuring an HA setup, see High availability.

**Note:** Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause inconsistency that requires that the appliance be restarted. In addition, if you use the CLI, the create ssl fipskey command is not propagated to the secondary node. When you execute the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not identical. You have to create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

**Important:** On the MPX 9700/10500/12500/15500 FIPS appliances, the HA setup should be completed within six minutes. If the process takes longer than six minutes, the internal timer of the FIPS card expires and the following error message appears:

```
ERROR: Operation timed out or repeated, please wait for 10 mins and redo the SIM/HA configuration steps.
```

If this message appears, restart the appliance or wait for 10 minutes, and then repeat the HA setup procedure.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.

**Configure FIPS appliances in a high availability setup by using the CLI**

1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:
   ```
   init ssl fipsSIMsource <certFile>
   ```
4. Copy this `<certFile>` file to appliance B, in the /nconfig/ssl folder.
5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:
   ```
   init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>
   ```
8. Copy this `<targetSecret>` file to appliance A.
9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:
   ```
   enable ssl fipsSIMSource <targetSecret> <sourceSecret>
   ```
10. Copy this `<sourceSecret>` file to appliance B.
11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:
    ```
    enable ssl fipsSIMtarget <keyVector> <sourceSecret>
    ```
12. **On appliance A**, create a FIPS key, as described in *Create a FIPS key*.
13. Export the FIPS key to the appliance’s hard disk, as described in *Export a FIPS key*.
14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in *Import an existing FIPS key*.

### Configure FIPS appliances in a high availability setup by using the GUI

1. On the appliance to be configured as the source appliance, navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Info tab, click Enable SIM.
3. In the Enable HA Pair for SIM dialog box, in the Certificate File Name text box, type the file name, with the path to the location at which the FIPS certificate should be stored on the source appliance.
4. In the Key Vector File Name text box, type the file name, with the path to the location at which the FIPS key vector should be stored on the source appliance.
5. In the Target Secret File Name text box, type the location for storing the secret data on the target appliance.
6. In the Source Secret File Name text box, type the location for storing the secret data on the source appliance.
7. Click OK. The FIPS appliances are now configured in HA mode.
8. Create a FIPS key, as described in Create a FIPS key. The FIPS key is automatically transferred from the primary to the secondary.

The following diagram summarizes the transfer process.

Figure 1. Transfer the FIPS key-summary

1. 
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

---

**Update the firmware to version 2.2 on a FIPS card**

January 23, 2019

Contributed by: C

FIPS firmware version 2.2 supports TLS protocol versions 1.1 and 1.2. From the command line, you can update the firmware version of the FIPS card of a Citrix ADC MPX 9700/10500/12500/15500 FIPS appliance from version 1.1 to version 2.2.

For successful SIM key propagation from primary to secondary in a high availability (HA) pair, the Cavium firmware version on each appliance should be identical. Perform the firmware update on the secondary appliance first. If executed on the primary appliance first, the long-running update process causes a failover.

**Limitations**

- Secure renegotiation is supported only on SSL virtual servers and front-end SSL services.
- Creating a certificate signing request by using a key that was created on firmware version 1.1 and updated to firmware version 2.2 fails.
- You cannot create a 1024-bit RSA key on firmware version 2.2. However, if you have imported or created a 1024-bit FIPS key on firmware version 1.1 and you then update to firmware version 2.2, you can use that FIPS key on firmware version 2.2.
- 1024-bit RSA keys are not supported.
- Secure renegotiation using SSLv3 protocol is not supported.
- After you upgrade the firmware, TLSv1.1 and TLSv1.2 are disabled by default on the existing virtual server, internal, front end, and backend services. To use TLS 1.1/1.2, you must explicitly enable these protocols, on the SSL entities, after the upgrade.
• FIPS keys that are created in firmware version 2.2 are not available if you downgrade the firmware to version 1.1.

Prerequisites

Download the following files from the download page on www.citrix.com. The files must be stored in the /var/nsinstall directory on the appliance.

• FW 2.2 File: FW-2.2-130013
• FW 2.2 Signature File: FW-2.2-130013.sign

FW-2.2-130013 is the recommended firmware version. It includes fixes to improve DRBG.

Update the FIPS firmware to version 2.2 on a standalone appliance

1. Log on to the appliance by using the administrator credentials.
2. At the prompt, type the following command to confirm that the FIPS card is initialized.

```
show fips
```

3. Save the configuration. At the prompt, type:

```
save config
```
4. Perform the update. At the prompt, type:

```
update ssl fips -fipsFW <path to the extracted contents>/CN16XX-NFBE-FW-2.2-1300013
```

Press Y when the following prompt appears:

```
This command will update compatible version of the FIPS firmware. You must save the current configuration (saveconfig) before executing this command. You must reboot the system after execution of this command, for the firmware update to take effect. Do you want to continue?(Y/N)Y
```

**Note:** You only need to specify the firmware file, because the firmware signature file is placed in the same location.

The update takes up to ten seconds. The update command is blocking, which means that no other actions are executed until the command finishes. The command prompt reappears when execution of the command is completed.

1. Restart the appliance. At the prompt, type:

```
reboot
```

```
Are you sure you want to restart NetScaler (Y/N)? [N]:Y
```

2. Verify that the update is successful. At the prompt, type:

```
show fips
```

The firmware version displayed in the output should be 2.2. For example:

```
sh fips
FIPS HSM Info:
  HSM Label : Citrix ADC FIPS
  Initialization : FIPS-140-2 Level-2
  HSM Serial Number : 2.1G1207-IC002429
  HSM State : 2
  HSM Model : NITROX XL CN1620-NFBE
  Hardware Version : 2.0-G
  Firmware Version : 2.2
  Firmware Build : NFBE-FW-2.2-130013
  Max FIPS Key Memory : 3996
```
Update the FIPS firmware to version 2.2 on appliances in a high availability pair

1. Log on to the secondary node and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

   Force the secondary node to become primary. At the prompt, type:

   `force failover`

   Press Y at the confirmation prompt.

2. Log on to the new secondary node (old primary) and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

3. Force the new secondary node to become primary again. At the prompt, type:

   `force failover`

   Press Y at the confirmation prompt.

Update the FIPS firmware to version 1.1 on a standalone appliance

1. Download the nfb_firmware-r1235_100604 and nfb_firmware-r1235_100604.sign files, to the same directory on the appliance, from the download page on www.citrix.com.

2. Log on to the appliance by using the administrator credentials.

3. At the prompt, type:

   `update ssl fips -fipsFW /<full path to the file>/nfb_firmware-r1235_100604`
**Reset a locked HSM**

January 25, 2019

Contributed by: C

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. This is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

**Important:** To avoid this situation, save the configuration after initializing the HSM.

If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

**Caution:** Do not reset the HSM unless it has become locked.

**Reset a locked HSM by using the CLI**

At the command prompt, type the following commands to reset and re-initialize a locked HSM:

```
1 reset ssl fips
2 reboot -warm
3 set ssl fips -initHSM Level-2 <new S0 password> <old S0 password> <user password> [-hsmLabel <string>]
4 save ns config
5 reboot -warm
```

**Example:**

```
1 reset fips
2
3 reboot -warm
4
5 set fips -initHSM Level-2 newsopin123 sopin123 userpin123 -hsmLabel NSFIPS
6
7 saveconfig
8
9 reboot -warm
10
```
Note: By default the HSM passwords are preconfigured. The <Old_SO_Password> = so12345, <User_Password> = user123, <New_SO_Password> = sopin12345, <New_User_Password> = userpin123.

Reset a locked HSM by using the GUI

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in Configuring the HSM.
4. In the details pane, click Save.

MPX 14000 FIPS appliances

January 25, 2019

Contributed by: C

Important:
Configuration steps for Citrix ADC MPX 14000 FIPS and Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances are different.

A FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0 build 56.x). The Critical Security Parameters (CSPs), primarily the server’s private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (ns-root) can perform operations on the keys stored inside the HSM.

Before configuring a FIPS appliance, you must check the state of the FIPS card and then initialize the card. Create a FIPS key and server certificate, and add any additional SSL configuration.

For information about the FIPS ciphers supported, see FIPS Approved Algorithms and Ciphers.

For information about configuring FIPS appliances in a high availability setup, see Configuring FIPS Appliances in a High Availability Setup.
Limitations

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an MPX FIPS appliance.
2. 1024-bit and 4096-bit keys and exponent value of 3 are not supported.

Configure the HSM

Before configuring the HSM on an MPX 14000 FIPS appliance, you must check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

```
show fips
FIPS Card is not configured
Done
```

The message “ERROR: Operation not permitted - no FIPS card present in the system” appears if the driver is not loaded correctly.

Initialize the FIPS card

The appliance must be restarted three times for proper initialization of the FIPS card.

Important

- Verify that the /nsconfig/fips directory has been successfully created on the appliance.
- Do not save the configuration before you restart the appliance for the 3rd time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1. Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance.
7. Verify that the password encrypted key for the default partition (default_pek.key) has been created in the /nsconfig/fips/ directory.
8. Restart the appliance.
9. Verify that the FIPS card is UP.
Initialize the FIPS card by using the CLI

At the command prompt, type the following commands:

1. reset fips
2. Done
3. reboot
4. set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS
5. This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. Do you want to continue? (Y/N) y
6. saveconfig
7. Done

Note: The following message appears when you run the set fips command:

1. This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue? (Y/N) y
2. saveconfig
3. Done
4. reboot
5. reboot
6. reboot
7. show fips
8. FIPS HSM Info:
9. HSM Label : NSFIPS
10. Initialization : FIPS-140-2 Level-2
11. HSM Serial Number : 3.0G1501-ICM000083
12. HSM State : 2
13. HSM Model : No Model Info
14. Hardware Version : 0.0-G
15. Firmware Version : 1.0
16. Firmware Build : NFBE-FW-1.0-39
17. Max FIPS Key Memory : 102235
18. Free FIPS Key Memory : 102233
19. Total SRAM Memory : 557396
Create FIPS keys

You can create a FIPS key on your MPX 14000 FIPS appliance or import an existing FIPS key to the appliance. The MPX 14000 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your appliance.

You must specify the key type (RSA or ECDSA) and specify the curve for ECDSA keys.

Note
1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

Create a FIPS key by using the CLI

At the command prompt, type:

```
create ssl fipsKey <fipsKeyName> -keytype ( RSA | ECDSA ) [-exponent (3 | F4)] [-modulus <positive_integer>] [-curve ( P_256 | P_384 )]
```

Example:

```
create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4
Done
show ssl fipskey ddvws
FIPS Key Name: f1  Key Type: RSA Modulus: 2048  Public Exponent: F4 (Hex: 0x10001)
Done
```

Import a FIPS key by using the CLI

At the command prompt, type:

```
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv<string>] -exponent F4
```
Example:

```
1 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
2 Done
3
4 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM
5 Done
```

Verify that the FIPS key is created or imported correctly by running the `show fipskey` command.

```
1 show fipskey
2 1) FIPS Key Name: Key-FIPS-2
3 Done
```

Create a certificate signing request by using the CLI

At the command prompt, type:

```
1 create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform ( DER | PEM ) { -PEMPassPhrase } -countryName <string> -stateName <string> -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] { -challengePassword } [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
```

Example:

```
1 >create certreq f1.req -fipsKeyName f1 -countryName US -stateName CA
   -organizationName Citrix -companyName Citrix -commonName ctx -emailAddress test@example.com
2 Done
```

Create a server certificate by using the CLI

At the command prompt, type:

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM ) { -PEMPassPhrase }
2
```
Example:

```
create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAserial ns-root.srl -days 1000
```

Done

The above example creates a server certificate using a local root CA on the appliance.

**Add a certificate-key pair by using the CLI**

At the command prompt, type:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>][-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]
```

Example:

```
add certkey cert1 -cert f1.cert -fipsKey f1
```

Done

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server. Save the configuration.

```
enable ns feature SSL LB
Done
4 add server s1 10.217.2.5
Done
7 add service srl s1 HTTP 80
Done
10 add lb vserver v1 SSL 10.217.2.172 443
Done
13 bind ssl vserver v1 -certkeyName cert1
```
The basic configuration of your MPX 14000 FIPS appliance is now complete.

For information about configuring secure HTTPS, click [here](#).

For information about configuring secure RPC, click [here](#).

**Support for hybrid FIPS mode on the MPX 14000 FIPS and SDX 14000 FIPS platforms**

**Note:**

This feature is supported only on the new MPX/SDX 14000 FIPS platform containing one primary FIPS card and one or more secondary cards. It is not supported on a VPX platform or a platform containing only one type of hardware card.

On a FIPS platform, all the encryption and decryption (asymmetric and symmetric) is performed on the FIPS card for security reasons. However, you can perform part of this activity (asymmetric) on a FIPS card and offload the bulk encryption and decryption (symmetric) to another card without compromising the security of your keys.

The new MPX/SDX 14000 FIPS platform contains one primary card and one or more secondary cards. If you enable the hybrid FIPS mode, the pre-master secret decryption commands are run on the primary card because the private key is stored on this card, but the bulk encryption and decryption is offloaded to the secondary card. This significantly increases the bulk encryption throughput on an MPX/SDX 14000 FIPS platform as compared to non-hybrid FIPS mode and the existing MPX 9700/10500/12500/15000 FIPS platform. Enabling the hybrid FIPS mode also improves the SSL transaction per second on this platform.

The hybrid FIPS mode is disabled by default to meet the strict certification requirements where all the crypto-computation must be done inside a FIPS certified module. You must enable the hybrid mode to offload the bulk encryption and decryption to the secondary card.

**Note:**

On an SDX 14000 FIPS platform, you must first assign an SSL chip to the VPX instance before you enable the hybrid mode.
Enable hybrid FIPS mode by using the CLI

At the command prompt, type:

```
set SSL parameter -hybridFIPSMode { ENABLED|DISABLED }
```

Arguments

- `hybridFIPSMode`

When this mode is enabled, system will use additional crypto hardware to accelerate symmetric crypto operations.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example:

```
set SSL parameter -hybridFIPSMode ENABLED
show SSL parameter
Advanced SSL Parameters
    . . . . . . . . .
Hybrid FIPS Mode : ENABLED
. . . . . . . . .
Done
```

Enable hybrid FIPS mode by using the GUI

1. Navigate to Traffic Management > SSL.
2. In the details pane, under Settings, click Change advanced SSL settings.
3. In the Change Advanced SSL Settings dialog box, select Hybrid FIPS Mode.

Limitations:

1. Renegotiation is not supported.
2. The “stat ssl parameter” command on an SDX 14000 platform does not display the correct secondary card utilization percentage. It always displays 0.00% utilization.
SDX 14000 FIPS appliances

January 25, 2019

Contributed by:

Citrix ADC SDX appliance is a multitenant platform on which you can provision and manage multiple virtual Citrix ADC instances. The SDX appliance addresses cloud computing and multitenancy requirements by allowing a single administrator to configure and manage the appliance and delegate the administration of each hosted instance to tenants.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance provides the capabilities of an SDX appliance with FIPS functionality. It is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0 build 56.x). The Critical Security Parameters (CSPs), primarily the server’s private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance contains one FIPS HSM module with 63 cores. The FIPS HSM module can be partitioned up to a maximum of 32 partitions. The SDX administrator can assign dedicated key storage, cryptographic resources, and number of crypto SSL FIPS cores to each partition. Keys and resources allocated to a partition are dedicated and secure and cannot be accessed or shared by another partition.

The FIPS HSM partition that you create can be assigned or attached to a VPX instance at the time of provisioning the instance, or later by editing the instance. The FIPS partition created and attached to
an instance acts like a virtual HSM module for that particular instance.

The VPX instances on an SDX 14030/14060/14080 FIPS appliance are assigned a FIPS virtual function (VF) partition, which is treated as an isolated FIPS virtual card or HSM. Therefore, the steps to configure a FIPS partition inside a VPX instance are similar to the steps to configure an MPX FIPS appliance. For compliance details, see the security policy details on the U.S. National Institute of Standards and Technology (NIST) website.

For information about configuring FIPS appliances in a high availability setup, see [FIPS Appliances in a High Availability Setup](#).

**Important**

Each key includes a private and a public key. As a result, it occupies two key spaces. Therefore, the maximum number of keys is limited to one less than half the key store size.

The SDX 14000 FIPS platform supports a hybrid FIPS mode. In this mode, you can offload part of the encryption and decryption activity to a non-FIPS card. For more information, see [Hybrid FIPS mode](#).

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an SDX FIPS appliance.
2. 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.
3. Backup and restore is not supported.
4. Cluster and administrative domains are not supported.
5. You can attach only one FIPS partition to an instance.
6. An instance with a FIPS partition can be assigned only one CPU core.
7. You can assign either a FIPS partition or an SSL core to an instance, but not both.

---

**Limitations**

---

January 23, 2019

Contributed by: C

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an SDX FIPS appliance.
2. 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.
3. Backup and restore is not supported.
4. Cluster and administrative domains are not supported.
5. You can attach only one FIPS partition to an instance.
6. An instance with a FIPS partition can be assigned only one CPU core.
7. You can assign either a FIPS partition or an SSL core to an instance, but not both.
**Terminology**

January 23, 2019

Contributed by: C

**Zeroize**: Reset the HSM. All the data on the HSM is deleted. This is a mandatory step before the HSM is initialized.

**Initialize**: Set the HSM capabilities. The Citrix ADC SDX FIPS appliance complies with FIPS-140-2 level 2. You can create partitions after you initialize the chip.

**Key store size**: Number of keys that can be stored on a partition. A maximum of 102235 keys can be specified. The maximum number of keys that can be stored is one less than half the number specified. For example, if you specify 100, you can create only 49 keys because one of the keys is the RSA key pair that consumes 2 key stores.

**Crypto Core Capacity**: Number of crypto cores assigned to a partition. A maximum of 63 cores are available.

**SSL Context**: Number of concurrent SSL connections that can be created on a partition.

1. Citrix ADC
2. Citrix ADC 12.1
3. SSL offload and acceleration

**Initialize the HSM**

January 25, 2019

Contributed by: C

Before initializing the HSM, you must first zeroize it.

**Zeroize the HSM by using the Management Service**

1. Open a browser and log on to the appliance.
2. On the Configuration tab, navigate to System > HSM Administration, and in the details plane, click **Zeroize**.
All data is wiped from the FIPS chip, and the state appears as “Zeroized.” Any HSM partitions created earlier are deleted.

**Initialize the HSM by using the Management Service**

1. On the Configuration tab, navigate to System > HSM Administration, and in the details plane, click Initialize.
2. Type a new user name, specify a password, and click OK.

The card state appears as “Initialized.”

1. 
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

**Create partitions**

January 25, 2019

Contributed by:

Create partitions for different tenants and specify the cryptographic resources for each partition. Each instance is assigned one partition, and a partition can be assigned to only one instance. Deleting an instance deletes the partition assigned to the instance. As a result, the partition data is also deleted and not left unsecured or accessible later. Number of keys and SSL context assignment depends on your application. For information about number of cores to assign, see the Citrix ADC datasheet.

**Important**

After you assign a key store size and cores to an HSM partition, you cannot change them at runtime. You must first detach the partition from the instance.

**Create a partition by using the Management Service**

1. On the Configuration tab, navigate to System > HSM Administration > Partitions, and in the details plane, click Add.
2. Specify a name for the partition, and the resources to be assigned to this partition.
3. Click OK.
The summary page displays all the partitions that were created. Some partitions are assigned an instance while some are free partitions.

3. SSL offload and acceleration

Provision a new instance or modify an existing instance and assign a partition

January 25, 2019
Contributed by: C

After creating the partitions, you must assign them to instances.

Important:
- You can attach only one FIPS partition to an instance.
- An instance with a FIPS partition can be assigned only one CPU core.
- You can assign either a FIPS partition or an SSL core to an instance, but not both.

Provision a new instance or modify an existing instance

1. On the Configuration tab, navigate to NetScaler > Instances, and add or modify an instance.
2. Select Enable FIPS, and from the Partitions list, select a partition to attach to this instance.

You can verify that the partition is attached to an instance by using either the GUI or the CLI.

In the GUI, navigate to System > HSM Administration > Partitions. The instance name attached to the partition is displayed.

To unassign a FIPS partition, navigate to NetScaler > Instances. Edit the instance and clear the Enable FIPS check box.

In the CLI, at the command prompt, type the following commands:

```
1  show fips
2
3  FIPS Card is not configured
4  Done
```
Citrix ADC 12.1

If you see the following output, see the troubleshooting section for debugging.

ERROR: Operation not permitted - no FIPS card present in the system

1. Citrix ADC
2. Citrix ADC 12.1
3. SSL offload and acceleration

Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance

January 23, 2019

Contributed by: C

You must first check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

```
show fips
```

```
FIPS Card is not configured
```

```
Done
```

If the driver is not loaded correctly, the message “ERROR: Operation not permitted - no FIPS card present in the system” appears.

Initialize the FIPS card

**Important:**
Verify that the /nsconfig/fips directory has successfully been created on the appliance.

Do not save the configuration before you restart the appliance for the third time.

Perform the following configuration before you restart the appliance for the third time.

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.  
   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance.
7. Verify that the FIPS card is UP.

**Initialize the FIPS card by using the CLI**

At the command prompt, type the following commands:

```plaintext
reset fips
reboot
set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -hsmLabel <string>
```

*Note:* The following message appears when you run the `set fips` command:

```plaintext
This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y
```

```plaintext
saveconfig
reboot
show fips
```

**Example:**

```plaintext
reset fips
Done
reboot
set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS
```
9 This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue? (Y/N) y

Create a FIPS key for an instance on an SDX 14030/14060/14080 FIPS appliance

January 25, 2019
Contributed by: C

You can create a FIPS key on your instance or import an existing FIPS key into the instance. An SDX 14030/14060/14080 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your instance.

Note:
1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

Create a FIPS key by using the CLI

At the command prompt, type:

```
create ssl fipsKey <fipsKeyName> -keytype (RSA | ECDSA) [-exponent (3 | F4)] [-modulus <positive_integer>] [-curve (P_256 | P_384)]
```

Example:

```
create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4
Done
show ssl fipskey ddvws
FIPS Key Name: f1  Key Type: RSA Modulus: 2048  Public Exponent: F4 (Hex: 0x10001)
Done
```

Import a FIPS key by using the CLI

At the command prompt, type:
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv<string>] [-exponent F4 ]

Example:

import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
Done

import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM
Done

Verify that the FIPS key is created or imported correctly by running the show fipskey command.

1 show fipskey
2 1) FIPS Key Name: Key-FIPS-2
3 Done

Create a certificate signing request by using the CLI

At the command prompt, type:

create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform ( DER | PEM ) { [-PEMPassPhrase ] [-countryName <string> -stateName <string> -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] { [-challengePassword ] [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )] ]

Example:

create certreq f1.req -fipsKeyName f1 -countryName US -stateName CA -organizationName Citrix -companyName Citrix -commonName ctx -emailAddress test@example.com'
2 ‘Done

Create a server certificate by using the CLI

At the command prompt, type:

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM ) { [-PEMPassPhrase ] }
Example:

```
create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAserial ns-root.srl -days 1000
```

Done

The above example creates a server certificate using a local root CA on the appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type:

```
add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]
```

Example:

```
add certkey cert1 -cert f1.cert -fipsKey f1
```

Done

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server, and save the configuration.

```
enable ns feature SSL LB
Done
add server s1 10.217.2.5
Done
add service srl s1 HTTP 80
Done
add lb vserver v1 SSL 10.217.2.172 443
Done
bind ssl vserver v1 -certkeyName cert1
Done
bind lb vserver v1 srl
Done
saveconfig
```

Upgrade the FIPS firmware

January 25, 2019
Contributed by: C

FIPS firmware updates are released from time to time. Download the latest firmware from the Citrix download page and upload it to the appliance. The upgrade process might take up to 10 minutes to complete. The instance is restarted after the upgrade.

Upgrade the FIPS firmware

1. Navigate to System > HSM Administration > Firmware Images.
2. Select Upload.
3. Navigate to the folder that contains the firmware image and select the file.
4. Navigate to System > HSM Administration, and select Upgrade Firmware.
5. Select the firmware image to upgrade to, and click OK.

2. Citrix ADC 12.1
3. SSL offload and acceleration

Support for Thales nShield® HSM

March 6, 2019
A non-FIPS Citrix ADC appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a Thales nShield® Connect external HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS appliances.

Thales nShield® Connect is an external FIPS-certified network-attached HSM. With a Thales HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the Thales HSM only.

If you are already using a Thales HSM, you can now use a Citrix ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

**Note:**

- Thales HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the Thales HSM. Only the Hardserver can read the response from the HSM to the Citrix ADC appliance, because it is encrypted.

Architecture overview

January 25, 2019
Contributed by: C

The three entities that are part of a Citrix ADC-Thales deployment are a Thales nShield Connect module, a remote file server (RFS), and a Citrix ADC.

The Thales nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

Hardserver, a proprietary daemon provided by Thales, is used for communication between the client (ADC), the Thales HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the Hardserver Gateway, is used to communicate between the Citrix ADC packet engine and the Hardserver.

Note: The terms Thales nShield Connect, Thales HSM, and HSM are used interchangeably in this documentation.

The following figure illustrates the interaction between the different components.

In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the GUI or command line to load the keys to the HSM. A virtual server on the ADC uses Thales to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

Note: The terms keys and application key tokens are used interchangeably in this documentation.

The following figure illustrates the packet flow in the SSL handshake with the Thales HSM.

Figure 1. SSL Handshake Packets Flow Diagram with Citrix ADC Using Thales HSM

Note: The communication between the ADC and the HSM uses a Thales proprietary communication protocol, called IMPATH.

Prerequisites

March 6, 2019
Before you can use a Thales nShield Connect with a Citrix ADC, make sure that the following prerequisites are met:

- A Thales nShield Connect device is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.
- A usable Security World exists. Security World is a unique key management architecture used by the Thales nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Thales. You can also find the guide in the CD provided with the Thales HSM module at CipherTools-linux-dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf.
  Note: Softcard or token/OCS protected keys are currently not supported on the Citrix ADC.
- Licenses are available to support the number of clients that will be connected to the Thales HSM. The ADC and RFS are clients of the HSM.
- A remote file server (RFS) is installed in the network and is accessible to the Citrix ADC.
- The Thales nShield Connect device, the RFS, and the Citrix ADC can initiate connections with each other through port 9004.
- You are using NetScaler release 10.5 build 52.1115.e or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.
  Important: Thales HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configure the ADC-Thales integration

January 25, 2019

The following flowchart depicts the tasks that you need to perform to use Thales HSM with a Citrix ADC:

As shown in the above flowchart, you perform the following tasks:

1. Enable remote configuration push on the HSM.
2. Configure the ADC to use the Thales HSM.
   • Add the NSIP address on the HSM.
   • Configure access permission for the ADC on the RFS.
   • Configure automatic start of the Hardserv at boot time.
   • Enroll the HSM on the ADC.
   • Add RFS details on the ADC.
   • Synchronize the ADC to the RFS.
   • Verify that Thales HSM is successfully enrolled on the ADC.

3. (Optional) Create an HSM RSA key.

4. Configure the entities on the Citrix ADC.
   • Add the HSM key.
   • Add a certificate-key pair by using the HSM key.
   • Add a virtual server.
   • Add a server object.
   • Add a service.
   • Bind the service to the virtual server.
   • Bind the certificate-key pair to the virtual server.
   • Verify the configuration.

**Configure the Thales HSM**

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

**Specify the IP address of a remote computer on the Thales HSM**

1. Navigate to **System Configuration > Config file options > Allow auto push**.
2. Select **ON**, and specify the IP address of the computer (RFS) from which to accept the configuration.

**Enable remote configuration push on the HSM**

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.
**Specify the IP address of a remote computer on the Thales HSM**

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

**Configure the ADC to use the Thales HSM**

Sample values used in this documentation:

- NSIP address=10.217.2.43
- Thales HSM IP address=10.217.2.112
- RFS IP address=10.217.2.6

**Add the NSIP address on the HSM**

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.

Alternately, use the RFS to add the ADC as a client to the HSM. To do this, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can do this, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

```
root@ns# /opt/nfast/bin/anonkneti <Thales HSM IP address>
```

**Example:**

```
root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
BD17-C807-58D9  5e30a698f7bab3b2068ca90a9488dc4e6c78d822
```

The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

```
vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

In the hs_clients section, add the following entries:

```
# Amount of data in bytes to encrypt with a session key before session key# renegotiation, or 0 for unlimited. (default=1024*1024*8b=8Mb).
# datalimit=INT
addr=10.217.2.43
```
Note: Include one or more hyphens as delimiters to add multiple entries in the same section.

To push the configuration to the HSM, run the following command on the RFS:

```
/opt/nfast/bin/cfg-pushnethsm --address=<Thales HSM IP address> --force
/opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

Example:

```
1 /opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
2 /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

Configure access permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:

```
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP address>
```

Example:

```
1 [root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-noauth 10.217.2.43
2 Adding read-only remote_file_system entries
3 Ensuring the directory /opt/nfast/kmdata/local exists
4 Adding new writable remote_file_system entries
5 Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
6 Saving the new config file and configuring the hardserver
7 Done
```

Verify that the ADC can reach both the RFS and Thales HSM by using port 9004.

Configure automatic start of the hardserver at boot time

Create a file and then restart the appliance. Now, whenever you restart the appliance, and if this file is found, the Hardserver is automatically started.
At the shell prompt, type:

```
touch /var/opt/nfast/bin/thales_hsm_is_enrolled
```

At the command prompt, type:

```
reboot
```

**Enroll the HSM on the ADC**

Change directory to `/var/opt/nfast/bin`.

To add HSM details into the ADC configuration, run the following command on the ADC:

```
nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti <Thales_nShield_Connect_ip_address>)
```

**Example:**

```
root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)
```

OK configuring hardserver's nethsm imports

This step adds the following entries after the line `# ntoken_esn=ESN` in the nethsm_imports section of the `/var/opt/nfast/kmdata/config/config` file.

```
...  
local_module=0  
remote_ip=10.217.2.112  
remote_port=9004  
remote_esn=BD17-C807-58D9  
keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822  
timelimit=86400  
datalimit=8388608  
privileged=0  
privileged_use_high_port=0  
ntoken_esn=
```

Change directory to `/var/opt/nfast/bin` and run the following command on the ADC:

```
touch ”thales_hsm_is_enrolled”
```

**Note:** To remove an HSM that is enrolled on the ADC, type:

```
./nethsmenroll -remove <NETHSM-IP>
```
Add RFS details on the ADC

To add RFS details, change directory to /var/opt/nfast/bin/ and then run the following command:

```bash
./rfs-sync --no-authenticate --setup <rfs_ip_address>
```

**Example:**

```
./rfs-sync --no-authenticate --setup 10.217.2.6
No current RFS synchronization configuration.
Configuration successfully written; new config details:
Using RFS at 10.217.2.6:9004: not authenticating.
```

This step adds the following entries after the # local_esn=ESN line in the rfs_sync_client section of the /var/opt/nfast/kmdata/config/config file.

```
... ...
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=
```

**Note:** To remove an RFS that is enrolled on the ADC, type:

```bash
./rfs_sync -remove
```

Synchronize the ADC to the RFS

To synchronize all the files, change directory to /var/opt/nfast/bin and then run the following command on the ADC:

```bash
./rfs-sync -update
```

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdata/local directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module_XXXX_XXXX_XXXX files, where XXXX_XXXX_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

Verify that the Thales HSM is successfully enrolled on the ADC

After you synchronize the ADC to the RFS, do the following:

- Verify that the local Hardserver is UP and running. (nCipher server running).
- Get the state of the configured HSMs, and verify that the values for the n_modules (number of modules) field and the km info fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state 0x2 Usable) by the ADC.
- Load tests using sigtest run properly.

Change directory to
/var/opt/nfast/bin, and at the shell prompt, run the following commands:

```
1 root@ns# ./chkserv root@ns# ./nfkminfo root@ns# ./sigtest
```

See
Appendix for an example.

**Create an HSM RSA Key**

Only RSA keys are supported as HSM keys.

**Note:** Skip this step if keys are already present in the
/opt/nfast/kmdata/local folder on the RFS.

Create an RSA key, a self-signed certificate, and a Certificate Signing Request (CSR). Send the CSR to a certificate authority to get a server certificate.

The following files are created in the example below:

- Embed RSA key: key_embed_2ed5428aaae1e159bdbd63f25292c7113ec2c78
- Self-Signed Certificate: example_selfcert
- Certificate Signing Request: example_req

**Note:** The
generatekey command is supported in strict FIPS 140-2 Level 3 Security World. An administrator card set (ACS) or an operator card set (OCS) is needed to control many operations, including the creation of keys and OCSs. When you run the
generatekey command, you are prompted to insert an ACS or OCS card. For more information about strict FIPS 140-2 Level 3 Security World, see the nShield Connect User Guide.

The following example uses Level-2 Security World. In the example, the commands are in boldface type.

**Example:**

```
1 [root@localhost bin]# ./generatekey embed
2 size: Key size? (bits, minimum 1024) [1024] > 2048
3 OPTIONAL: pubexp: Public exponent for RSA key (hex)? []
4 >
5 embedsavefile: Filename to write key to? []
```
You have created a CSR (example_req), a self-signed certificate (example_selfcert), and an application key token file in embed format (/opt/nfast/kmdata/local/key_embed_2ed5428aaeeae1e159bdbd63f25292c7113ec2c78)

Because the ADC supports keys in simple format only, you must convert the embed key to a simple key.

To convert the embed key to a simple key, run the following command on the RFS:

```
# example
plaintext: Key name? [] > example
x509country: Country code? [] > US
x509province: State or province? [] > CA
x509locality: City or locality? [] > Santa Clara
x509org: Organisation? [] > Citrix
x509orgunit: Organisation unit? [] > NS
x509dnscommon: Domain name? [] > www.citrix.com
x509email: Email address? [] > example@citrix.com
nvram: Blob in NVRAM (needs ACS)? (yes/no) [no] > [default sha1] > sha512
digest: Digest to sign cert req with? (md5, sha1, sha256, sha384, sha512)
[default sha1] > sha512

key generation parameters:
operation: Operation to perform generate
application: Application embed
verify: Verify security of key yes
type: Key type RSA
size: Key size 2048
pubexp: Public exponent for RSA key (hex) example
embedsavefile: Filename to write key to example
plaintext: Key name example
x509country: Country code US
x509province: State or province CA
x509locality: City or locality Santa Clara
x509org: Organisation Citrix
x509orgunit: Organisation unit NS
x509dnscommon: Domain name www.citrix.com
x509email: Email address example@citrix.com
nvram: Blob in NVRAM (needs ACS) no
digest: Digest to sign cert req with sha512
Key successfully generated.
Path to key: /opt/nfast/kmdata/local/
    key_embed_2ed5428aaeeae1e159bdbd63f25292c7113ec2c78
You have new mail in /var/spool/mail/root
```
```
[root@localhost bin]# ./generatekey -r simple
from-application: Source application? (embed, simple) [embed] > embed
from-ident: Source key identifier? (c6410ca00af7e394157518cb53b2db46ff18ce29,
                    2
ed5428aaeae1e159bdbg63f25292c7113ec2c78
)
[default c6410ca00af7e394157518cb53b2db46ff18ce29]
> 2ed5428aaeae1e159bdbg63f25292c7113ec2c78
ident: Key identifier? [] > examplersa2048key
plainname: Key name? [] > examplersa2048key
key generation parameters:
operation          Operation to perform     retarget
application        Application             simple
verify             Verify security of key   yes
from-application  Source application     embed
from-ident         Source key identifier  2
                    ed5428aaeae1e159bdbg63f25292c7113ec2c78
ident               Key identifier        examplersa2048key
plainname           Key name               examplersa2048key
Key successfully retargetted.
Path to key: /opt/nfast/kmdata/local/key_simple_examplersa2048key
```

**Important:**
When prompted for the source key identifier, enter `2ed5428aaeae1e159bdbg63f25292c7113ec2c78` as the embed key.

**Result:**
A key with the prefix key_simple (for example key_simple_examplersa2048key) is created.

**Note:** examplersa2048key is the key identifier (ident) and is referred to as the HSM key name on the ADC. A key identifier is unique. All the simple files have the prefix key_simple.

**Configure the Entities on the ADC**
Before the ADC can process traffic, you must do the following:

1. Enable features.
2. Add a subnet IP (SNIP) address.
3. Add the HSM key to the ADC.
4. Add a certificate-key pair by using the HSM key.
5. Add a virtual server.
6. Add a server object.
7. Add a service.
8. Bind the service to the virtual server.
9. Bind the certificate-key pair to the virtual server.
10. Verify the configuration.

Enable features on the ADC

Licenses must be present on the ADC before you can enable a feature.

Enable a feature by using the CLI

At the command prompt, run the following commands:

```
1 enable feature lb
2 enable feature ssl
```

Enable a feature by using the GUI

Navigate to System > Settings and, in the Modes and Features group, select Configure basic features••, and then select ••SSL Offloading.

Add a subnet IP address

For more information about subnet IP addresses, see Configuring Subnet IP Addresses.

Add a SNIP address and verify the configuration by using the CLI

At the command prompt, run the following commands:

```
1 add ns ip <IPAddress> <netmask> -type SNIP
2 show ns ip
```

Example:

```
1 add ns ip 192.168.17.253 255.255.248.0 -type SNIP
2 Done
3 show ns ip

<table>

</tr>
</tbody>
</table>
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Add a SNIP address and verify the configuration by using the GUI

Navigate to System > Network > IPs, add an IP address, and select the IP Type as Subnet IP.

Copy the HSM key and certificate to the ADC

Use a secure file transfer utility to securely copy the key (key_simple_examplersa2048key) to the /var/opt/nfast/kmdata/local folder, and the certificate (example_selfcert) to the /nsconfig/ssl folder on the ADC.

Add the key on the ADC

All the keys have a key-simple prefix. When adding the key to the ADC, use the ident as the HSM key name. For example, if the key that you added is key_simple_XXXX, the HSM key name is XXXX.

Important:

- The HSM key name must be the same as the ident that you specified when you converted an embed key to a simple key format.
- The keys must be present in the /var/opt/nfast/kmdata/local/ directory on the ADC.

Add an HSM key by using the CLI

At the shell prompt, run the following command:

```
1  add ssl hsmKey <hsmKeyName> -key <string>
```

Example:

```
1  add ssl hsmKey examplersa2048key -key key_simple_examplersa2048key
2  Done
```

Add an HSM key by using the GUI

Navigate to Traffic Management > SSL > HSM, and add an HSM key.
**Add a certificate-key pair on the ADC**

For information about certificate-key pairs, see *Add or update a certificate-key pair*.

**Add a certificate-key pair by using the CLI**

At the command prompt, run the following command:

```
add ssl certKey <certkeyName> -cert <string> -hsmKey <string>
```

**Example:**

```
add ssl certKey key22 -cert example_selfcert -hsmKey examplersa2048key
Done
```

**Add a certificate-key pair by using the GUI**

Navigate to Traffic Management > SSL > Certificates, and add a certificate-key pair.

**Add a virtual server**

For information about a virtual server, see *SSL virtual server configuration*.

**Configure an SSL-based virtual server by using the CLI**

At the command prompt, run the following command:

```
add lb vserver <name> <serviceType> <IPAddress> <port>
```

**Example:**

```
add lb vserver v1 SSL 192.168.17.252 443
```

**Configure an SSL-based virtual server by using the GUI**

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.
Add a server object

Before you can add a server object on the ADC, make sure that you have created a backend server. The following example uses the built-in python HTTP Server module on a Linux system.

Example:

```
1  python -m SimpleHTTPServer 80
```

Add a server object by using the CLI

At the command prompt, run the following command:

```
1  add server <name> <IPAddress>
```

Example:

```
1  add server s1 192.168.17.246
```

Add a server object by using the GUI

Navigate to Traffic Management > Load Balancing > Servers, and add a server.

Add a service

For more information, see Configuring services.

Configure a service by using the CLI

At the command prompt, run the following command:

```
1  add service <name> <serverName> <serviceType> <port>
```

Example:

```
1  add service sr1 s1 HTTP 80
```

Configure a service by using the GUI

Navigate to Traffic Management > Load Balancing > Services, and create a service.
Bind the service to the virtual server

For more information, see
Bind services to the SSL virtual server.

Bind a service to a virtual server by using the CLI

At the command prompt, run the following command:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver v1 sr1
```

Bind a service to a virtual server by using the GUI

2. Open a virtual server, and click in the Services pane to bind a service to the virtual server.

Bind the certificate-key pair to the virtual server on the ADC

For more information, see
Bind the certificate-key pair to the SSL virtual server.

Bind a certificate-key pair to a virtual server by using the CLI

At the command prompt, run the following command:

```
bind ssl vserver <vServerName> -certkeyName <string>
```

Example:

```
bind ssl vserver v1 -certkeyName key22
Warning: Current certificate replaces the previous binding
```

Bind a certificate-key pair to a virtual server by using the GUI

2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate to the virtual server.
Verify the configuration

To view the configuration by using the CLI:

At the command prompt, run the following commands:

1. `show lb vserver <name>`
2. `show ssl vserver <vServerName>`

Example:

```
1  show lb vserver v1
2      v1 (192.168.17.252:443) - SSL  Type: ADDRESS
3      State: UP
4      Last state change was at Wed Oct 29 03:11:11 2014
5      Time since last state change: 0 days, 00:01:25.220
6      Effective State: UP
7      Client Idle Timeout: 180 sec
8      Down state flush: ENABLED
9      Disable Primary Vserver On Down : DISABLED
10     Appflow logging: ENABLED
11     No. of Bound Services : 1 (Total)  1 (Active)
12     Configured Method: LEASTCONNECTION
13     Current Method: Round Robin, Reason: Bound service’s state changed to UP
14      Mode: IP
15      Persistence: NONE
16      Vserver IP and Port insertion: OFF
17      Push: DISABLED   Push VServer:
18      Push Multi Clients: NO
19      Push Label Rule: none
20      L2Conn: OFF
21      Skip Persistency: None
22      IcmpResponse: PASSIVE
23      RHIsate: PASSIVE
24      New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
25      Mac mode Retain Vlan: DISABLED
26      DBS_LB: DISABLED
27      Process Local: DISABLED
28      Traffic Domain: 0
29 1) sr1 (192.168.17.246: 80) - HTTP State: UP    Weight: 1
30 Done
```
To view the configuration by using the GUI:

Navigate to Traffic Management > Load Balancing > Virtual Servers, and double-click an SSL virtual server to open it and view the configuration.

1. Citrix ADC
2. Citrix ADC 12.1
3. SSL offload and acceleration

Limitations

January 23, 2019

Contributed by: C
Citrix ADC 12.1

- SSL version 3 (SSLv3) is not supported on an MPX appliance but is supported on a VPX virtual appliance. A VPX instance provisioned on an SDX appliance supports SSLv3 only if an SSL chip is not assigned to the instance.
- Export ciphers are not supported.
- SSL server key exchange using HSM keys is not supported.
- If you have added or removed keys after you last saved the configuration, you must save the configuration before you perform a warm restart. If you do not save the configuration, there will be a key mismatch between the ADC and the HSM.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot bind a certificate-key pair that is created by using an HSM key to an SSL service.
- You cannot use the GUI to enroll the ADC as a client of the HSM or check the status of the HSM from the configuration utility.
- From release 11 build 62.x, SSL renegotiation is supported.
- You cannot sign OCSP requests by using a certificate-key pair that is created by using an HSM key.
- A certificate bundle with HSM keys is not supported.
- An error does not appear if the HSM key and certificate do not match. Therefore, while adding a certificate-key pair, you need to make sure that the HSM key and certificate match.
- Clustering and admin partitions are not supported.

Support for Gemalto SafeNet Network hardware security module

April 19, 2019
Contributed by: C

A non-FIPS Citrix ADC appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted with special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances and the MPX/SDX 14000 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX/SDX appliances, or on the Citrix ADC VPX appliances. This limitation is addressed by supporting a SafeNet network HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS and the MPX/SDX 14000 FIPS appliances.

A SafeNet network HSM is designed to protect critical cryptographic keys and to accelerate sensitive cryptographic operations across a wide range of security applications.

4. SSL offload and acceleration

Prerequisites

January 23, 2019
Contributed by: C

Before you can use a SafeNet network HSM with a Citrix ADC, make sure that the following prerequisites are met:

- A SafeNet network HSM is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.
- Licenses are available to support the required number of partitions on the HSM.
- The SafeNet network HSM and the Citrix ADC can initiate connections with each other through port 1792.
- You are using NetScaler release 11.1 or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.

Important
SafeNet network HSMs are not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

1. 
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

Configure a SafeNet client on the ADC

January 25, 2019
Contributed by: C

After you have configured the SafeNet HSM and created the required partitions, you must create clients and assign them to partitions. Begin by configuring the SafeNet clients on the Citrix ADC and setting up the network trust links (NTLs) between the SafeNet clients and the SafeNet HSM. A sample configuration is given in the Appendix.

1. Change directory to /var/safenet and install the Safenet client. At the shell prompt, type:
To install Safenet client version 6.0.0, type:

```bash
cd /var/safenet
install_client.sh -v 600
```

To install Safenet client version 6.2.2, type:

```bash
cd /var/safenet
install_client.sh -v 622
```

**Note**
SafeNet client version 6.2.2 is supported in release 12.0 build 51.x and later.

2. Configure the NTLs between SafeNet client (ADC) and HSM.

After the ‘/var/safenet/’ directory is created, perform the following tasks on the ADC.

a) Change directory to ‘/var/safenet/config/’ and run the ‘safenet_config’ script. At the shell prompt, type:

```bash
cd /var/safenet/config
sh safenet_config
```

This script copies the “Chrystoki.conf” file into the /etc/ directory. It also generates a symbolic link ‘libCryptoki2_64.so’ in the ‘/usr/lib/’ directory.

b) Create and transfer a certificate and key between the ADC and the SafeNet HSM.

In order to communicate securely, the ADC and the HSM must exchange certificates. Create a certificate and key on the ADC and then transfer it to the HSM. Copy the HSM certificate to the ADC.

i) Change directory to /var/safenet/safenet/lunaclient/bin.

ii) Create a certificate on the ADC. At the shell prompt, type:

```bash
./vtl createCert -n <ip address of Citrix ADC>
```

This command also adds the certificate and key path to the “/etc/Chrystoki.conf” file.

iii) Copy this certificate to the HSM. At the shell prompt, type:

```bash
scp /var/safenet/safenet/lunaclient/cert/client/<ip address of NS>.pem <LunaSA_HSM account>@<IP address of Luna SA>
```

iv) Copy the HSM certificate to the Citrix ADC. At the shell prompt, type:
3) Register the Citrix ADC as a client and assign it a partition on the SafeNet HSM.

Log on to the HSM and create a client. Enter the NSIP as the client IP. This must be the IP address of the ADC from which you transferred the certificate to the HSM. After the client is successfully registered, assign a partition to it. Run the following commands on the HSM.

a) Use SSH to connect to the SafeNet HSM and enter the password.

b) Register the Citrix ADC on the SafeNet HSM. The client is created on the HSM. The IP address is the client’s IP address. That is, the NSIP address.

At the prompt, type:

```bash
client register -client <client name> -ip <Citrix ADC ip>
```

c) Assign the client a partition from the partition list. To view the available partitions, type:

```bash
<luna_sh> partition list
```

Assign a partition from this list. Type:

```bash
<lunash:> client assignPartition -client <Client Name> -par <Partition Name>
```

4) Register the HSM with its certificate on the Citrix ADC.

On the ADC, change directory to “/var/safenet/safenet/lunaclient/bin” and, at the shell prompt, type:

```bash
./vtl addserver -n <IP addr of HSM> -c /var/safenet/safenet/lunaclient/server_<HSM IP>.pem
```

To remove the HSM that is enrolled on the ADC, type:

```bash
./vtl deleteServer -n <HSM IP> -c <cert path>
```

To list the HSM servers configured on the ADC, type:

```bash
./vtl listServer
```

Note:

Before removing the HSM by using vtl, make sure all the keys for that HSM are manually removed from the appliance. HSM keys cannot be deleted after the HSM server is removed.
5) Verify the network trust links (NTLs) connectivity between the ADC and HSM. At the shell prompt, type:

```
./vtl verify
```

If verification fails, review all the steps. Errors are generally due to an incorrect IP address in the client certificates.

6) Save the configuration.

The above steps update the “/etc/Chrystoki.conf” configuration file. This file is deleted when the ADC is started. Copy the configuration to the default configuration file, which is used when an ADC is restarted.

At the shell prompt, type:

```
root@ns# cp /etc/Chrystoki.conf /var/safenet/config/
```

Recommended practice is to run this command every time there is a change to the SafeNet-related configuration.

7) Start the SafeNet gateway process.

At the shell prompt, type:

```
sh /var/safenet/gateway/start_safenet_gw
```

8) Configure automatic start of the gateway daemon at boot time.

Create the “safenet_is_enrolled” file, which indicates that SafeNet HSM is configured on this ADC. Whenever the ADC restarts and this file is found, the gateway is automatically started.

At the shell prompt, type:

```
touch /var/safenet/safenet_is_enrolled
```

**Configure Safenet HSMs in a high availability setup on the ADC**

January 25, 2019
Configuring SafeNet HSMs in a high availability (HA) ensures uninterrupted service even if all but one of the devices are unavailable. In an HA setup, each HSM joins an HA group in active-active mode. SafeNet HSMs in an HA setup provide load balancing of all the group members to increase performance and response time while providing the assurance of high availability service. For more information, contact SafeNet Sales and Support.

**Prerequisites:**

- Minimum two SafeNet HSM devices. All the devices in an HA group must have either PED (trusted path) authentication or password authentication. A combination of trusted path authentication and password authentication in an HA group is not supported.
- Partitions on each HSM device must have the same password even if the label (name) is different.
- All partitions in HA must be assigned to the client (Citrix ADC appliance).

After configuring a SafeNet client on the ADC as described in [Configure a SafeNet client on the ADC](#), perform the following steps to configure Safenet HSMs in HA:

1. On the Citrix ADC shell prompt, launch “lunacm” (/usr/safenet/lunaclient/bin)

   **Example:**
   ```
   1 root@ns# cd /var/safenet/safenet/lunaclient/bin/
   2
   3 root@ns# ./lunacm
   ```

2. Identify the slot IDs of the partitions. To list the available slots (partitions), type:

   **Example:**
   ```
   1 lunacm:> slot list
   ```

<table>
<thead>
<tr>
<th>Slot Id</th>
<th>HSM Label</th>
<th>HSM Serial Number</th>
<th>HSM Model</th>
<th>HSM Firmware Version</th>
<th>HSM Configuration</th>
<th>HSM Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>trinity-p1</td>
<td>481681014</td>
<td>LunaSA 6.2.1</td>
<td>6.10.9</td>
<td>Luna SA Slot (PED) Signing With Cloning Mode</td>
<td>OK</td>
</tr>
<tr>
<td>1</td>
<td>trinity-p2</td>
<td>481681018</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

© 1999-2018 Citrix Systems, Inc. All rights reserved.
3. Create the HA group. The first partition is called the primary partition. You can add more than one
secondary partitions.

```
1 lunacm:> hagroup createGroup -slot <slot number of primary partition> -
label <group name> -password <partition password>
2 lunacm:> hagroup createGroup -slot 1 -label gp12 -password ******
```

4. Add the secondary members (HSM partitions). Repeat this step for all partitions to be added to the
HA group.

```
1 lunacm:> hagroup addMember -slot <slot number of secondary partition to
be added> -group <group name> -password <partition password>
Code:
1 lunacm:> hagroup addMember -slot 2 -group gp12 -password ******
```

5. Enable HA only mode.

```
1 lunacm:> hagroup HAOnly - enable
```

6. Enable active recovery mode.

```
1 lunacm:> hagroup recoveryMode - mode active
```

7. Set auto recovery interval time (in seconds). Default is 60 seconds.

```
1 lunacm:> hagroup interval - interval <value in seconds>
Example:
1 lunacm:> hagroup interval - interval 120
```

8. Set recovery retry count. A value of -1 allows infinite number of retries.

```
1 lunacm:> hagroup retry -count <xxx>
Example:
1 lunacm:> hagroup retry -count 2
```

After configuring SafeNet HSM in HA, see Additional ADC configuration for further configuration on the
ADC.

1.
2. Citrix ADC
3. Citrix ADC 12.1
4. SSL offload and acceleration

Additional ADC configuration

January 25, 2019
Contributed by:
C

1) Generate a key on the HSM.
Use third party tools to create keys on the HSM.

2) Add an HSM key on the ADC.

**Important**: The # character is not supported in a key name. If the key name include this character, the load key operation fails.

**To add a Safenet HSM key by using the CLI:**

At the command prompt, type:

```
1 add ssl hsmkey <KeyName> -hsmType SAFENET -serialNum <serial #> -password
```

where:

-keyName is the key created on the HSM by using third party tools.

-serialNum is the serial number of the partition on the HSM on which the keys are generated.

**Note:** For HSM in a high availability setup, use the serial number of the high availability group.

-password is the password of the partition on which the keys are present.

**To add a Safenet HSM key by using the GUI:**

Navigate to Traffic Management > SSL > HSM and add an HSM key. You must specify the HSM Type as SAFENET.

3) Add a certificate-key pair on the ADC. You must first use a third party tool to generate a certificate associated with the key. Then, copy the certificate to the /nsconfig/ssl/ directory on the ADC.

**Note:** The key must be an HSM key.

**To add a certkey pair on the ADC by using the CLI:**

At the command prompt, type:
To add a certkey pair on the ADC by using the GUI:

1. Navigate to Traffic Management > SSL.
2. In Getting Started, select Install Certificate (HSM) and create a certificate-key pair using an HSM key.

4) Create a virtual server and bind the certificate-key pair to this virtual server.

For information about creating a virtual server, click SSL virtual server configuration.

For information about adding a certificate-key pair, click Add or update a certificate-key pair.

For information about binding a certificate-key pair to an SSL virtual server, click Bind the certificate-key pair to the SSL virtual server.

Citrix ADC appliances in a high availability setup

January 23, 2019
Contributed by: C

You can configure a high availability (HA) setup on the Citrix ADC appliances with a SafeNet HSM configuration in either of the following two ways:

- First, configure a SafeNet HSM on the two nodes, using the same HSM and partition. Then create an HA pair. Finally, add the Citrix ADC configuration, such as keys, certificate-key pairs, and virtual servers, on the primary node.
- If a SafeNet HSM is already configured on one node with the Citrix ADC configuration, add a similar configuration on the other node. Copy “/var/safenet/sfgw_ident_file” from the first node to the other and restart the safenet_gw binary. After the gateway is up and running, add the nodes in an HA setup.
Limitations

January 23, 2019

Contributed by:
C

1. For any changes to the HSM-related configuration in an existing setup, such as adding or removing an HSM, or creating a high availability setup, you must copy '/etc/Chrystoki.conf' to '/var/safenet/config'.

2. After adding, removing, or restarting an HSM, you must restart the '/var/safenet/gateway/safenet_gw' binary. If you don’t restart the gateway binary, the HSM will not serve any traffic after it is added back or after it restarts.

3. To reboot or stop the current '/var/safenet/gateway/safenet_gw' binary, use

```
1 kill -SIGTERM <PID>
2 kill -SIGINT <PID>
```

**Important!** Do not use `kill -9 <PID>` or `kill -6 <PID>`

4. Before removing an existing HSM from the ADC, remove, from the ADC, all the keys and certificate-key pairs that are associated with that HSM. You cannot delete these files from the ADC after you remove the HSM.

5. On a standalone Citrix ADC appliance, SafeNet HSMs in HA are not supported.

6. EXPORT ciphers are not supported.

7. Update certificate-key pair operation is not supported.

8. When you generate an HSM key on a third-party tool, the private and public key names must be the same. When you add the HSM key on the appliance, provide this name as the key name.

9. The # character is not supported in a key name.

10. Cluster and admin partitions are not supported.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Sample commands with their outputs are given below.

**Run the script**

```
1  root@ns# pwd
2  /var/safenet/config
3  root@ns# sh safenet_config
```

**Create a certificate**

```
1  root@ns# cd /var/safenet/safenet/lunaclient/bin
2  root@ns# ./vtl createcert -n 10.102.59.175
3  Private Key created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175Key.pem
4  Certificate created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175.pem
```

**Copy the certificate to the HSM**

```
1  root@ns# scp /var/safenet/safenet/lunaclient/cert/client/10.102.59.175.pem admin@10.217.2.7:
2    admin@10.217.2.7's password:
3
4  10.102.59.175.pem              100%  818  0.8KB/s   00:00
```

**Copy the certificate and key from the HSM to the Citrix ADC appliance**

```
1  root@ns# scp admin@10.217.2.7:server.pem /var/safenet/safenet/lunaclient/server.2.7.pem
2    admin@10.217.2.7's password:
3```
Use SSH to connect to the SafeNet HSM

```bash
ssh admin@10.217.2.7
Connecting to 10.217.2.7:22...
Connection established.
To escape to local shell, press 'Ctrl+Alt+]'.

FAQ

January 30, 2019
Contributed by: C

- **How do I check that the SafeNet process is running?**
  
  At the Citrix ADC shell prompt, type:
  
  ```
  ps -aux | grep safenet_gw
  ```

- **How do I verify the network trust links (NTLs) connectivity between the ADC and HSM?**
  
  After configuring SafeNet, change directory to “/var/safenet/safenet/lunaclient/bin” and type:
  
  ```
  ./vtl verify
  ```

Troubleshooting

January 25, 2019
Contributed by: C

If the SSL feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

**Resources for troubleshooting**

For best results, use the following resources to troubleshoot an SSL issue on a Citrix ADC appliance:

- The relevant ns.log file
- The latest ns.conf file
- The messages file
- The relevant newnslog file
- Trace files
- A copy of the certificate files, if possible
- A copy of the key file, if possible
- The error message, if any

In addition to the above resources, you can use the Wireshark application customized for the Citrix ADC trace files to expedite troubleshooting.

**Troubleshooting SSL issues**

To troubleshoot an SSL issue, proceed as follows:

- Verify that the Citrix ADC appliance is licensed for SSL Offloading and load balancing.
- Verify that SSL Offloading and load balancing features are enabled on the appliance.
- Verify that the status of the SSL virtual server is not displayed as DOWN.
- Verify that the status of the service bound to the virtual server is not displayed as DOWN.
- Verify that a valid certificate is bound to the virtual server.
- Verify that the service is using an appropriate port, preferably port 443.

**Decrypting TLS1.3 traffic from packet trace**

To troubleshoot protocols that run over TLS1.3, you must first decrypt the TLS1.3 traffic. To decrypt TLS 1.3 in Wireshark, the secrets must be exported in the NSS key log format. For more information about the key log format, see [NSS Key Log Format](#).

For information about how to capture a packet trace, see [Capturing SSL Session Keys During a Trace](#).

**Note**: Citrix ADC automatically logs each connection's secrets in the appropriate format for the TLS/SSL protocol version in use.

4. SSL offload and acceleration

**SSL FAQs**

January 30, 2019

Contributed by: C
Basic questions

HTTPS access to the GUI fails on a VPX instance. How do I gain access?

A certificate-key pair is required for HTTPS access to the GUI. On a Citrix ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes and bind it to the internal service for HTTPS access to the configuration utility or update the ns-server-certificate to 1024 bytes. You can use HTTP access to the configuration utility or the CLI to install the certificate.

If I add a license to an MPX appliance, the certificate-key pair binding is lost. How do I resolve this problem?

If a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding. You must reinstall the certificate and bind it to the internal service.

Citrix recommends that you install an appropriate license before starting the appliance.

What are the various steps involved in setting up a secure channel for an SSL transaction?

Setting up a secure channel for an SSL transaction involves the following steps:

1. The client sends an HTTPS request for a secure channel to the server.
2. After selecting the protocol and cipher, the server sends its certificate to the client.
3. The client checks the authenticity of the server certificate.
4. If any of the checks fail, the client displays the corresponding feedback.
5. If the checks pass or the client decides to continue even if a check fails, the client creates a temporary, disposable key called the pre-master secret and encrypts it by using the public key of the server certificate.
6. The server, upon receiving the pre-master secret, decrypts it by using the server’s private key and generates the session keys. The client also generates the session keys from the pre-master secret. Thus both client and server now have a common session key, which is used for encryption and decryption of application data.
I understand that SSL is a CPU-intensive process. What is the CPU cost associated with the SSL process?

The following two stages are associated with the SSL process:

- The initial handshake and secure channel setup by using the public and private key technology.
- Bulk data encryption by using the asymmetric key technology.

Both of the preceding stages can affect server performance, and they require intensive CPU processing for the following reasons:

1. The initial handshake involves public-private key cryptography, which is very CPU intensive because of large key sizes (1024bit, 2048bit, 4096bit).
2. Encryption/decryption of data is also computationally expensive, depending on the amount of data that needs to be encrypted or decrypted.

What are the various entities of an SSL configuration?

An SSL configuration has the following entities:

- Server certificate
- Certificate Authority (CA) certificate
- Cipher suite that specifies the protocols for the following tasks:
  - Initial key exchange
  - Server and client authentication
  - Bulk encryption algorithm
  - Message authentication
- Client authentication
- CRL
- SSL Certificate Key Generation Tool that enables you to create the following files:
  - Certificate request
  - Self signed certificate
  - RSA and DSA keys
  - DH parameters

I want to use the SSL offloading feature of the Citrix ADC appliance. What are the various options for receiving an SSL certificate?

You must receive an SSL certificate before you can configure the SSL setup on the Citrix ADC appliance. You can use any of the following methods to receive an SSL certificate:

- Request a certificate from an authorized CA.
- Use the existing server certificate.
- Create a certificate-key pair on the Citrix ADC appliance.

**Note:** This is a test certificate signed by the test Root-CA generated by the Citrix ADC appliance. Test certificates signed by this Root-CA are not accepted by browsers. The browser throws a warning message stating that the server's certificate cannot be authenticated.

- For anything other than test purposes, you must provide a valid CA certificate and CA key to sign the server certificate.

### What are the minimum requirements for an SSL setup?

The minimum requirements for configuring an SSL setup are as follows:

- Obtain the certificates and keys.
- Create a load balancing SSL virtual server.
- Bind HTTP or SSL services to the SSL virtual server.
- Bind certificate-key pair to the SSL virtual server.

### What are the limits for the various components of SSL?

SSL components have the following limits:

- Bit size of SSL certificates: 4096.
- Number of SSL certificates: Depends on the available memory on the appliance.
- Maximum linked intermediate CA SSL certificates: 9 per chain.
- CRL revocations: Depends on the available memory on the appliance.

### What are the various steps involved in the end-to-end data encryption on a Citrix ADC appliance?

The steps involved in the server-side encryption process on a Citrix ADC appliance are as follows:

1. The client connects to the SSL VIP configured on the Citrix ADC appliance at the secure site.
2. After receiving the secure request, the appliance decrypts the request, applies layer 4-7 content switching techniques and load balancing policies, and selects the best available backend Web server for the request.
3. The Citrix ADC appliance creates an SSL session with the selected server.
4. After establishing the SSL session, the appliance encrypts the client request and sends it to the Web server by using the secure SSL session.
5. When the appliance receives the encrypted response from the server, it decrypts and re-encrypts the data, and sends the data to the client by using the client side SSL session.

The multiplexing technique of the Citrix ADC appliance enables the appliance to reuse SSL sessions that have been established with the Web servers. Therefore, the appliance avoids the CPU intensive key exchange, known as full handshake. This process reduces the overall number of SSL sessions on the server and maintains end-to-end security.

Certificates and Keys

Can I place the certificate and key files at any location? Is there any recommended location to store these files?

You can store the certificate and key files on the Citrix ADC appliance or a local computer. However, Citrix recommends that you store the certificate and key files in the /nsconfig/ssl directory of the Citrix ADC appliance. The /etc directory exists in the flash memory of the Citrix ADC appliance. This provides portability and facilitates backup and restoration of the certificate files on the appliance.

Note: Make sure that the certificate and the key files are stored in the same directory.

What is the maximum size of the certificate key supported on the Citrix ADC appliance?

A Citrix ADC appliance running a software release earlier than release 9.0 supports a maximum certificate key size of 2048 bits. Release 9.0 and later support a maximum certificate key size of 4096 bits. This limit is applicable to both RSA and DSA certificates.

An MPX appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A virtual appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server from release 12.0-56.x. Older releases support 2048-bit certificates.
• 4096-bit client certificate (if client authentication is enabled on the virtual server) from release 12.0-56.x. Older releases support 2048-bit certificates.

What is the maximum size of the DH parameter supported on the Citrix ADC appliance?
The Citrix ADC appliance supports a DH parameter of maximum 2048 bits.

What is the maximum certificate-chain length, that is, the maximum number of certificates in a chain, supported on a Citrix ADC appliance?
A Citrix ADC appliance can send a maximum of 10 certificates in a chain when sending a server certificate message. A chain of the maximum length includes the server certificate and nine intermediate CA certificates.

What are the various certificate and key formats supported on the Citrix ADC appliance?
The Citrix ADC appliance supports the following certificate and key formats:
  • Privacy Enhanced Mail (PEM)
  • Distinguished Encoding Rule (DER)

Is there a limit for the number of certificates and keys that I can install on the Citrix ADC appliance?
No. The number of certificates and keys that can be installed is limited only by the available memory on the Citrix ADC appliance.

I have saved the certificate and key files on the local computer. I want to transfer these files to the Citrix ADC appliance by using the FTP protocol. Is there any preferred mode for transferring these files to the Citrix ADC appliance?
Yes. If using the FTP protocol, you should use binary mode to transfer the certificate and key files to the Citrix ADC appliance.

Note: By default, FTP is disabled. Citrix recommends using the SCP protocol for transferring certificate and key files. The configuration utility implicitly uses SCP to connect to the appliance.

What is the default directory path for the certificate and key?
The default directory path for the certificate and key is ‘/nsconfig/ssl’.
When adding a certificate and key pair, what happens if I do not specify an absolute path to the certificate and key files?

When adding a certificate and key pair, if you do not specify an absolute path to the certificate and key files, the Citrix ADC appliance searches the default directory, /nsconfig/ssl, for the specified files and attempts to load them to the kernel. For example, if the cert1024.pem and rsa1024.pem files are available in the /nsconfig/ssl directory of the appliance, both of the following commands are successful:

```
1 add ssl certKey cert1 -cert cert1204.pem -key rsa1024.pem
```

I have configured a high availability setup. I want to implement the SSL feature on the setup. How should I handle the certificate and key files in a high availability setup?

In a high availability setup, you must store the certificate and key files on both the primary and the secondary Citrix ADC appliance. The directory path for the certificate and key files must be the same on both appliances before you add an SSL certificate-key pair on the primary appliance.

Thales nShield® HSM

When integrating with Thales nShield® HSM, do we have to keep in mind any specific configuration when adding the Citrix ADC appliance to HA?

You must configure the same Thales device(s) on both the nodes in HA. Thales configuration commands don’t synchronize in HA. For information about the prerequisites for Thales nShield® HSM, see Prerequisites.

Do we have to individually integrate both the appliances with Thales nShield® HSM and RFS? Do we need to do this before or after the HA setup?

You can complete the integration before or after the HA setup. However, if the integration is done after the HA setup, the keys imported on the primary node prior to configuring the secondary node are not synced to the secondary node. Therefore, Citrix recommends Thales integration before the HA setup.
Do we have to import the key into both the primary and secondary Citrix ADC appliances, or are the keys synchronized from the primary node to the secondary node?

If Thales is integrated on both devices before forming the HA, the keys are automatically synchronized from RFS in the process of integration.

Given that the HSM is not on the Citrix ADC appliance, but on Thales, what happens to the keys and certificates when a node fails and is replaced?

If a node fails, it is possible to synchronize the keys and certificates to the new node, by first integrating Thales on the new node and then running the following commands:

```
1  sync ha files ssl
2  force ha sync
```

The certificates are synchronized and added if the keys are synchronized in the process of integrating Thales.

Ciphers

What is a NULL-Cipher?

Ciphers with no encryption are known as NULL-Ciphers. For example, NULL-MD5 is a NULL-Cipher.

Are the NULL-Ciphers enabled by default for an SSL VIP or an SSL service?

No. NULL-Ciphers are not enabled by default for an SSL VIP or an SSL service.

What is the procedure to remove NULL-Ciphers?

To remove the NULL-Ciphers from an SSL VIP, run the following command:

```
1  bind ssl cipher <SSL_VIP> REM NULL
```

To remove the NULL-Ciphers from an SSL Service, run the following command:

```
1  bind ssl cipher <SSL_Service> REM NULL -service
```
What are the various cipher aliases supported on the Citrix ADC appliance?

To list the cipher aliases supported on the appliance, at the command prompt, type:

```
sh cipher
```

What is the command to display all the predefined ciphers of the Citrix ADC appliance?

To display all the predefined ciphers of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher
```

What is the command to display the details of an individual cipher of the Citrix ADC appliance?

To display the details of an individual cipher of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher <Cipher_Name/Cipher_Alias_Name/Cipher_Group_Name>
```

Example:

```
show cipher SSL3-RC4-SHA
1) Cipher Name: SSL3-RC4-SHA
2) Description: SSLv3 Kx=RSA Au=RSA Enc=RC4(128)
3) Mac=SHA1
4) Done
```

What is the significance of adding the predefined ciphers of the Citrix ADC appliance?

Adding the predefined ciphers of the Citrix ADC appliance causes the NULL-Ciphers to get added to an SSL VIP or an SSL service.

Certificates

Is the distinguished name in a client certificate available for the length of the user session?

Yes. You can access the distinguished name of the client certificate in subsequent requests during the length of the user session, that is even after the SSL handshake is complete and the certificate is not sent again by the browser. To do this, use a variable and an assignment as detailed in the following sample configuration:

Example:
add ns variable v2 -type "text(100)"
add ns assignment a1 -variable "$v2" -set "CLIENT.SSL.CLIENT_CERT .SUBJECT.TYPECAST_NVLIST_T('=', '/').VALUE('CN')"
add rewrite action act1 insert_http_header subject "$v2" // example: to insert the distinguished name in the header
add rewrite policy pol1 true a1
add rewrite policy pol2 true act1
bind rewrite global pol1 1 next -type RES_DEFAULT
bind rewrite global pol2 2 next -type RES_DEFAULT
set rewrite param -undefAction RESET

**Why do I need to bind the server certificate?**

Binding the server certificates is the basic requirement for enabling the SSL configuration to process SSL transactions.

To bind the server certificate to an SSL VIP, at the CLI, type:

```
bind ssl vserver <vServerName> -certkeyName <cert_name>
```

To bind the server certificate to an SSL service, at the CLI, type:

```
bind ssl service <serviceName> -certkeyName <cert_name>
```

**How many certificates can I bind to an SSL VIP or an SSL service?**

On a Citrix ADC virtual appliance, you can bind a maximum of three certificates to an SSL VIP or an SSL service, one each of type RSA, ECDSA, and DSA. On a Citrix ADC MPX (N2) or MPX-FIPS appliance, if SNI is enabled, you can bind multiple server certificates of type RSA. If SNI is disabled, you can bind a maximum of one certificate of type RSA. On a Citrix ADC MPX (N3) and Citrix ADC MPX/SDX FIPS appliance, you can bind a maximum of two certificates to an SSL VIP or an SSL service, one each of type RSA and type ECDSA.

**Note:** DSA certificates are not supported on MPX or MPX-FIPS platforms.
Does SNI support Subject Alternative Name (SAN) certificates?

No. On a Citrix ADC appliance, SNI is not supported with a SAN extension certificate.

What happens if I unbind or overwrite a server certificate?

When you unbind or overwrite a server certificate, all the connections and SSL sessions created by using the existing certificate are terminated. When you overwrite an existing certificate, the following message appears:

```
1  ERROR:
2
3  Warning: Current certificate replaces the previous binding.
```

How do I install an intermediate certificate on Citrix ADC and link to a server certificate?

See the article at http://support.citrix.com/article/ctx114146 for information about installing an intermediate certificate.

Why am I getting a “resource already exists” error when I try to install a certificate on the Citrix ADC?

See the article at http://support.citrix.com/article/CTX117284 for instructions for resolving the “resource already exists” error.

I want to create a server certificate on a Citrix ADC appliance to test and evaluate the product. What is the procedure to create a server certificate?

Perform the following procedure to create a test certificate.

**Note:** A certificate created with this procedure cannot be used to authenticate all the users and browsers. After using the certificate for testing, you should obtain a server certificate signed by an authorized Root CA.

To create a self-signed server certificate:

1. To create a Root CA certificate, at the CLI, type:
2. Perform the following procedure to create a server certificate and sign it with the root CA certificate that you just created

   a) To create the request and the key, at the CLI, type:

   ```
   create ssl rsakey /nsconfig/ssl/test-server.key 1024
   create ssl certreq /nsconfig/ssl/test-server.csr -keyfile /nsconfig/ssl/test-server.key
   ```

   b) Enter the required information when prompted.

   c) To create a serial-number file, at the CLI, type:

   ```
   shell
   # echo '01' > /nsconfig/ssl/serial.txt
   # exit
   ```

   d) To create a server certificate signed by the root CA certificate created in step 1, at the CLI, type:

   ```
   create ssl cert /nsconfig/ssl/test-server.cer /nsconfig/ssl/test-server.csr SRVR_CERT -CAcert /nsconfig/ssl/test-ca.cer -CAkey /nsconfig/ssl/test-ca.key -CAserial /nsconfig/ssl/serial.txt
   ```

   e) To create a Citrix ADC certkey, which is the in-memory object that holds the server certificate information for SSL handshakes and bulk encryption, at the CLI, type:

   ```
   add ssl certkey test-certkey -cert /nsconfig/ssl/test-server.cer -key /nsconfig/ssl/test-server.key
   ```

   f) To bind the certkey object to the SSL virtual server, at the CLI, type:
I have received a Citrix ADC appliance on which NetScaler software release 9.0 is installed. I have noticed an additional license file on the appliance. Is there any change in the licensing policy starting with NetScaler software release 9.0?

Yes. Starting with Citrix NetScaler software release 9.0, the appliance might not have a single license file. The number of license files depends on the Citrix ADC software release edition. For example, if you have installed the Enterprise edition, you might need additional license files for the full functionality of the various features. However, if you have installed the Platinum edition, the appliance has only one license file.

**How do I export the certificate from Internet Information Service (IIS)?**

There are many ways to do this, but by using the following method the appropriate certificate and private key for the Web site are exported. This procedure must be performed on the actual IIS server.

1. Open the Internet Information Services (IIS) Manager administration tool.
2. Expand the Web Sites node and locate the SSL-enabled Web site that you want to serve through the Citrix ADC appliance.
3. Right-click this Web site and click Properties.
4. Click the Directory Security tab and, in the Secure Communications section of the window, select the View Certificate box.
5. Click the Details tab, and then click Copy to File.
7. Select Yes, export the private key and click Next.
   
   **Note:** The private key MUST be exported for SSL Offload to work on the Citrix ADC.

8. Make sure that the Personal Information Exchange -PKCS #12 radio button is selected, and select only the Include all certificates in the certification path if possible check box. Click Next.
9. Enter a password and click Next.
10. Enter a file name and location, and then click Next. Give the file an extension of .PFX.
11. Click Finish.
How do I convert the PKCS#12 certificate and install it on the Citrix ADC?

1. Move the exported .PFX certificate file to a location from where it may be copied to the Citrix ADC (that is, to a machine that permits SSH access to the management interface of a Citrix ADC appliance). Copy the certificate to the appliance by using a secure copy utility such as SCP.

2. Access the BSD shell and convert the certificate (for example, cert.PFX) to .PEM format:

   root@ns# openssl pkcs12 -in cert.PFX -out cert.PEM

3. To make sure that the converted certificate is in correct x509 format, verify that the following command produces no error:

   root@ns# openssl x509 -in cert.PEM -text

4. Verify that the certificate file contains a private key. Begin by issuing the following command:

   root@ns# cat cert.PEM

   1 Verify that the output file includes an RSA PRIVATE KEY section.
   2 -----BEGIN RSA PRIVATE KEY-----
   3 Mkm^s9KMs9023pz/s...
   4 -----END RSA PRIVATE KEY-----

   The following is another example of an RSA PRIVATE KEY section:

   1 Bag Attributes
   2 1.3.6.1.4.1.311.17.2: <No Values>
   3 localKeyID: 01 00 00 00
   4 Microsoft CSP Name: Microsoft RSA SChannel Cryptographic Provider
   5 friendlyName:
   6 4b9cef4cc8c9b849ff5c662fd3e0ef7e_76267e3e-6183-4d45-886e-6e067297b38f
   7
   8 Key Attributes
   9 X509v3 Key Usage: 10
   10 -----BEGIN RSA PRIVATE KEY-----
   11 Proc-Type: 4, ENCRYPTED
   12 DEK-Info: DES-EDE3-CBC, 43E7ACA5F4423968
   13 pZJ2SfsSVqMbRrf6ug37Clua5gYOwld4frPIxFYjQuUHR31dilW5ta3hbIAQ+
   14 Rg
   15 ...
   16 (more random characters)
The following is a SERVER CERTIFICATE section:

Bag Attributes
localKeyID: 01 00 00 00
friendlyName: AG Certificate
subject=/C=AU/ST=NSW/L=Wanniassa/O=Dave Mother
Asiapacific/OU=Support/CN=davemother.food.lan
issuer=/DC=lan/DC=food/CN=hotdog
-----BEGIN CERTIFICATE-----
MIIFiTCCBHGgAwIBAgIKCGryDgAAAAAHzANBgkqhkiG9w0BAQUFADA8MRMwEQYK
... (more random characters) 5
pLDWYVHhLkA1pSxFjNJHRSIydWHc5ltGyKqIUCbeZaVyel94pNSUYx07NpPV/
MY2ovQyQM8Ge3+lGFum0VHbvy/y/gB9HhFesog=
-----END CERTIFICATE-----

The following is an INTERMEDIATE CA CERTIFICATE section:

Bag Attributes: <Empty Attributes>
ssubject=/DC=lan/DC=food/CN=hotdog
issuer=/DC=lan/DC=food/CN=hotdog
-----BEGIN CERTIFICATE-----
MIIESDCCAzCGawIBAgIQah20fCRRTY9LRXYMIRAjgANBkqhkjiG9w0BAQUFADA8
... (more random characters)
Nt0nksawDnbKo86rQcNnY5Us7c7pj2xxj/I0sgNHUp5W6dDI9pQoqFFaDk=
-----END CERTIFICATE-----

Further Intermediate CA certificates may follow, depending on the certification path of the exported certificate.

5. Open the .PEM file in a text editor
6. Locate the first line of the .PEM file and the first instance of the following line, and copy those two lines and all the lines between them:

```
1 -----END CERTIFICATE-----
2 
3 Note: Make sure that last copied line is the first
4 -----END CERTIFICATE----- line in the .PEM file.
```

7. Paste the copied lines into a new file. Call the new file something intuitive, such as cert-key.pem. This is the certificate-key pair for the server hosting the HTTPS service. This file should contain both the section labeled RSA PRIVATE KEY and the section labeled SERVER CERTIFICATE in the example above.

**Note:** The certificate-key pair file contains the private key and must therefore be kept secure.

8. Locate any subsequent sections beginning with —–BEGIN CERTIFICATE—– and ending with — END CERTIFICATE—–, and copy each such section to a separate new file.

These sections correspond to certificates of trusted CAs that have been included in the certification path. These sections should be copied and pasted into new individual files for these certificates. For example, the INTERMEDIATE CA CERTIFICATE section of the example above should be copied and pasted into a new file.

For multiple intermediate CA certificates in the original file, create new files for each intermediate CA certificate in the order in which they appear in the file. Keep track (using appropriate filenames) of the order in which the certificates appear, as they need to be linked together in the correct order in a later step.

9. Copy the certificate-key file (cert-key.pem) and any additional CA certificate files into the /nsconfig/ssl directory on the Citrix ADC appliance.

10. Exit the BSD shell and access the Citrix ADC prompt.

11. Follow the steps in “Install the certificate-key files on the appliance” to install the key/certificate once uploaded on the device.

**How do I convert the PKCS#7 certificate and install it on the Citrix ADC appliance?**

You can use OpenSSL to convert a PKCS #7 Certificate to a format recognizable by the Citrix ADC appliance. The procedure is identical to the procedure for PKCS #12 certificates, except that you invoke OpenSSL with different parameters. The steps for converting PKCS #7 certificates are as follows:

1. Copy the certificate to the appliance by using a secure copy utility, such as SCP.
2. Convert the certificate (for example, cert.P7B ) to PEM format:
3. Follow steps 3 through 7 as described in the answer for PKCS #12 certificates.
   Note: Before loading the converted PKCS #7 certificate to the appliance, be sure to verify that it contains a private key, exactly as described in step 3 for the PKCS #12 procedure. PKCS #7 certificates, particularly those exported from IIS, do not typically contain a private key.

**When I bind a cipher to a virtual server or service by using the bind cipher command, I see the error message “Command deprecated.”?**

The command for binding a cipher to a virtual server or service has changed.

Use the bind ssl vserver <vsername> -ciphername <ciphername> command to bind an SSL cipher to an SSL virtual server.

Use the bind ssl service <serviceName> -ciphername <ciphername> command to bind an SSL cipher to an SSL service.

**Note:** New ciphers and cipher groups are added to the existing list and not replaced.

**Why can’t I create a new cipher group and bind ciphers to it by using the add cipher command?**

The add cipher command functionality has changed in release 10. The command only creates a cipher group. To add ciphers to the group, use the bind cipher command.

**OpenSSL**

**How do I use OpenSSL to convert certificates between PEM and DER?**

To use OpenSSL, you must have a working installation of the OpenSSL software and be able to execute Openssl from the command line.

x509 certificates and RSA keys can be stored in a number of different formats.

Two common formats are DER (a binary format used primarily by Java and Macintosh platforms) and PEM (a base64 representation of DER with header and footer information, which is used primarily by UNIX and Linux platforms). There is also an obsolete NET (Netscape server) format that was used by earlier versions of IIS (up to and including 4.0) and various other less common formats that are not covered in this article.

A key and the corresponding certificate, as well as the root and any intermediate certificates, can also be stored in a single PKCS#12 (.P12, .PFX) file.
Procedure

Use the OpenSSL command to convert between formats as follows:

1. To convert a certificate from PEM to DER:
   ```bash
   x509 -in input.crt -inform PEM -out output.crt -outform DER
   ```

2. To convert a certificate from DER to PEM:
   ```bash
   x509 -in input.crt -inform DER -out output.crt -outform PEM
   ```

3. To convert a key from PEM to DER:
   ```bash
   rsa -in input.key -inform PEM -out output.key -outform DER
   ```

4. To convert a key from DER to PEM:
   ```bash
   rsa -in input.key -inform DER -out output.key -outform PEM
   ```

   **Note:** If the key you are importing is encrypted with a supported symmetric cipher, you are prompted to enter the pass-phrase.

   **Note:** To convert a key to or from the obsolete NET (Netscape server) format, substitute NET for PEM or DER as appropriate. The stored key is encrypted in a weak unsalted RC4 symmetric cipher, so a pass-phrase will be requested. A blank pass-phrase is acceptable.

System Limits

**What are the important numbers to remember?**

1. Create Certificate Request:
   - Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase (For Encrypted Key): Maximum 31 characters
   - Common Name: Maximum 63 characters
   - City: Maximum 127 characters
   - Organization Name: Maximum 63 characters
   - State/Province Name: Maximum 63 characters
   - Email Address: Maximum 39 Characters
   - Organization Unit: Maximum 63 characters
   - Challenge Password: Maximum 20 characters
   - Company Name: Maximum 127 characters
2. Create Certificate:
   - Certificate File Name: Maximum 63 characters
   - Certificate Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - Validity Period: Maximum 3650 days
   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - CA Serial Number File: Maximum 63 characters

3. Create and Install a Server Test Certificate:
   - Certificate File Name: Maximum 31 characters
   - Fully Qualified Domain Name: Maximum 63 characters

4. Create Diffie-Hellman (DH) key:
   - DH Filename (with path): Maximum 63 characters
   - DH Parameter Size: Maximum 2048 bits

5. Import PKCS12 key:
   - Output File Name: Maximum 63 characters
   - PKCS12 File Name: Maximum 63 characters
   - Import Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters
   - Verify PEM Passphrase: Maximum 31 characters

6. Export PKCS12
   - PKCS12 File Name: Maximum 63 characters
   - Certificate File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - Export Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters

7. CRL Management:
   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - CA Key File Password: Maximum 31 characters
   - Index File Name: Maximum 63 characters
   - Certificate File Name: Maximum 63 characters

8. Create RSA Key:
• Key Filename: Maximum 63 characters
• Key Size: Maximum 4096 bits
• PEM Passphrase: Maximum 31 characters
• Verify Passphrase: Maximum 31 characters

9. Create DSA Key:
• Key Filename: Maximum 63 characters
• Key Size: Maximum 4096 bits
• PEM Passphrase: Maximum 31 characters
• Verify Passphrase: Maximum 31 characters

10. Change advanced SSL settings:
• Maximum CRL memory size: Maximum 1024 Mbytes
• Encryption trigger timeout (10 mS ticks): Maximum 200
• Encryption trigger packet count: Maximum 50
• OCSP cache size: Maximum 512 Mbytes

11. Install Certificate:
• Certificate-Key pair Name: Maximum 31 characters
• Certificate File Name: Maximum 63 characters
• Private Key File Name: Maximum 63 characters
• Password: Maximum 31 characters
• Notification Period: Maximum 100

12. Create Cipher Group:
• Cipher Group Name: Maximum 39 characters

13. Create CRL:
• CRL Name: Maximum 31 characters
• CRL File: Maximum 63 characters
• URL: Maximum 127 characters
• Base DN: Maximum 127 characters
• Bind DN: Maximum 127 characters
• Password: Maximum 31 characters
• Day(s): Maximum 31

14. Create SSL Policy:
• Name: Maximum 127 characters

15. Create SSL Action:
• Name: Maximum 127 characters
16. Create OCSP Responder:
   - Name: Maximum 32 characters
   - URL: Maximum 128 characters
   - Batching Depth: Maximum 8
   - Batching Delay: Maximum 10000
   - Produced At Time Skew: Maximum 86400
   - Request Time-out: Maximum 120000

17. Create Virtual Server:
   - Name: Maximum 127 characters
   - Redirect URL: Maximum 127 characters
   - Client Time-out: Maximum 31536000 secs

18. Create Service:
   - Name: Maximum 127 characters
   - Idle Time-out (secs):
     Client: Maximum 31536000
     Server: Maximum 31536000

19. Create Service Group:
   - Service Group Name: Maximum 127 characters
   - Server ID: Maximum 4294967295
   - Idle Time-out (secs):
     Client: Maximum value 31536000
     Server: Maximum 31536000

20. Create Monitor:
   - Name: Maximum 31 characters

21. Create Server:
   - Server Name: Maximum 127 characters
   - Domain Name: Maximum 255 characters
   - Resolve Retry: Maximum 20939 secs
Global site certificates

January 25, 2019
Contributed by: C

A global site certificate is a special-purpose server certificate whose key length is greater than 128 bits. A global site certificate consists of a server certificate and an accompanying intermediate-CA certificate. You must import the global site certificate and its key from the server to the Citrix ADC appliance.

How global site certificates work

Export versions of browsers use 40-bit encryption to initiate connections to SSL Web-servers. The server responds to connection requests by sending its certificate. The client and server then decide on an encryption strength based on the server certificate type:

- If the server certificate is a normal certificate and not a global site certificate, the export client and server complete the SSL handshake and uses 40-bit encryption for data transfer.
- If the server certificate is a global site certificate (and if the export client feature is supported by the browser), the export client automatically upgrades to 128-bit encryption for data transfer.

If the server certificate is a global site certificate, the server sends its certificate, along with the accompanying intermediate-CA certificate. The browser first validates the intermediate-CA certificate by using one of the Root-CA certificates that are normally included in web browsers. Upon successful validation of the intermediate-CA certificate, the browser uses the intermediate-CA certificate to validate the server certificate. Once the server is successfully validated, the browser renegotiates (upgrades) the SSL connection to 128-bit encryption.

With Microsoft’s Server Gated Cryptography (SGC), if the Microsoft IIS server is configured with an SGC certificate, export clients that receive the certificate renegotiate to use 128-bit encryption.

Import a global site certificate

To import a global site certificate, first export the certificate and server key from the Web server. Global site certificates are generally exported in some binary format, therefore, before importing the global site certificate, convert the certificate and key to the PEM format.
To import a global site certificate

1. Using a text editor, copy the server certificate and the accompanying intermediate-CA certificate into two separate files.
   
   The individual PEM encoded certificate will begin with the header —— BEGIN CERTIFICATE—— and end with the trailer ——END CERTIFICATE——.

2. Use an SFTP client to transfer the server certificate, intermediate-CA certificate, and server-key to the Citrix ADC appliance.

3. Use the following OpenSSL command to identify the server certificate and intermediate-CA certificate from the two separate files.

   **Note:** You can launch the OpenSSL interface from the configuration utility. In the navigation pane, click SSL. In the details pane, under Tools, click Open SSL interface.

   ```
   openssl x509 -in >path of the CA cert file< text X509v3 Basic Constraints: CA:TRUE
   X509v3 Key Usage:
   Certificate Sign, CRL Sign
   Netscape Cert Type:
   SSL CA, S/MIME CA
   
   openssl x509 -in >path of the server certificate file< -text
   
   X509v3 Basic Constraints:
   CA:FALSE
   Netscape Cert Type:
   SSL Server
   ```

4. At the FreeBSD shell prompt, enter the following command:

   ```
   openssl x509 -in cert.pem -text | more
   ```

   Where **cert.pem** is one of the two certificate files.

   Read the **Subject** field in the command output. For example,

   ```
   Subject: C=US, ST=Oregon, L=Portland, O=mycompany, Inc., OU=IT, CN =www.mycompany.com
   ```

   If the CN field in the Subject matches the domain-name of your Web site, then this is the server certificate and the other certificate is the accompanying intermediate-CA certificate.
5. Use the server certificate and its private key to create a certificate key pair on the Citrix ADC appliance. For details on creating a certificate-key pair on the Citrix ADC, see Add a certificate key pair.

6. Add the intermediate-CA certificate on the Citrix ADC appliance. Use the server certificate you created in step 4 to sign this intermediate certificate. For details on creating an Intermediate-CA certificate on the Citrix ADC, see Generate a test certificate.

---

**Security**

January 23, 2019

Contributed by: C

The following topics cover configuration and installation information for Citrix ADC security features. Most of these features are policy based.

| Authentication, Authorization, Auditing (AAA) | Keeps unauthorized users out of the network, denies users access to tasks for which they are not authorized, and tracks the resources used during user sessions. |
| Application Firewall | Prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information. |
| Content Filtering | Blocks inappropriate HTML requests, preventing the requests from reaching the Web servers. |
| HTTP Denial-of-Service Protection | Prevents hackers from attacking your Web site with large numbers of HTTP requests. |
Priority Queuing | Detects high-priority connections and allows those connections to proceed ahead of other connections, guaranteeing unimpeded access to those users.

SureConnect | Services all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

Surge Protection | Detects any rapid rise in connection attempts and adjusts the rate at which connections are allowed to proceed to the server, preventing server overload.

3. Citrix ADC 12.1

**Content filtering**

January 25, 2019

Contributed by: C

Content filtering can do some of the same tasks as the Citrix Web App Firewall, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex Web site that makes extensive use of scripts and accesses back-end databases, the Application Firewall may be the better tool for protecting that Web site. For more information about the Citrix Web App Firewall, see Application Firewall.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you could use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:
• Prevent users from accessing certain parts of your Web sites unless they are connecting from authorized locations.
• Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
• Redirect specified requests to a different server or service.

To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

3. Citrix ADC 12.1

Enabling content filtering

January 23, 2019
Contributed by: C

By default, content filtering is enabled on Citrix ADC appliances running the Citrix ADC operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you may need to enable the content filtering feature itself manually.

Enable content filtering by using the CLI

At the command prompt, type the following commands to enable content filtering and verify the configuration:

```
1 > enable ns feature ContentFiltering
2 > show ns feature
```

Example:

```
1 > enable ns feature ContentFiltering
2   Done
3 > show ns feature
```
<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>ON</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>OFF</td>
</tr>
<tr>
<td>11) Http DoS Protection</td>
<td>HDOSP</td>
<td>OFF</td>
</tr>
<tr>
<td>12) Content Filtering</td>
<td>CF</td>
<td>ON</td>
</tr>
<tr>
<td>23) HTML Injection</td>
<td>HTMLInjection</td>
<td>ON</td>
</tr>
<tr>
<td>24) Citrix ADC Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

**Enable content by filtering by using the GUI**

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Configure basic features.
3. In the Configure Basic Features pane, select the Content Filter check box, and then click OK.

1. Citrix ADC
2. Citrix ADC 12.1

**Configure a content filtering action**

January 23, 2019

Contributed by: C

After you enable the content filtering feature, you create one or more actions to tell your Citrix ADC appliance how to handle the connections it receives.

Content filtering supports the following actions for HTTP requests:

- **Add**: Adds the specified HTTP header before sending the request to the web server.
- **Reset**: Terminates the connection, sending the appropriate termination notice to the user’s browser.
• **Forward**: Redirects the request to the designated service.

• **Drop**: Silently deletes the request, without sending a response to the user’s browser.

• **Corrupt**: Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

Content filtering supports the following actions for HTTP responses:

• **Add**: Adds the specified HTTP header before sending the response to the user’s browser.

• **ErrorCode**: Returns the designated HTTP error code to the user’s browser.

• **Corrupt**: Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the response to the user’s browser.

**Configure a content filtering action by using the CLI**

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:

```
1 - add filter action <name> <qualifier> [<serviceName>] [<value>] [<respCode>] [<page>]
2 - show filter action <name>
```

**Example:**

```
1 > add filter action act_drop Drop
2   Done
3 > show filter action act_drop
4 1) Name: act_drop   Filter Type: drop
5   Done
```

**Configure a content filtering action by using the GUI**

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, do one of the following:
   • To create a new action, click Add.
   • To modify an existing action, select the action, and then click Open.
3. In the Add Filter Action or Configure Filter Action dialog box, specify values for the parameters:
   • Action Name*—name
   • Qualifier*—qualifier (Determines which of the following parameters you can configure)
   • Service Name—servicename
   • HeaderName:Value—value
Configure a content filtering policy

To implement content filtering, you must configure at least one policy to tell your Citrix ADC appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.

Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

- **URL**: The URL in the HTTP request.
- **URL query**: Only the query portion of the URL, which is the portion after the query (?) symbol.
- **URL token**: Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.
- **HTTP method**: The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.
- **HTTP version**: The HTTP version in the request, which is usually HTTP 1.1.
- **Standard HTTP header**: Any of the standard HTTP headers defined in the HTTP 1.1 specification.
- **Standard HTTP header value**: The value portion of the HTTP header, which is the portion after the colon and space (: ).
• **Custom HTTP header:** A non-standard HTTP header issued by your Web site or that appears in a user request.

• **Custom header value:** The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:) .

• **Client Source IP:** The IP from which the client request was sent.

Content filtering policies use the simpler of two Citrix ADC expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see “Policies and Expressions.”

**Note:** Users who are not experienced in configuring policies at the Citrix ADC command line will usually find using the configuration utility considerably easier.

### Configure a content filtering policy by using the CLI

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

```
1 - add filter policy <name> -rule <expression> (-reqAction <action> | -resAction <string>)
2 - show filter policy <name>
```

**Example:**

```
1 > add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com" -reqAction DROP
2   Done
3 > show filter policy cf-pol
4 1) Name: cf-pol   Rule: REQ.HTTP.URL CONTAINS http://abc.com
5         Request action: DROP
6         Response action: 
7         Hits: 0
8   Done
```

### Configure a content filtering policy by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. Navigate to Protection Features > Filter.
3. In the details pane, to create a new policy, click Add.
4. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.
5. Select either Request Action or Response Action to activate the drop-down list to the right of that item.

6. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.

   Note: You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.

7. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.
   a) Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.
   b) Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.
   c) Click Add Expression to add that named expression to the Expression list.
      Note: You should perform either this step or step 7, but not both.

8. If you want to create a new expression to define your policy, use the Expression Editor.
   a) Click the Add button. The Add Expression dialog box appears.
   b) In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the Citrix ADC appliance to look at incoming connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.
   c) If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.
      Note: In the Citrix ADC classic expressions language, “HTTP” includes HTTPS requests, as well.
   d) Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:
      • METHOD: The HTTP method used in the request.
      • URL: The contents of the URL header.
      • URLOKENS: The URL tokens in the HTTP header.
      • VERSION: The HTTP version of the connection.
      • HEADER: The header portion of the HTTP request.
      • URLLEN: The length of the contents of the URL header.
      • URLQUERY: The query portion of the contents of the URL header.
- **URLQUERYLEN**: The length of the query portion of the URL header.
  The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name* appears below the Flow Type list box.

e) Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:
  - `==`: Matches the following text string exactly.
  - `!=`: Does not exactly match the following text string.
  - `>`: Is greater than the following integer.
  - **CONTAINS**: Contains the following text string.
  - **CONTENTS**: The contents of the designated header, URL, or URL query.
  - **EXISTS**: The specified header or query exists.
  - **NOTCONTAINS**: Does not contain the following text string.
  - **NOTEXISTS**: The specified header or query does not exist.

f) If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.
g) If you chose HEADER as the Protocol, type the header you want in the Header Name* text box.
h) Click OK to add your expression to the Expressions list.
i) Repeat steps B through H to create any additional expressions you want for your profile.
j) Click Close to close the Expressions Editor.

9. If you created a new expression, in the Expression frame select an option from the Match Any Expression drop-down list. Your choices are:
  - **Match Any Expression**: If a request matches any expression in the Expressions list, the request matches this policy.
  - **Match All Expressions**: If a request matches all expressions in the Expressions list, the request matches this policy. If it does not match all of them, it does not match this policy.
  - **Tabular Expression**: Switches the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [()] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.
  - **The AND [&&] operator**: tells the appliance to require that a request match both the current expression and the following expression.
The OR operator tells the appliance to require that a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

- The END operator tells the appliance that this is the last expression in this expression group or policy.
  Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression basis. You are not limited to just one or the other.
- Advanced Free-Form Switches off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the Citrix ADC appliance and PCRE-format regular expressions.
  Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.

10. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the Citrix ADC appliance, they are all the same.
11. Click Create to create your new policy. Your new policy appears in the Policies pane list.
12. Click Close. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the Policies tab and click Remove.

1. 2. Citrix ADC
3. Citrix ADC 12.1

Binding a content filtering policy

January 23, 2019
You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific vserver are evaluated only when that vserver receives traffic that matches the policy.

**Bind a policy to a virtual server by using the CLI**

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

```
1 - bind lb vserver <name>@ -policyName <string> -priority <positive_integer>
2 - show lb vserver <name>
```

**Example:**

```
1 > bind lb vserver vs-loadbal -policyName policyTwo -priority 100
2   Done
3 > show lb vserver vs-loadbal
4   1) vs-loadbal (10.102.29.20:80) - HTTP   Type: ADDRESS
5       State: OUT OF SERVICE
6       Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
7       Time since last state change: 2 days, 00:58:03.260
8       Effective State: DOWN
9       Client Idle Timeout: 180 sec
10      Down state flush: ENABLED
11      Disable Primary Vserver On Down : DISABLED
12      Port Rewrite : DISABLED
13      No. of Bound Services : 0 (Total) 0 (Active)
14      Configured Method: LEASTCONNECTION
15      Mode: IP
16      Persistence: NONE
17      Vserver IP and Port insertion: OFF
18      Push: DISABLED   Push VServer:
19      Push Multi Clients: NO
20      Push Label Rule: none
21
22   Done
```
Globally bind a policy by using the CLI

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

```
1 - bind filter global (<policyName> [-priority <positive_integer>]] [-state ( ENABLED | DISABLED )]
2 - show filter global
```

Example:

```
1  bind filter global cf-pol -priority 1
2  Done show filter global
3  1) Policy Name: cf-pol Priority: 1
4  Done
```

Bind a policy to a virtual server by using the GUI

2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click OK. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

Globally bind a policy by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, in the Policies tab, select the policy that you want to bind, and then click Global Bindings.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select a policy, and then click Add. The policy is added to the Configured list.
   Note: To select multiple policies from the list, press and hold the Ctrl key, then click each policy you want.
4. Click OK, and then click Close. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

1. 2. Citrix ADC
Configuring content filtering for a commonly used deployment scenario

January 23, 2019
Contributed by: C

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy filter-CF-nimda is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

Enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

Configure the content filtering policy filter-CF-nimda

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name filter-CF-nimda.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type cmd.exe, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type root.exe. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy filter-CF-nimda appears in the Filter list.
14. Click Close.

Globally bind the content filtering policy

2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy filter-CF-nimda, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

Bind the content filtering policy to a virtual server

2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy filter-CF-nimda, and then click OK. Your content filtering policy is now active, and should be filtering requests. If it is functioning correctly, the Hits counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.

Verify the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:
show filter policy filter-CF-nimda

Example:

```
1  sh filter policy filter-CF-nimda
2       Name:  filter-CF-nimda  Rule:  REQ.HTTP.URL CONTAINS cmd.exe ||
2                REQ.HTTP.URL CONTAINS root.exe
3       Request action:  RESET
4       Response action:
5         Hits:  0
6  Done
```

Note: The

Hits counter displays an integer that denotes the number of times the filter-CF-nimda policy is evaluated. In the preceding steps, the Hits counter is set to zero because no requests for a URL containing either cmd.exe or root.exe have been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

Verify the content filtering configuration by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, select the filter policy filter-CF-nimda. The bottom of the pane should display the following:

```
**Request Action:**

RESET

**Rule:**

REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe

**Hits:**

0
```

3. Citrix ADC 12.1
Troubleshooting

January 23, 2019

Contributed by: C

If the content filtering feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

You can use the following tools and resources to troubleshoot most Content Filtering issues on a Citrix ADC appliance:

- The Wireshark application customized for the Citrix ADC trace files
- Trace files recorded when accessing the resource
- The configuration files
- The ns.log file
- The iehttpheaders, or a Fiddler trace or a similar utility

Troubleshooting content filtering issues

To troubleshoot a content filtering issue, proceed as follows:

- Verify that the feature is enabled.
- Verify that the content filtering policy is configured correctly. Pay special attention to the expression that evaluates the incoming requests.
  
  Note: Most content filtering issues are caused by incorrect configuration, and the error is most often in the policy configuration.
- Check the policy’s Hits counter to verify that it is incrementing. If it is not, the policy is not getting evaluated.
- If the policy is getting evaluated and the required filtering is still not performed, you need to look into the policy expressions and action.
- If the policy’s expression seems valid, test it by assigning a simple NSTRUE value to see if the evaluation of the expression is creating any issue.
- Reevaluate whether the filtering should be based on the request or the response.
- Verify that the action is configured correctly. For example, if a custom action is used to corrupt a header in the request, verify that the header name in the action is correct. If you are not sure about the header name, start a browser with iehttpheaders or a similar utility, and then verify
HTTP denial-of-service protection

January 25, 2019

Contributed by:

C

Warning

HTTP Denial of Service Protection (HDoSP) is deprecated from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use AppQoE. For more information, see AppQoE.

Internet hackers can bring down a site by sending a surge of GET requests or other HTTP-level requests. HTTP Denial-of-Service (HTTP DoS) Protection provides an effective way to prevent such attacks from being relayed to your protected Web servers. The HTTP DoS feature also ensures that a Citrix ADC appliance located between the internet cloud and your Web servers is not brought down by an HTTP DoS attack.

Most attackers on the Internet use applications that discard responses to reduce computation costs, and minimize their size to avoid detection. The attackers focus on speed, devising ways to send attack packets, establish connections or send HTTP requests as rapidly as possible.

Real HTTP clients such as Internet Explorer, Firefox, or NetScape browsers can understand HTML Refresh meta tags, Java scripts, and cookies. In standard HTTP the clients have most of these features enabled. However, the dummy clients used in DoS attacks cannot parse the response from the server.
If malicious clients attempt to parse and send requests intelligently, it becomes difficult for them to launch the attack aggressively.

When the Citrix ADC appliance detects an attack, it responds to a percentage of incoming requests with a Java or HTML script containing a simple refresh and cookie. (You configure that percentage by setting the Client Detect Rate parameter.) Real Web browsers and other Web-based client programs can parse this response and then resend a POST request with the cookie. DoS clients drop the Citrix ADC appliance’s response instead of parsing it, and their requests are therefore dropped as well.

Even when a legitimate client responds correctly to the Citrix ADC appliance’s refresh response, the cookie in the client’s POST request may become invalid in the following conditions:

- If the original request was made before the Citrix ADC appliance detected the DoS attack, but the resent request was made after the appliance had come under attack.
- When the client’s think time exceeds four minutes, after which the cookie becomes invalid.

Both of these scenarios are rare, but not impossible. In addition, the HTTP DoS protection feature has the following limitations:

- Under an attack, all POST requests are dropped, and an error page with a cookie is sent.
- Under an attack, all embedded objects without a cookie are dropped, and an error page with a cookie is sent.

The HTTP DoS protection feature may affect other Citrix ADC features. Using DoS protection for a particular content switching policy, however, creates additional overhead because the policy engine must find the policy to be matched. There is some overhead for SSL requests due to SSL decryption of the encrypted data. Because most attacks are not on a secure network, though, the attack is less aggressive.

If you have implemented priority queuing, while it is under attack a Citrix ADC appliance places requests without proper cookies in a low-priority queue. Although this creates overhead, it protects your Web servers from false clients. HTTP DoS protection typically has minimal effect on throughput, since the test JavaScript is sent for a small percentage of requests only. The latency of requests is increased, because the client must re-issue the request after it receives the JavaScript. These requests are also queued.

To implement HTTP DoS protection, you enable the feature and define a policy for applying this feature. Then you configure your services with the settings required for HTTP DoS. You also bind a TCP monitor to each service and bind your policy to each service to put it into effect.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
Any Citrix ADC appliance with system software version 8.1 or later automatically provides protection against SYN DoS attacks.

To mount such an attack, a hacker initiates a large number of TCP connections but does not respond to the SYN-ACK messages sent by the victimized server. The source IP addresses in the SYN messages received by the server are typically spoofed. Because new SYN messages arrive before the half-open connections initiated by previous SYN messages time out, the number of such connections increases until the server no longer has enough memory available to accept new connections. In extreme cases, the system memory stack can overflow.

A Citrix ADC appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted.

SYN DoS protection on the Citrix ADC appliance ensures the following:

- The memory of the Citrix ADC is not wasted on false SYN packets. Instead, memory is used to serve legitimate clients.
- Normal TCP communications with legitimate clients continue uninterrupted, even when the Web site is under SYN flood attack.

In addition, because the Citrix ADC appliance allocates memory for HTTP connection state only after it receives an HTTP request, it protects Web sites from idle connection attacks.

SYN DoS protection on your Citrix ADC appliance requires no external configuration. It is enabled by default.

**Disable SYN Cookies**

SYN cookies are enabled by default on a Citrix ADC appliance to prevent SYN attacks. If your deployment requires you to disable SYN cookies, for example, for server-initiated data connections or in cases where a connection is not established because the first packet is dropped or reordered, use one of the following methods to disable SYN cookies.
Disable SYN cookies by using the CLI

At the command prompt, type:

```
set nstcpprofile nstcp_default_profile -synCookie DISABLED
**Arguments**
synCookie
Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the Citrix ADC appliance.
```

Possible values: ENABLED, DISABLED
Default: ENABLED

Disable SYN cookies by using the GUI

1. Navigate to **System > Profiles > TCP Profiles**.
2. Select a profile and click **Edit**.
3. Clear the **TCP SYN Cookie** check box.
4. Click **OK**.

Enable HTTP DoS protection

January 23, 2019

Contributed by: C

To configure HTTP DoS protection, you must first enable the feature.
Enable HTTP DoS protection by using the CLI

At the command prompt, type the following commands to enable HTTP DoS protection and verify the configuration:

```
1 - enable ns feature HttpDoSProtection
2 - show ns feature
```

Example:

```
1 > enable ns feature HttpDoSProtection
   Done
3 > show ns feature

<table>
<thead>
<tr>

Define an HTTP DoS policy

January 25, 2019

Contributed by: C

After you enable HTTP DoS protection, you next create a policy.

**Note:** Before changing the default setting for Client Detect Rate, see Tuning the Client Detection/JavaScript Challenge Response Rate.

**Configure a HTTP DoS policy by using the CLI**

At the command prompt, type one of the following commands to configure an HTTP DoS policy and verify the configuration:

1. `add dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]`
2. `set dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]`

**Example:**

```
1 > add dos policy pol-HTTP-DoS -qDepth 30
2 Done
3 > set dos policy pol-HTTP-DoS -qDepth 40
4 Done
5 > show dos policy
6 1) Policy: pol-HTTP-DoS QDepth: 40
7 Done
```

**Configure an HTTP DoS policy by using the GUI**

1. Navigate to Security > Protection Features > HTTP DoS.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. In the Create HTTP DoS Policy or Configure HTTP DoS Policy dialog box, specify values for the parameters:
   - Name*—name (You cannot change the name of an existing policy.)
After you configure an HTTP DoS policy, you must configure a service for your policy. The service accepts HTTP traffic that is protected by the HTTP DoS policy.

**Configure an HTTP DoS service by using the CLI**

At the command prompt, type one of the following commands to configure an HTTP DoS service and verify the configuration:

1. `add service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED`
2. `set service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED`

**Example:**

```
1 > add service ser-HTTP-Dos1 10.102.29.40 HTTP 87
2 Done
3 > set service ser-HTTP-Dos1 -maxReq 20
4 Done
5 > show service

**Configure an HTTP DoS service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.
3. In the Create Server or Configure Server dialog box, specify values for the following parameters, which correspond to the descriptions in “Parameters for configuring an HTTP DoS service” as follows (asterisk indicates a required parameter):
   - Service Name*—name (You cannot change the name of an existing service.)
   - Server*—IP or serverName (Specify one or the other, not both.)
   - Port*—port
4. If the Enable Service check box is not selected, select it.
5. Select the Advanced tab, and select the Override Global check box to enable those choices.
6. Specify values for the following parameters.
   - Max Clients*—maxClient
   - Max Requests*—maxReq
7. Click Create or OK, and then click Close. The service appears in the list of services.

---

**Bind an HTTP DoS monitor and policy**

January 23, 2019

Contributed by:
C

To put HTTP DoS protection into effect after you have configured an HTTP DoS service, you must bind the monitor, and then bind the service to the HTTP DoS policy.

**Bind the monitor to the service by using the CLI**

At the command prompt, type the following commands to bind the monitor to the service and verify the configuration:

```
1 - bind lb monitor <monitorName> <serviceName>
2 - show lb monitor
```

**Example:**

```
1 > bind lb monitor tcp ser-HTTP-DoS
2   Done
3 > show lb monitor
```
Bind the policy to the service by using the CLI

At the command prompt, type the following commands to bind the policy to the service and verify the configuration:

```
bind service <serviceName> -policyName <policyName>
```

**Example:**

```
1 > bind service ser-HTTP-DoS -policyName pol-HTTP-DoS
   Done
3 > show service
4 1)   srv-http-10 (10.102.29.30:80) - HTTP
5       State: DOWN
6       Last state change was at Wed Jul 8 07:49:52 2009
7       Time since last state change: 34 days, 01:24:58.510
8       Server Name: 10.102.29.30
9       Server ID : 0   Monitor Threshold : 0
10      Max Conn: 0   Max Req: 0   Max Bandwidth: 0 kbits
11 Use Source IP: NO
12 Client Keepalive(CKA): NO
13 Access Down Service: NO
14 TCP Buffering(TCPB): NO
15 HTTP Compression(CMP): NO
16 Idle timeout: Client: 180 sec   Server: 360 sec
17 Client IP: DISABLED
18 Cacheable: NO
```
SC: OFF
SP: ON
Down state flush: ENABLED

4) ser-HTTP-Dos (10.102.29.18:88) - HTTP
State: DOWN
Last state change was at Tue Aug 11 08:19:45 2009
Time since last state change: 0 days, 00:55:05.40
Server Name: 10.102.29.18
Server ID: 0 Monitor Threshold: 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO

SP: OFF
Down state flush: ENABLED
Done
Bind the monitor and policy to the service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to bind, and then click Open.
3. In the Configure Service dialog box, select the Monitor tab, click the name of the monitor you want in the Monitors list, and then click Add. The selected monitor is added to the Configured frame.
4. Select the Policies tab, then select the HTTP DoS tab.
5. Select a policy from the Available Policies list, and then click Add. The policy appears in the Configured Policies list.
6. Click OK, and then click Close. A message appears in the status bar, stating that the service has been configured.

1. Citrix ADC
2. Citrix ADC 12.1

Tuning the client detection/JavaScript challenger response rate

January 25, 2019
Contributed by: C

After you have enabled and configured HTTP DoS protection, if more than the maximum specified number of clients are waiting in the Citrix ADC surge queue for the HTTP DoS service, the HTTP DoS protection function is triggered. The default rate of challenged JavaScript responses sent to the client is one percent of the server response rate. The default response rate is inadequate in many real attack scenarios, however, and may need to be tuned.

For example, assume that the Web server is capable of a maximum of 500 responses/sec, but is receiving 10,000 Gets/sec. If 1% of the server responses are sent as JavaScript challenges, responses are reduced to almost none: 5 client (500 * 0.01) JavaScript responses, for 10000 waiting client requests. Only about 0.05% of the real clients receive JavaScript challenge responses. However, if the client detection/JavaScript challenge response rate is very high (for example, 10%, generating 1000 challenge JavaScript responses per second), it may saturate the upstream links or harm the upstream network devices. Exercise care when modifying the default Client Detect Rate value.

If the configured triggering surge queue depth is, for example, 200, and the surge queue size is toggling between 199 and 200, the Citrix ADC toggles between the “attack” and “no-attack” modes, which is not desirable. The HTTP DoS feature includes a window mechanism with a default size of 20. After
the surge queue size reaches the specified queue depth value, triggering “attack” mode, the surge queue size must fall to 20 less than the specified queue depth for the Citrix ADC appliance to enter “no-attack” mode. In the example, the surge queue size must fall below 180 before the appliance enters “no-attack” mode. During configuration, you must specify a value more than 20 for the QDepth parameter when adding a DoS policy or setting a DoS policy.

The triggering surge queue depth should be configured on the basis of previous observations of traffic characteristics. For more information about setting up a correct configuration, see Guidelines for HTTP DoS protection deployment.

2. Citrix ADC 12.1

Guidelines for HTTP DoS protection deployment

January 23, 2019

Contributed by:
C

Citrix recommends you to deploy the HTTP DoS protection feature in a tested and planned manner and closely monitor its performance after the initial deployment. Use the following information to fine-tune the deployment of HTTP DoS Protection.

- The maximum number of concurrent connections supported by your servers.
- The average and normal values of the concurrent connections supported by your servers.
- The maximum output rate (responses/sec) that your server can generate.
- The average traffic that your server handles.
- The typical bandwidth of your network.
- The maximum bandwidth available upstream.
- The limits affecting bandwidth (such as external links, a particular router, or other critical devices on the path that may suffer from a traffic surge).
- Whether allowing a greater number of clients to connect is more important than protecting upstream network devices.

To determine the characteristics of a HTTP DoS attack, you should consider the following issues.

- What is the rate of incoming fake requests that you have experienced in the past?
- What types of requests have you received (complete posts, incomplete gets)?
- Did previous attacks saturate your downstream links? If not, what was the bandwidth?
• What types of source IP addresses and source ports did the HTTP requests have (e.g., IP addresses from one subnet, constant IP, ports increasing by one).
• What types of attacks do you expect in future? What type have you seen in the past?
• Any or all information that can help you tune DoS attack protection.

2. Citrix ADC
3. Citrix ADC 12.1

Priority queuing

February 25, 2019
Contributed by:
C

Warning
Priority Queuing (PQ) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use AppQoE. For more information, see AppQoE.

The priority queuing feature lets you filter incoming HTTP traffic on the basis of categories that you create and define, and prioritize those HTTP requests accordingly. Priority queuing directs high-priority requests to the server ahead of low-priority requests, so that users who need resources for important business uses receive expedited access to your protected Web servers.

Note:
This feature is available with a Citrix ADC enterprise or platinum edition license.

To implement priority queuing, you create priority queuing policies that specify a priority, weight, threshold, and implicit action. When an incoming request matches a priority queuing policy, the request is processed as the associated action indicates. For example, you can create a priority queuing policy that places all matching requests above a certain threshold in a surge queue, while giving priority treatment to other requests.

You can bind up to three priority queuing policies to a single load balancing virtual server. The priority levels are:

• **Level 1**: A Level 1 policy processes priority requests.
• **Level 2**: A Level 2 policy processes requests that should receive responses as soon as Level 1 requests have been cleared from the queue.
• **Level 3**: A Level 3 policy processes non-priority requests that receive responses only after requests in the first two queues have been cleared.
You can use weighted queuing to adjust the relative priority of each of these queues. Weights can range from 0 to 101. A weight of 101 tells the Citrix ADC appliance to clear all requests in that queue before forwarding any requests in the lower-priority queues to the Web server. A weight of 0 tells the appliance to send requests in that queue to the Web server only when there are no requests waiting in any of the other queues.

You must assign a unique name to each priority queuing policy. Policy names can be up to 127 characters. Multiple policies bound to the same load balancing virtual server cannot have the same priority level. No two virtual servers that have one or more common underlying physical services can have priority queuing configured or enabled on both virtual servers simultaneously.

To configure priority queuing the Citrix ADC, you perform the following steps:

- Enable the load balancing feature
- Define a server and service
- Define a load balancing virtual server
- Bind the service to the load balancing virtual server
- Enable the priority queuing feature
- Create the priority queuing policies
- Bind the priority queuing policies to the load balancing virtual server
- Enable priority queuing on load balancing virtual server

Enable priority queuing

January 23, 2019

Contributed by: C

To use the priority queuing feature the Citrix ADC appliance, you must first enable it.

Enable priority queuing by using the CLI

At the command prompt, type the following commands to enable priority queuing and verify the configuration:

1.  enable ns feature PriorityQueuing
2.  show ns feature
Example:

```
1. > enable ns feature PriorityQueuing
2. Done
3. > show ns feature
4. 
5. | Feature           | Acronym | Status |
6. | ----------------- | ------- | ------ |
7. | 1) Web Logging    | WL      | ON    |
8. | 2) Surge Protection| SP      | OFF   |
9. | 3) Load Balancing | LB      | ON    |
10. 
11. 
12. 
13. | 8) Priority Queuing| PQ      | ON    |
14. 
15. | 23) HTML Injection| HTMLInjection | ON |
16. | 24) Citrix ADC Push| push    | OFF   |
17. Done
```

**Enable priority queuing by using the GUI**

1. Navigate to System > Settings.
2. In the details pane, click Configure advanced features.
3. In the Configure Advanced Features dialog box, select the Priority Queuing check box.
4. Click OK.

**Configure a priority queuing policy**
Configure a priority queuing policy by using the CLI

At the command prompt, type the following command to configure a priority queuing policy and verify the configuration:

```
add pq policy <policyName> -rule <expression> -priority <positive_integer> > [-weight <positive_integer>] [-qDepth <positive_integer> | -polqDepth <positive_integer>]
```

**Example:**

```
1 > add pq policy pol_cgibin -rule "URL == '/cgi-bin/'" -priority 1
2 Done
3 > show pq policy pol_cgibin
4 1) Policy: pol_cgibin  Rule: URL == '/cgi-bin/'
   Priority: 1  Weight: 10
5 Hits: 0
6 Done
```

Configure a priority queuing policy by using the GUI

1. Navigate to Security > Protection Features > Priority Queuing.

2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.

3. If you are creating a new policy, in the Create PQ Policy dialog box, in the Name text box, type a name for your new policy.
   - The name can consist of from one to 127 letters, numbers and the hyphen and underscore symbol.
   - If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:
   - a) In the Create Expression dialog box, click Add.
b) In the Add Expression dialog box, leave Expression Type set to General, and in the Flow Type drop-down list, select a Flow Type. Your choices are REQ (for requests) and RES (for responses).

c) In the Protocol drop-down list, select a protocol. If you selected REQ in the previous step, your choices are HTTP (Web-based connections), SSL (secure Web connections), TCP and IP. If you selected RES in the previous step, your choices are HTTP, TCP and IP.

d) In the Qualifier drop-down list, select a qualifier.

Your choices depend upon your selections in the previous step. Common choices are HTTP VERSION (the version of the HTTP connection), HTTP HEADER (the specified HTTP header), TCP SOURCEPORT/DESTPORT (the source or destination port of a TCP connection), and IP SOURCEIP/DESTIP (the source or destination IP of the connection).

If you choose HTTP HEADER, the Header text box appears beneath the original row of text boxes. You fill in the name of the HTTP header you want.

For a complete description of the available choices, see “Policies and Expressions.”

e) In the Operator drop-down list, select an operator.

For a complete description of the available choices, see “Policies and Expressions.”

f) In the Value text box, type the value you want to test for.

This may be a text string or a number, depending upon the context. For a complete description of values appropriate to the specific context, see “Policies and Expressions.”

g) Click OK. The expression is added in the Expression text box.

h) Click Create. The expression appears in the Rule text box.

5. In the Priority and Weight text boxes, type numeric values, for example, 1 and 30. For more information about Priority and Weight, see “Set up weighted queuing.”

6. Enter a numeric value for either Queue Depth or Policy Queue Depth, for example 234, and click Create.

   • Queue Depth Defines the total number of waiting clients or requests on the virtual server to which the policy is bound.
   • Policy Queue Depth Defines the total number of waiting clients or requests belonging to the policy.

The policy is created and appears in the Priority Queuing page.

Note: To create additional priority queuing policies, repeat the procedure in the preceding section, and click Close after you finish.
Bind a priority queuing policy

January 23, 2019

Contributed by: C

After you create a priority queuing policy, you must bind it to the appropriate virtual server to put it into effect.

Bind a priority queuing policy by using the CLI

At the command prompt, type the following commands to bind a policy and verify the configuration:

```plaintext
1 - bind lb vserver <name> -policyName <policyname>
2 - show lb vserver <name>
```

Example:

```plaintext
1 > bind lb vserver lbvip -policyName pol_cgibin
2   Done
3 > show lb vserver lbvip
   lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
   State: DOWN
   Last state change was at Wed Jul 15 05:54:24 2009 (+782 ms)
   Time since last state change: 26 days, 05:44:37.370
   Effective State: DOWN
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Port Rewrite : DISABLED
   No. of Bound Services : 0 (Total)    0 (Active)
   Configured Method: LEASTCONNECTION
   Mode: IP
   Persistence: NONE
   Vserver IP and Port insertion: OFF
   Push: DISABLED   Push VServer:
   Push Multi Clients: NO
   Push Label Rule: none
```
Bind a priority queuing policy by using the GUI

1. In the navigation pane, locate and select the virtual server to which you want to bind the priority queuing policy.
   - To select a load balancing virtual server, expand Traffic Management > Load Balancing > Virtual Servers, then select the load balancing virtual server that you want.
   - To select a content switching virtual server, expand Traffic Management > Content Switching > Virtual Servers, then select the content switching virtual server that you want.
2. In the Configure Virtual Server dialog box, select the Policies tab.
3. Click the double right-arrow (») symbol to display the complete list of policy types, and then select Priority Queuing from the drop-down list.
4. Click Insert Policy.
5. In the Policy Name row, select the policy that you want to bind from the drop-down list.
6. Click OK to save your changes.

Set up weighted queuing

January 25, 2019
Contributed by: C

When priority queuing is implemented, lower-priority requests are typically kept on hold while higher-priority requests are served. The lower-priority requests may therefore be delayed if there is a constant flow of higher-priority requests.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities are:

- Gold - Priority 1 - Weight 3
• Silver - Priority 2 - Weight 2
• Bronze - Priority 3 - Weight 1

You assign the minimum weight, zero (0), to requests that the Citrix ADC appliance should send to the server only if no requests are stored in any of the other queues. You assign the maximum weight, 101, to requests that the appliance should send to the server immediately, ahead of any requests stored in any of the other queues. Weights between these two set the relative priority of a particular queue in relation to the other queues. Queues with a higher weight are processed first; queues with a lower weight after the others have been processed. To assign the weights, see “Configure a priority queuing policy.”

**Note:** The weight assigned to a higher-priority queue must be larger than the weight assigned to a lower-priority queue. For example, the weight assigned to The Gold (Priority 1) queue must be greater than the weight assigned to the Silver (Priority 2) queue.

1. **SureConnect**

January 25, 2019

Contributed by:

© 1999-2018 Citrix Systems, Inc. All rights reserved.

---

**Warning**

SureConnect (SC) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. For more information, see [AppQoE](#).

You can use the SureConnect feature of the Citrix ADC appliance to service all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

When servers are overloaded with the requests, the servers might either respond slowly or not at all. The SureConnect feature enables the Citrix ADC appliance to detect and compensate such conditions by ensuring that every client request gets serviced in some way, such as either a custom Web page or actual content is sent to the client.

SureConnect is activated when the response time or maximum server connections to a client request exceeds a limit that you have set. The SureConnect browser window displays one of the following:

- A progress bar with the amount of time remaining until the requested content will be available.
• Alternate Web content of your choice (alternate page).
• Both a progress bar and alternate page.
• Complete custom content of your choice.

You can configure whether the SureConnect progress bar alone is displayed or both the progress bar and the alternate page are displayed.

When the server becomes responsive again, the original request for content is served. If the user chooses, the alternate content window can remain in focus.

Subsequent requests from the same user within the same session are served immediately. This can be configured using the settings described later in this section.

SureConnect can be activated when a response is delayed, and when the number of user connections to a given URL exceeds a specified threshold.

SureConnect works with all standard browsers, including Microsoft Internet Explorer, Netscape Navigator, and Mozilla Firefox.

SureConnect is advantageous in the following situations:

• **Full server queue:** The server can respond fast, but there are too many users. This results in the server’s queue being full and unable to process additional client requests.

  **SureConnect Solution:** In this situation, the SureConnect window is displayed, showing the time left until the content will be available. The alternate page is displayed under the progress bar, if an alternate page has been configured.

• **Large response delay:** The server response is slow. Typically, if a Web server does not respond to a client request quickly, the user will leave the site.

  **SureConnect Solution:** When the predicted delay reaches a configured time threshold, the SureConnect window displays the progress bar and the optional alternate page in the client browser.

• **Client time-out:** When the client requests content from a very slow Web site, a time-out message displays in the client browser, and the content is not delivered. The user may leave the site.

  **SureConnect Solution:** The appliance stores the request until the server is no longer busy and delivers the requested content to the client.

• **Server experiencing a traffic surge:** The server typically responds quickly, but the current load of open connections is greater than the server capacity to serve them. Therefore, the server response is delayed.

  **SureConnect Solution:** A SureConnect window is displayed in the client browser, showing the time left. The alternate page from the server is also displayed if it has been configured.

3. Citrix ADC 12.1

Installing SureConnect

January 23, 2019
Contributed by: C

SureConnect files must be installed on the alternate content server, which can be the same as the primary server.

On a Windows server, extract the sc_xx.exe file (where xx is the build number), or on a UNIX server, extract the sc_xx.tar file (where xx is the build number).

**Note:** You must install SureConnect in the default Web root directory.

If the alternate content server is the same as the primary server, place the SureConnect and alternate content files in any directory under the Web root directory. Specify this path when you add a policy to configure SureConnect. By default, SureConnect files are installed in the /NetScaler appliance directory under the default Web root directory.

If the alternate content server is different than the primary server, the SureConnect and alternate content files must be in a unique directory under the Web root directory. By default, this unique directory is the /NetScaler system directory. Specify this path when you add a policy to configure SureConnect.

The following files are extracted:

- Alternate content files (progressbar.htm, alternatepage.htm, and barandpage.htm)
- System-Logo.gif
- Customer-Logo.gif
- Sample.gif
- README.txt.

Installing on UNIX

This section describes how to install SureConnect alternate content on a UNIX server. The following are the prerequisites:

- The UNIX server is running the Apache server.
- The shell with the # prompt is in use.
• Apache is installed in the default location.
• The sc_xx.tar file is downloaded from the organization’s Web site into the /var/ftp/incoming directory.

To install SureConnect

1. At the command prompt, navigate to the htdocs directory:
   ```
   cd /usr/local/apache/htdocs
   ```

2. Type the following command:
   ```
   tar xvpf /var/ftp/incoming/sc_xx.tar
   ```

The output from the .tar file is displayed. A /NetScaler system directory is created under the specified path and the SureConnect files are installed.

Installing on Windows

This section describes how to install SureConnect alternate content on a Windows server. The following are the prerequisites:

• The server is running the Microsoft Internet Information Server.
• The DOS prompt is being used.
• The SureConnect zip (self-extracting) file is downloaded from the organization Web site using FTP into the C:inetpubwwwroot directory.

To install SureConnect on Windows

Do one of the following:

• At the command prompt, navigate to the wwwroot directory:
   ```
   cd c:inetpubwwwroot
   ```

• Type the name of the executable file:
   ```
   sc_xx.exe
   ```

• Double-click the sc_xx.exe icon from the Microsoft Windows Explorer Web browser, extract from the compressed file into the default path (for example, the c:inetpubwwwroot directory).

Output from the zip file is displayed. A /NetScaler system directory is created under the specified path, and the SureConnect files are installed.
The following topics describe how to configure SureConnect for scenarios involving alternate server failure.

**Configure the response for alternate server failure**

If the alternate server fails, and the primary server cannot immediately deliver the requested content to the client, SureConnect does not display alternate content from the failed alternate server in the client Web browser.

The Citrix ADC appliance automatically sends a response to the client browser. You can customize the server response to display information suited to your needs.

The default response is:

Your Request is being processed… Estimated Time: __ Secs

**Customize the default response**

The Citrix ADC appliance automatically sends the response to the client if the alternate server fails, or if the appliance is configured to send the default response.

To customize the default response of the appliance, create a vsr.htm file (a sample is provided in this section) as follows:

- The file can contain any valid HTML statements other than embedded objects.
- The file size cannot exceed 800 bytes.
- The file must reside on the Citrix ADC appliance. If you have a high availability (HA) setup, the file must reside on the primary and secondary nodes. Any changes made to the file on the primary node must also be applied to the file on the secondary node.
- Put vsr.htm file in the /etc directory.
To customize the default response

Change any of the contents between the </HEAD> and </HTML> tags in the vsr.htm file. Following is the sample content from vsr.htm file. The sections that you can edit are in bold text.

```
HTTP/1.1 200 OK
Server: NS_WS3.0
Content-Type: text/html
Cache-control: no-cache
Pragma: no-cache
Set-Cookie: NSC_BPIP=@@SID@@; path=/
</HTML> <HEAD> <META HTTP-EQUIV="Refresh" CONTENT="0">
</HEAD> <font color=blue size=5>Your request is being processed...
<br>Estimated Delay: @@DELAY@@ Sec </font> </HTML>
```

Note: Include @@DELAY@@ to display the predicted delayed response time in seconds.

SureConnect with in-memory response (NS action)

When defining the SureConnect policy by using the add sc policy command, you can configure the Citrix ADC appliance to serve alternative content to the client.

To enable SureConnect and configure the in-memory response, perform the following tasks:

- Enable the SureConnect feature on the appliance by using the enable feature SC command
- Define the services by using the add service <servicename> <IP address> <servicetype> <port> command. This identifies the original server for which the SureConnect is configured and the types of services.
- Add a SureConnect policy by using the add sc policy command. You can configure a URL-based policy or a rule-based policy. The incoming requests are validated against the URL or rule you specify in the policy.

Note: You can configure the SureConnect feature on a load balancing virtual server. In that case, perform the following additional actions:

- Enable Load Balancing by using the enable feature LB command.
- Enable SureConnect feature on the virtual server by using the set lb vserver <servername> -sc ON command.
- Bind services to the virtual server by using the bind lb vserver <name> <serviceName> command.
- Bind policies to the virtual server by using the bind lb vserver <name> -policyname <name> command.

The following example illustrates how to configure SureConnect for the load balancing feature so that SureConnect will display alternative content from the Citrix ADC appliance.
In this example, two physical servers, with IP addresses, 10.101.3.187 and 10.101.3.188 are load-balanced by the Citrix ADC appliance. The appliance has one configured virtual server, vs-NSact, whose IP address is 10.101.3.201. The file that contains the alternative content is vsr.htm. It is copied from the file system into system memory. Services are loaded until the SureConnect policy triggers, and the appliance supplies the alternate content.

Table 1. Parameter values used in this example

<table>
<thead>
<tr>
<th>Service</th>
<th>Name</th>
<th>Server</th>
<th>Protocol</th>
<th>Port</th>
</tr>
</thead>
<tbody>

![Configuration commands]

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To configure this example by using the GUI

1. In the navigation pane, navigate to System > Settings. In the Modes and Features pane, perform the following actions:
   a) Click Configure Basic Features, select Load Balancing, and Click Go.
   b) Click Configure Advanced Features, select SureConnect, and Click Go.
2. In the navigation pane, navigate to Security > Protection Features > SureConnect. In the details pane, click Parameters. In the Configure SureConnect Parameters window, browse and select the VSR filename.
3. Navigate to Traffic Management > Load Balancing > Services. In the details pane, click Add. In the Create Services window, enter the parameter values as shown in Table 5-1, and click OK.
4. Navigate to Traffic Management > Load Balancing > Virtual servers. In the details pane, click Add. In the Create Virtual Server (Load Balancing) dialog box, enter the values shown in Table 5.1 for the Load Balancing Virtual Server parameters and click OK.
5. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. The Configure Virtual system (Load Balancing) dialog box, displays the list of configured services. Select services psvc1 and psvc2 and click OK.
6. In the navigation pane, expand Security > Protection Features > SureConnect. In the details pane, click Add. Create the policy with the values as given in the parameters table.
7. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, click the Policies tab. Click » to expand the features. Select SureConnect. When the list of SureConnect policies appear, select policyNS and click OK.
8. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, on the Advanced tab, select SC and click OK.

Configure the SureConnect policies

You can configure the following SureConnect policies. The Citrix ADC appliance matches incoming requests in the order the policies are configured:

- Exact URL-based policies
- Wildcard rule-based policies
Configure exact URL based policies

When you configure an exact URL based policy, the Citrix ADC appliance matches the incoming request against the URL that has been configured in the policy. URL based policies take precedence over rule based policies.

Configure an exact URL based policy by using the CLI

At the command prompt, type:

```
add sc policy <name> [-url <URL> | -rule <expression>] [-delay <usecs>] [-maxConn <positive_integer>] [-action (ACS <altContentSvcName> <altContentPath>) | NS | NOACTION])
```

Configure an exact URL based policy by using the GUI

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, set the following parameters:
   - Name*
   - URL (Make sure that the URL check box is selected)
   - Value*
   - Delay (microseconds)*
   - Maximum Client Connections
   - Action (Select from the Choose Action list.)
   - Alternate Service Name (if you select ACS as the Action)
   - Alternate Content Path (if you select ACS as the Action)
   *A required parameter
4. Click Create, and click Close. The URL based policy appears in the right pane, and a message displays in the status bar that the policy is successfully configured.

Configure wildcard rule-based policies

SureConnect matches the incoming requests to a defined rule, if you configure a rule-based policy.

Configure a SureConnect policy based on a wildcard rule by using the CLI

1. Create the expression(s).
   
   Use the add expression command to create each expression.
2. Create the rule(s).

Use the add sc policy command with the -rule expression_logic argument to specify the rule(s). In the -rule expression_logic argument, refer to the expression(s) you created in step 1.

Repeat this command to create and name each rule.

The following example creates a rule “rule = = /*.cgi”:

```
1 add vserver vs-lb http 1.1.1.1 80
2 add expression expr1 url == /cgi-bin/*.cgi
3 add expression expr2 url == /index.html
4 add sc policy surecpolicy1 -rule (expr1||expr2) -delay 1000000 -action NS
5 bind lb vserver vs-lb -policyName surecpolicy1
```

To complete the SureConnect configuration, you will need to enter additional commands, beyond those shown in the example.

**Configure a wildcard rule-based policy by using the GUI**

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, in the Name text box, type the name of the policy.
4. Under What to Monitor, click Expression, and then click Configure.
5. In the Create Expression dialog box, click Add.
6. In the Add Expression dialog box, enter an expression. For example, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA. For more information about expressions, see “Policies and Expressions.”
7. Click OK, and click Close.
8. In the Create Expression dialog box, click Create.

Examples of wildcard rules:

“/sports/*” matches all URLs under /sports

“/sports/**” matches all URLs whose prefix matches “/sports”, starting at the beginning of the URL.

“/*.jsp” matches all URLs whose file extension is “jsp”

When configuring rule-based policies, first add the more specific rule-based policies, before adding more generic rules (for example, add /cgi-bin/sports.cgi before adding /cgi-bin/.cgi).
Display the configured SureConnect policy

To view the SureConnect policy that you have configured, at the Citrix ADC command prompt, enter the show sc policy command.

Customize the alternate content file

When SureConnect activates, it can display alternate content from one of the following files that you have configured:

- `progressbar.htm`. Displays the progress information.
- `alternatepage.htm`. Displays an alternate page.
- `barandpage.htm`. Displays both the progress information and an alternate page.

The alternate content files are JavaScript files. During SureConnect installation, these files are copied onto the server that contains the alternate content. These files can contain alternate content (including an alternate page) or references to other files that contain the alternate content.

This section describes the changes you can make to the alternate content file provided by the appliance.

```
1 //**** DEFINE YOUR VALUES HERE ****
2 var alt_url = "netscaler_system/sports.htm";
3 var alt_url = "http://www.DomainName.com";
4 var netscaler_system_logo = "netscaler_logo.gif";
5 var our_logo = "netscaler_logo.gif";
6 var height = 450;
7 var width = 550;
8 var top = 200;
9 var left = 200;
10 var popunder = "no"; //specify yes for pop-under & no for pop-up
11 var shift_focus = "yes" //if you want to send pop-up to background on getting primary content else specify no
12 //**** YOUR DEFINITIONS ENDS HERE ****
```

You can make these changes:

- `var alt_url`. Specify the URL for the alternate content if a file provides the alternate content. For example:

```
1 var alt_url = "netscaler_system/sports.htm"
```

**Note:** The alternate content file must be present in the /netscaler system directory under the documents root of the Web server.
- **var our_logo.** Specify the image file of your organization logo.
- **var height.** Specify the height of the SureConnect window.
- **var width.** Specify the width of the SureConnect window.
- **var top and var left.** Specify the position of the SureConnect window.
- **var popunder.** Specifies the position of the alternate content window. Specify the value as NO to place the alternate content window above the original window. Specify the value as YES to place the alternate content window beneath the original window.
- **var shift_focus.** Specify the focus of the alternate content window. YES places the pop-up window in the background when getting the primary content. NO always keeps the pop-up window in focus, even when getting the primary content.

**Note:** For more information, see the README.txt file provided by the appliance with other alternate content files.

### Configure SureConnect for Citrix ADC features

This section describes how SureConnect works in combination with the load balancing, content switching, cache redirection, and high availability features of the Citrix ADC appliance.

### Configure SureConnect for load balancing

You can use SureConnect in environments where the primary servers use the load balancing feature, with or without alternate servers. If the load balancing virtual server configured for SureConnect fails, the backup virtual server (if there is one) handles the traffic. Backup virtual servers do not support SureConnect policies.

**Note:** For information about load balancing, see [Load Balancing](#).

### Configure SureConnect for cache redirection

You can use SureConnect in environments where cache redirection is configured. The primary server is a load balancing virtual server bound to the cache redirection virtual server. Regardless of any rules configured for the cache redirection feature:

- You can configure any URL for SureConnect.
- Once SureConnect is activated for a client, requests from the client are always sent to the origin server.
Configure SureConnect for high availability

SureConnect is compatible with Citrix ADC appliances operating in high availability mode.

Note: If the optional vsr.htm file is used, it must be present in both nodes (primary and secondary) and must use the same name and directory.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Activating SureConnect

January 23, 2019

Contributed by: C

You can set the Citrix ADC appliance to activate SureConnect if either of two criteria match. Both criteria are arguments to the add sc policy command, as described here:

- -delay <microseconds>
  The first time the client requests the URL, the appliance records how long the server takes to respond. The appliance will not activate SureConnect until the second time the URL is requested. The first and second requests may be from the same or different clients.
  If you set -delay argument, SureConnect will be activated the second time the delay reaches the threshold you set.
</div>

- -maxConn
  When the appliance receives a request, it checks the number of connections to the server for the configured URL. SureConnect is activated if the number of connections is greater than or equal to the value that you set for the -maxConn argument.
  If you will be providing alternate content to be displayed in the client’s Web browser, you should configure the -action argument of the add sc policy command. This specifies for the Citrix ADC appliance whether the alternate content is coming from a dedicated alternate server (-action ACS) or the appliance (-action NS).
When SureConnect is activated by the –maxConn argument, the SureConnect window and progress bar are displayed in the client’s browser (with an alternate page, if configured).

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

SureConnect environments

January 25, 2019
Contributed by: C

The following topics describe SureConnect environments.

Primary and alternate servers

The SureConnect environment uses a dedicated server to provide alternate content when the requested content is not available. The alternate content may include an alternate page, plus optional components such as frame set, organization logo, and so on. The alternate and primary servers can be the same server.

You can configure SureConnect to display a progress bar when the requested content is not available (or the progress bar and an alternate page).

The following figure illustrates the SureConnect environment.

Figure 1. SureConnect - Primary and Alternate Servers

Configuration checklist

Complete the following checklist before you start configuration:

• The same builds are running for the appliance and for the SureConnect files as suggested by appliance staff.
  - Appliance Build Number: _________
  - SureConnect (sc_xx.exe) Build Number: _________

• The latest SureConnect files (style files) are extracted to:
  - All primary servers (required for NS action).
The alternate content server (required for ACS action).

- All customizations to the latest style and vsr.htm files are applied.
- The alternate content server is accessible from the Internet (required for ACS action).
- If the -redirectURL URL argument of the add vserver CLI command needs to be specified:
  - The URL is up and running.
  - This URL is not on the configured servers.
  - This URL does not match any content in the vserver (that is, do not redirect a missing URL to itself). Redirecting a missing URL to itself can send some browsers into an infinite loop.
- All URLs to be configured for SureConnect are top-level URLs only. (Only the URLs that occupy the whole window or frame can be configured, not the embedded objects).

Following are the steps to configure SureConnect in a setup with a primary server and a dedicated alternate server:

- Enable the SureConnect feature
- Add the SureConnect policy
- Bind the SureConnect policy

You can optionally configure the following:

- Redirect the client to another URL if the primary server fails, or send a customized response to the client if the alternate server fails.
- If the servers do not provide alternate content, send a default or customized response.

**Redirect the client to another URL**

1. Enable the SureConnect feature.

2. Define the primary server and its service.

   You must identify the original server for which SureConnect support is being configured. At the Citrix ADC command prompt, type the following command:

   ```
   add service <serviceName> <IP> HTTP <port>
   ```

   where `<serviceName>` assigns a name for the service; `<IP>` is the server's IP address; and `<port>` is the port number that the service will use.

   Repeat use of the add service CLI command for each service that is to be added.

   You can also configure SureConnect on a load balancing virtual server. At the Citrix ADC command prompt, type the following command:

   ```
   add vserver <name> HTTP <IP> <port>
   ```
3. Define and bind the SureConnect policy as follows. If you are configuring a rule-based policy, perform this step as described in “Configure wildcard rule-based policies.” To configure a URL-based policy, at the Citrix ADC command prompt, type the following command:

```
add sc policy <name> [-url <URL>] [-delay <microsec>] [-maxConn <positiveInteger>]
```

For a detailed description of the add sc policy command, see “[Command Reference](https://developer-docs.citrix.com/projects/netscaler-command-reference/en/latest/).”

To bind the SureConnect policy, at the Citrix ADC command prompt, type the following command:

```
bind service <serviceName> -policyName <string>
```

where `<serviceName>` is the name of the service defined in step 2, and `<string>` is the name of the SureConnect policy.

Repeat the bind service command for each policy created.

You must include the alternate content page in the altContSvcName argument, and in the altContPath argument of the add sc policy command.

In the following example, the name of the alternate content file is /Citrix ADC system /barand-page.htm, and this file resides in svc2.

4. To save the configuration, at the netscaler command prompt, type the following command:

```
save config
```

**Example configurations**

The following examples illustrate various SureConnect configurations.

The examples assume that monitoring of physical services is enabled. If the alternate system is down, SureConnect will deliver the alternate content from the system itself.

**Example 1 - SureConnect progress bar and alternate page**

You can configure SureConnect to display both the progress bar and an alternate page to the user.

To bind a SureConnect policy to a load balancing virtual server, at the command prompt, type the following commands:

```
bind lb vserver <virtualServerName> -policyName <string>
```
where `<virtualServerName>` is the name of the load balancing virtual server defined in step 2 of the configuration process, and `<string>` is the name of the SureConnect policy defined in step 3.

Figure 2. SureConnect Configuration - Example 1

At the Citrix ADC command prompt, type the following commands:

```
1 enable feature SC
2 show ns info
3 add service svc2 192.2.3.6 HTTP 9002
4 show server
5 show service svc2
6 add service svc9 192.2.3.5 HTTP 8002
7 add sc policy policy8 -url /cgi-bin/slow.asp
8 -delay 3000000 -action ACS svc2 /netscaler 9000 system barandpage.htm
9 bind service svc9 -policyname policy8
10 set service svc9 -sc ON
11 save config
```

After you configure SureConnect, you can enter commands that show information to verify what you have configured.

**Example 2 - SureConnect progress bar only**

In this example, SureConnect will display only the progress bar. The server orgsrvr with IP address 10.101.8.187 has service orgsvc. This server is connected to the appliance. The service is bound to the appliance. The progressbar.htm file specifies that only the progress bar will be displayed.

At the Citrix ADC command prompt, type the following commands:

```
1 enable feature SC
2 add service orgsvc 10.101.3.187 HTTP 80
3 add sc policy policy9 -url /cgi-bin/slow.asp
4 -delay 4000000 -action ACS orgsvc /netscaler 9000 system /progressbar.htm
5 bind service orgsvc -policyname policy9
6 set service orgsvc -sc ON
7 save config
```

**Example 3 - SureConnect with load balancing**

This example illustrates how to configure the load balancing feature so that SureConnect will display alternate contents from the primary server. For information about load balancing, see Load Balancing.
In this example, two physical servers with IP 10.101.3.187 and 10.101.3.188 are being load balanced by the appliance. The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on both servers.

The appliance has one configured virtual server address: 10.101.3.201. At the Citrix ADC command prompt, type the following commands:

```plaintext
1   enable feature SC LB
2   add service psvc1 10.101.3.187 HTTP 80
3   add service psvc2 10.101.3.188 HTTP 80
4   add vserver vs-SureC HTTP 10.101.3.201 80
5   bind lb vserver vs-SureC psvc1
6   bind lb vserver vs-SureC psvc2
7   add sc policy policy9 -url /cgi-bin/slow.asp -delay 4000000
8   -action ACS vs-SureC /netscaler system /alternatepage.htm
9   bind lb vserver vs-SureC -policyName policy9
10  set lb vserver vs-SureC -sc ON
11  save config
```

Example 4 - SureConnect with load balancing (ACS action)

This example illustrates how to configure the Citrix ADC appliance load balancing feature so that SureConnect will display alternate content from the alternate server. For information about load balancing, see Load Balancing.

In this case, there are two physical servers, IP 10.101.3.187 and 10.101.3.188. Both are being load balanced by the appliance.

The name and location of the alternate page file are specified in file barandpage.htm, which resides on a third server not being load balanced.

The third server’s IP address is 10.101.3.189. Because barandpage.htm is specified, the progress bar and alternate page will both be displayed.

The appliance has one configured virtual server “vsrv” whose IP address (Virtual Server) is 10.101.3.200.

At the Citrix ADC command prompt, type the following commands:

```plaintext
1   enable feature SC LB
2   add service psvc1 10.101.3.187 HTTP 80
3   add service psvc2 10.101.3.188 HTTP 80
4   add service alt-cont-svc 10.101.3.189 HTTP 80
5   add vserver vsrv HTTP 10.101.3.200 80
6   bind lb vserver vsrv psvc1
7   bind lb vserver vsrv psvc2
```
Example 5 - SureConnect with content switching

This example illustrates how to configure SureConnect where the Citrix ADC content switching and load balancing features are being used. SureConnect is configured on a load balancing virtual server bound to a content switching virtual server.

The alternate content is distributed under the content switching virtual server according to the content switching rules. For more information about load balancing and content switching, see “Load Balancing” and “Content Switching.”

In this case, three physical services with IP addresses 10.100.100.104, 10.100.100.105, and 10.100.100.106 are bound to three load balancing virtual servers with IP addresses 10.100.100.101, 10.100.100.102, and 10.100.100.103. These three load balancing virtual servers are bound to a content switching virtual server with IP address 10.100.100.100.

In this setup, lbvip1 contains .cgi content, lbvip2 contains .gif content, and lbvip3 contains .html content.

The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on lbvip3. The embedded objects in this file must be distributed according to the content switching rules (any embedded gif will reside on lbvip2, any embedded htm will reside on lbvip3, and so on).

Figure 3. SureConnect Configuration - Example 5

At the Citrix ADC command prompt, type the following commands:

```bash
enable feature CS LB SC
add vserverv cswvip HTTP 10.100.100.100 80 -type CONTENT
add vserverv lbvip1 HTTP 10.100.100.101 80 -type ADDRESS
add vserverv lbvip2 HTTP 10.100.100.102 80 -type ADDRESS
add vserverv lbvip3 HTTP 10.100.100.103 80 -type ADDRESS
add service psvc1 10.100.100.104 HTTP 80
add service psvc2 10.100.100.105 HTTP 80
add service psvc3 10.100.100.106 HTTP 80
bind lb vserverv lbvip1 psvc1
bind lb vserverv lbvip2 psvc2
bind lb vserverv lbvip3 psvc3
add cs policy CSWpolicy1 -url /*.cgi
```
Surge protection

January 25, 2019

Contributed by: C

When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The Citrix ADC appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as will be the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the Citrix ADC appliance will allow before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a Web site.

Figure 1. A Functional Illustration of Citrix ADC Surge Protection
Note: If the Citrix ADC appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the crash, usually several minutes later, it sends resets for all pending requests, which is abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection

Disable and reenable surge protection

January 23, 2019

Contributed by:
C

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.
Disable or reenable surge protection by using the CLI

At the command prompt, type one of the following sets of commands to disable or reenable surge protection and verify the configuration:

<table>
<thead>
<tr>
<th></th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>disable ns feature SurgeProtection</td>
</tr>
<tr>
<td>2</td>
<td>show ns feature</td>
</tr>
<tr>
<td>3</td>
<td>enable ns feature SurgeProtection</td>
</tr>
<tr>
<td>4</td>
<td>show ns feature</td>
</tr>
</tbody>
</table>

Example:

```
1 disable ns feature SurgeProtection
2 Done show ns feature
3
4 Feature Acronym Status
5 ------- ------- -----
6 1) Web Logging WL ON
7 2) Surge Protection SP OFF
8 .
9 .
10 23) HTML Injection HTMLInjection ON
11 24) Citrix ADC Push push OFF
12 Done

1 enable ns feature SurgeProtection
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 ------- ------- -----
7 1) Web Logging WL ON
8 2) Surge Protection SP ON
9 .
10 .
11 23) HTML Injection HTMLInjection ON
12 24) Citrix ADC Push push OFF
13 Done
14 >
```
Disable or reenable surge protection by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change Advanced Features.
3. In the Configure Advanced Features dialog box, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click OK.
5. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

Disable or reenable surge protection for a particular service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.

Note: Surge protection works only when both the feature and the service setting are enabled.

Set thresholds for surge protection

January 25, 2019
Contributed by: C

To set the rate at which the Citrix ADC appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.
Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

Set the threshold for surge protection by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step.
   Note: If you do not set an explicit value here, the default value will be used.
4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the Citrix ADC appliance allows connections to the server to be opened. The throttle can be set to the following values:
   - Aggressive: Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent connections to the server.
- **Normal**: Choose this option when there is no external load balancer behind the Citrix ADC appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.

- **Relaxed**: Choose this option when the Citrix ADC appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.

5. Click OK. A message appears in the status bar, stating that the global settings are configured.

---

**Flush the surge queue**

January 23, 2019

Contributed by: C

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.
The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note:
- You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.
- Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

Flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member <servername> and <port> without specifying the name of the service group <name> and you cannot specify <port> without a <servername>. Specify the <servername> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]

Examples

```
1. flush ns surgeQ - name SVC1ANZGB - serverName 10.10.10.1 80
2. The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10
3. 2. flush ns surgeQ
4. The above command flushes all the surge queues on the appliance.
```

Flush a surge queue by using the GUI

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

DNS security options

January 23, 2019

Contributed by: C

You can now configure the DNS security options from the Add DNS Security Profile page in the Citrix ADC GUI. To configure the DNS security options from the Citrix ADC CLI or the NITRO API, use the App-Expert components. For instructions, see the NITRO API documentation and the Citrix ADC Command Reference Guide.

One option, cache poisoning protection, is enabled by default and cannot be disabled. You can apply the other options to all DNS endpoints or to specific DNS virtual servers in your deployment, as shown in the following table:

<table>
<thead>
<tr>
<th>Security option</th>
<th>Can be applied to all DNS endpoints?</th>
<th>Can be applied to specific DNS virtual servers?</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS DDoS protection</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Security option</td>
<td>Can be applied to all DNS endpoints?</td>
<td>Can be applied to specific DNS virtual servers?</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>--------------------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>Manage exceptions – whitelist/blacklist servers</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Prevent random subdomain attacks</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Bypass the cache</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Enforce DNS transactions over TCP</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Provide root details in the DNS response</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Cache poisoning protection**

A cache poisoning attack redirects users from legitimate sites to malicious websites.

For example, the attacker replaces a genuine IP address in the DNS cache with a fake IP address that they control. When the server responds to requests from these addresses, the cache is poisoned and the subsequent requests for the addresses of the domain are redirected to the attacker’s site.

The Cache Poisoning Protection option prevents insertion of corrupt data into the database that caches DNS server requests and responses. This is an inbuilt feature of the Citrix ADC appliances and is always enabled.

**DNS DDoS protection**

You can configure the DNS DDoS Protection option for each type of request that you suspect might be used in a DDoS attack. For each type, the Citrix ADC appliance drops any requests received after a threshold value for the number of requests received in a specified period of time (time slice) is exceeded. You can also configure this option to log a warning to the SYSLOG server. For example:

- **DROP**: Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen DROP. When the incoming requests exceed 15 in 1 second, then the packets start getting dropped.
- **WARN**: Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen WARN. When the incoming requests exceeds around 15 queries in 1 second, a warning message is logged indicating a threat and then the packets start getting dropped. It is recommended to set threshold values for WARN smaller than that of DROP for a record type.
This will help administrators identify an attack by logging a warning message before the actual attack happens and Citrix ADC starts dropping incoming requests.

**Set a threshold for incoming traffic by using the Citrix ADC GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profile** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   4. Expand **DNS DDoS Protection**.
      a) Select the record type and enter the threshold limit and the time slice value.
      b) Select **DROP** or **WARN**.
      c) Repeat steps a and b for each of the other record types that you want to protect against.
5. Click **Submit**.

**Manage exceptions – whitelist/blacklist servers**

Manage excepts enables you to add exceptions either to blacklist or whitelist domain name and IP addresses. For example:

- When a particular IP address is identified posting an attack, such IP address can be blacklisted.
- When administrators find that there is unexpectedly high request for a particular domain name, then that domain name can be blacklisted.
- NXDomains and some of the existent domains which can consume the server resources can be blacklisted.
- When administrators whitelist domain names or IP addresses, queries or requests only from these domains or IP addresses are answered and all others are dropped.

**Create a whitelist or blacklist by using the GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) Expand **Manage exceptions – Whitelist/Blacklist Servers**.
   b) Select **Block** to block queries from blacklisted domains/addresses, or select **Allow** only to allow queries from whitelisted domains/addresses.
   c) In the **Domain name / IP Address** box, enter the domain names, IP addresses, or IP address ranges. Use commas to separate the entries.
   
   **Note:** If you select **Advanced Option**, you can use the “start with,” “contains,” and “ends with” options to set the criteria.
For example, you can set criteria to block a DNS query that starts with “image” or ends with “.co.ru” or contains “mobilesites.”

4. Click **Submit**.

**Prevent random subdomain attacks**

In random subdomain attacks, queries are sent to random, nonexistent subdomains of legitimate domains. This increases the load on the DNS resolvers and servers. As a result, they can become overloaded and slow down.

The Prevent Random Subdomain Attacks option directs the DNS responder to drop DNS queries that exceed a specified length.

Assume that example.com is a domain name owned by you and hence the resolution request comes to your DNS server. The attacker can append a random subdomain to example.com and send a request. Based on the specified query length and the FQDN, the random queries will be dropped.

For example, if the query is www.image987trending.example.com, it will be dropped if the query length is set to 20.

**Specify a DNS query length by using the GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) **Expand Prevent Random Subdomain Attacks**.
   b) Enter the numerical value for the query length.
4. Click **Submit**.

**Bypassing the cache**

During an attack, the data that is already cached must be protected. To protect the cache, new requests for certain domains or record types or response codes can be sent to the origin servers instead of cached.

The Bypassing the cache option directs the Citrix ADC appliance to bypass the cache for specified domains, record types, or response codes when an attack is detected.

**Bypass the cache for specified domains or record types or response types by using the GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.

3. On the **Add DNS Security Profile** page, expand **Bypassing the cache** and enter the domain names and / or choose the record types or the response types for which the cache has to be bypassed.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
   - Click **Response Types** and choose the response type.

4. Click **Submit**.

### Enforce DNS transactions over TCP

Some DNS attacks can be prevented if the transactions are forced to use TCP instead of UDP. For example, during a bot attack, the client sends a flood of queries but cannot handle responses. If the use of TCP is enforced for these transactions, then the bots cannot understand the responses and therefore cannot send requests over TCP.

### Force domains or record types to operate at the TCP level by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Enforce DNS Transactions over TCP** and enter the domain names and / or choose the record types for which the DNS transactions must be enforced over TCP.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
4. Click **Submit**.

### Provide root details in the DNS response

In some attacks, the attacker sends a flood of queries for unrelated domains that are not configured or cached on the Citrix ADC appliance. If the dnsRootReferral parameter is ENABLED, it exposes all the root servers.

The Provide Root Details in the DNS Response option directs the Citrix ADC appliance to restrict access to root referrals for a query that is not configured or cached. The appliance sends a blank response.

The Provide Root Details in the DNS Response option can also mitigate or block amplification attacks. When the dnsRootReferral parameter is DISABLED, there will be no root referral in the Citrix ADC responses and hence they do not get amplified.
Enable or disable access to the root server by using the GUI

2. On the DNS Security Profiles page, click Add.
3. On the Add DNS Security Profile page, do the following:
   a) Expand Provide Root Details in the DNS Response.
   b) Click ON or OFF to allow or restrict access to the root server.
4. Click Submit.

ICAP for remote content inspection

January 25, 2019
Contributed by: C

The Internet Content Adaptation Protocol (ICAP) is a simple lightweight protocol for executing value-added transformation service on HTTP messages. In a typical scenario, an ICAP client forwards HTTP requests and responses to one or more ICAP servers for processing. The ICAP servers performs content transformation on the requests and sends back responses with appropriate action to take on the request or response.

ICAP on a Citrix ADC appliance

In a Citrix ADC setup, the appliance acts as an ICAP client interoperating with third-party ICAP servers such as antimalware and Data Leak Prevention (DLP). When the appliance receives an incoming web traffic, the appliance intercepts the traffic and uses a Content Inspection policy to evaluate if the HTTP request needs an ICAP processing. If yes, the appliance decrypts and sends the message as a plain text to the ICAP servers. The ICAP servers execute the content transformation service on the request message and sends back a response to the appliance. The adapted messages can either be an HTTP request or an HTTP response. If the appliance interoperates with multiple ICAP servers, the appliance performs load balancing of ICAP servers. This happens in scenarios where one ICAP server is not sufficient to handle all the traffic load. Once the ICAP servers return a modified message, the appliance forwards the modified message to the back-end origin server.
The Citrix ADC appliance also provides a secured ICAP service if the incoming traffic is an HTTPS type. The appliance uses a SSL based TCP service to establish a secured connection between the appliance and ICAP servers.

**How ICAP request modification (REQMOD) works**

In the request modification (REQMOD) mode, the Citrix ADC appliance forwards the HTTP request received from client to the ICAP server. The ICAP server then performs one of the following:

1. Sends back a modified version of the request and the appliance in turn sends the modified request to the back-end origin server or it pipelines the modified request to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message back to the user.

**How ICAP response modification (RESPMOD) works**

In the response modification (RESPMOD) mode, the Citrix ADC appliance sends an HTTP response to the ICAP server (the response sent by the appliance is typically the response sent by the origin server). The ICAP server then performs one of the following:

1. Sends back a modified version of the response and the appliance in turn sends the modified response to the user or pipeline the modified response to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message to the user.

**ICAP license**

The ICAP feature works on a Citrix ADC standalone or high availability setup with Citrix ADC Platinum or Enterprise license edition.

**Configure ICAP for content transformation service**

To use ICAP for content transformation service, you must begin by enabling the Content inspection and load balancing features. Once you enable the features, you can complete the following tasks.

**To enable content inspection**

If you want the Citrix ADC appliance to act as an ICAP client and send requests or responses to third-party ICAP server, you must first enable the Content Inspection and load balancing features.

At the command prompt, type:
Add ICAP profile

ICAP configurations for a Citrix ADC appliance can be specified in an entity called ICAP profile. The profile has a collection of ICAP settings. The ICAP profile is then associated to content Inspection action that want to use the ICAP configurations.

At the command prompt, type:

```
add nsicapProfile <name> -uri <string> -Mode ( REQMOD | RESPMOD )
```

Example:

```
add nsicapProfile icap_reqmod -uri "servicename" -mode REQMOD
add nsicapProfile icap_respmod -uri "servicename" -mode RESPMOD
add nsicapProfile icap_reqmod_query -uri "servicename?query=data" -mode REQMOD
```

Add ICAP service as a TCP or SSL_TCP service

After you enable the Content Inspection feature, you must add an ICAP service for the ICAP servers that will be part of the load balancing setup. The service that you add provides the ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

**Note:** As an administrator, you can add an ICAP service and directly configure the ICAP server IP address in the Content Inspection action.

At the command prompt, type the following:

```
add service <name> <IP> <serviceType> <port>
```

Example:

```
add service icapsv1 10.102.29.200 TCP 80 -gslb NONE -maxclient 0 -maxReq 0 -cip DISABLED -usip NO -useproxport YES -sp ON -cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO
add service icapsv2 10.102.29.200 SSL_TCP 11344 -gslb NONE -maxclient 0 -maxReq 0 -cip DISABLED -usip NO -useproxport YES -sp ON -cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO
```
Add a TCP or SSL_TCP based load balancing virtual server

After creating an ICAP service, you must create a virtual server to accept ICAP traffic and load balance the ICAP servers.

Note: You can also use a SSL based TCP service over a secured channel. To do this, you must use a SSL_TCP service and bind to the Content Inspection action.

At the command prompt, type the following:

```
1 add lb vserver <name> <serviceType> <port>
```

Example:

```
1 add lb vserver vicap TCP 0.0.0.0 -persistenceType NONE -cltTimeout 9000
2
3 add lb vserver vicap SSL_TCP 0.0.0.0 0 -persistenceType NONE -cltTimeout 9000
```

Bind ICAP service to the load balancing virtual server

After you create an ICAP service and virtual server, you must bind the ICAP service to the virtual server.

At the command prompt, type the following:

```
1 bind lb vserver <name> <serviceName>
```

Example:

```
1 bind lb vserver vicap icapsv1
```

Add content inspection action

After you enable the Content Inspection feature, you must add an ICAP action for handling the ICAP request information. The ICAP profile and services, or load balancing virtual server that are created are bound to the ICAP action.

At the command prompt, type the following:

```
1 add contentInspection action <name> -type ICAP -serverName <string> -icapProfileName <string>
2
3 **add ContentInspection action <name> -type ICAP -serverip <ip> -serverport <port> -icapProfileName <string>**
```
Note:
If you can configuring ICAP service instead of a load balancing virtual server, you can mention the service name in the `<serverip>` option. When adding the Content Inspection action, the TCP service is automatically created for the given IP address with port 1344 and it is used for ICAP communication.

Example:

1. `add ContentInspection action ci_act_lb -type ICAP -serverName vicap -icapProfileName icap_reqmod`
2. `add ContentInspection action ci_act_svc -type ICAP -serverName icapsv1 -icapProfileName icap_reqmod`
3. `add ContentInspection action ci_act_svc -type ICAP -serverip <ip> -serverport <port> -icapProfileName icap_reqmod`

Add content inspection policies

After you create a Content Inspection action, you must create content inspection policies to evaluate requests for ICAP processing and audit logging. The policy is based on a rule which consists of one or more expressions. The rule is associated to the content inspection action that is associated if a request matches the rule.

At the command prompt, type the following:

```
add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

1. `add ContentInspection policy ci_pol_basic -rule true -action ci_act_svc`
2. `add ContentInspection policy ci_pol_HTTP -rule HTTP.REQ.URL.CONTAINS("html") -action ci_act_svc`

Bind content inspection policies to the content switching or load balancing virtual server

To put an ICAP policy into effect, you must bind it globally or bind it to a Content Switching or load balancing virtual server, which frontend the application. When you bind the policy, you must assign a priority to it. The priority determines the order in which the policies you define are evaluated.
For information about configuring a load balancing setup for forwarding the traffic to back-end origin server after content transformation, see Load Balancing.

**Configure secured ICAP service**

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.
3. Bind SSL-based TCP service or load balancing virtual server to Content Inspection action.

**Add SSL-based TCP service to load balancing virtual server**

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.

Bind SSL-based TCP service or load balancing virtual server to Content Inspection action

**Add SSL-based TCP service to load balancing virtual server**

After you enable the Content Inspection feature, you must add a secured ICAP service that will be part of the load balancing setup. The service that you add provides a secured ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

At the command prompt, type the following:

```
1 add service <name> <IP> <serviceType> <port>
```

**Example:**

```
1 add service icapsv2 10.102.29.200 SSL_TCP 11344 -gslb NONE -maxclient 0 -maxReq 0 -cip DISABLED -usip NO -useproxport YES -sp ON -cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO
```
Bind SSL-based TCP service to SSL_TCP or TCP load balancing virtual server

After you create a secured ICAP service, you must bind the service to the load balancing virtual server (if you are using a load balancing virtual server to load balance the ICAP servers).

At the command prompt, type the following:

```bash
bind lb vserver <name> <serviceName>
```

Example:

```bash
bind lb vserver vicap icapsv2
```

Bind SSL-based TCP service or load balancing virtual server to the Content Inspection action

You must add an ICAP action for handling the ICAP request information and also bind the SSL-based TCP service to the action.

At the command prompt, type the following:

```bash
add contentInspection action <name> -type ICAP -servername <string> -icapProfileName <string>
```

Example:

```bash
add ContentInspection action ci_act_svc -type ICAP -servername icapsv2 -icapProfileName icap_reqmod
add ContentInspection action ci_act_svc -type ICAP -servername vicap -icapProfileName icap_reqmod
```

Configure ICAP protocol by using the GUI

1. Navigate to Load Balancing > Services and click Add.
2. In the Services page, enter the service details.
3. Navigate to Load Balancing > Servers. Add a virtual server of type TCP. Or, you can select a virtual server and click Edit.
4. After entering the server details, click OK and again OK.
5. In the Advanced Settings section, click Policies.
6. Go the Policies section and click the Pencil icon to configure Content Inspection policy.
7. On the Choose Policy page, select Content Inspection. Click Continue.
8. In the Policy Binding section, click “+” to add a Content Inspection policy.
9. In the Create ICAP Policy page, enter a name for the policy.
10. In the Action field, click the “+” sign to add an ICAP action.
11. In the Create ICAP Action page, enter a name for the action.
12. Enter a name for the action.
13. In the Server Name field, enter the name of the TCP service already created.
14. In ICAP Profile field, click the “+” sign to add an ICAP profile.
15. In the Create ICAP Profile page, enter a profile name, URI, and MODE.
16. Click Create.
17. In the Create ICAP Action page, click Create.
18. In the Create ICAP Policy page, enter “true” in the Expression Editor and then click Create.
19. Click Bind.
20. When prompted to enable the Content Inspection feature, click Yes.
21. Click Done.

For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to back-end origin server after content transformation, see Load Balancing.

**Configure secured ICAP protocol by using the GUI**

1. Navigate to Load Balancing > Services and click Add.
2. In the Services page, enter the service details.
3. Navigate to Load Balancing > Servers. Add a virtual server of type TCP_SSL. Or, you can select a virtual server of type TCP_SSL and click Edit.
4. After entering the server details, click OK and again OK.
5. In the Advanced Settings section, click Policies.
6. Go the Policies section and click the Pencil icon to configure Content Inspection policy.
7. On the Choose Policy page, select Content Inspection. Click Continue.
8. In the Policy Binding section, click “+” to add a Content Inspection policy.
9. In the Create ICAP Policy page, enter a name for the policy.
10. In the Action field, click the “+” sign to add an ICAP action.
11. In the Create ICAP Action page, enter a name for the action.
12. Enter a name for the action.
13. In the Server Name field, enter the name of the TCP_SSL service already created.
14. In ICAP Profile field, click the “+” sign to add an ICAP profile.
15. In the Create ICAP Profile page, enter a profile name, URI, and MODE.
16. Click Create.
17. In the Create ICAP Action page, click Create.
18. In the Create ICAP Policy page, enter “true” in the Expression Editor and then click Create.
19. Click Bind.
20. When prompted to enable the Content Inspection feature, click Yes.
21. Click **Done**.

**Auditlog support for remote content inspection**

If an incoming request or outgoing response is content inspected, the Citrix ADC appliance logs the ICAP details. The appliance stores the details as a log message in the ns.log file.

Each log message typically contains the following details:

<table>
<thead>
<tr>
<th>Source IP</th>
<th>Destination IP</th>
<th>Domain</th>
<th>ICAP server IP</th>
<th>ICAP Mode</th>
<th>Service URI</th>
<th>ICAP response</th>
<th>Policy action</th>
</tr>
</thead>
</table>

**Example for content inspected request log message:**

```
```

**Example for content inspected response log message:**

```
```

**Inline device integration with Citrix ADC**

March 14, 2019

Contributed by:
C

Security devices such as Intrusion Prevention System (IPS) and Next Generation Firewall (NGFW) protect servers from network attacks. These devices are deployed in layer 2 inline mode and their primary function is to protect servers from network attacks and report security threats on the network.
To prevent vulnerable threats and provide advanced security protection, a Citrix ADC appliance is integrated with one or more inline devices. The inline devices can be any security device such as IPS, NGFW.

Following are some of the use cases that benefit in using the inline device integration with Citrix ADC appliance:

- **Inspecting encrypted traffic.** Most IPS and NGFW appliances bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to inline devices for inspection. This enhances customer’s network security.

- **Offloading inline devices from TLS/SSL processing.** TLS/SSL processing is expensive and this issue can result in high system CPU in IPS or NGFW appliances if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading inline devices from TLS/SSL processing. This results in inline device supporting a high volume of traffic inspection.

- **Loading balancing inline devices.** The Citrix ADC appliance load balances multiple inline devices when there is a high volume of traffic.

- **Smart selection of traffic.** Every packet flowing into the appliance might be content inspected, for example download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example .exe files) for inspection and send the traffic to inline devices for processing the data

**How Citrix ADC is integrated with inline devices**

The following diagram shows how a Citrix ADC is integrated with inline security devices.

When you integrate inline devices with Citrix ADC appliance, the component interacts as given below:

1. A client sends a request to Citrix ADC appliance.
2. The appliance receives the request and sends it to an inline device based on policy evaluation.
   **Note:** If there are two or more inline devices, the appliance load balances the devices and sends the traffic.
   If the incoming traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text to the inline device for content inspection.
3. The inline device inspects the data for threats and decides whether to drop, reset, or send the data back to the appliance.
4. If there are security threats, the device modifies the data and sends it to the appliance.
5. The Citrix ADC in turn re-encrypts the data and forwards the request to the back-end server.
6. The back-end server sends the response to the Citrix ADC appliance.
7. The appliance again decrypts the data and sends it to the inline device for inspection.
8. Appliance re-encrypts the data and sends the response to the client.
Software licensing

To deploy the inline device integration, your Citrix ADC appliance must be provisioned with one of the licenses given below:

1. ADC Platinum
2. ADC Enterprise
3. Telco Advanced
4. Telco Premium
5. SWG license

Configuring inline device integration

You can configure a Citrix ADC appliance with an inline device in three different ways. The configuration scenarios are given below.

Scenario 1 for using a single inline device

If you want to integrate a security device (IPS or NGFW) in inline mode, you must begin by first enabling the Content Inspection feature and enabling Citrix ADC in MBF (MAC-based forwarding) in global mode. Once you have enabled the features, you must add the Content Inspection profile, add Content Inspection action for inline devices to reset, block, or drop the traffic based on inspection. Then, add the Content Inspection policy for the appliance to decide what subset of traffic to send to the inline devices. Then, configure the load balancing virtual server with layer 2 connection enabled on the server. Finally, bind the content inspection policy to the load balancing virtual server.

Enable MBF (MAC-based forwarding) mode

If you want the Citrix ADC appliance to be integrated to inline devices such as IPS, or firewalls, you must enable this mode. For more information about MBF, see Configure MAC-based Forwarding topic.

At the command prompt, type:

`enable ns mode mbf`

Enable Content Inspection

If you want Citrix ADC appliance to decrypt and then send the content for inspection to the inline devices, you must enable the Content Inspection and load balancing features.

`enable ns feature contentInspection LoadBalancing`
Add Content Inspection profile for service

Inline device configuration for a Citrix ADC appliance can be specified in an entity called Content Inspection profile. The profile has a collection of settings that explains how to integrate with an inline device.

At the command prompt, type:

```
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

Example:

```
add contentInspection profile Inline_profile1 -type InlineInspection -ingressinterface "1/2" -egressInterface "1/3"
```

Add IPS-TCP monitor (optional)

If you want to configure monitors, you first decide whether to use a built-in monitor or add a TCP monitor.

**Note:** If you want to configure monitors, you must use a user defined monitor. When you bind any other monitor to a TCP service, you must unbind the default monitor from the service. If you are adding a monitor, you must enable the transparent parameter.

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr>] [-destPort <port>] [-transparent ( YES | NO )]
```

Example:

```
add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent YES
```

Add service

You must add a service for each inline device to which the appliance is integrated. The service provides the device configuration details. The service now represents the inline device.

At the command prompt, type:

```
add service <Service_name> <IP> TCP <Port> -contentInspectionProfileName <Name> -healthMonitor OFF -usip ON -useproxyport OFF
```

Example:

```
add service Inline_service1 10.102.29.200 TCP * -contentInspectionProfileName Inline_profile1 -healthMonitor OFF -usip ON -useproxyport OFF
```
Bind service to TCP monitor (optional)

You must bind the service to the TCP monitor.
At the command prompt, type the following

```
bind service <name>@ (-policyName <string> | (-monitorName <string>@ [-monState ( ENABLED | DISABLED )] [-weight <positive_integer>] [-passive]))
```

Example:

```
bind service ips_svc -monitorName ips_tcp
```

Add Content Inspection action for service

After you enable the Content Inspection feature and then after add the inline profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the inline device can drop, reset, or block action after it has inspected the data.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-ifserverdown <ifserverdown>] [-reqTimeout <positive_integer>] [-reqTimeoutAction <reqTimeoutAction>]
add ContentInspection action <action_name> -type InlineINSPECTION -serverName Service_name/Vserver_name
```

Example:

```
add ContentInspection action <Inline_action> -type InlineSPECTION -serverName Inline_service1
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name>
```

Example

```
add contentInspection policy Inline_pol1 -rule true -action Inline_action
```
Add content switching or load balancing virtual server of type HTTP/SSL

To receive the web traffic, you must add a load balancing virtual server. Also you must enable the layer 2 connection on the virtual server.

At the command prompt, type:
```
add lb vserver <name> <vserver name> -l2Conn ON
```

Example:
```
add lb vserver HTTP_vserver HTTP 10.102.29.200 8080 -l2Conn ON
```

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL

You must bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:
```
bind lb vserver <vserver name> -policyName <policy_name> -priority <priority> -type <REQUEST>
```

Example:
```
bind lb vserver HTTP_vserver -policyName Inline_poll -priority 100 -type REQUEST
```

Scenario 2: Load balancing multiple inline devices using dedicated interfaces

If you are using two or more inline devices, you must load balance the devices using different content inspection services in a dedicated VLAN setup. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device through a dedicated interface.

For basic configuration steps, refer to scenario 1.

Add content inspection profile1 for service1

Inline configurations for a Citrix ADC appliance can be specified in an entity called Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for inline service 1 and the communication is through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:
```
add contentInspection profile <name> -typeInlineInspection -egressInterface <interface_name> -ingressInterface <interface_name>[<egressVlan <positive_integer>]][<ingressVlan <positive_integer>]]
```
Example:

```bash
add contentInspection profile Inline_profile1 -type InlineInspection -ingressinterface “1/2” -egressInterface “1/3”
```

Add content inspection profile2 for service2

The Content Inspection profile2 is added for service2 and the inline device communicates with the appliance through 1/4 and 1/5 dedicated interfaces.

At the command prompt, type:

```bash
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

Example:

```bash
add contentInspection profile Inline_profile2 -type InlineInspection -ingressinterface “1/4” -egressInterface “1/5”
```

Add service 1 for inline device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service1 for inline device1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```bash
add service <Service_name_1> <Pvt_IP1> TCP * -contentInspectionProfileName Inline_Profile_1 -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:

```bash
add service Inline_service1 10.102.29.200 TCP 80 -contentInspectionProfileName Inline_profile1 -healthmonitor OFF -usip ON -useproxyport OFF
```

Add service 2 for inline device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service2 for inline device2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```bash
add service <Service_name_1> <Pvt_IP1> TCP * -contentInspectionProfileName <Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```

Example:
Add load balancing virtual server

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:
```
add lb vserver <vserver_name> TCP <Pvt_IP3> <port>
```

Example:
```
add lb vserver lb-Inline_vserver TCP *
```

Bind service 1 to the load balancing virtual server

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.

At the command prompt, type:
```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:
```
bind lb vserver lb-Inline_vserver Inline_service1
```

Bind service 2 to the load balancing virtual server

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:
```
bind lb vserver <Vserver_name> <Service_name_1>
```

Example:
```
bind lb vserver lb-Inline_vserver Inline_service2
```

Add content inspection action for the service

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the inline device drops, resets, or blocks after it has examined the given subset of traffic.

At the command prompt, type:
```
add service Inline_service1 10.29.20.205 TCP 80 -contentInspectionProfileName Inline_profile2 -healthmonitor OFF -usip ON -useproxyport OFF
```
add contentInspection action <name> -type <type> [-serverName <string>] [-ifserverdown <ifserverdown>] [-reqTimeout <positive_integer>] [-reqTimeoutAction <reqTimeoutAction>]

add ContentInspection action < action_name > -type InlineINSPECTION -serverName Service_name/Vserver_name>

Example:

add ContentInspection action Inline_action -type InlineINSPECTION -serverName lb-Inline_vserver

Add content inspection policy for inspection

After you create a Content Inspection action, you must add Content Inspection policy to evaluate requests for service. The policy is based on a rule which consists of one or more expressions. The rule is associated to the Content Inspection action that is associated if a request matches the rule.

At the command prompt, type the following:

add contentInspection policy <policy_name> -rule <Rule> -action <action_name>

Example:

add contentInspection policy Inline_poll -rule true -action Inline_action

Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer2 connection on the virtual server.

For more information about load balancing, see How load balancing works topic.

At the command prompt, type:

add lb vserver <name> <vserver name> -l2Conn ON

Example:

add lb vserver http_vserver HTTP 10.102.29.200 8080 -l2Conn ON

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:
bind lb vserver <vserver name> -policyName <policy_name> -priority <> -type <L7InlineREQUEST | L4Inline-REQUEST>

Example:
bind lb vserver http_vserver -policyName Inline_poll -priority 100 -type REQUEST

Scenario 3: Load balancing multiple inline devices using shared interfaces

You can refer to this configuration, if you are using multiple inline devices and if you want to load balance the devices using different services in a shared VLAN interface. This configuration using shared VLAN interfaces is similar to use case 2. For basic configuration, refer to scenario 2.

Bind VLAN A with sharing option enabled

At the command prompt, type the following:
bind vlan <id> -ifnum <interface> -tagged

Example:
bind vlan 100 -ifnum 1/2 tagged

Bind VLAN B with sharing option enabled

At the command prompt, type the following:
bind vlan <id> -ifnum <interface> -tagged

Example:
bind vlan 200 -ifnum 1/3 tagged

Bind VLAN C with sharing option enabled

At the command prompt, type the following:
bind vlan <id> -ifnum <interface> -tagged

Example:
bind vlan 300 -ifnum 1/2 tagged
Bind VLAN D with sharing option enabled

At the command prompt, type the following:

```bash
bind vlan <id> -ifnum <interface> -tagged
```

**Example:**

```bash
bind vlan 400 -ifnum 1/3 tagged
```

Add content inspection profile1 for service1

Inline configurations for a Citrix ADC appliance can be specified in an entity called Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for inline service 1 and the communication is through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:

```bash
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

**Example:**

```bash
add contentInspection profile Inline_profile1 -type InlineInspection -ingressInterface "1/2" -egressInterface "1/3" -egressVlan 100 -ingressVlan 300
```

Add content inspection profile2 for service2

The Content Inspection profile2 is added for service2 and the inline device communicates with the appliance through 1/2 and 1/3 dedicated interfaces.

At the command prompt, type:

```bash
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

**Example:**

```bash
add contentInspection profile Inline_profile2 -type InlineInspection -ingressInterface "1/2" -egressInterface "1/3" -egressVlan 200 -ingressVlan 400
```

Configure inline service integration using the Citrix ADC GUI

1. Log on to Citrix ADC appliance and navigate to **Configuration** tab page.
2. Navigate to **System > Settings > Configure Modes**.

3. In the **Configure Modes** page, select **Mac Based Forwarding**.

4. Click **OK** and **Close**.

5. Navigate to **System > Settings > Configure Advanced Features**.

6. In the **Configure Advanced Feature** page, select **Content Inspection**.

7. Click **OK** and **Close**.

8. Navigate to **Security > Content Inspection > ContentInspection Profiles**.

9. In the **ContentInspection Profiles** page, click **Add**.

10. In the **Create ContentInspection Profiles** page, set the following parameters.
    
    a) **Profile Name.** Name of the content inspection profile.
    
    b) **Type.** Select the profile type as inlineInspection.
    
    c) **Egress Interface.** Interface through which the appliance sends traffic from Citrix ADC to the Inline device.
    
    d) **Ingress Interface.** Interface through which the appliance receives traffic from Inline device to Citrix ADC.
    
    e) **Egress VLAN.** Interface VLAN ID through which the traffic is sent to the Inline device.
    
    f) **Ingress VLAN.** Interface VLAN ID through which the appliance receives traffic from Inline to Citrix ADC (if it is configured).

11. Click **Create** and **Close**.

12. Navigate to **Traffic Management > Load Balancing > Services** and click **Add**.

13. In the **Services** page, set the following parameters:
    
    a) **Service name.** Name of the load balancing service.
    
    b) **IP address.** Use a dummy IP address. Note: Address should not be owned by any device.
    
    c) **Protocol.** Select protocol type as TCP.
    
    d) **Port.** Enter *
    
    e) **Health Monitoring.** Turn off this option and enable this only if you want to bind the service to TCP type monitor. If you want to bind monitor to service then TRANSPARENT option in monitor should be ON. See step 14 on how to add monitor and how to bind it to service.
    
    f) Click **OK**.

14. In the **Settings** section, edit the following and click **OK**.
    
    a) **Use Proxy Port: Turn it OFF**
    
    b) **Use Source IP Address: Turn it ON**

15. In the **Advanced Settings** section, click **Profiles**.

16. Go to **Profiles** section, and add the inline content inspection profile and click **OK**.
17. Go to **Monitors** section, **Add Bindings > Select Monitor > Add.**
   a) Name: Name of monitor
   b) Type: Select TCP type
   c) Destination IP, PORT: Destination IP address and Port.
   d) Transparent: Turn ON

   **Note:** Monitor packets should flow through inline device to monitor inline device status.

18. Click **Create.**

19. Click **Done.**

20. Navigate to **Traffic Management > Load Balancing > Virtual Servers.** Add a virtual server of type HTTP or SSL.

21. After entering the server details, click OK and again OK.

22. In the **Traffic Settings** section of Load Balancing Virtual Server, turn Layer 2 Parameters ON.

23. In the **Advanced Settings** section, click **Policies.**

24. Go the **Policies** section and click the “+” icon to configure content inspection policy.

25. On the **Choose Policy** page, select Content Inspection. Click **Continue.**

26. In the **Policy Binding** section, click **Add** to add a Content Inspection policy.

27. In the **Create ContentInspection Policy** page, enter a name for the Inline content inspection policy.

28. In the **Action** field, click **Add** to create an Inline content inspection action.

29. In the **Create CI Action** page, set the following parameters:
   a) Name. Name of the content inspection Inline policy.
   b) Type. Select the type as inlineInspection.
   c) Server. Select the server/service as Inline devices.
   d) If Server Down. Select an operation if server goes down.
   e) Request Time-out. Select a time-out value. You can use default values.
   f) Request Time-out Action. Select a time-out action. You can use default values.

30. Click **Create.**

31. Click **Create.**

32. In the **Create CI Policy** page, enter other details:

33. Click **OK** and **Close.**

System

January 25, 2019
Contributed by: C

This section provides system-level information of the Citrix ADC. This includes a detailed explanation of system-level features, the scenarios in which the features can be used, the configuration steps, and examples to help you better understand the features.

- Basic Operations
- Authentication and Authorization
- TCP Configurations
- HTTP Configurations
- SNMP
- Audit Logging
- Web Server Logging
- Call Home
- Reporting Tool
- CloudBridge Connector
- High Availability
- TCP Optimization

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Basic operations

January 23, 2019
Contributed by: C

Any changes you make to the configuration of a Citrix ADC appliance are not saved automatically. You have to save the settings manually. When an appliance is restarted, it loads the latest saved configuration.
**View and save configurations**

Configurations are stored in the /nsconfig/ns.conf directory. For configurations to be available across sessions, you must save the configuration after every configuration change.

To view the running configuration by using the command line interface

At the command prompt, type:

```
show ns runningConfig
```

To view the running configuration by using the GUI

- Navigate to **System > Diagnostics** and, in the **View Configuration group**, click **Running Configuration**.

To find the difference between two configuration files by using the command line interface

At the command prompt, type:

```
diff ns config <configfile> <configfile2>
```

To find the difference between two configuration files by using the GUI

- Navigate to **System > Diagnostics** and, in the **View Configuration group**, click **Configuration difference**.

To save configurations by using the command line interface

At the command prompt, type:

```
save ns config
```

To save configurations by using the GUI

On the **Configuration** tab, in the top-right corner, click the **Save** icon.

To view the saved configurations by using the command line interface

At the command prompt, type:

```
show ns ns.conf
```

To view the saved configurations by using the GUI

Navigate to **System > Diagnostics > View Configuration group**, click **Saved Configuration**.

**Clear configuration**

You have the following three options for clearing the Citrix ADC configuration.

**Basic level.** Clearing your configuration at the basic level clears all settings except the following:
Extended level. Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (nsroot)

Feature and mode settings revert to their default values.

Full level. Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them could cause the appliance to lose network connectivity.

To clear the configuration by using the command line interface

At the command prompt, type:

clear ns config -force

Example: To forcefully clear the basic configurations on an appliance.

1. clear ns config -force basic

To clear the configuration by using the GUI

- Navigate to System > Diagnostics and, in the Maintenance group, click Clear Configuration and select the configuration level to be cleared from the appliance.

Clock synchronization

May 13, 2019

Contributed by:

C
You can configure your Citrix ADC appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the ntp.conf file from either the GUI or the command line interface, or by manually modifying the ntp.conf file and then starting the NTP daemon (NTPD). The clock synchronization configuration does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration does not get propagated to the secondary Citrix ADC in a high availability setup.

**Note:**
If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site, [http://www.ntp.org](http://www.ntp.org), under Public Time Servers List. Before configuring your Citrix ADC to use a public NTP server, be sure to read the Rules of Engagement page (link included on all Public Time Servers pages).

In Citrix ADC release 11, the NTP version has been updated from 4.2.6p3 to 4.2.8p2.

**Set clock synchronization**

To configure clock synchronization, you must add NTP servers and then enable NTP synchronization.

**To add an NTP server by using the command line interface**

At the command prompt, type the following commands to add an NTP server and verify the configuration:

- `add ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>]`
- `show ntp server`

**Example**

```
> add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11
```

**To configure an NTP server by using the GUI**

Navigate to **System > NTP Servers**, and create the NTP server.

**Note:**
You can now configure the time zone and the NTP server IP address required for clock synchro-
Start NTP daemon

When you enable NTP synchronization, the Citrix ADC starts the NTP daemon and uses the NTP server entries in the ntp.conf file to synchronize its local time setting. If you do not want to synchronize the appliance time with the other servers in the network, you can disable NTP synchronization, which stops the NTP daemon (NTPD).

To enable NTP synchronization by using the command line interface

At the command prompt, type one of the following commands:

```
enable ntp sync
```

To enable NTP synchronization by using the GUI

Navigate to System > NTP Servers, click Action and select NTP Synchronization.

Configure clock synchronization

You can configure clock synchronization manually by logging on to the Citrix ADC appliance and editing the ntp.conf file.

To enable clock synchronization on your Citrix ADC appliance by modifying the ntp.conf file

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the `etc/ntp.conf` file to `/nsconfig/ntp.conf`, unless the `/nsconfig` directory already contains an `ntp.conf` file.
4. For each NTP server you want to add, you must add the following two lines to the `/nsconfig/ntp.conf` file:

```
server <IP address for NTP server> iburst
restrict <IP address for NTP server> mask <netmask> nomodify notrap nopeer noquery
```

**Note:**
For security reasons, there should be a corresponding restrict entry for each server entry.
Example:

In the following example, an administrator has inserted # characters to “comment out” an existing NTP entry, and then added a new entry:

```plaintext
##server 1.2.3.4 iburst
##restrict 1.2.3.4 mask 55.255.255.255 nomodify notrap nopeer noquery
server 10.102.29.160 iburst
restrict 10.102.29.160 mask 255.255.255.255 nomodify notrap nopeer noquery
```

5. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.

   1. Add the following entry to /nsconfig/rc.netscaler: /bin/sh /etc/ntpd_ctl full_start

This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory. This process runs every time the Citrix ADC is restarted.

7. Restart the Citrix ADC appliance to enable clock synchronization. Or, to start the time synchronization process without restarting the appliance, enter the following commands at the shell prompt:

   - `rm /etc/ntp.conf`
   - `ln -s /nsconfig/ntp.conf /etc/ntp.conf`
   - `/bin/sh /etc/ntpd_ctl full_start`

Session timeout

January 23, 2019

Contributed by: C

A session timeout interval is provided to restrict the time duration for which a session (GUI, CLI, or API) remains active when not in use. For the Citrix ADC, the system session timeout can be configured at the following levels:

- **User level timeout.** Applicable to the specific user.
## Interface type | Time out configuration
---|---
**GUI** | Navigate to System > User Administration > Users, select a user, and edit the user’s timeout setting.
**CLI** | At the command prompt, enter the following command: `set system user <name> - timeout <secs>`

- **User group level timeout.** Applicable to all users in the

  Interface type | Time out configuration
---|---
**GUI** | Navigate to System > User Administration > Groups, select a group, and edit the group’s timeout setting.
**CLI** | At the command prompt, enter the following command: `set system group <groupName> -timeout <secs>`

- **Global system timeout.** Applicable to all users and users from groups who do not have a timeout configured.

  Interface type | Time out configuration
---|---
**GUI** | Navigate to System > Settings, click Change global system settings, and update the timeout value as required.
**CLI** | At the command prompt, enter the following command: `set system parameter -timeout <secs>`

The timeout value specified for a user has the highest priority. If timeout is not configured for the user, the timeout configured for a member group is considered. If timeout is not specified for a group (or the user does not belong to a group), the globally configured timeout value is considered. If timeout is not configured at any level, the default value of 900 seconds is set as the system session timeout.

Additionally, you can specify timeout durations for each of the interfaces you are accessing. However, the timeout value specified for a specific interface is restricted to the timeout value configured for the
user that is accessing the interface. For example, let us consider an user “publicadmin” who has a timeout value of 20 minutes. Now, when accessing an interface, the user must specify a timeout value that is within 20 minutes.

Note:
You can choose to keep a check on the minimum and maximum timeout values by specifying the timeout as restricted (in CLI by specifying the restrictedTimeout parameter). This parameter is provided to account for previous Citrix ADC versions where the timeout value was not restricted.

- When enabled, the minimum configurable timeout value is 5 minutes (300 secs) and the maximum value is 1 day (86400 secs). If the timeout value is already configured to a value larger than 1 day, when this parameter is enabled, you are prompted to change it. If you do not change the value, the timeout value will automatically be reconfigured to the default timeout duration of 15 minutes (900 secs) on next reboot. The same will happen is the configured timeout value is less than 5 minutes.
- When disabled, the configured timeout durations are considered.

To configure the timeout duration at each interface:

<table>
<thead>
<tr>
<th>Interface type</th>
<th>Time out configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLI</td>
<td>Specify the timeout value on the command prompt by using the following command: \texttt{set cli mode __timeout &lt;secs&gt;}</td>
</tr>
<tr>
<td>API</td>
<td>Specify the timeout value in the login payload.</td>
</tr>
</tbody>
</table>

1. Citrix ADC
2. Citrix ADC 12.1

System date and time

April 24, 2019

Contributed by:
C

The Time Zone settings enables you to set the date and time for the Citrix ADC appliance. When you set your time zone, you must configure the same local time and date in Citrix ADC GUI and CLI.
change the local time zone, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the GUI.

To view the system date and time by using the command line interface

At the command prompt, type:
```
show ns param
```

**Sample configuration**

```
$ show ns param
**
Timezone: GMT+06:54-CST-Asia/Shanghai
```

View system date and time by using the Citrix ADC GUI

Follow the procedure given below to view the system date and time.

1. Sign into Citrix ADC and navigate to **System > Settings > Change Time Zone**.
2. In the **Set Time Zone** page, select a time zone from the drop-down list.

3. Click **OK**.

4. The system asks you to confirm if the configuration must be saved and the system must be re-booted for the new time zone settings to take effect.

5. Click **Yes**.

Backup and restore a Citrix ADC appliance

April 11, 2019

Contributed by: C
There are many ways to back up and restore your Citrix ADC appliance. You can perform backups if your appliance gets corrupted or you prefer to upgrade your appliance. You can backup and restore your appliance using Citrix ADC GUI or CLI interface.

**Points to remember**

You must remember the following points when you backup and restore your appliance.

- There must be a support for network configuration on a new platform.
- The new platform build must be same as the backup file or a later version.

**Back up a Citrix ADC appliance**

Depending on data and backup requirement, you can create a “basic” backup or a “full” backup.

- **Basic backup.** You can perform this type of backup if you want to back up files that constantly change. The files that you can back up are in the following table.

For information about the basic backup details, see the [Table](#) topic.

- **Full backup.** In addition to the files that are backed up by a basic backup, a full backup has less frequently updated files. The files that are backed up when you use the “Full” backup option are:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Sub-Directory or Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>nsconfig</td>
<td>ssl, license, fips*</td>
</tr>
<tr>
<td>/var/</td>
<td>netscaler/ssl/, wi/-</td>
</tr>
<tr>
<td></td>
<td>java_home/jre/lib/security/cacerts/, wi/-</td>
</tr>
<tr>
<td></td>
<td>java_home/lib/security/cacerts/*</td>
</tr>
</tbody>
</table>

The backed-up data is stored as a compressed TAR file in the `/var/ns_sys_backup/` directory. To avoid issues due to non-availability of disk space, you can store up to 50 backup files in this directory. You can use the `rm system backup` command to delete existing backup files and create more backups.

**Note**

When the backup operation is in progress, do not execute commands that affect the configuration.

If a file that is required to be backed up is not available, the operation skips that file.
To back up a Citrix ADC appliance

Follow the procedure given below to back up a Citrix ADC appliance by using the Citrix ADC command line interface.

At the command prompt, do the following:

1. Save the Citrix ADC configurations.
   ```
   save ns config
   ```

2. Create the backup file.
   ```
   create system backup [<fileName>] -level <basic | full> -comment <string>
   ```

   **Note:** If the file name is not specified, the appliance creates a TAR file with the following naming convention:
   ```
   backup_<level>_<nsip_address>_<date-timestamp>.tgz
   ```

   **Example:** To back up the full appliance using the default naming convention for the backup file.
   ```
   > create system backup -level full
   ```

3. Verify that the backup file was created.
   ```
   show system backup
   ```

You can view properties of a specific backup file by using the `fileName` parameter.

Restore a Citrix ADC appliance

**Important**

You cannot successfully restore your appliance, if you rename or modify your backup file.

When you restore your appliance, the restore operation untars the backup file from the `/var/ns_sys_backup/` directory. Once the files are untarred, the files are copied to the respective directories.

To restore the Citrix ADC from a local backup file by using the command line interface

**Note:** Citrix recommends you to back up the current configuration before restoring a previous configuration. However, if you do not want the restore command to automatically create a backup of the current configuration, use the `--skipBackup` parameter.

At the command prompt, do the following:

1. Obtain a list of the backup files available on the appliance.
   ```
   show system backup
   ```
2. Restore the appliance by specifying one of the backup files.

   ```bash
   restore system backup <filename> [-skipBackup]
   ```

   **Example:** To restore by using a full backup of an appliance

   ```bash
   > restore system backup backup_full_<nsip_address>_<date-timestamp>.tgz
   ```

3. Reboot the appliance.

   ```bash
   reboot
   ```

---

**To backup and restore a Citrix ADC appliance by using the GUI**

1. Navigate to **System > Backup and Restore**.

2. Click **Backup/Import** to start the process.

3. In the **Backup/Import** page, select **Create** and set the following parameters.
   a) File Name. Name of the appliance backup file.
   b) Level. Select a backup level as basic or full.
   c) Comment. Provide a brief description for the backup.

4. Click **Backup**.

5. If you want to import a backup, you must select **Import**.

6. Once backup is complete, you can select the file and click **Download**.

7. To restore, select the backup file and click **Restore**.

8. In the **Restore** page, verify backup file details and click **Restore**.

For more information on how to backup and restore Citrix ADC instances, see **Backup and Restore using Citrix ADM** topic.

For more information on how to backup and restore an SDX appliance, see **Backup and restore SDX appliance**

For information about operations performed on system backup, see **System Backup** topic.

1.  
   2.  **Citrix ADC**
   3.  **Citrix ADC 12.1**

---

**Restart or shut down**

January 23, 2019
The Citrix ADC appliance can be remotely restarted or shut down from the available user interfaces. When a standalone Citrix ADC appliance is restarted or shut down, the unsaved configurations (configurations performed since the last save ns config command was issued) are lost.

In a high availability setup, when the primary appliance is rebooted/shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance.

You can also restart the appliance by only rebooting the Citrix ADC software and not rebooting the underlying operating system. This is called a warm reboot. For example, when you add a new license or change the IP address, you can warm reboot the Citrix ADC appliance for these changes to take place.

**Note**

Warm reboot can be performed only on nCore appliances.

To restart by using the command line interface

At the command prompt, type:

`reboot [-warm]`

To restart the Citrix ADC by using the GUI

1. In the GUI, click Reboot on the home page of the Configuration tab.
2. When prompted to reboot, select Save configuration to make sure that you do not lose any configurations.

**Note**

You can perform a warm reboot by selecting Warm reboot.

To shut down the Citrix ADC by using the command line interface

At the command prompt, type:

- `shutdown -p now`: Shuts down the software and switches off the Citrix ADC. To restart Citrix ADC MPX, press the AC power switch. To Restart Citrix ADC VPX, restart the VPX instance.
- `shutdown -h now`: Shuts down the software and leaves the Citrix ADC switched on. Press any key to restart the Citrix ADC. This command does not switch off the Citrix ADC. Therefore, do not switch off the AC power or remove the AC power cables.

**Note**

The appliance cannot be shut down from the GUI.
Generate technical support bundle

January 23, 2019
Contributed by: C

For help with analyzing and resolving any issues with a Citrix ADC appliance, you can generate a technical support bundle on the appliance and send the bundle to Citrix Technical Support. The Citrix ADC technical support bundle is a gzipped tar archive of system configuration data and statistics. It collects the following data from the Citrix ADC appliance on which you generate the bundle:

- **Configuration files.** All files in the /flash/nsconfig directory.
- **Newsnlog files.** The currently running newsnlog and some previous files. To minimize the archive file size, newsnlog collection is restricted to 500 MB, 6 files, or 7 days, whichever occurs first. If older data is needed, it might require manual collection.
- **Log files.** Files in /var/log/messages, /var/log/ns.log, and other files under /var/log and /var/nslog.
- **Application core files.** Files created in the /var/core directory within the last week, if any.
- **Output of some CLI show commands.**
- **Output of some CLI stat commands.**
- **Output of BSD shell commands.**

You can use a single command to generate the technical support bundle and securely upload it to the Citrix Technical Support server. To upload, you must specify your My Citrix credentials. When you generate the bundle, you can specify the case or service request number that was allotted to you by Citrix Technical Support. If you have already generated a technical support bundle, you can upload the existing archive file to the Citrix Technical Support server by specifying the file name with the full path.

The technical support bundle is saved on the Citrix ADC appliance in an archive at the following location:

/var/tmp/support/support.tgz

The above path is a symlink to the most recent collector for easy access. The full filename varies, depending on the deployment topology, but generally follows a format similar to:

collector_<P/S>_<NS IP>_<DateTime>.tgz.
If your Citrix ADC appliance does not have direct Internet connectivity, you can use a proxy server to directly upload the technical support bundle to the Citrix Technical Support server. The basic format of the proxy string is:

proxy_IP:<proxy_port>

If the proxy server requires authentication, the format is:

username:password@proxy_IP:<proxy_port>

Note

For Citrix ADC appliances in a high availability pair, you must generate the technical support bundle on each of the two nodes.

For Citrix ADC appliances in a Cluster setup, you can generate the technical support bundle on each node individually, or you can generate smaller abbreviated archives for all nodes by using the cluster IP address.

For Citrix ADC Admin Partitions, you must generate the technical support bundle from the default admin partition. To get the technical support bundle for a specific partition, you must specify the name of the partition for which you want to generate the technical support bundle. If you do not specify the name of the partition, data is collected from all admin partitions.

To generate the Citrix ADC technical support bundle by using the command line interface

At the command prompt, type:

show techsupport [-scope <scope> <partitionName>] [-upload [-proxy <string>]] [-casenumber <string>] [-file <string>] [-description <string>] [-userName <string> -password ]]

<table>
<thead>
<tr>

**Extra management CPU**

January 25, 2019

Contributed by: C

If you need better performance for configuration and monitoring of a Citrix ADC MPX appliance, you can allocate an extra management CPU from the appliance’s packet engine pool. This feature is supported on certain Citrix ADC MPX models and all VPX models except the VPX instances that run on Citrix ADC SDX appliances. It affects the output of the stat system cpu and stat system commands.

Supported Citrix ADC MPX models:

- 25xxx
- 22xxx
- 14xxx
- 115xx
- 15xxx
- 26xxx
Note
For Citrix ADC MPX 26xxx models with more than 20 cores, the mandatory extra management CPU feature is enabled by default. For Citrix ADC VPX models, a license that supports at least 12 vCPUs is required to enable this feature.

Allocate or deallocate an extra management CPU by using the Citrix ADC CLI

At the command prompt, type one of the following commands:

- `enable extramgmtcpu`
- `disable extramgmtcpu`

Note
After you enable and disable this feature, the Citrix ADC appliance displays a warning to restart the appliance, for the changes to take effect.

To show the configured and effective state of an extra management CPU.

At the command prompt, type:

```
> show extramgmtcpu
```

Example

```
1 > show extramgmtcpu
2
3 ConfiguredState: ENABLED EffectiveState: ENABLED
```

Note
In this example, the show command is entered before restarting the appliance.

Parameter descriptions of commands listed in the command line interface

- `enable extramgmtcpu`

Enables and dedicates extra CPU for management from PE pool.

See also:

- `disable system extramgmtcpu`
- `show system extramgmtcpu`
- `disable extramgmtcpu`
Disables extra CPU for management and returns it to the PE pool.

See also:

- `enable system extramgmtcpu`
- `show system extramgmtcpu`
  - `show extramgmtcpu`

Displays configured and effective states of the extra management CPU.

Configured and effective state are different if `enable extramgmtcpu` command has been entered but system is has not been restarted.

See also:

- `enable system extramgmtcpu`
- `disable system extramgmtcpu`

Allocate an extra management CPU by using the GUI

To allocate an extra management CPU by using the GUI, navigate to **System > Settings** and click **Configure Extra Management CPU**. From the **Configured State** drop-down menu, select **Enabled** and then select **OK**.

To check CPU usage, go to **System > Settings > Dashboard**.

Configure an extra management CPU by using the NITRO API

Use the following NITRO methods and formats to enable, disable, and show an extra management CPU.

**To enable an extra management CPU:**

**HTTP Method:** POST

**URL:** `http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=enable`

**Payload:**

```bash
1   curl -v -X POST -H "Content-Type: application/json" -u nsroot:
2     nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?
3       action=enable -d '{
4         "systemextramgmtcpu":{
5             ...
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To disable an extra management CPU

HTTP Method: POST

URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=disable

```
Payload: {
  "systemextramgmtcpu": {
  }
}
```

curl -v -X POST -H "Content-Type: application/json" -u nsroot:
   nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?
   action=disable -d '{
  "systemextramgmtcpu": {
  }
}

To show an extra management CPU

HTTP Method: GET

URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu

Example

```
curl -v -X GET -H "Content-Type: application/json" -u nsroot:nsroot
   http://10.102.201.92/nitro/v1/config/systemextramgmtcpu
```

Statistics and monitoring

The following examples show the differences in the output of the stat system cpu and stat system commands before and after adding an extra management CPU.

1. stat system cpu

This command displays statistics of CPUs.

Here is a sample output before adding an extra management CPU on one of the supported models.

Example output

```
> stat system cpu
CPU statistics
```
Here is the output after adding an extra management CPU on the same MPX appliance.

```
> stat system cpu
CPU statistics

  ID  Usage
  9   1
  7   1
  5   1
  8   1
 11  2
 10  1
  6  1
```
2. stat system

This command displays CPU use. In the following example, the output before adding an extra management CPU on one of the supported models is:

Mgmt Additional-CPU usage (%)  0.00

Example output

```
> stat system
Citrix ADC Executive View
System Information:
Up since Wed Oct 11 11:17:54 2017

    /flash Used (%)  0
    Packet CPU usage (%)  1.30
    Management CPU usage (%)  4.00
    Mgmt CPU0 usage (%)  4.00
    Mgmt Additional-CPU usage (%)  0.00
    Memory usage (MB)  2167
    InUse Memory (%)  5.76
    /var Used (%)  0
```

In the following example, the output after adding an extra management CPU on the same MPX appliance is:

Mgmt Additional-CPU usage (%)  0.80

```
> stat system
```
Configure HTTP and HTTPS management ports

January 23, 2019

Contributed by:

C

In a single-IP mode deployment of a Citrix ADC appliance, a single IP address is used as NSIP, SNIP, and VIP addresses. This single IP address uses different port numbers to function as NSIP, SNIP, and VIP addresses.

Port numbers 80 and 443 are well-known ports for HTTP and HTTPS services. Earlier, port 80 and 443 of Citrix ADC IP address (NSIP) were dedicated ports for internal HTTP and HTTPS management services. Because these ports were reserved for internal services, you cannot use these well-known ports for providing HTTP and HTTPS data services from a VIP address, which has the same address as the NSIP address in a single-IP mode deployment.
To address this requirement, you can now configure ports for internal HTTP and HTTPS management services (of the NSIP address) other than port 80 and 443.

The following lists the default port numbers for internal HTTP and HTTPS management services in Citrix ADC MPX, VPX, and CPX appliances:

- Citrix ADC MPX and VPX appliances: 80 (HTTP) and 443 (HTTPS)
- Citrix ADC CPX appliances: 9080 (HTTP) and 9443 (HTTPS)

How to collect technical support bundle from a Citrix ADC appliance

January 25, 2019
Contributed by:
C

A Citrix ADC appliance has a built-in mechanism to collect log files. The log files are in turn sent to Citrix Insight Services for analysis.

**Note:** All procedures are applicable for software release 9.2 or later.

Download technical support bundle from Citrix ADC MPX and VPX appliances

To run a collector file by using the Citrix ADC GUI, you must complete the following procedure:

**Note:** The procedure is applicable for software release 9.2 or later.

1. Navigate to **System > Diagnostic.**
2. In the Technical Support Tools section, click **Generate Support File** link.
3. In the **Tech Support** page, set the following parameters:
   a) Scope. To collect data from one or more nodes.
   b) Partition. Name of the partition.
   c) Citrix Technical Support pload Options. Set all options such as proxy server, service case number, collector archive file name. and a brief description of the archive file for uploading the technical support bundle.
   d) My Citrix Account. Enter your Citrix credentials.
4. Click **Run.**
5. The Technical Support bundle is generated.

6. Click Yes to download the Technical support bundle to your local desktop.

**Obtain technical support bundle by using the command interface**

1. Download the file from the appliance using a Secure FTP (SFTP) or Secure Copy (SCP) utility, such as WinSCP, and upload it to Citrix Insight Services for analysis.

   **Note:** In NetScaler software release earlier than 9.0, the collector script must be downloaded separately and executed.

   ```
   > show techsupport -scope CLUSTER
   ```

2. This will collect show techsupport information from all nodes in the cluster and compress the files into a single archive.

3. After the appliance generates the collector archive the location of the file is displayed as shown in the following screen shot.

The file is stored in /var/tmp/support and you can verify it by logging into a Citrix ADC appliance and running the following command from a shell prompt.

```bash
root@NS## cd /var/tmp/support/
root@NS## ls -l
```

**Obtain technical support bundle by using the GUI**

In order to generate the collector file from Graphical User Interface (GUI) please select “Partition” option from the Scope.

1. In the **Tech Support** page, enter the details and click **Run**. Wait for the script to generate the collector archive.

2. After the appliance generates the collector archive, download and save the file on your local computer before uploading it to **Citrix Insight Services**.

**Upload and run collector script on Citrix ADC appliance**

To upload and run the updated collector script on a NetScaler appliance, complete the following procedure:

**Note:** The procedure is applicable for software release 9.2 or later.

1. Copy the updated collector script showtechsupport.pl (attached with this article) to the /nsconfig directory of the NetScaler appliance. Use an SFTP or SCP utility, such as WinSCP, to copy the file to the NetScaler appliance.
2. Run the following commands from the CLI of the appliance:

```bash
1  > shell
2  # cd /nsconfig
3  # chmod +x showtechsupport.pl
4  # ./showtechsupport.pl
```

1. Switch to the CLI of the appliance.
2. Run the following command to create log files for analysis:

```bash
> show techsupport
```

The `collector_<NSIP>_<P/S>_<DateTime>.tgz` file is created in the `/var/tmp/support` directory of the appliance.

Note: You must then upload the .tgz file to Citrix Insight Services for analysis.

3. If you must uninstall this script, run the following commands from the CLI of the appliance:

```bash
> shell
rm /nsconfig/showtechsupport.pl
```

**Obtain diagnostic bundle from Citrix ADC SDX**

1. Open the NetScaler SDX Configuration Utility with the NetScaler SDX Management IP address from a web browser.
2. Expand the **Diagnostics** node.
3. Select the **Technical Support** node.
4. Click Generate Technical Support File.
5. Select **Appliance** (Including Instances) from the drop-down menu.
6. Click **Add**.
7. Select one or more instances to add in.
8. Click **OK**. Wait for the process to complete.
9. Select the bundle name that was generated and then click **Download**
10. Upload the bundle file to **Citrix Insight Services**.

For information on collecting/deleting NetScaler SDX support bundle using CLI/serial console refer to Citrix Documentation.
Authentication and authorization

January 23, 2019
 Contributed by:
 C

To configure Citrix ADC authentication and authorization, you must first define the users who have access to the Citrix ADC appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default Citrix ADC administrator user name is nsroot. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the Citrix ADC appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

**Note**
Local users can authenticate to the Citrix ADC even if external authentication servers are configured. You can restrict this by disabling the localAuth parameter of the set system parameter command.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
You must define your users by configuring accounts for them. To simplify the management of user accounts, you can organize them into groups. You can create command policies, or use built-in command policies, to regulate user access to commands.

You can also customize the command-line prompt for a user. Prompts can be defined in a user’s configuration, in a user-group configuration, and in the global system configuration settings. The prompt displayed for a given user is determined by the following order of precedence:

1. Display the prompt as defined in the user’s configuration.
2. Display the prompt as defined in the group configuration for the user’s group.
3. Display the prompt as defined in the system global configuration settings.

You can now specify a timeout value for inactive CLI sessions for a system user. If a user’s CLI session is idle for a time that exceeds the timeout value, the Citrix ADC appliance terminates the connection. The timeout can be defined in a user’s configuration, in a user-group configuration, and in the global system configuration settings. The timeout for inactive CLI sessions for a user is determined by the following order of precedence:

1. Timeout value as defined in the user’s configuration.
2. Timeout value as defined in the group configuration for the user’s group.
3. Timeout value as defined in the global system configuration settings.

A Citrix ADC root administrator can configure the maximum concurrent session limit for system users. By restricting the limit, you can reduce the number of open connections and improve server performance. As long as the CLI count is within the configured limit, concurrent users can log on to the GUI any number of times. However, if the number of CLI sessions reaches the configured limit, users can no longer log on to the GUI. For example, if the number of concurrent session is configured to 20, concurrent users can log on to 19 CLI sessions. But if the user is logged on to the 20th CLI session, any attempt to log on to the GUI, CLI or NITRO results in an error message (ERROR: Connection limit to CFE exceeded).

**Note**

The default the number of concurrent sessions is configured to 20 and the maximum number of concurrent sessions is configured to 40.
Configuring user accounts

To configure user accounts, you simply specify usernames and passwords. You can change passwords and remove user accounts at any time.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:

- `add system user <username> [-externalAuth ( ENABLED | DISABLED )] [-promptString <string>] [-timeout \<secs>] [-logging ( ENABLED | DISABLED )] [-maxsession <positive_integer>]`
- `show system user <userName>`

Where Logging option is for external users to collect log data externally using weblogging or audit logging mechanism. If enabled, the auditing client authenticates itself with Citrix ADC to collect logs through this user account.

Example

```
> add system user johnd -promptString user-%u-at-%T
```

```
1 Enter password:
2 Confirm password:
3 > show system user johnd
4 user name: john
5 Timeout:900 Timeout Inherited From: Global
6 External Authentication: ENABLED
7 Logging: DISABLED
8 Maximum Client Sessions: 20
```

To configure a user account by using the GUI

Navigate to System > User Administration > Users, and create the user.
Configuring user groups

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account to more than one group. Binding user accounts to multiple groups might allow more flexibility when applying command policies.

To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- \texttt{add system group <groupName> [-promptString <string>]} [-timeout <secs>]
- \texttt{show system group <groupName>}

Example

\texttt{> add system group Managers -promptString Group-Managers-at-} \%

To bind a user to a group by using the command line interface

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

- \texttt{bind system group <groupName> -userName <userName>}
- \texttt{show system group <groupName>}

Example

\texttt{> bind system group Managers -userName user1}

To configure a user group by using the GUI

Navigate to \textbf{System > User Administration > Groups}, and create the user group.

\textbf{Note:}

To add members to the group, in the Members section, click \textbf{Add}. Select users from the Available list and add them to the Configured list.

Configuring command policies

Command policies regulate which commands, command groups, virtual servers, and other entities that users and user groups are permitted to use.
The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them to users and/or groups.

Here are the key points to keep in mind when defining and applying command policies.

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
- Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to execute any configuration commands until the proper command policies are bound to their accounts.
- All users inherit the policies of the groups to which they belong.
- You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.
- The following commands are available by default to any user and are unaffected by any command you specify:
  - help, show cli attribute, set cli prompt, clear cli prompt, show cli prompt, alias, unalias, history, quit, exit, whoami, config, set cli mode, unset cli mode, and show cli mode.

**Built-in Command Policies**

The following table describes the built-in policies.

<table>
<thead>
<tr>
<th>Policy name</th>
<th>Allows</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>read-only</strong></td>
<td>Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the Citrix ADC command group.</td>
</tr>
<tr>
<td><strong>operator</strong></td>
<td>Read-only access and access to commands to enable and disable services and servers.</td>
</tr>
<tr>
<td><strong>network</strong></td>
<td>Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.</td>
</tr>
</tbody>
</table>
Policy name | Allows
---|---
sysadmin | [Included in Citrix ADC 12.0 and later] A sysadmin is lower than a superuser is terms of access allowed on the appliance. A sysadmin user can perform all Citrix ADC operations with the following exceptions: no access to the Citrix ADC shell, cannot perform user configurations, cannot perform partition configurations, and some other configurations as stated in the sysadmin command policy.
superuser | Full access. Same privileges as the nsroot user.

**Creating custom command policies**

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need additional levels of control but are unfamiliar with regular expressions might want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that will be affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with show, type the following:
  - “`show .*`”
- To create a command policy that includes all commands that begin with `rm`, type the following:
  - “`rm .*`”
- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions:

**Table 2. Examples of Regular Expressions for Command Policies**

<table>
<thead>
<tr>
<th>Command specification</th>
<th>Matches these commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>“<code>rm\s+. *$</code>”</td>
<td>All remove actions, because all remove actions begin with the <code>rm</code> string, followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
</tbody>
</table>
### Command specification

**Matches these commands**

<table>
<thead>
<tr>
<th>Command specification</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>^show\s+. *$</td>
<td>All show commands, because all show actions begin with the show string, followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
<tr>
<td>^shell$</td>
<td>The shell command alone, but not combined with any additional parameters such as command groups, command object types, and arguments.</td>
</tr>
<tr>
<td>^add\svserver\s+. *$</td>
<td>All create virtual server actions, which consist of the add virtual server command followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
<tr>
<td>^add\slb\svserver\s+. *$</td>
<td>All create lb virtual server actions, which consist of the add lb virtual server command followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
</tbody>
</table>

The following table shows the command specifications for each of the built-in command policies.

Table 3. Expressions Used in the Built-in Command Policies

<table>
<thead>
<tr>
<th>Policy name</th>
<th>Command specification regular expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>read-only</td>
<td>(^man.*)</td>
</tr>
<tr>
<td>operator</td>
<td>(^man.*)</td>
</tr>
<tr>
<td>network</td>
<td>(?!clear ns config.<em>)(?!scp.</em>)</td>
</tr>
<tr>
<td>sysadmin</td>
<td>[From Citrix ADC 11 onwards] ^(?!shell)(?!sftp)(?!scp)(?!batch)(?!source)(?!.*superuser)(?!.*nsroot)(?!show\s+system\s+(user</td>
</tr>
</tbody>
</table>
To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

- `add system cmdPolicy <policyName> <action> <cmdspec>`
- `show system cmdPolicy <policyName>

Example

```
> add system cmdPolicy read_all ALLOW (^shows+(!system)(!ns ns.conf)(!ns runningConfig).*|^stat.*)
```

To configure a command policy by using the GUI

Navigate to **System > User Administration > Command Policies**, and create the command policy.

### Binding command policies to users and groups

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

- `bind system user <userName> -policyName <policyName> <priority>`
- `show system user <userName>

Example

```
> bind system user user1 -policyName read_all 1
```
To bind command policies to a user by using the GUI

Navigate to **System > User Administration > Users**, select the user and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user group and verify the configuration:

- `bind system group <groupName> -policyName <policyName> <priority>
- `show system group <groupName>

Example

```
> bind system group Managers -policyName read_all 1
```

To bind command policies to a group by using the GUI

Navigate to **System > User Administration > Groups**, select the group and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

**Resetting the default administrator (nsroot) password**

March 4, 2019

Contributed by:
C

The nsroot account provides complete access to all features of the appliance. Therefore, to preserve security, the nsroot account should be used only when necessary, and only individuals whose duties require full access should know the password for the nsroot account. Frequently changing the nsroot password is advisable. If you lose the password, you can reset it to the default and then change it.

To reset the nsroot password, you must boot the appliance into single user mode, mount the file systems in read/write mode, and remove the set Citrix ADC user nsroot entry from the ns.conf file. You can then reboot, log on with the default password, and choose a new password.
To reset the nsroot password

1. Connect a computer to the console port of the Citrix ADC and log on.
   
   **Note**
   You cannot log on by using SSH to perform this procedure; you must connect directly to the appliance.

2. Reboot the Citrix ADC.

3. Press CTRL+C when the following message appears:
   
   Press [Ctrl-C] for command prompt, or any other key to boot immediately.
   
   Booting [kernel] in # seconds.

4. Run the following command to start the Citrix ADC in a single user mode:
   
   `boot -s`
   
   **Note** If `boot -s` does not work, then try `reboot -- -s` and appliance will reboot in single user mode.

After the appliance boots, it displays the following message:

Enter full path name of shell or RETURN for /bin/sh:

5. Press ENTER key to display the # prompt, and type the following commands to mount the file systems:
   
   a) Run the following command to check the disk consistency:
   
   `fsck /dev/ad0s1a`
   
   **Note:**
   Your flash drive will have a specific device name depending on your Citrix ADC; hence, you have to replace ad0s1a in the preceding command with the appropriate device name.

   b) Run the following command to display the mounted partitions:
   
   `df`
   
   If the flash partition is not listed, you need to mount it manually.

   c) Run the following command to mount the flash drive:
   
   `mount /dev/ad0s1a /flash`

6. Run the following command to change to the nsconfig directory:
   
   `cd /flash/nsconfig`
7. Run the following commands to rewrite the ns.conf file and remove the set of system commands defaulting to the nsroot user:
   
a) Run the following command to create a new configuration file that does not have commands defaulting to the nsroot user:
   
   ```
   grep -v "set system user nsroot" ns.conf > new.conf
   ```
   
b) Run the following command to make a backup of the existing configuration file:
   
   ```
   mv ns.conf old.ns.conf
   ```
   
c) Run the following command to rename the new.conf file to ns.conf:
   
   ```
   mv new.conf ns.conf
   ```
   
8. Run the following command to reboot the Citrix ADC:
   
   ```
   reboot
   ```
   
9. Log on using the default nsroot user credentials.

10. Run the following command to reset the nsroot user password:
   
   ```
   set system user nsroot <New_Password>
   ```
   
   **Note:**
   
   To use the “?” character in a password string, precede this character with the “\" character.
   
   For example, yourexamplepasswd? is set for the nsroot account after you perform the following operation:
   
   ```
   > set system user nsroot yourexamplepasswd?
   ```
   
**Example of a user scenario**

January 25, 2019

Contributed by:

C

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the Citrix ADC appliance:
• **John Doe.** The IT manager. John needs to be able to see all parts of the Citrix ADC configuration but does not need to modify anything.

**Maria Ramiez.** The lead IT administrator. Maria needs to be able to see and modify all parts of the Citrix ADC configuration except for Citrix ADC commands (which local policy dictates must be performed while logged on as nsroot).

• **Michael Baldrock.** The IT administrator in charge of load balancing. Michael needs to be able to see all parts of the Citrix ADC configuration, but needs to modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Citrix ADC host name</td>
<td>ns01.example.net</td>
<td>N/A</td>
</tr>
<tr>
<td>User accounts</td>
<td>johnd, mariar, and michaelb</td>
<td>John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.</td>
</tr>
<tr>
<td>Groups</td>
<td>Managers and SysOps</td>
<td>All managers and all IT administrators.</td>
</tr>
<tr>
<td>Command Policies</td>
<td>read_all, modify_lb, and modify_all</td>
<td>Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.</td>
</tr>
</tbody>
</table>

The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the Citrix ADC appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the Citrix ADC.
Configuration steps

1. Use the procedure described in “Configuring User Accounts” to create user accounts john, mariar, and michaelb.

2. Use the procedure described in “Configuring User Groups” to create user groups Managers and SysOps, and then bind the users mariar and michaelb to the SysOps group and the user john to the Managers group.

3. Use the procedure described in “[Creating Custom Command Policies] to create the following command policies:
   - read_all with action Allow and command spec "(^show\s+(?!system)(?!ns ns. conf)(?!ns runningConfig).*)|(^stat.*)"
   - modify_lb with action as Allow and the command spec "^set\s+lb\s+.*$"
   - modify_all with action as Allow and the command spec "^\s+(?!system).*

4. Use the procedure described in “Binding Command Policies to Users and Groups” to bind the read_all command policy to the SysOps group, with priority value 1.

5. Use the procedure described in “Binding Command Policies to Users and Groups” to bind the modify_lb command policy to user michaelb, with priority value 5.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire Citrix ADC configuration, but he cannot make modifications.
- Maria Ramirez, the IT lead, has near-complete access to all areas of the Citrix ADC configuration, having to log on only to perform Citrix ADC-level commands.
- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the Citrix ADC configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user’s account and command policies applied to the group(s) of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the Citrix ADC appliance’s default deny policy.

Note
When placing a user into multiple groups, take care not to cause unintended user command re-
Authentication in a Citrix ADC appliance can be local or external. For authenticating external users, the appliance uses an external authentication server such as LDAP, RADIUS and TACACS+. In order to authenticate an external user and grant user access into the appliance, you must use an authentication policy. The Citrix ADC system authentication uses Advanced authentication policy. Advanced authentication policies use Citrix ADC advanced policy expressions. Advanced authentication policies are used for system user management in a partitioned Citrix ADC appliance.

**Note:**
If your appliance has Classic policies and its expressions, you must stop using it and migrate Classic policy usage to Advanced policy infrastructure.

Once you create an authentication policy, you must bind it to system global entity. You can configure an external authentication server (for example, TACACS) by binding a single authentication policy to the system global entity. Or, you can configure a cascade of authentication servers by binding multiple policies to the system global entity.

**Note:**
When an external user logs into the appliance, the system generates an error message, “User does not exist” in ns.log file. This occurs because the system runs the systemuser_systemcmdpolicy_binding command to initialize the GUI for the user.

### Configuring LDAP authentication

You can configure the Citrix ADC appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in Active Directory, on the LDAP server, and on the appliance. The characters and case must also be the same.
By default, LDAP authentication is secured by using SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecure and secure LDAP connections and is handled by a single port on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the LDAP command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:
- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all of the subdirectories are also searched to find the user attribute. In large directories, this can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of the base distinguished name (DN).

<table>
<thead>
<tr>
<th>LDAP server</th>
<th>Base DN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Active Directory</td>
<td>DC=citrix, DC=local</td>
</tr>
<tr>
<td>Novell eDirectory</td>
<td>dc=citrix, dc=net</td>
</tr>
<tr>
<td>IBM Directory Server</td>
<td>cn=users</td>
</tr>
<tr>
<td>Lotus Domino</td>
<td>OU=City, O=Citrix, C=US</td>
</tr>
<tr>
<td>Sun ONE directory (formerly iPlanet)</td>
<td>ou=People, dc=citrix, dc=com</td>
</tr>
</tbody>
</table>

Table 2. Examples of Base Distinguished Name

The following table lists examples of the bind distinguished name (DN).
Configure LDAP authentication by using the command line interface

To configure LDAP classic policy

At the command prompt, do the following:

Step 1: Create an LDAP action.

```
add authentication ldapAction <name> { -serverIP <ip_addr|ipv6_addr>* | { -serverName <string> } } [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] { -ldapBindDnPassword } [-ldapLoginName <string>] [-groupAttrName <string>] [-subAttributeName <string>]
```

Example:

```
add authentication ldapAction ldap_act -serverIP <IP> -authTimeout 30 -ldapBase "CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDn "CN=xxxxx,CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDnPassword abcd -ldapLoginName sAMAccountName -groupattrName memberOf -subAttributeName CN
```

Step 2: Create an LDAP policy.
add authentication ldapPolicy <name> <rule> [reqAction]

Example:
add authentication ldappolicy ldap_pol_classic ns_true ldap_act.

Step 3: Create an LDAP policy

Creating an LDAP advanced authentication policy:
add authentication ldapPolicy <name> <rule> [reqAction]

Example:
add authentication policy ldap_pol_advance -rule true -action ldap_act

Step 4: Bind the LDAP policy to the following bind points at which the policy will be evaluated.

System Global: bind system global <policyName> [-priority <positive_integer>]

VPN Global: bind vpn global <policyName> [-priority <positive_integer>]

Authentication Server: bind authentication vserver <name> [-policy <string> [-priority <positive_integer>]]

VPN Server: bind vpn vserver <name> [-policy <string> [-priority <positive_integer>]]

To configure LDAP classic policy

At the command prompt, type:
add authentication Policy <name> -rule <expression> -action <string>

Example:
add authentication policy ldap_pol_classic -rule true -action ldap_act

To configure LDAP authentication by using the GUI

Navigate to System > Authentication > LDAP, and create the LDAP authentication policy.

Determining attributes in the LDAP directory

If you need help determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator Web site at http://www.ldapbrowser.com. After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.
• The base DN field can be left blank.
• The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
• The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

**Configuring RADIUS authentication**

You can configure the Citrix ADC appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:

• If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
• If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
• When the NAS IP is enabled, the appliance ignores any NAS ID that was configured by using the NAS IP to communicate with the RADIUS server.

**To configure RADIUS authentication by using the GUI**

Navigate to **System > Authentication > Radius**, and create the RADIUS authentication policy.

**Choosing RADIUS authentication protocols**

The Citrix ADC appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:

• Password Authentication Protocol
• Challenge-Handshake Authentication Protocol (CHAP)
• Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment of the appliance is configured to use RADIUS authentication and your RADIUS server is configured to use Password Authentication Protocol, you can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are at least
22 characters long. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. If you do this, you must configure separately each policy that uses RADIUS authentication.

Shared secrets are configured on the appliance when a RADIUS policy is created.

**Configuring IP address extraction**

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:

- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type ipaddress, including those that are vendor encoded.

When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the RADIUS attribute **framed IP address**. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

**To configure IP address extraction by using the GUI**

1. Navigate to **System > Authentication > Radius**, and select a policy.
2. Modify the server parameters and set relevant values in **Group Vendor Identifier** and **Group Attribute Type** fields.

**Configuring TACACS+ authentication**

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the
To configure TACACS+ authentication by using the GUI

Navigate to System > Authentication > TACACS, and create the TACACS authentication policy. After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity.

Binding authentication policies to the system global entity

When the authentication policies are configured, bind the policies to the system global entity.

To bind a classic authentication policy to system global using the command line interface

At the command line prompt, do the following:

```
bind system global <policyName> [-priority <positive_integer>]
```

Example:

```
bind system global ldap_pol_classic -priority 10
```

To bind advanced authentication policy to system global using the command line interface

At the command line prompt, do the following:

```
bind system global <policyName> [-priority <positive_integer>]
```

Example:

```
bind system global ldap_pol_advanced -priority 10
```

To bind an authentication policy to system global using the GUI

1. Navigate to System > Authentication, and select the authentication type.
2. On the Policies tab, click Global Bindings and bind the authentication policies.

SSH Key-based authentication for Citrix ADC administrators

January 23, 2019
Contributed by: C

SSH key-based authentication is preferred over traditional username/password type authentication for following reasons:

- provides better cryptographic strength than user passwords.
- eliminates the need of remembering complicated passwords and prevents shoulder-surfing attacks which are possible if passwords are used.
- provides a password-less login for making automation scenarios more secured.

Citrix ADC supports SSH key-based authentication by leveraging the public and private key concept. The SSH key-based authentication in Citrix ADC can be enabled either at a user-specific level for Citrix ADC local users or enabled for Citrix ADC local users in common.

Note: This is currently supported only for Citrix ADC local users and not supported for external users.

Configuring SSH key-based authentication for local system users

In a Citrix ADC appliance, an administrator can set up SSH key-based authentication for a secured system access. When a user log into Citrix ADC using a private key, the system authenticates using the public key configured on the appliance.

To configure SSH key-based authentication for Citrix ADC local system users by using command line interface

Follow the below configuration to configure key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. By default your sshd_config file will access this path: `AuthorizedKeysFile /nsconfig/ssh/authorized_keys`
3. Append the public key to the authorized_keys file.

Once you have configured, restart the sshd process in your appliance.
Configuring user-specific SSH key-based authentication for local system users

In a Citrix ADC appliance, an administrator can now set up a user specific key-based authentication for a secured system access. To do this, the administrator must first configure the Authorizedkeysfile option in sshd_config file and then add the public key in the authorized_keys file for a system user.

**Note**
If the authorized_keys file is not available for a user, the administrator must first create one and then add the public key to it.

**To configure user-specific SSH key-based authentication by using command line interface**

Follow the procedure below to configure user-specific SSH key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. At the shell prompt, access the sshd_config file and add the following configuration line: `AuthorizedKeysFile ~/.ssh/authorized_keys`
3. Change directory to system user folder and add the public keys in the `authorized_keys` file.
Once you have completed the above steps, restart the ssdh process on your appliance.

Note

If authorized_keys file is not available, you must first create one and then add the public key.

```bash
> shell
Copyright (c) 1992-2013 The FreeBSD Project.

The Regents of the University of California. All rights reserved.

root@ns# cd /var/pubkey/<username>/

root@ns# ls

.ssh

root@ns# cd .ssh

root@ns# vi authorized_keys

### Add public keys in authorized_keys file
```

2. Citrix ADC 12.1

**Display unsuccessful external user logon attempts**

January 23, 2019

Contributed by: C

When an external LDAP user successfully logs on to a Citrix ADC appliance, the command interface now displays the number of unsuccessful logon attempts since the last successful logon. The feature works only if the persistentLoginAttempts option is enabled on the appliance.
A Citrix ADC administrator can use this information to verify if any unauthorized activity has occurred on a secured LDAP user account.

To use this feature, at the Citrix ADC command prompt, type:

```
set aaa parameter -maxloginAttempts <value> -failedLoginTimeout <value> -persistentLoginAttempts (ENABLED | DISABLED )]
```

```
Set aaa parameter -maxloginAttempts 5 -failedLoginTimeout 4 -persistentLoginAttempts ENABLED'
```

Two Factor Authentication for Citrix ADC Console

March 14, 2019

Contributed by: C

Two-factor authentication is a security mechanism where a Citrix ADC appliance authenticates a system user at two authenticator levels. The appliance grants access to the user only after successful validation of passwords by both levels of authentication. If a user is authenticated locally, the user profile must be created in Citrix ADC database. If the user is authenticated externally then, the user name and password must match the user identity registered in the external authentication server.

**Note:**

Two factor authentication feature works on Citrix ADC 12.1 build 51.16 onwards.

How two-factor authentication works

Consider a user trying to log on to a Citrix ADC appliance. The requested application server sends the user name and password to the first external authentication server (RADIUS, TACACS, LDAP or AD). Once the username and password are validated, the user is prompted for second level of authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance. The below diagram is an illustration of how two-factor authentication works for a Citrix ADC appliance.

Following are the different use cases for configuring two factor authentication for external and system users.
Configuring two-factor authentication for Citrix ADC management access

You can configure two-factor authentication feature on a Citrix ADC appliance in different ways. The configuration scenarios are given below:

1. Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH.
2. External authentication enabled and local authentication disabled for system users.
3. External authentication enabled with policy based local authentication for system users.
4. External authentication disabled for system users with local authentication enabled.
5. External authentication enabled and local authentication enabled for system users.
6. External authentication enabled for selected LDAP users

Case 1: Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH

Two-factor authentication is enabled and available across all Citrix ADC management access for GUI, API, and SSH.

Case 2: Two factor authentication is supported on external authentication servers such as LDAP, RADIUS, Active Directory and TACACS

You can configure two-factor authentication on the following external authentication servers for first-level and second-level user authentication.

- RADIUS
- LDAP
- Active Directory
- TACACS

Case 3: External authentication enabled and local authentication disabled for system users

You begin the authentication process by enabling the external authentication option and disabling local authentication for system users.

Complete the following steps by using the command line interface:

1. Add authentication action for LDAP policy
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add and bind authentication policy label to RADIUS server
7. Bind system global authentication for LDAP policy
8. Disable local authentication in system parameter

**Add authentication action for LDAP server (first level authentication)**

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password> -ldaploginname <loginname> -groupattrname <grp attribute name> -subAttribute name <string> -ssoNameAttribute <string>
```

**Example:**

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttribute Name name -ssoNameAttribute name
```

**Add authentication policy for LDAP server (first level authentication)**

At the command prompt, type:

```
add authentication policy <ldap policy name> -rule true -action <ldap action name>
```

**Example:**

```
add authentication policy pol1 -rule true -action ldapact1
```

**Add authentication action for RADIUS server (second level authentication)**

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>
```

**Example:**

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttributeType 2
```

**Add authentication policy for RADIUS server (second level authentication)**

At the command prompt, type:
add authentication policy <radius policy name> -rule true -action <rad action name>

**Example:**

add authentication policy radpoll1 -rule true -action radact11

**Add authentication login schema**

You can use the “SingleAuth.xml” login schema for system users to provide the second password for the Citrix ADC appliance. At the command prompt, type:

add authentication loginSchema <login schema name> -authenticationSchema LoginSchema/SingleAuth.xml

**Example:**

add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml

**Add and bind authentication policy label to RADIUS server**

At the command prompt, type:

add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )] [-comment <string>][-loginSchema <string>]

bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>][-nextFactor <string>]

**Example:**

add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel label1 -policyName rad_poll1 -priority 1

**Bind authentication system global for LDAP policy**

At the command prompt, type:

bind system global ldappolicy -priority <priority> -nextFactor <policy label name>

**Example:**

bind system global radpoll1 -priority 1 -nextFactor label1
Disable local authentication in system parameter

At the command prompt, type:

set system parameter -localauth disabled

Case 4: External authentication enabled for system user with local authentication policy attached

In this scenario, the user is allowed to log on to the appliance using two-factor authentication with local authentication policy evaluation at the second level of user identification.

Complete the following steps by using the command line interface.

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add local authentication policy
4. Add authentication policy label
5. Bind LDAP policy as system global
6. Disable local authentication in system parameter

Add authentication action for LDAP server (first level authentication)

At the command prompt, type:

add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginnname < loginname> -groupAttrName <grp attribute name> -subAttributename <string>-ssoNameAttribute <string>

Example:

add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name -ssoNameAttribute name

Add authentication policy for LDAP server (first level authentication)

At the command prompt, type:

add authentication policy <ldap policy name> -rule true -action <ldap action name>

Example:
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDN name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name

Add local authentication policy for system users (second level authentication)

At the command prompt, type:

add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>

Example:

add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttributeType 2

Add and bind authentication policy label

At the command prompt, type:

add authentication policylabel <labelName> [-type (AAATM_REQ | RBA_REQ)] [-comment <string>] [-loginSchema <string>] bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]

Example:

add authentication policylabel label1 -type RBA_REQ -loginSchema radschema bind authentication policylabel label1 -policyName rad_pol11 -priority 1

Disable local authentication in system parameter

At the command prompt, type:

set system parameter -localauth disabled

Case 5: External authentication disabled and local authentication enabled for system user

If the user has “externalAuth” disabled, it indicates the user does not exist on the authentication server. User will not be authenticated with the external authenticated server even if user with same username exists on the external authenticated server. User will be authenticated locally.
To enable system user password and disable external authentication

At the command prompt, type the following:

```
add system user <name> <password> -externalAuth DISABLED
```

**Example:**

```
add system user user1 password1 -externalAuth DISABLED
```

**Case 6: External authentication enabled and local authentication enabled for system users**

To configure the appliance to authenticate system users using local password. If this authentication fails, the user is then authenticated using external authentication password on the external authentication servers at two levels.

To configure using command line interface, follow the steps given below:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy
9. Bind authentication system global for LDAP policy

**Add authentication action for LDAP server**

At the command prompt, type:

```
add authentication ldapaction <ldap_action_name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn_name> -ldapbinddnpassword <password>-ldaploginname <loginnname> -groupattrname <grp_attribute_name> -subAttributename <>-ssoNameAttribute <>
```

**Example:**

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name
```
Add authentication policy for LDAP policy

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action name>
```

Example:

```
add authentication policy poll --rule true -action ldapact1
```

Add authentication action for RADIUS server

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttributeType 2
```

Add advanced authentication policy for RADIUS server

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <rad action name>
```

Example:

```
add authentication policy radpoll --rule true -action radact1
```

Add authentication login schema

You can use the SingleAuth.xml login schema to display the login page and authenticate the system user at the second level authentication.

At the command prompt, type:

```
add authentication loginSchema <name> -authenticationSchema <string>
```

Example:

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml
```
Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )] [-comment <string>] [-loginSchema <string>]
```

**Example:**

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
```

```
bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]
```

**Example:**

```
bind authentication policylabel label1 -policyName rad_pol11 -priority 1
```

Bind authentication policy global

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor <string>] [-gotoPriorityExpression <expression>]]
```

**Example:**

```
bind system global radpol11 -priority 1 -nextFactor label11
```

Case 7: External authentication enabled for selected external users only

To configure selective external users with two-factor authentication as per the search filter configured in LDAP action while other system users are authenticated using single factor authentication.

To configure using command line interface, follow the steps given below:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy
Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase < > -ldapbinddn <binddn name> -ldapbindDnpassword <password>-ldaploginname <loginname> -groupattrname <grp attribute name> -subAttributename <>-ssoNameAttribute <>
```

**Example:**

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDnpassword password -ldapLoginName name -groupAttrName name -subAttribute name -ssoNameAttribute name
```

Add authentication policy for LDAP policy

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action name>
```

**Example:**

```
add authentication policy pol1 -rule true -action ldapact1
```

Add authentication action for RADIUS server

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip> -
-radkey <key> -radVendorID <ID >-radattributetype <rad attribute type>
```

**Example:**

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
-radVendorID 1234 -radAttributeType 2
```

Add advanced authentication policy for RADIUS server

At the command prompt, type:

```
add authentication policy <policy name> -rule true -action <rad action name>
```

**Example:**

```
add authentication policy radpol11 -rule true -action radact11
```
Add authentication login schema

You can use the SingleAuth.xml login schema to provide the login page for the appliance to authenticate a system user at second level of authentication.

At the command prompt, type:

```
add authentication loginSchema <name> -authenticationSchema <string>
```

**Example:**

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml
```

Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:

```
add authentication policylabel <labelName> [-type (AAATM_REQ | RBA_REQ)] [-comment <string>] [-loginSchema <string>]
```

**Example:**

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]
```

**Example:**

```
bind authentication policylabel label1 -policyName rad_pol11 -priority
```

Bind authentication policy global

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor <string>] [-gotoPriorityExpression <expression>]]
```

**Example:**

```
bind system global radpol11 -priority 1 -nextFactor label1
```

To configure without two-factor authentication for group users using search filter:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP server
3. Bind authentication system global for LDAP server
Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname <loginname> -groupattrname <grp attribute name> -subAttribute name <>-searchFilter<>
```

**Example:**

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name - searchFilter "memberOf=CN=grp4,CN=Users,DC=aaatm-test,DC=com"
```

Add authentication policy for LDAP server

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action name>
```

**Example:**

```
add authentication policy pol1 -rule true -action ldapact1
```

Bind authentication system global for LDAP policy

At the command prompt, type:

```
bind system global ldappolicy -priority <priority> -nextFactor <policy label name>
```

**Example:**

```
bind system global radpol11 -priority 1 -nextFactor label11
```

Display customized prompt message for two factor authentication

When you configure two factor password field with SingleAuth.xml file at `/flash/nsconfig/loginschema/LoginSchema`

Following is the snippet of SingleAuth.xml file where ‘SecondPassword:’ is the 2nd password field name which will be prompted to user to enter 2nd password.
Configuring two-factor authentication by using the Citrix ADC GUI

1. Log onto Citrix ADC appliance.

2. Go to System > Authentication > Advanced Policies > Policy.

3. Click Add to create the first level authentication policy.
4. In **Create Authentication Policy** page, set the following parameters.
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS etc.
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create a new action of the proper type.
   d) Expression. Provide an advanced policy expression.

5. Click **Create** and then **Close**.
   a) Expression. Provide an advanced policy expression.

6. Click **Create**.

7. Click **Add** to create the second level authentication policy.

8. In the **Create Authentication Policy** page, set the follow parameters
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS etc.
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create an action of the proper type.
   d) Expression. Provide an advanced policy expression

9. Click **Create** and then **Close**.
   a) Expression. Provide an advanced policy expression.

10. Click **Create**.

11. In the **Authentication Policies** page, click **Global Binding**.

12. In the **Create Global Authentication Policy Binding** page, select the first level authentication policy and click **Add Binding**.

13. In the **Policy Binding** page, select the authentication policy and set the following policy binding parameter.
   a) Next Factor. Select the second level authentication policy label.

14. Click **Bind** and **Close**.

15. Click **Done**.

16. Log on to the Citrix ADC appliance for the second level authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance.

For more information about Configuring login schema, see **Native OTP Support** feature.

TCP Configurations

January 25, 2019
Contributed by: C

TCP configurations for a Citrix ADC appliance can be specified in an entity called a TCP profile, which is a collection of TCP settings. The TCP profile can then be associated with services or virtual servers that want to use these TCP configurations.

A default TCP profile can be configured to set the TCP configurations that will be applied by default, globally to all services and virtual servers.

**Note**
When a TCP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence. The Citrix ADC appliance also provides other approaches for configuring TCP. Read on for more information.

**Supported TCP configuration**

The Citrix ADC appliance supports the following TCP capabilities:

**Defending TCP against spoofing attacks**

The Citrix ADC implementation of window attenuation is RFC 4953 compliant.

**Explicit Congestion Notification (ECN)**

The appliance sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption. The Citrix ADC implementation of ECN is RFC 3168 compliant.

**Round trip time measurement (RTTM) using the timestamp option**

For the TimeStamp option to work, at least one side of the connection (client or server) must support it. The Citrix ADC implementation of TimeStamp option is RFC 1323 compliant.
Detection of spurious retransmissions

This can be done using TCP duplicate selective acknowledgement (D-SACK) and forward RTO-Recovery (F-RTO). In case of spurious retransmissions, the congestion control configurations are reverted to their original state. The Citrix ADC implementation of D-SACK is RFC 2883 compliant, and F-RTO is RFC 5682 compliant.

Congestion control

This functionality use New-Reno, BIC, CUBIC, Nile and TCP Westwood algorithms.

Window scaling

This increases the TCP receive window size beyond its maximum value of 65,535 bytes.

Points to consider before you configure window scaling

- You do not set a high value for the scale factor, because this could have adverse effects on the appliance and the network.
- You do not configure window scaling unless you clearly know why you want to change the window size.
- Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, window scaling is not used for the connection.
- Each connection for same session is an independent window scaling session. For example, when a client’s request and the server’s response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.

TCP maximum congestion window

The window size is a user configurable one. The default value is 8190 bytes.

Selective acknowledgment (SACK)

This uses the data receiver (either a Citrix ADC appliance or a client) notifies the sender about all the segments that have been received successfully.
Forward acknowledgment (FACK)

This functionality avoids TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either a Citrix ADC or a client) control the amount of data injected into the network during retransmission timeouts.

TCP connection multiplexing

This functionality enables reuse of existing TCP connections. The Citrix ADC appliance stores established TCP connections to the reuse pool. Whenever a client request is received, appliance checks for an available connection in the reuse pool and serves the new client if the connection is available. If it is unavailable, the appliance creates a new connection for the client request and stores the connection to the reuse pool. Citrix ADC supports connection multiplexing for HTTP, SSL, and DataStream connection types.

Dynamic receive buffering

This allows the receive buffer to be adjusted dynamically based on memory and network conditions.

MPTCP Connection

MPTCP connections between client and Citrix ADC. MPTCP connections are not supported between Citrix ADC and the backend server. The Citrix ADC implementation of MPTCP is RFC 6824 compliant.

You can view MPTCP statistics such as active MPTCP connections and active subflow connections by using the command line interface.

At the command prompt, type one of the following commands to display a summary or detailed summary of MPTCP statistics, or to clear the statistics display:

1. Stat MPTCP
2. Stat mptcp –detail
3. Clearstats basic

Note

To establish an MPTCP connection, both the client and the Citrix ADC appliance must support the same MPTCP version. If you use the Citrix ADC appliance as an MPTCP gateway for your servers, the servers do not have to support MPTCP. When the client starts a new MPTCP connection, the appliance identifies the client’s MPTCP version from the MP_CAPABALE option in the SYN packet. If the client’s version is higher than the one supported on the appliance, the
appliance indicates its highest version in the MP_CAPABALE option of the SYN-ACK packet. The client then falls back to a lower version and sends the version number in the MP_CAPABALE option of the ACK packet. If that version is supportable, the appliance continues the MPTCP connection. Otherwise, the appliance falls back to a regular TCP. The Citrix ADC appliance does not initiate subflows (MP_JOIN’s). The appliance expects the client to initiate subflows.

**Extracting the TCP/IP path overlay option and inserting client-IP HTTP header**

Extracting TCP/IP path overlay and inserting client-IP HTTP header. Data transport through overlay networks often uses connection termination or Network Address Translation (NAT), in which the IP address of the source client is lost. To avoid this, the Citrix ADC appliance extracts the TCP/IP path overlay option and inserts the source client’s IP address into the HTTP header. With the IP address in the header, the web server can identify the source client that made the connection. The extracted data is valid for lifetime of the TCP connection and therefore, this prevents the next hop host from having to interpret the option again. This option is applicable only for web services that have the client-IP insertion option enabled. For more information, see Client Insertion on backend topic.

**TCP segmentation offload**

**Synchronizing cookie for TCP handshake with clients**

**Learning MSS to enable MSS learning for all the virtual servers configured on the appliance**

**Supportable TCP Parameters**

The following table provides a list of TCP parameters and its default value configured on a Citrix ADC appliance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window Management</td>
<td></td>
<td></td>

</table>

**Setting Global TCP Parameters**

The Citrix ADC appliance allows you to specify values for TCP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default TCP profile
- Global TCP command
- TCP buffering feature

**Note:**
The recvBuffSize parameter of the set ns tcpParam command is deprecated from release 9.2 onwards. In later releases, set the buffer size by using the bufferSize parameter of the set ns tcpProfile command. If you upgrade to a release where the recvBuffSize parameter is deprecated, the bufferSize parameter is set to its default value.

**Default TCP profile**

A TCP profile, named as nstcp_default_profile, is used to specify TCP configurations that will used if no TCP configurations are provided at the service or virtual server level.

**Note:**
Not all TCP parameters can be configured through the default TCP profile. Some settings have to be performed by using the global TCP command (see section below).

- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default TCP profile

- Using the command line interface, at the command prompt enter:
  
  set ns tcpProfile nstcp_default_profile ...

- On the GUI, navigate to System > Profiles, click TCP Profiles and update nstcp_default_profile.

**Global TCP command**

Another approach you can use to configure global TCP parameters is the global TCP command. In addition to some unique parameters, this command duplicates some parameters that can be set by
using a TCP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default TCP profile.

For example, if the SACK parameter is updated using this approach, the value is reflected in the SACK parameter of the default TCP profile (nstcp_default_profile).

**Note:**

Citrix recommends that you use this approach only for TCP parameters that are not available in the default TCP profile.

To configure the global TCP command

- Using the command line interface, at the command prompt enter:
  
  ```
  set ns tcpParam ...
  ```

- On the GUI, navigate to System > Settings, click Change TCP parameters and update the required TCP parameters.

**TCP buffering feature**

Citrix ADC provides a feature called TCP buffering that you can use to specify the TCP buffer size. The feature can be enabled globally or at service level.

**Note**

The buffer size can also be configured in the default TCP profile. If the buffer size has different values in the TCP buffering feature and the default TCP profile, the greater value is applied.

**To configure the TCP buffering feature globally**

- At the command prompt enter:
  
  ```
  enable ns mode TCPB
  set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>
  ```

- On the GUI, navigate to **System > Settings**, click **Configure Modes** and select **TCP Buffering**. And, navigate to **System > Settings**, click **Change TCP parameters** and specify the values for **Buffer size** and **Memory usage limit**.

**Setting Service or Virtual Server Specific TCP Parameters**

Using TCP profiles, you can specify TCP parameters for services and virtual servers. You must define a TCP profile (or use a built-in TCP profile) and associate the profile with the appropriate service and virtual server.
Note:
You can also modify the TCP parameters of default profiles as per your requirements.

- You can specify the TCP buffer size at service level using the parameters specified by the TCP buffering feature.

To specify service or virtual server level TCP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the TCP profile.

   `set ns tcpProfile <profile-name>...`

2. Bind the TCP profile to the service or virtual server.

   `set service <name> ....`

   **Example**: `set service service1 -tcpProfileName profile1`

   To bind the TCP profile to the virtual server:

   `set lb vserver <name> ....`

   **Example**: `set lb vserver lbvserver1 -tcpProfileName profile1`

   To specify service or virtual server level TCP configurations by using the GUI

At the GUI, perform the following:

1. Configure the TCP profile.

   Navigate to **System > Profiles > TCP Profiles**, and create the TCP profile.

2. Bind the TCP profile to the service or virtual server.

   Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the TCP profile, which should be bound to the service or virtual server.

**Built-in TCP Profiles**

For convenience of configuration, the Citrix ADC provides some built-in TCP profiles. Review the built-in profiles listed below and select a profile and use it as it is or modify it to meet your requirements.
You can bind these profiles to your required services or virtual servers.

<table>
<thead>
<tr>
<th>Built-in profile</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nstcp_default_profile</td>
<td>Represents the default global TCP settings on the appliance.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lan</td>
<td>Useful for back-end server connections, where these servers reside on the same LAN as the appliance.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lan_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lan profile; however, the settings are tuned to small size packet flows.</td>
</tr>
<tr>
<td>nstcp_default_tcp_interactive_stream</td>
<td>Similar to the nstcp_default_tcp_lan profile; however, it has a reduced delayed ACK timer and ACK on PUSH packet settings.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lfp</td>
<td>Useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lfp_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lfp profile; however, the settings are tuned for small size packet flows.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lnp</td>
<td>Useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss once in a while.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lnp_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lnp profile; however, the settings are tuned for small size packet flows.</td>
</tr>
<tr>
<td>nstcp_internal_apps</td>
<td>Useful for internal applications on the appliance (for example, GSLB sitesyncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.</td>
</tr>
<tr>
<td>nstcp_default_Mobile_profile</td>
<td>Useful for mobile devices.</td>
</tr>
<tr>
<td>nstcp_default_XA_XD_profile</td>
<td>Useful for a XenApp or XenDesktop deployment.</td>
</tr>
</tbody>
</table>
Sample TCP Configurations

Sample command line interface examples for configuring the following:

Defending TCP against spoofing attacks

Enable the Citrix ADC to defend TCP against spoof attacks. By default the “rstWindowAttenuation” parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable, it will reply with corrective acknowledgement (ACK) for an invalid sequence number. Possible values are Enabled, Disabled.

Where RST window attenuate parameter protects the appliance against spoofing. When enabled, will reply with corrective ACK when a sequence number is invalid.

```
1 > set ns tcpProfile profile1 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```

Explicit Congestion Notification (ECN)

Enable ECN on the required TCP profile

```
1 > set ns tcpProfile profile1 -ecn ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```

Selective ACKnowledgment (SACK)

Enable SACK on the required TCP profile.

```
1 > set ns tcpProfile profile1 -sack ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```
**Forward ACKnowledgment (FACK)**

Enable FACK on the required TCP profile.

```
1 > set ns tcpProfile profile1 -FACK ENABLED
2  Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4  Done
```

**Window Scaling (WS)**

Enable window scaling and set the window scaling factor on the required TCP profile.

```
1 > set ns tcpProfile profile1 -WS ENABLED -WSVal 9
2  Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4  Done
```

**Maximum Segment Size (MSS)**

Update the MSS related configurations.

```
1 > set ns tcpProfile profile1 -mss 1460 -maxPktPerMss 512
2  Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4  Done
```

**Citrix ADC to learn the MSS of a virtual server**

Enable the Citrix ADC to learn the VSS and update other related configurations.

```
1 > set ns tcpParam -learnVsvrMSS ENABLED -mssLearnInterval 180 -mssLearnDelay 3600
2  Done
```

**TCP keep-alive**

Enable TCP keep-alive and update other related configurations.
Buffer size - using TCP profile

Specify the buffer size.

MPTCP

Enable MPTCP and then set the optional MPTCP configurations.
**Congestion control**

Set the required TCP congestion control algorithm.

```
1 > set ns tcpProfile profile1 -flavor Westwood
2  Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4  Done
```

**Dynamic receive buffering**

Enable dynamic receive buffering on the required TCP profile.

```
1 > set ns tcpProfile profile1 -dynamicReceiveBuffering ENABLED
2  Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4  Done
```

**Support for TCP Fast Open (TFO) in Multipath TCP (MPTCP)**

A Citrix ADC appliance now supports TCP Fast Open (TFO) mechanism for establishing Multipath TCP (MPTCP) connections and speed up data transfers. The mechanism allows subflow data to be carried during the initial MPTCP connection handshake in SYN and SYN-ACK packets and also enables data to be consumed by the receiving node during the MPTCP connection establishment.

For more information, see [TCP Fast Open](#) topic.

**Support for Variable TFO Cookie Size for MPTCP**

A Citrix ADC appliance now enables you to configure a variable length TCP Fast Open (TFO) cookie of a minimum size of 4 bytes and a maximum size of 16 bytes in a TCP profile. By doing this, the appliance can respond with the configured TFO cookie size in the SYN-ACK packet to the client.

To configure TCP Fast Open (TFO) cookie in a TCP profile by using the command line interface

At the command prompt, type:

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize <positive_integer>
```

Example

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize 8
```

To configure TCP Fast Open (TFO) cookie in a TCP profile by using GUI
1. Navigate to **Configuration > System > Profiles**.
2. In the details pane, go to **TCP Profiles** tab and select a TCP profile.
3. In the **Configure TCP Profile** page, set the **TCP Fast Open** cookie size.
4. Click **OK** and **Done**.

**SYN-Cookie timeout interval**

In a Citrix ADC appliance, by default, the SYN cookie parameter on the TCP profile is enabled to resist SYN attacks. If you prefer to detect an attack for a virtual server and check the SYN-ACK retransmission rate, the SYN cookie value is toggled from Enabled to Disabled state. However, the toggling effect of the cookie from Enabled to Disabled state and vice versa causes a configuration inconsistency between nodes in a cluster deployment. To overcome this, you can use the second SYN cookie parameter maintained on each virtual server of the appliance. When a SYN attack is detected, the SYN cookie on the TCP profile is disabled and the second SYN cookie value on the server is toggled from Disabled to Enabled state. The cookie remains in Enabled state for an autosyncookietimeout interval that you can specify. During the timeout interval, the virtual server fights the SYN attack in SYN Cookie mode. After the interval times out, the SYN Cookie value is toggled back to Disabled state if the virtual server’s SYN-ACK retransmission rate is below the threshold. Otherwise, if the rate is still above the threshold, it implies it is a SYN attack and the cookie is again toggled to Enabled state for the specified timeout period.

To configure the maximum SYN ACK retransmission threshold by using the command line interface

At the command prompt, type:

```
set ns tcpparam [-maxSynAckRetx <positive_integer>]
```

```
Set ns tcpparam [-maxSynAckRetx 150]
```

To configure auto SYN cookie timeout interval by using the command line interface

At the command prompt, type:

```
set ns tcpparam [-autosyncookietimeout <positive_integer>]
```

```
Set ns tcpparam [-autosyncookietimeout 90]
```

HTTP configurations

May 16, 2019
Contributed by:
C
HTTP configurations for a Citrix ADC appliance can be specified in an entity called an HTTP profile, which is a collection of HTTP settings. The HTTP profile can then be associated with services or virtual servers that want to use these HTTP configurations.

A default HTTP profile can be configured to set the HTTP configurations that will be applied by default, globally to all services and virtual servers.

Note: When a HTTP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.

The Citrix ADC appliance also provides other approaches for configuring HTTP. Read on for more information.

The Citrix ADC supports WebSocket protocol which allows browsers and other clients to create a bi-directional, full duplex TCP connection to the servers. The Citrix ADC implementation of WebSocket is RFC 6455 compliant.

Note
A Citrix ADC appliance now supports the User Source IP (USIP) address configuration for both HTTP/1.1 and HTTP/2 protocols.

Setting global HTTP parameters

The Citrix ADC appliance allows you to specify values for HTTP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default HTTP profile
- Global HTTP command

Default HTTP profile

A HTTP profile, named as nshttp_default_profile, is used to specify HTTP configurations that will be used if no HTTP configurations are provided at the service or virtual server level.
Note:

• Not all HTTP parameters can be configured through the default HTTP profile. Some settings have to be performed by using the global HTTP command (see section below).
• The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default HTTP profile

• Using the command line interface, at the command prompt enter:
  
  set ns httpProfile nshttp_default_profile ...

• On the GUI, navigate to System > Profiles, click HTTP Profiles and update nshttp_default_profile.

Global HTTP command

Another approach you can use to configure global HTTP parameters is the global HTTP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a HTTP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default HTTP profile.

For example, if the maxReusePool parameter is updated using this approach, the value is reflected in the maxReusePool parameter of the default HTTP profile (nshttp_default_profile).

Note:

Citrix recommends that you use this approach only for HTTP parameters that are not available in the default HTTP profile.

To configure the global HTTP command

• Using the command line interface, at the command prompt enter:
  
  set ns httpParam ...

• On the GUI, navigate to System > Settings, click Change HTTP parameters and update the required HTTP parameters.

Setting service or virtual server specific HTTP parameters

Using HTTP profiles, you can specify HTTP parameters for services and virtual servers. You must define a HTTP profile (or use a built-in HTTP profile) and associate the profile with the appropriate service and virtual server.

Note:

You can also modify the HTTP parameters of default profiles as per your requirements.
To specify service or virtual server level HTTP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the HTTP profile.
   
   ```
   set ns httpProfile <profile-name>...
   ```

2. Bind the HTTP profile to the service or virtual server.
   
   To bind the HTTP profile to the service:
   ```
   set service <name> ..... 
   ```

   **Example:**
   ```
   > set service service1 -httpProfileName profile1
   ```

   To bind the HTTP profile to the virtual server:
   ```
   > set lb vserver <name> ..... 
   ```

   **Example:**
   ```
   > set lb vserver lbvserver1 -httpProfileName profile1
   ```

To specify service or virtual server level HTTP configurations by using the GUI

At the GUI, perform the following:

1. Configure the HTTP profile.

   Navigate to **System > Profiles > HTTP Profiles**, and create the HTTP profile.

2. Bind the HTTP profile to the service or virtual server.

   Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the HTTP profile, which should be bound to the service/virtual server.
Built-in HTTP profiles

For convenience of configuration, the Citrix ADC provides some built-in HTTP profiles. Review the profiles listed below and use it as it is or modify it to meet your requirements. You can bind these profiles to the required services or virtual servers.

<table>
<thead>
<tr>
<th>Built-in profile</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nshttp_default_profile</td>
<td>Represents the default global HTTP settings on the appliance.</td>
</tr>
<tr>
<td>nshttp_default_strict_validation</td>
<td>Settings for deployments that require strict validation of HTTP requests and responses.</td>
</tr>
</tbody>
</table>

Sample HTTP configurations

Sample command line interface examples to configure the following:

- HTTP band statistics
- WebSocket connections

HTTP band statistics

Specify the band size for HTTP requests and responses.

```
1 > set protocol httpBand reqBandSize 300 respBandSize 2048
2 Done
3 > show protocol httpband -type REQUEST
```

WebSocket connections

Enable webSocket on the required HTTP profile.

```
1 > set ns httpProfile http_profile1 -webSocket ENABLED
2 Done
3 > set lb vserver lbvserver1 -httpProfileName profile1
4 Done
```
Configuring HTTP/2 on the Citrix ADC appliance

January 25, 2019
Contributed by: C

Note: The HTTP/2 functionality is supported on the Citrix ADC MPX, VPX, and SDX models. For Citrix ADC VPX, the HTTP/2 functionality is supported from 11.0 release onwards.

The problem with web application performance is directly related to the trend toward increasing the page size and the number of objects on the web pages. HTTP/1.1 was developed to support smaller web pages, slower Internet connections, and more limited server hardware than are common today. It is not well suited for newer technologies such as JavaScript and cascading style sheets (CSS), nor for new media types such as Flash videos and graphics-rich images, because it can request only one resource per connection to the server. This limitation significantly increases the number of round trips, causing longer page-rendering time and reduced network performance.

The HTTP/2 protocol addresses these limitations by allowing communication to occur with less data transmitted over the network, and providing the ability to send multiple requests and responses across a single connection. At its core, HTTP/2 addresses the key limitations of HTTP/1.1 by using the underlying network connections more efficiently. It changes the way requests and responses travel over the network.

HTTP/2 is a binary protocol. It is more efficient to parse, more compact on the wire, and most importantly, it is less error-prone, compared to textual protocols like HTTP/1.1. The HTTP/2 protocol uses a binary framing layer that defines the frame type and how HTTP messages are encapsulated and transferred between the client and server. The HTTP/2 functionality supports the use of the CONNECT method to establish a tunnel connection through a single HTTP/2 stream to a remote host.

The HTTP/2 protocol includes a lot of performance-enhancing changes that significantly improve performance, particularly for clients connecting over a mobile network.

The following table lists the major improvements in HTTP/2 over HTTP/1.1:

<table>
<thead>
<tr>
<th>HTTP/2 Features</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header Compression</td>
<td>HTTP headers have a lot of repetitive information and therefore consume unnecessary bandwidth during data transmission. HTTP/2 reduces bandwidth requirements by compressing the header and minimizing the requirement to transport HTTP headers with every request and response.</td>
</tr>
</tbody>
</table>
Connection Multiplexing
Latency can have a huge impact on page load times and the end user experience. Connection multiplexing overcomes this problem by sending multiple requests and responses across a single connection.

Server Push
Server push enables the server to proactively push content to the client browser, avoiding round trip delay. This feature caches the responses it thinks the client will need, reduces the number round trips, and improves the page rendering time. Important: The Citrix ADC appliance does not support the server push functionality.

No Head-of-line Blocking
Under HTTP/1.1, browsers can download one resource at a time per connection. When a browser has to download a large resource, it blocks all other resources from downloading until the first download is complete. HTTP/2 overcomes this problem with a multiplexing approach. It allows the client browser to download other web components in parallel over the same connection and display them as they become available.
HTTP/2 Features | Description
---|---
Request Prioritization | Not all resources have equal priority when the browser renders a web page. To accelerate the load time, all modern browsers prioritize requests by type of asset, their location on the page, and even by learned priority from previous visits. With HTTP/1.1, the browser has limited ability to leverage the priority data, because this protocol does not support multiplexing, and there is no way to communicate request prioritization by the server. The result is unnecessary network latency. HTTP/2 overcomes this problem by allowing the browser to dispatch all requests. The browser can communicate its stream prioritization preference via stream dependencies and weights, enabling the servers to optimize response delivery. Important: The Citrix ADC appliance does not support the request prioritization functionality.

**How HTTP/2 works on a Citrix ADC appliance**

A Citrix ADC appliance supports HTTP/2 on the client side as well on the server side. On the client side, the Citrix ADC appliance acts as a server that hosts an HTTP/HTTPS virtual server for HTTP/2. On the backend side, the Citrix ADC acts as a client to the servers that are bound to the virtual server.

Therefore, the Citrix ADC appliance maintains separate connections on the client side as well on the server side. The Citrix ADC appliance has separate HTTP/2 configurations for the client side and the server side.

**HTTP/2 for HTTPS (SSL) load balancing configuration**

For an HTTPS load balancing configuration, the Citrix ADC appliance uses the TLS ALPN extension (RFC 7301) to determine whether the client/server supports HTTP/2. If it does, the appliance chooses HTTP/2 as the application-layer protocol to transmit data (as described in RFC 7540 - Section 3.3) on the client/server side.
The appliance uses the following order of preference when choosing the application-layer protocol through the TLS ALPN extension:

- HTTP/2 (if enabled in the HTTP profile)
- SPDY (if enabled in the HTTP profile)
- HTTP/1.1

**HTTP/2 for HTTP load balancing configuration**

For an HTTP load balancing configuration, the Citrix ADC appliance uses one of the following methods to start communicating with the client/server using HTTP/2.

**Note**

In the following method descriptions, client and server are general terms for an HTTP/2 connection. For example, for a load balancing setup of a Citrix ADC appliance using HTTP/2, the Citrix ADC appliance acts as a server on the client side and acts as a client to the server side.

- **HTTP/2 Upgrade.** A client sends an HTTP/1.1 request to a server. The request includes an upgrade header, which asks the server for upgrading the connection to HTTP/2. If the server supports HTTP/2, the server accepts the upgrade request and notifies it in its response. The client and the server start communicating using HTTP/2 after the client receives the upgrade confirmation response.

- **Direct HTTP/2.** A client directly starts communicating to a server in HTTP/2 instead of using the HTTP/2 upgrade method. If the server does not support HTTP/2 or is not configured to directly accept HTTP/2 requests, it drops the HTTP/2 packets from the client. This method is helpful if the admin of the client device already knows that the server supports HTTP/2.

- **Direct HTTP/2 using Alternative Service (ALT-SVC).** A server advertises that it supports HTTP/2 to a client by including an Alternative Service (ALT-SVC) field in its HTTP/1.1 response. If the client is configured to understand the ALT-SVC field, the client and the server start directly communicating using HTTP/2 after the client receives the response.

The Citrix ADC appliance provides configurable options in an HTTP profile for the HTTP/2 methods. These HTTP/2 options can be applied to the client side as well to the server side of an HTTPS or HTTP load balancing setup. For more information for HTTP/2 methods and options, refer to the [HTTP/2 options pdf](#).

**Before you Begin**

Before you begin configuring HTTP/2 on a Citrix ADC appliance, note the following points:

- The Citrix ADC appliance supports HTTP/2 on the client side as well on the server side.
• The Citrix ADC appliance does not support the HTTP/2 server push functionality.
• The Citrix ADC appliance does not support the HTTP/2 request prioritization functionality.
• The Citrix ADC appliance does not support HTTP/2 SSL renegotiation for HTTPS load balancing setups.
• The Citrix ADC appliance does not support HTTP/2 NTLM authentication.
• HTTP/2 does not work if User Source IP (USIP) mode is enabled and the Proxy mode is disabled on the Citrix ADC appliance.

**Configuring HTTP/2**

Configuring HTTP/2 for a load balancing setup (HTTPS or HTTP) consists of the following tasks:

• **Enable HTTP/2 and set optional HTTP/2 parameters in an HTTP Profile.** Enable HTTP/2 in an HTTP profile. When you only enable HTTP/2 in an HTTP profile, the Citrix ADC appliance uses only the upgrade method (for HTTP) or TLS ALPN method (for HTTPS) for communicating in HTTP/2.

  For the Citrix ADC appliance to use the direct HTTP/2 method, **Direct HTTP/2** option must be enabled in the HTTP profile. For the Citrix ADC appliance to use the direct HTTP/2 using the alternative service method, **Alternative Service (altsvc)** option must be enabled in the HTTP profile.

• **Bind the HTTP profile to a virtual server or a service.** Bind the HTTP profile to a virtual server to configure HTTP/2 for the client side of the load balancing setup. Bind the HTTP profile to a service to configure HTTP2 for the server side of the load balancing setup.

  **Note.**
  Citrix recommends binding separate HTTP profiles for the client side and the server side.

• **Enable the global parameter for HTTP/2 server side support.** Enable the **HTTP/2 Service Side (HTTP2Serverside)** global HTTP parameter for enabling the HTTP/2 support on the server side of all the load balancing setups that has HTTP/2 configured.

  HTTP/2 does not work on the server side of any load balancing setups if **HTTP/2 Service Side** is disabled even if the **HTTP/2** is enabled on the HTTP profile bound to the related load balancing services.

**Citrix ADC Command Line procedures:**

To enable HTTP/2 and set HTTP/2 parameters by using the Citrix ADC command line

• To enable HTTP/2 and set HTTP/2 parameters while adding an HTTP profile, at the command prompt, type:

  ```
  - add ns httpProfile <name> - http2 ( ENABLED | DISABLED ) [-http2Direct ( ENABLED | DISABLED )] [-altsvc ( ENABLED | DISABLED )]
  ```
To enable HTTP/2 and set HTTP/2 parameters while modifying an HTTP profile, at the command prompt, type:

```
set ns httpProfile <name> -http2 ( ENABLED | DISABLED ) \[-http2Direct ( ENABLED | DISABLED)\] \[-altsvc ( ENABLED | DISABLED )\]
```

To bind the HTTP profile to a virtual server by using the Citrix ADC command line

At the command prompt, type:

```
set lb vserver <name> - httpProfileName** <string>
show lb vserver** <name>
```

To bind the HTTP profile to a load balancing service by using the Citrix ADC command line

At the command prompt, type:

```
set service <name> -httpProfileName <string>
show service <name>
```

To enable HTTP/2 support globally on the server side by using the Citrix ADC command line

At the command prompt, type:

```
set ns httpParam -HTTP2Serverside ( ENABLED | DISABLED )
show ns httpParam
```

GUI Procedures

To enable HTTP/2 and set HTTP/2 parameters by using the GUI

1. Navigate to **System > Profiles**, and click **HTTP Profiles** tab.
2. Enable **HTTP/2** while adding an HTTP profile or modifying an existing HTTP profile.

To bind the HTTP profile to a virtual server by using the GUI

2. In **Advanced Settings**, click **+ HTTP Profile** to bind the created HTTP profile to the virtual server.

To bind the HTTP profile to a load balancing service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > service**, and open the service.
2. In **Advanced Settings**, click **+ HTTP Profile** to bind the created HTTP profile to the service.

To enable HTTP/2 support globally on the server side by using the GUI

Navigate to **System > Settings**, click **Change HTTP parameters** and enable **HTTP/2 Server Side**.
Sample configurations

In the following sample configuration, HTTP/2 and direct HTTP/2 is enabled on HTTP profile HTTP-PROFILE-HTTP2-CLIENT-SIDE. The profile is bound to virtual server LB-VS-1.

```
> set ns httpProfile HTTP-PROFILE-HTTP2-CLIENT-SIDE -http2 enabled -http2Direct enabled
Done

> set lb vserver LB-VS-1 -httpProfileName HTTP-PROFILE-HTTP2-CLIENT-SIDE
Done
```

In the following sample configuration, HTTP/2 and alternative service (ALT-SVC) is enabled on HTTP profile HTTP-PROFILE-HTTP2-SERVER-SIDE. The profile is bound to service LB-SERVICE-1.

```
> set ns httpparam -HTTP2Serverside ENABLED
Done

> set ns httpProfile HTTP-PROFILE-HTTP2-SERVER-SIDE -http2 ENABLED -altsvc ENABLED
Done

> set service LB-SERVICE-1 -httpProfileName HTTP-PROFILE-HTTP2-SERVER-SIDE
Done
```

3. Citrix ADC 12.1

SNMP

January 25, 2019

Contributed by:
C
You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix ADC appliance to generate asynchronous events, which are called traps. The traps are generated whenever there are abnormal conditions on the Citrix ADC. The traps are then sent to a remote device called a trap listener, which signals the abnormal condition on the Citrix ADC appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an SNMP manager. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

For information about SNMP parameters, traps, and its descriptions, see Citrix ADC SNMP OID reference.

The SNMP agent on the Citrix ADC can generate traps compliant with SNMPv1, SNMPv2, and SNMPv3. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

The following figure illustrates a network with a Citrix ADC that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the Citrix ADC. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.

Figure 1. Citrix ADC Supporting SNMP

Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a Citrix ADC appliance, you must download the MIB object definition files. The MIB files include the following:

‘MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP’

Citrix ADC-specific configuration and statistics.

You can obtain the MIB object definition files from the /netscaler/snmp directory or from the Downloads tab of the GUI.

If the SNMP management application is other than WhatsUpGold, download the following files to the SNMP management application:

NS-MIB-smiv1.mib. Used by SNMPv1 managers and trap listeners.

If the SNMP management application is WhatsUpGold, download the following files to the SNMP management application:

1. ‘mib.txt’
2. traps.txt
Configuring the Citrix ADC to generate SNMP traps

January 23, 2019
Contributed by: C

You can configure the Citrix ADC appliance to generate asynchronous events, which are called traps. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a trap listener. This helps administrators monitor the appliance and respond promptly to any issues.

The Citrix ADC appliance provides a set of condition entities called SNMP alarms. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the Citrix ADC appliance to generate traps, you need to enable and configure alarms. Then, you specify trap listeners to which the appliance will send the generated trap messages.

Enabling an SNMP alarm

The Citrix ADC appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `enable snmp alarm <trapName>`
- `show snmp alarm <trapName>`

To enable an SNMP alarm by using the GUI

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.
Configuring alarms

The Citrix ADC appliance provides a set of condition entities called **SNMP alarms**. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure will be assigned with the warning severity level.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the command line interface

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

- `set snmp alarm <trapName> [-thresholdValue <positive_integer>] [-normalValue <positive_integer>]] [-time <secs>] [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]

- `show snmp alarm <trapName>

Where,

ThresholdValue: Value for the high threshold. The Citrix ADC appliance generates an SNMP trap message when the value of the attribute associated with the alarm is greater than or equal to the specified high threshold value.

NormalValue: Value for the normal threshold. A trap message is generated if the value of the respective attribute falls to or below this value after exceeding the high threshold.

To configure SNMP alarms by using the GUI

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.
Configuring SNMPv1 or SNMPv2 traps

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the Citrix ADC IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener on the basis of a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

To add an SNMP trap by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
- add snmp trap <trapClass> <trapDestination> -version (V1 | V2) -
  destPort <port> -communityName <string> -srcIP <ip_addr> -severity <
  severity>
- show snmp trap
```

Example:

```
1 > ‘add snmp trap specific 10.102.29.3 -version V2 -destPort 80 -
  communityName com1 -severity Major’
```

To configure SNMP traps by using the GUI

Navigate to **System > SNMP > Traps**, and create the SNMP trap.
Configuring SNMPv3 traps

SNMPv3 provides security capabilities such as authentication and encryption by using the credentials of SNMP users. An SNMP manager can receive SNMPv3 trap messages only if its configuration includes the password assigned to the SNMP user.

The trap destination can now receive SNMPv1, SNMPv2, and SNMPv3 trap messages.

To configure an SNMPv3 trap by using the command line interface

At the command prompt, do the following:

1. Add an SNMPv3 trap.

   ```bash
   add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 | V3) -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>
   ```

   **Note:**
   Once set, the SNMP trap version cannot be modified.

   **Example**
   ```bash
   1 > add snmp trap specific 10.102.29.3 -version V3 -destPort 80 -communityName com1 -severity Major
   ```

2. Add an SNMP user.

   ```bash
   add snmp user <name> -group <string> [ -authType ( MD5 | SHA ){ -authPasswd } [ -privType ( DES | AES ){ -privPasswd } ]]
   ```

   **Example**
   ```bash
   1 > add snmp user edocs_user -group edocs_group
   ```

3. Bind the SNMPv3 trap to the SNMP user.

   ```bash
   bind snmp trap <trapClass> <trapDestination> [-version <version>] [-userName <string> [ -securityLevel <securityLevel>]]
   ```

   **Example**
   ```bash
   1 Example
   2  
   3   
   4   > bind snmp trap specific 10.102.29.3 -version V3 -userName edocs_user -securityLevel authPriv
   5   
   ```
To configure an SNMPv3 trap by using the GUI

1. Add an SNMPv3 trap.
   Navigate to System > SNMP > Traps, and create the SNMP trap by selecting V3 as the SNMP version.

2. Add an SNMP user.
   Navigate to System > SNMP > **Users and create the SNMP user.

3. Bind the SNMPv3 trap to the SNMP user.
   • Navigate to System > SNMP > Traps, and select the SNMP version 3 trap.
   • Select the user to which the trap should be bound and define the appropriate Security Level.

SNMP trap logging

A Citrix ADC appliance can log SNMP trap messages (for SNMP alarms in which logging capability is enabled) when you enable the SNMP trap logging option and at least one trap listener is configured on the appliance. Now, you can specify the audit log level of trap messages sent to an external log server. The default log level is Informational. Possible values are Emergency, Alert, Critical, Error, Warning, Debug, and Notice.

For example, you can set the audit log level to Critical for an SNMP trap message generated by a logon failure. That information is then available on the NSLOG or SYSLOG server for troubleshooting.

To enable SNMP trap logging and configure trap log level by using the command line interface

At the command prompt, type the following commands to configure SNMP trap logging and verify the configuration:

- set snmp option [-snmpTrapLogging (ENABLED | DISABLED)][-snmpTrapLoggingLevel <snmpTrapLoggingLevel>]
- show snmp option

To enable SNMP trap logging and configure SNMP trap log level by using the GUI

Navigate to System > SNMP, click Change SNMP Options and set the following parameters:

1. SNMP Trap Logging—Select this check box to enable SNMP trap logging when at least one trap listener is configured on the appliance.
2. SNMP Trap Logging Level—Select an audit log level for the SNMP trap. By default, the audit level for SNMP trap is set to “Informational.”

**Configuring Citrix ADC for SNMP v1 and v2 queries**

February 4, 2019
Contributed by: C

You can query the Citrix ADC SNMP agent for system-specific information from a remote device called SNMP managers. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called community strings and associate each of these to query types. You can associate one or more community strings to each query type. Community string are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as abc and bcd, to the query type GET NEXT, the SNMP agent on the Citrix ADC appliance considers only those GET NEXT SNMP query packets that contain abc or bcd as the community string.

**Specifying an SNMP manager**

You must configure the Citrix ADC appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required Citrix ADC-specific information. You can add up to a maximum of 100 SNMP managers or networks.

For an IPv4 SNMP manager you can specify a host name instead of the manager’s IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.
Note:
The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.

If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager

Example

> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30

To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager's host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager’s IP address. For more information, see “Adding a Name Server.”

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> [-domainResolveRetry *****<integer>]
- show snmp manager

Example

add nameserver 10.103.128.15
add snmp manager engwiki.eng.example.net -domainResolveRetry 10
To add an SNMP manager by using the GUI

1. Navigate to **System > SNMP > Managers**, and create the SNMP manager.

   **Important:**
   If you specify the SNMP manager’s host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager’s IP address.

   **Note:**
   The appliance does not support host names for SNMP managers that have IPv6 addresses.

Specifying an SNMP community

You can create strings called community strings and associate them with the following SNMP query types on the appliance:

- GET
- GET NEXT
- ALL
- GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as `abc` and `bcd`, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain `abc` or `bcd` as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp community <communityName> <permissions>`
- `show snmp community`

**Example**

> `add snmp community com all`
To configure an SNMP community string by using the GUI

Navigate to System > SNMP > Community, and create the SNMP community.

Configuring Citrix ADC for SNMPv3 queries

January 23, 2019
Contributed by:
C

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

• **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
  - **Data integrity:** To protect messages from being modified during transmission through the network.
  - **Data origin verification:** To authenticate the user who sent the message request.
  - **Message timeliness:** To protect against message delays or replays.
  - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.

• **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

Citrix ADC supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
SNMP Groups
SNMP Users

These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

Note:
The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each Citrix ADC appliance.

To implement message authentication and access control, you need to do the following:

### Setting the engine ID

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The Citrix ADC appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to override the engineID. However, if you want to change the engine ID, you can reset it.

**To set the engine ID by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `set snmp engineId <engineID>`
- `show snmp engineId`

**Example**

> `set snmp engineId 8000173f0300c095f80c68`

**To set the engine ID by using GUI**

Navigate to **System > SNMP > Users**, click **Configure Engine ID** and type an engine ID.
Configure a view

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.

To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp view <name> <subtree> -type (included | excluded)`
- `show snmp view <name>`
- `rm snmp view <name> <subtree>`

Where,

Name. Name for the SNMPv3 view. It can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 view.

Subtree. A particular branch (subtree) of the MIB tree that you want to associate with this SNMPv3 view. You must specify the subtree as an SNMP OID. This is an argument of maximum Length: 99.

type. Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view. This is a mandatory argument. Possible values: included, excluded.

Examples

```
add snmp view SNMPv3test 1.1.1.1 -type included
sh snmp view SNMPv3test
rm snmp view SNMPv3test 1.1.1.1
```

To configure an SNMP view by using the GUI

Navigate to System > SNMP > Views, and create the SNMP view.

Configure a group

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned
to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.

**To add an SNMP group by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp group <name> <securityLevel> -readViewName <string>`
- `show snmp group <name> <securityLevel>`

Where,

**Name.** Name for the SNMPv3 group. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 group.

**securityLevel.** Security level required for communication between the Citrix ADC appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

- `noAuthNoPriv`. Require neither authentication nor encryption.
- `authNoPriv`. Require authentication but no encryption.
- `authPriv`. Require authentication and encryption. Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for each group member. This is a mandatory argument. Possible values: noAuthNoPriv, authNoPriv, authPriv.

**readViewName.** Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the Citrix ADC appliance has multiple SNMPv3 view entries with the same name, all such entries are associated with the SNMPv3 group. This is a mandatory argument. Maximum Length: 31

**To configure an SNMP group by using the GUI**

Navigate to **System > SNMP > Groups**, and create the SNMP group.

**Configuring a user**

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.
You need to configure users at the agent and assign each user to a group.

**To configure a user by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp user <name> -group <string> [-authType ( MD5 | SHA ){ -authPasswd } [-privType ( DES | AES ){ -privPasswd } ]]`
- `show snmp user <name>`

Where,

- **authType** is the authentication option available while configuring an user. There are two authentication types such as MD5 and SHA.
- **privType** is the encryption option available while configuring an user. There are two types of encryption such as DES of key size 128 bit, and AES of key size 128 bit.

**Example**

```
$ > add snmp user edocs_user -group edocs_group
```

**To configure an SNMP user by using the GUI**

Navigate to **System > SNMP > Users**, and create the SNMP user.

1. Citrix ADC
2. Citrix ADC 12.1

**Configuring SNMP Alarms for rate limiting**

January 25, 2019

Contributed by: C

Citrix ADC appliances such as the Citrix ADC MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for
Citrix ADC 12.1

the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the Citrix ADC logs the events associated with the traps in the /var/log/ns.log file as EVENT ALERTSTARTED and EVENT ALERTENDED.

Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see “Configuring the Citrix ADC to generate SNMP v1 and v2 Traps.”

This document includes the following details:

- Configuring an SNMP Alarm for Throughput or PPS
- Configuring SNMP Alarm for Dropped Packets

**Configuring an SNMP alarm for throughput or PPS**

To monitor both throughout and PPS, you must configure separate alarms and set threshold pps value in Mbps.

**To configure an SNMP alarm for the throughput rate by using the command line interface**

At the command prompt, type the following commands to configure the SNMP alarm, set threshold value in Mbps and verify the configuration:

```
set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer>] [-normalValue <positive_integer>] [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]
```

```
show snmp alarm PF-RL-RATE-THRESHOLD
```

**Example**

```
> set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue 50
```
To configure an SNMP alarm for PPS by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state ( **ENABLED** | **DISABLED** )] [-severity <severity>] [-logging ( **ENABLED** | **DISABLED** )]
- show snmp alarm PF-RL-PPS-THRESHOLD

Example

```
$ > set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for throughput or PPS by using the GUI

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-THRESHOLD (for throughput rate) or PF-RL-PPS-THRESHOLD (for packets per second).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP alarm for dropped packets

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```
To configure an SNMP alarm for dropped packets by using the GUI

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-PKTS-DROPPED (for packets dropped because of excessive throughput) or PF-RL-PPS-PKTS-DROPPED (for packets dropped because of excessive PPS).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP in FIPS mode

January 23, 2019
Contributed by: C

FIPS mode requires Simple Network Management Protocol version 3 (SNMPv3) with the authentication and privacy (authPriv) option. SNMP version 1 and version 2 use a community string mechanism to provide secured access to management data. The community string is sent as clear text between an SNMP manager and an SNMP agent. This type of communication is unsecure, allowing intruders to access SNMP information on the network.

The SNMPv3 protocol uses the User-based Security Model (USM) and View-based Access Control Model (VACM) to authenticate and control management access to SNMP messaging data. SNMPv3 has three security levels: no authentication no privacy (noAuthNoPriv), authentication and no privacy (authNoPriv), and authentication and privacy (authPriv).

Enabling FIPS mode and restarting the Citrix ADC appliance removes the following SNMP configurations from the appliance:

1. Community configuration for SNMPv1 and SNMPv2 protocols.
2. SNMPv3 groups configured with the noAuthNoPriv or authNoPriv security-level option.
3. Traps configured for SNMPv1 or SNMPv2, or SNMPv3 with the noAuthNoPriv security-level option.

After restarting the appliance, configure SNMPv3 with the authPriv option. For more information about configuring authPriv option in SMNP v3, see SNMPV3 topic

Note:
Enabling FIPS mode and restarting your appliance blocks execution of the following SNMP trap
Audit logging

January 23, 2019

Contributed by:

Audit logging is a methodical examination or review of a condition or situation. The Audit Logging feature enables you to log the Citrix ADC states and status information collected by various modules in the kernel and in the user-level daemons. For audit logging, you can use the SYSLOG protocol, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components: the SYSLOG auditing module, which runs on the Citrix ADC appliance, and the SYSLOG server, which can run on the underlying FreeBSD operating system (OS) of the Citrix ADC appliance or on a remote system. SYSLOG uses user data protocol (UDP) for data transfer.

Similarly, the native NSLOG protocol has two components: the NSLOG auditing module, which runs on the Citrix ADC appliance, and the NSLOG server, which can run on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system. NSLOG uses transmission control protocol (TCP) for data transfer.

When you run a SYSLOG or NSLOG server, it connects to the Citrix ADC appliance. The Citrix ADC appliance then starts sending all the log information to the SYSLOG or NSLOG server, and the server can...
Citrix ADC 12.1

filter the log entries before storing them in a log file. An NSLOG or SYSLOG server can receive log information from more than one Citrix ADC appliance, and a Citrix ADC appliance can send log information to more than one SYSLOG server or NSLOG server.

If multiple SYSLOG servers are configured, the Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastPackets, and AuditlogHash.

Note
The Citrix ADC appliance can send audit log messages up to 16 KB to an external SYSLOG server.

The log information that a SYSLOG or NSLOG server collects from a Citrix ADC appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a Citrix ADC appliance that generated the log message.
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
- The message information

To configure audit logging, you first configure the audit modules on the Citrix ADC appliance. That involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system.

Note:
Because SYSLOG is an industry standard for logging program messages, and various vendors provide support, this documentation does not include SYSLOG server configuration information.

The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making additional modifications to the configuration file (auditlog.conf).

1. Citrix ADC
2. Citrix ADC 12.1
Configuring Citrix ADC appliance for audit logging

April 26, 2019
Contributed by: C

Auditing module allows logging of all states and status information from different modules so that an administrator can see event history in the chronological order. Main components of Audit framework are ‘audit action’, ‘audit policy’. ‘Audit action’ describes Audit Server configuration information whereas ‘audit policy’ links a bind entity to an ‘audit action’. The audit policies use ‘Classic Policy Engine’ (CPE) framework to link ‘audit action’ to ‘bind entities’ or Progress Integration (PI) framework to link ‘audit action’ to ‘system global bind entities’.

The policy frameworks differ from each other in the way the audit-log policies are bound to the global entities. Previously, the audit module supported only Classic expression but now it supports both Classic and Advanced policy expressions. Currently, the Advanced expression can bind audit-log policies only to System global entities.

Note
When binding a policy to global entities, you must bind a policy it to a system global entity of the same expression type. For example, you cannot bind a classic policy to an advanced global entity or bind an advanced policy to a classic global entity.

Configuring audit-log policies in a Classic policy expression

Configuring audit-logging in Classic policy consists of the following steps:

1. Configuring an audit-log action. You can configure an audit action for different servers and for different log levels. ‘Audit action’ describes Audit Server configuration information whereas ‘audit policy’ links a bind entity to an ‘audit action’. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After the after which the logs are sent to the SYSLOG server.

2. Configuring audit-log policy. Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.

3. Binding audit-log policies to global entities. You must globally bind the audit log policies to global entities such SYSTEM, VPN, AAA etc., to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority
0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Each of these steps are explained in the following sections.

**Configuring audit-log action**

To configure SYSLOG action in Advanced Policy infrastructure by using the command line interface.

**Note**
The Citrix ADC appliance allows you to configure only one SYSLOG action to SYSLOG server IP address and port. The appliance does not allow you to configure multiple SYSLOG actions to the same server IP address and port.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - add audit syslogAction <name> <serverIP> [-serverPort <port>] {-logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)] [-transport (TCP | UDP)]}
2 - show audit syslogAction [<name>]
```

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - add audit nslogAction <name> <serverIP> [-serverPort <port>] {-logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]}
2 - show audit nslogAction [<name>]
```

**Configuring audit-log policies**

To configure audit-log Policies in Classic Policy infrastructure by using the command line interface

At the command prompt, type:

```
1 add audit syslogpolicy <name> <-rule> <action>
2 add audit nslogpolicy <name> <rule> <action> rm audit nslogpolicy <name> show audit nslogpolicy [<name>] set audit nslogpolicy <name> [-rule <expression>] [-action <name>]
```
Binding audit syslog policies to audit syslog global

To bind audit-log policy in Classic policy framework by using the command line interface
At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType>
unbind audit syslogGlobal <policyName>[-globalBindType <globalBindType>]
```

Configuring audit-log policies using advanced policy expression

Configuring audit-logging in Advanced policy consists of the following steps:

1. **Configuring an audit-log action.** You can configure an audit action for different servers and for different log levels. ‘Audit action’ describes Audit Server configuration information whereas ‘audit policy’ links a bind entity to an ‘audit action’. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After the after which the logs are sent to the SYSLOG server.

2. **Configuring audit-log policy.** Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.

3. **Binding audit-log policies to global entities.** You must globally bind the audit log policies to SYSTEM global entity to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Configuring audit-log action

To configure syslog action in Advanced Policy infrastructure by using the command line interface
At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1  add audit syslogAction <name> <serverIP> [-serverPort <port>] -
   logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )]
   [-transport ( TCP | UDP )]
2  show audit syslogAction [<name>]
```

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface
At the command prompt, type the following commands to set the parameters and verify the configuration:
Configuring audit-log policies

To add a syslog audit action by using the command line interface

At the command prompt, type:

```
1  add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
2  show audit nslogAction [<name>]
```

Example

```
1  add audit syslogAction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateFormat MMDDYYYY
2  add audit nslogAction nslog-action1 10.102.1.3 -serverport 520 -loglevel INFORMATIONAL -dateFormat MMDDYYYY
3  add audit syslogPolicy syslog-poll ns_true audit-action1
4  add audit nslogPolicy syslog-poll ns_true nslog-action1
5  bind system global nslog-poll -priority 20
```

To add a nslog audit action by using the command line interface

At the command prompt, type:

```
1  add audit nslogAction <name> ((<serverIP> | ((<serverDomainName>[~domainResolveRetry <integer>]] | -lbVserverName <string>))[-serverPort <port>] -logLevel <logLevel> [-dateFormat <dateFormat>] [-logFacility <logFacility>] [-tcp (NONE | ALL)] [-acl (ENABLED | DISABLED)] [-timeZone (GMT_TIME | LOCAL_TIME)] [-userDefinedAuditlog (YES | NO)] [-appflowExport (ENABLED | DISABLED)] [-lsn (ENABLED | DISABLED)] [-alg (ENABLED | DISABLED)] [-subscriberLog (ENABLED | DISABLED)] [-transport (TCP | UDP)] [-tcpProfileName <string>] [-maxLogDataSizeToHold]

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3813
```
Binding audit-log policies to global entities

To bind syslog audit-log policy in Advanced policy framework by using the command line interface
At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType]
unbind audit syslogGlobal <policyName> [-globalBindType <globalBindType>]
```

Configuring audit-log policy by using the GUI

1. Navigate to Configuration > System > Auditing > Syslog.
2. Select Servers tab.
3. Click Add.
4. In the Create Auditing Server page, populate the relevant fields, and click Create.
5. To add the policy, select the Policies tab, and click Add.
6. In the Create Auditing Syslog Policy page, populate the relevant fields, and click Create.
7. To bind the policy globally, select Advanced Policy Global Bindings from the drop-down list. Select the best_syslog_policy_ever policy. Click Select.
8. From the drop-down list, select the bind point as SYSTEM_GLOBAL and click Bind, and then click Done.

Configuring policy-based logging

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages, and associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats

Pre Requisites

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format.
- The related audit policy is bound to system global.
Configuring an audit message action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]
```

```
add audit messageaction log-act1 CRITICAL "Client:"+CLIENT.IP.SRC+" accessed "+HTTP.REQ.URL' -bypassSafetyCheck YES
```

To configure an audit message action by using the GUI

Navigate to System > Auditing > Message Actions, and create the audit message action.

Binding audit message action to a policy

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see "Rewrite" or “Responder

Configure Audit Server

You can configure SYSLOG audit server on a Citrix ADC appliance.

Configure SYSLOG through Citrix GUI

To configure the SYSLOG audit server, complete the following steps:

1. Sign into Citrix ADC and navigate to System > Auditing > Syslog.
2. In Servers tab, click Add.
3. In the Create Auditing Server page, set the following parameters:
a) Auditing Type. Name of the auditing server type, example SYSLOG.
b) Name. Provide a name to the SYSLOG type auditing server.
c) Server Type. Select a server type from the drop-down list.
d) IP Address. Provide an IP address for the SYSLOG server.
e) Port. Provide the server port number.
f) Log Levels. Select an audit log level which specifies the events to be logged.
g) Log Facility. Select a log facility that is assigned to the log message. Log facility values are numbers 0 to 7 (LOCAL0 through LOCAL7). Each number indicates where a specific message originated from, such as the Citrix ADC itself, the VPN, or external.
h) Date format. Select the format in which the date must appear in the log message.
i) Time Zone. Select the time zone for date and timestamps in the log message.
j) TCP Logging. Select this option to log TCP messages globally.
k) ACL Logging. Select this option to log access control list messages.
l) User Configurable Log Messages. Select this option to log user configurable log message globally.
m) AppFlow Logging. Select this option to export log messages to AppFlow collectors.
n) Large Scale NAT Logging. Select this option to log lsn information.
o) ALG messaging Logging. Select this option to log alg information.
p) Subscriber Logging. Select this option to log subscriber’s session event information.
q) DNS. Select this option to log DNS related SYSLOG messages.
r) SSL interception. Select this option to log SSL Interception event information.
s) URL Filtering. Select this option to log URL filtering event information.
t) Content Inspection Logging. Select this option to log content inspection events for ICAP or IPS integration at the global level.
4. Net Profile. Select a network profile The SNIP configured in the network profile will be used as source IP when sending log messages.
5. Transport Type. Select a transport type for sending auditlog messages to syslog server. Default type is UDP.
6. Transport Profile. Add a transport profile whose settings are to be applied to the audit server information to tune the TCP connection parameters.
7. Max Log Data Size to hold. Provide the maximum size of log data that can be held in NSB chain of server information.
8. Click Create.

For information about SYSLOG parameters, see Audit SyslogParams command reference page.

2. Citrix ADC
3. Citrix ADC 12.1
Installing and configuring the NSLOG server

January 30, 2019

Contributed by:

C

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server, including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the Citrix ADC appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

Attention:
The version of the NSLOG server package must be the same as that of the Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSLOG server must also be of the same version.

The following table lists the operating systems on which the NSLOG server is supported.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Software requirements</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>RedHat Linux 4 or later, SUSE Linux Enterprise 9.3 or later</td>
<td></td>
</tr>
<tr>
<td>FreeBSD</td>
<td>FreeBSD 6.3 or later</td>
<td>For Citrix ADC 10.5, use only FreeBSD 8.4.</td>
</tr>
<tr>
<td>Mac OS</td>
<td>Mac OS 8.6 or later</td>
<td>Not supported on Citrix ADC 10.1 and later releases.</td>
</tr>
</tbody>
</table>
The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)
- RAM - 512 megabytes (MB)
- Controller - SCSI

**Installing NSLOG server on the Linux operating system**

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

**To install the NSLOG server package on a Linux operating system**

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:

   ```
   cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp
   ```

2. Type the following command to install the NSauditserver.rpm file.

   ```
   rpm -i NSauditserver.rpm
   ```

   This command extracts the files and installs them in the following directories:

   - `/usr/local/netscaler/etc`
   - `/usr/local/netscaler/bin`
   - `/usr/local/netscaler/samples`

**To uninstall the NSLOG server package on a Linux operating system**

1. At a command prompt, type the following command to uninstall the audit server logging feature:

   ```
   rpm -e NSauditserver
   ```

2. For more information about the NSauditserver RPM file, use the following command:

   ```
   rpm -qpi \*.rpm
   ```

3. To view the installed audit server files use the following command:

   ```
   rpm -qpl \*.rpm
   ```

   \*.rpm: Specifies the file name.
Installing NSLOG server on the FreeBSD operating system

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format:

AuditServer_<release number>-<build number>.zip

For example: AuditServer_10.5-58.11.zip

This package contains files for all supported platforms: Linux, Windows, and FreeBSD. On a FreeBSD operating system, install the NSLOG package that has the following name format:

audserver_bsd-<release number>-<build number>.tgz

For example: audserver_bsd-10.5-58.11.tgz

To download NSLOG package from www.citrix.com:

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. From the Select a product list, select Citrix ADC.
6. On the Citrix ADC page, select the release for which you want to download the NSLOG package (for example, Release 10.5), and then select Firmware.
7. Under Firmware, select the Citrix ADC firmware for the build number for which you want to download the NSLOG package.
8. On the page that appears, scroll down, select Audit Servers, and click Download File next to the package that you want to download.

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) from the package.
2. Copy the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) to a directory on a system running FreeBSD OS.
3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:

   pkg_add audserver_bsd-<release number>-<build number>.tgz

   Example:

   ```bash
   pkg_add audserver_bsd-9.3-51.5.tgz
   ```
The following directories are extracted:

- <root directory extracted from the FreeBSD NSLOG server package tgz file>\Citrix ADCbin (for example, /var/auditserver/netscaler/bin)
- <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler/etc (for example, /var/auditserver/netscaler/etc)
- <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\samples (for example, /var/auditserver/samples)

4. At a command prompt, type the following command to verify that the package is installed:

```
pkg_info | grep NSaudserver
```

To uninstall the NSLOG server package on a FreeBSD operating system

At a command prompt, type:

```
pkg_delete NSaudserver
```

Installing NSLOG Server Files on the Windows Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5.zip`). This package contains NSLOG installation packages for all supported platforms.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format `AuditServer_<release number>-<build number>.zip`, to your local system (for example, `AuditServer_9.3-51.5.zip`).

To install NSLOG server on a Windows operating system

1. On the system, where you have downloaded the NSLOG package `AuditServer_<release number>-<build number>.zip` (for example, `AuditServer_9.3-51.5`.)
zip), extract audserver_win-<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) from the package.

2. Copy the extracted file audserver_<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) to a Windows system on which you want to install the NSLOG server.

3. Unzip the audserver_<release number>-<build number>.zip file (for example, audserver_win-9.3-51.5.zip).

4. The following directories are extracted:
   a) <root directory extracted from the Windows NSLOG server package zip file>\bin (for example, C:\audserver_win-9.3-51.5\bin)
   b) <root directory extracted from the Windows NSLOG server package zip file>\etc (for example, C:\audserver_win-9.3-51.5\etc)
   c) <root directory extracted from the Windows NSLOG server package zip file>\samples (for example, C:\audserver_win-9.3-51.5\samples)

5. At a command prompt, run the following command from the <root directory extracted from the Windows NSLOG server package zip file>\bin path:

   audserver -install -f <directorypath>\auditlog.conf

   <directorypath>: Specifies the path to the configuration file (auditlog.conf). By default, log.conf is under \<root directory extracted from Windows NSLOG server package zip file>\samples directory. But you can copy auditlog.conf to your desired directory.

To uninstall the NSLOG server on a Windows operating system

At a command prompt, run the following command from the <root directory extracted from Windows NSLOG server package zip file>\bin path:

audserver -remove

NSLOG Server Command Options

For information about NSLOG server commands, see Audit Server Options.

Run the audserver command from the directory in which the audit server executable is present:

- ‘On Windows: \ns\bin’
- On Solaris and Linux: \usr\local\netscaler\bin

The audit server configuration files are present in the following directories:
• On Windows: \ns\etc
• On Linux: \usr\local\netscaler\etc

The audit server executable is started as ./auditserver in Linux and FreeBSD.

Adding the Citrix ADC Appliance IP Addresses on the NSLOG Server

In the configuration file (auditlog.conf), add the IP addresses of the Citrix ADC appliances whose events must be logged.

To add the IP addresses of the Citrix ADC appliance

At a command prompt, type the following command:

```
audserver -addns -f <directorypath>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (auditlog.conf).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the Citrix ADC appliance, for example, 10.102.29.1.

Userid: Specifies the user name, for example, nsroot.

Password: Specifies the password, for example, nsroot.

If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of the Citrix ADC appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the auditlog.conf file. For a high availability (HA) setup, you must add both primary and secondary Citrix ADC IP addresses to auditlog.conf by using the audserver command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (audit log.conf) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

```
audserver -verify -f <directorypath>\auditlog.conf
```

<directorypath>: Specifies the path to the configuration file (audit log.conf).

1. Citrix ADC
2. Citrix ADC 12.1
Running the NSLOG server

January 23, 2019
Contributed by: C

To start audit server logging

Type the following command at a command prompt:

audserver -start -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

audserver -stop

To stop audit server logging that starts as a service in Windows

Type the following command:

audserver -stopservice

Customizing logging on the NSLOG server

January 23, 2019
Contributed by: C

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.
To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a Citrix ADC appliance or a set of Citrix ADC appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

- Creating Filters
- Specifying Log Properties

**Creating filters**

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

**Note:**

For consolidated logging, if a log transaction occurs for which there is no filter definition, the default filter is used (if it is enabled.) The only way you can configure consolidated logging of all the Citrix ADC appliances is by defining the default filter.

**To create a filter**

At the command prompt, type the following command in the configuration file (auditlog.conf):

```
filter <filterName> [IP <ip>] [NETMASK <mask>] ON | OFF
```

- **filterName:** Specify the name of the filter (maximum of 64 alphanumeric characters).
- **ip:** Specify the IP addresses.
- **mask:** Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument is specified, the filter is ON.

**Examples:**

```
filter F1 IP 192.168.100.151 ON
```

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

```
filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON
```

**filterName** is a required parameter if you are defining a filter with other optional parameters, such as IP address, or the combination of IP address and Netmask.
Specifying log properties

Log properties associated with the filter are applied to all the log entries present in the filter. The log property definition starts with the key word BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
  logFilenameFormat ...
  logDirectory ...
  logInterval ...
  logFileSizeLimit ....
END
```

Entries in the definition can include the following:

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: A constant string that specifies the absolute path and the file name.
  - Dynamic: An expression that includes the following format specifiers:
    * Date (%{format}t)
    * creates file name with NSIP

**Example:**

```
LogFilenameFormat Ex%'{
  '%m%d%y }
  t.log
```

This creates the first file name as Exmmddyy.log. New files are named: Exmmddyy.log.0, Exmmddyy.log.1, and so on. In the following example, the new files are created when the file size reaches 100MB.

**Example:**

```
LogInterval size
2  LogFileSize 100
3  LogFilenameFormat Ex%'{
  '%m%d%y }
  t
```

**Caution**

The date format %t specified in the LogFilenameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the speci-
fied log file size is reached, do not use %t in the LogFilenameFormat parameter.

- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:
  - Static: Is a constant string that specifies the absolute path and file name.
  - Dynamic: Is an expression containing the following format specifiers:
    * Date (%{format}t)
    * creates directory with NSIP

The directory separator depends on the operating system. In Windows, use the directory separator.

**Example:**
```
LogDirectory dir1\dir2\dir3
```

In the other operating systems (Linux, FreeBsd, etc.), use the directory separator.

- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour. Default value.
  - Daily: A file is created every day at midnight.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly: A file is created on the first day of the month at midnight.
  - None: A file is created only once, when audit server logging starts.
  - Size: A file is created only when the log file size limit is reached.

**Example:**
```
LogInterval Hourly
```

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

**Note**
You can override the loginterval property by assigning size as its value.

The default LogFileSizeLimit is 10 MB.

**Example:**
```
LogFileSizeLimit 35
```

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
Syslog is a standard for sending event notification messages. These messages can be stored locally or on an external log server. Syslog enables network administrators to consolidate log messages and derive insights from the collected data.

Syslog was originally designed to work over UDP, which can transmit a huge amount of data within the same network with minimal packet loss. However, telco operators prefer to transmit syslog data over TCP, because they need reliable, ordered data transmission between networks (for example, telco tracks user activities), and TCP provides retransmission in the event of network failure.

**How Syslog over TCP works**

To understand how syslog over TCP works, consider two hypothetical cases:

Sam, a network administrator, wants to log significant events on an external syslog server.

XYZ Telecom, an Internet service provider, has to transmit and store a significant amount of data on syslog servers to comply with government regulations.

In both cases, the log messages must be transmitted over a reliable channel and stored safely on an external syslog server. Unlike UDP, TCP establishes a connection, transmits messages securely, and retransmits (from sender to receiver) any data that is corrupted or lost because of network failure.

The Citrix ADC appliance sends log messages over UDP to the local syslog daemon, and sends log messages over TCP or UDP to external syslog servers.

**SNIP support for Syslog**

When the audit-log module generates syslog messages, it uses a Citrix ADC subnet IP (SNIP) address as the source address for sending the messages to an external syslog server. To configure a SNIP as the source address, you must make it part of the netProfile option and bind the netProfile to the syslog action.

**Note**

If a netProfile is not bound to a syslog action, the Citrix ADC IP (NSIP) is used as the source address for transmitting data to the external log server.

**Use of a SNIP address is not supported in internal logging.**
FQDN Support for audit Log

Previously, the audit-log module was configured with the destination IP address of the external syslog server to which the log messages are sent. Now, the audit-log server uses a Fully Qualified Domain Name (FQDN) instead of the destination IP address. The FQDN configuration resolves the configured domain name of the syslog server to the corresponding destination IP address for sending the log messages from the audit-log module. To resolve the domain name and avoid domain based service issues, the name server must be properly configured.

Note

When configuring a FQDN, server domain name configuration of the same Citrix ADC appliance in syslog action or nslog action is not supported.

Configuring Syslog over TCP by using Command Line Interface

To configure a Citrix ADC appliance to send syslog messages over TCP by using the command line interface

At the command prompt, type:

```
1 add audit syslogAction <name> ((<serverIP> | (((<serverDomainName>[-domainResolveRetry <integer>]) | -lbVserverName<string>))[-serverPort <port>] -logLevel <logLevel>[-dateFormat <dateFormat>] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )][-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog ( YES | NO )][-appflowExport ( ENABLED | DISABLED )][-lsn ( ENABLED | DISABLED )][-alg ( ENABLED | DISABLED )][-subscriberLog ( ENABLED | DISABLED )][-transport ( TCP | UDP )][-tcpProfileName <string>][-maxLogDataSizeToHold <positive_integer>])[-dns ( ENABLED | DISABLED )][-netProfile <string>]
```

```
1 add audit syslogAction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateFormat MMDDYYYY -transport TCP
```

Adding SNIP IP address to netprofile option by using the command line interface

To add a SNIP IP address to netprofile by using the command line interface

At the command prompt, type:
Adding netprofile in a syslog action by using the command line interface

To add a netProfile option in a syslog action by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> (<serverIP> | -lbVserverName <string>) -logLevel <logLevel>
```

Where -net Profile specifies the name of the configured net profile. The SNIP address is configured as part of the netProfile and this netProfile option is bound to the syslog action.

| Note |
| You must always bind the netProfile option to the SYSLOGUDP or SYSLOGTCP services bound to the SYSLOGUDP or SYSLOGTCP load balancing virtual server when LB vserver name is configured in syslogaction.

Configuring FQDN support by using the command line interface

To add a server domain name to a Syslog action by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> ((<serverDomainName>[<domainResolveRetry <integer>]] | -lbVserverName <string>) -logLevel <logLevel> ...
```

```
set audit syslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>] -serverDomainName <string> [-lbVserverName <string>] -domainResolveRetry <integer> [-domainResolveNow]
```
To add a server domain name to a Nslog action by using the command line interface.

At the command prompt, type:

```bash
1
add audit nslogAction <name> (<serverIP> | (<serverDomainName>[ -domainResolveRetry <integer>])) -logLevel <logLevel> ...
2
set audit nslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>][ -serverDomainName <string>] [-domainResolveRetry <integer>][-domainResolveNow]
```

Where

- serverDomainName. Domain name of the log server. This is mutually exclusive with serverIP/ lb-VserverName.
- DomainResolveRetry integer. Time (in seconds) that the Citrix ADC appliance waits, after a DNS resolution fails, before sending the next DNS query to resolve the domain name.
- DomainResolveNow. Included if the DNS query has to be sent immediately to resolve the server’s domain name.

**Configuring Syslog over TCP by using the GUI**

To configure the Citrix ADC appliance to send Syslog messages over TCP by using the GUI

1. Navigate to System > Auditing > Syslog and select the Servers tab.
2. Click Add and select Transport Type as TCP.

**Configuring netprofile for SNIP support by using the GUI**

To configure netprofile for SNIP support by using the GUI

1. Navigate to System > Auditing > Syslog and select the Servers tab.
2. Click Add and select a netprofile from the list.

**Configuring FQDN by using the GUI**

To configure FQDN by using the GUI

1. Navigate to System > Auditing > Syslog and select the Servers tab.
2. Click Add and select a Server Type and Server Domain Name from the list.

1. Citrix ADC
2. Citrix ADC 12.1
**Load balancing SYSLOG servers**

January 23, 2019

Contributed by:

C

The Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.
   
   ```
   add service <name> (<IP> | <serverName>) <serviceType (SYSLOGTCP | SYSLOGUDP)> <port>
   ```

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGUDP, and load balancing method as AUDITLOGHASH.
   
   ```
   add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod <AUDITLOGHASH>] 
   ```

3. Bind the service to the load balancing virtual server.

   ```
   Bind lb vserver <name> <serviceName>
   ```

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   ```
   add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel <logLevel>]
   ```

5. Add a SYSLOG policy by specifying the rule and action.

   ```
   add syslogpolicy <name> <rule> <action>
   ```

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   ```
   bind system global <policyName>
   ```

*Load balancing of SYSLOG servers using the GUI*
1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.
   Navigate to **Traffic Management > Services**, click **Add** and select **SYSLOGTCP** or **SYSLOGUDP** as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.
   Navigate to **Traffic Management > Virtual Servers**, click **Add** and select **SYSLOGTCP** or **SYSLOGUDP** as protocol.

3. Bing the service to the load balancing virtual server to the service.
   Bing the service to the load balancing virtual server.
   Navigate to **Traffic Management > Virtual Servers**, select a virtual server and then select **AUDITLOGHASH** in the **Load Balancing Method**.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.
   Navigate to **System > Auditing**, click **Servers** and add a server by selecting **LB Vserver** option in **Servers**.

5. Add a SYSLOG policy by specifying the rule and action.
   Navigate to **System > Syslog**, click **Policies** and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.
   Navigate to **System > Syslog**, select a SYSLOG policy and click **Action**, and then click **Global Bindings** and bind the policy to system global.

**Example:**

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. AUDITLOGHASH method load balances the traffic based on input hash value from the audit agents. The agents are the modules which generate auditlog in a Citrix ADC appliance. For example, if an agent LSN wants to load balance auditlogs based on client IP address, LSN module generates the hash value based on clientIP and passes the hash value to auditlog module. The auditlog module sends the auditlog messages which have same hash value to the external syslog server.

The Citrix ADC appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
1  add service service1 192.0.2.10 SYSLOGUDP 514
2  add service service2 192.0.2.11 SYSLOGUDP 514
3  add service service3 192.0.2.11 SYSLOGUDP 514
4  add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH
```
bind lb vserver lbvserver1 service1
bind lb vserver lbvserver1 service2
bind lb vserver lbvserver1 service3
add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
add syslogpolicy syspol1 ns_true sysaction1
bind system global syspol1

Limitations:

- The Citrix ADC appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Default settings for the log properties

January 23, 2019
Contributed by: C

The following is an example of the default filter with default settings for the log properties:

```plaintext
begin default
logInterval Hourly
logFileSizeLimit 10
logFilenameFormat auditlog%'{
%Y%m%d }
t.log
end default
```

Following are two examples of defining the default filters:

**Example 1:**

```plaintext
Filter f1 IP 192.168.10.1
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

**Example 2:**

```plaintext
Filter f1 IP 192.168.10.1
begin f1
```
logFilenameFormat logfiles.log
end

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1

Sample configuration file (audit.conf)

January 23, 2019

Contributed by:
C

Following is a sample configuration file:

```
# This is the Auditserver configuration file
# Only the default filter is active
# Remove leading # to activate other filters
#
MYIP <NSAuditserverIP>
MYPORT 3023
# Filter filter_nsip IP <Specify the Citrix ADC IP address to filter on > ON
# begin filter_nsip
#     logInterval    Hourly
#     logFileSizeLimit  10
#     logDirectory    logdir\%A\%
#     logFilenameFormat nsip\%
#
\%d%m%Y }
t.log
# end filter_nsip
Filter default
begin default
#     logInterval    Hourly
#     logFileSizeLimit  10
#     logFilenameFormat auditlog\%
#
\%y%m%d }
t.log
```
Web server logging

January 23, 2019
Contributed by: C

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the Citrix ADC.
- The Citrix ADC Web Logging (NSWL) client, which runs on the client system.

When you run the Citrix ADC Web Logging (NSWL) client:

1. It connects to the Citrix ADC.
2. The Citrix ADC buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the Citrix ADC and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the Citrix ADC IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the Citrix ADC for web server logging

January 23, 2019
Contributed by: C
To configure the Citrix ADC for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the Citrix ADC Web Logging (NSWL) client.
- Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

**To configure web server logging by using the command line interface**

At the command prompt, perform the following operations:

- Enable the web server logging feature.
  ```
  enable ns feature WL
  ```
- [Optional] Modify the buffer size for storing the logged information.
  ```
  set ns weblogparam -bufferSizeMB <size>
  ```
  **Note:**
  To activate your modification, you must disable and then re-enable the Web server logging feature.
- [Optional] Specify the custom HTTP header names that you want to export.
  ```
  set ns weblogparam [-customReqHdrs <string> ...] [-customRspHdrs <string> ...]
  ```

```
1  > enable ns feature WL
  Done
2  > set ns weblogparam -bufferSizeMB 60
  Done
3  > show ns weblogparam
   Web Logging parameters:
   Log buffer size: 60MB
   Custom HTTP request headers: (none)
   Custom HTTP response headers: (none)
  Done
4  > set ns weblogparam -customReqHdrs req1 req2 -customRspHdrs res1 res2
  Done
5  > show ns weblogparam
   Web Logging parameters:
   Log buffer size: 60MB
   Custom HTTP request headers: req1, req2
   Custom HTTP response headers: res1, res2
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To configure web server logging by using the GUI

1. Navigate to **System > Settings** and perform the following operations:

   a) To enable the web server logging feature, click **Change Advanced Features** and select **Web Logging**.

   b) To modify the buffer size, click **Change Global System Settings** and under **Web Logging**, enter the buffer size.

   c) To specify the custom HTTP headers to be exported, click **Change Global System Settings** and under **Web Logging**, specify the header values.

Installing the Citrix ADC web logging (NSWL) client

March 14, 2019
Contributed by: C

During installation, the NSWL client executable file (nswl) is installed along with other files. The nswl executable file provides a list of options that you can use. For details, see Configuring the NSWL Client.

Attention:

The version of the NSWL client must be the same as that of the Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSWL client must also be of the same version. Also, Citrix ADC web logging (NSWL) client works only on 32 bit appliance and not on 64 bit appliance.

The following table lists the operating systems on which the NSWL client can be installed.
<table>
<thead>
<tr>
<th>Operating system</th>
<th>Version</th>
<th>Hardware requirements</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mac OS</td>
<td>Mac OS 8.6 or later</td>
<td>-</td>
<td>Not supported on Citrix ADC 10.1 and later releases.</td>
</tr>
<tr>
<td>Linux</td>
<td>RedHat Linux 4 or later, SUSE Linux Enterprise 9.3 or later</td>
<td>Processor - Intel x86 ~501 MHz, RAM - 512 MB, Controller - SCSI</td>
<td></td>
</tr>
<tr>
<td>Solaris</td>
<td>Solaris Sun OS 5.6 or later</td>
<td>Processor - UltraSPARC-IIi 400 MHz, RAM - 512 MB, Controller - SCSI</td>
<td>Not supported on Citrix ADC 10.5 and later releases.</td>
</tr>
<tr>
<td>FreeBSD</td>
<td>FreeBSD 6.3 or later</td>
<td>Processor - Intel x86 ~501 MHz, RAM - 512 MB, Controller - SCSI</td>
<td>For Citrix ADC 10.5, use only FreeBSD 8.4.</td>
</tr>
<tr>
<td>AIX</td>
<td>AIX 6.1</td>
<td>-</td>
<td>Not supported on Citrix ADC 10.5 and later releases.</td>
</tr>
</tbody>
</table>

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

**Caution:**
Reinitiation of logging can result in loss of log transactions.

To temporarily solve a NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the Citrix ADC appliance. To solve the problem, you need a client system that can handle the site's throughput.
**Downloading the NSWL client**

You can obtain the NSWL client package from either the Citrix ADC product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platforms.

**To download the NSWL client package from the Citrix site**

2. Log in to the site using your credentials.
3. Open the page for the required release number and build.
4. In the page, under Weblog Clients, click Download. The package has the name format as follows: `Weblog- <release number>-<build number>.zip`.

**Installing the NSWL client on a Solaris system**

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_solaris-<release number>-<build number>.tar` file from the package.
2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.
3. Extract the files from the tar file with the following command:
   
   ```
   tar xvf nswl_solaris-9.3-51.5.tar
   ```

   A directory NSweblog is created in the temporary directory, and the files are extracted to the NSweblog directory.

4. Install the package with the following command:
   
   ```
   pkgadd -d
   ```

   The list of available packages appears. In the following example, one NSweblog package is shown:

   ```
   1 1 NSweblog Citrix ADC Weblogging (SunOS,sparc) 7.0
   ```

5. You are prompted to select the packages. Select the package number of the NSweblog to be installed.

   After you select the package number and press Enter, the files are extracted and installed in the following directories:
6. To check whether the NSWL package is installed, execute the following command:

```bash
pkginfo | grep NSweblog
```

**Note:** To uninstall the NSWL package, execute the following command:

```bash
pkgrm NSweblog
```

## Installing the NSWL client on a Linux system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_linux-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```bash
rpm -i nswl_linux-9.3-51.5.rpm
```

This command extracts the files and installs them in the following directories.

- `/usr/local/netscaler/etc`
- `/usr/local/netscaler/bin`
- `/usr/local/netscaler/samples`

**Note:** To uninstall the NSWL package, execute the following command:

```bash
rpm -e NSweblog
```

**Note:**
To get more information about the NSweblog RPM file, execute the following command:

```bash
rpm -qpi *.rpm
```

**Note:**
To view the installed Web server logging files, execute the following command:

```bash
rpm -qpl *.rpm
```
Installing the NSWL client on a FreeBSD system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_bsd-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
1 pkg_add nswl_bsd-9.3-51.5.tgz
```

This command extracts the files and installs them in the following directories:

- `/usr/local/netscaler/etc`
- `/usr/local/netscaler/bin`
- `/usr/local/netscaler/samples`

**Note:** To uninstall the NSWL package, execute the following command:

```
1 pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```
1 pkg_info | grep NSweblog
```

Installing the NSWL client on a Mac system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_macos-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running Mac OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
1 pkg_add nswl_macos-9.3-51.5.tgz
```

This command extracts the files and installs them in the following directories:

- `/usr/local/netscaler/etc`
- `/usr/local/netscaler/bin`
- `/usr/local/netscaler/samples`
Note: To uninstall the NSWL package, execute the following command:

```bash
pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```bash
pkg_info | grep NSweblog
```

**Installing the NSWL client on a Windows system**

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_win-<release number>-<build number>.zip` file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as `<NSWL-HOME>`). The following directories are extracted: bin, etc, and samples.
4. At the command prompt, run the following command from the `<NSWL-HOME>\bin` directory:

```bash
nswl-install -f <directorypath>\log.conf
```

where,

directorypath refers to the path of the configuration file (log.conf). By default, the file is in the `<NSWL-HOME>` etc directory. However, you can copy the configuration file to any other directory.

Note: To uninstall the NSWL client, at the command prompt, run the following command from the `<NSWL-HOME>` directory:

```bash
> nswl -remove
```

**Installing the NSWL client on a AIX system**

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_aix-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/
- usr/local/netscaler/samples

**Note:** To uninstall the NSWL package, execute the following command:

```
rpm -e NSweblog
```

**Note:** To get more information about the NSweblog RPM file, execute the following command:

```
rpm -qpi *.rpm
```

**Note:** To view the installed Web server logging files, execute the following command:

```
rpm -qpl *.rpm
```

Configure NSWL client

January 23, 2019

Contributed by:
C

After installing the NSWL client, you can configure the NSWL client using the nswl executable. These configurations are then stored in the NSWL client configuration file (log.conf).

**Note:**
You can further customize logging on the NSWL client system by making additional modifications to the NSWL configuration file (log.conf). For details, see Customizing Logging on the NSWL Client System.

The following table describes the commands that you can use to configure the NSWL client.
**NSWL command** | **Specifies**
---|---
nswl -help | The available NSWL help options.
nswl -addns -f <path-to-configuration-file> | The system that gathers the log transaction data. You are prompted to enter the IP address of the Citrix ADC appliance. Enter a valid user name and password.
nswl -verify -f <path-to-configuration-file> | Check for syntax or semantic errors in the configuration file.
nswl -start -f <path-to-configuration-file> | Start the NSWL client based on the settings in the configuration file. Note: For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&) at the end of the command.
nswl -stop (Solaris and Linux only) | Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.
nswl -install -f <path-to-configuration-file> (Windows only) | Install the NSWL client as a service in Windows.
nswl -startservice (Windows only) | Start the NSWL client by using the settings in the configuration file specified in the nswl install option. You can also start NSWL client from Start > Control Panel > Services. Note: The NSWL log files will be created in C:\Windows\SysWOW64.
nswl -stopservice (Windows only) | Stops the NSWL client.
nswl -remove | Remove the NSWL client service from the registry.

Run the following commands from the directory in which the NSWL executable is located:

- **Windows**: \ns\bin
- **Solaris and Linux**: \usr\local\netscaler\bin

The Web server logging configuration files are located in the following directory path:

- **Windows**: \ns\etc
- **Solaris and Linux**: \usr\local\netscaler\etc
The NSWL executable is started as .\nswl in Linux and Solaris.

**Add the IP addresses of the Citrix ADC appliance**

In the NSWL client configuration file (log.conf), add the Citrix ADC IP address (NSIP) from which the NSWL client will start collecting logs.

**To add the NSIP address of the Citrix ADC appliance**

1. At the client system command prompt, type:
   ```
   nswl -addns -f <directorypath> \log.conf
   <directorypath>: Specifies the path to the configuration file (log.conf).
   ```
2. At the next prompt, enter the following information:
   - **NSIP**: Specify the IP address of the Citrix ADC appliance.
   - **Username and Password**: Specify the nsroot user credentials of the Citrix ADC appliance.

   **Note:**
   If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of Citrix ADC system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the log.conf file. During a failover setup, you must add both primary and secondary Citrix ADC IP addresses to the log.conf by using the command. Before adding the IP address, make sure the user name and password exist on the Citrix ADC appliances.

**Verify the NSWL configuration file**

To make sure that logging works correctly, check the NSWL configuration file (log.conf) on the client system for syntax errors.

**To verify the configuration in the NSWL configuration file**

At the client system command prompt, type:
```
   nswl -verify -f <directorypath>\log.conf
   <directorypath>: Specifies the path to the configuration file (log.conf).
```
Running the NSWL Client

To start Web server logging

At the client system command prompt, type:

```
nswl -start -f <directorypath>/log.conf
```

<directorypath>: Specifies the path to the configuration file (log.conf).

To stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

```
nswl -stop
```

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

```
nswl -stopservice
```

3. Citrix ADC 12.1

Customize logging on the NSWL client system

January 25, 2019

Contributed by:
C

You can customize logging on the NSWL client system by making additional modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
  - **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.
Sample configuration file

Following is a sample configuration file:

```
# This is the NSWL configuration file
# Only the default filter is active
# Remove leading # to activate other filters
#
# Default filter (default on)
# W3C Format logging, new file is created every hour or on reaching 10 MB file size,
# and the file name is Exyymmdd.log
#
Filter default
begin default
  logFormat W3C
  logInterval Hourly
  logFileSizeLimit 10
  logFilenameFormat Ex{%'{%y%m%d} t.log
end default
#
# Citrix ADC caches example
# CACHE_F filter covers all the transaction with HOST name www.netscaler.com and the listed server ip's
#
Filter CACHE_F HOST www.netscaler.com IP 192.168.100.89 192.168.100.95 192.168.100.52 192.168.100.53 ON
#
# netscaler origin server example
# Not interested in Origin server to Cache traffic transaction logging
#
Filter ORIGIN_SERVERS IP 192.168.100.64 192.168.100.65 192.168.100.66 192.168.100.67 192.168.100.225 192.168.100.226 192.168.100.227 OFF
#
# netscaler image server example
# all the image server logging.
#
Filter IMAGE_SERVER HOST www.netscaler.images.com IP 192.168.100.71 192.168.100.72 192.168.100.169 192.168.100.170 192.168.10 0.171 ON
```
# NCSA Format logging, new file is created every day midnight or on reaching 20MB file size,
# and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmddyy.log.
# Exclude objects that ends with .gif .jpg .jar.

### begin ORIGIN_SERVERS

```bash
# logFormat NCSA
# logInterval Daily
# logFileSizeLimit 40
# logFilenameFormat /datadisk5/ORGIN/log/%v/NS'{%m%d%y }
```

```bash
log
# logExclude .gif .jpg .jar
```

### end ORIGIN_SERVERS

### begin CACHE_F

```bash
# logFormat NCSA
# logInterval Daily
# logFileSizeLimit 20
# logFilenameFormat /datadisk5/netscaler/log/%v/NS'{%m%d%y }

log
```

```bash
# logtime GMT
```

### end CACHE_F

### begin IMAGE_SERVER

```bash
# logFormat W3C
# logInterval Size
# logFileSizeLimit 20
# logFilenameFormat /datadisk6/netscaler/log/%AEx'{%m%d%y }
```

### end IMAGE_SERVER

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Creating filters

You can use the default filter definition located in the configuration file (log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.

If the server hosts multiple Web sites and each Web site has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each Web site. The following table displays the parameters for creating a filter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>filterName</td>
<td>Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.</td>
</tr>
<tr>
<td>HOST name</td>
<td>Host name of the server for which the transactions are being logged.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Specifies</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP ip</td>
<td>IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).</td>
</tr>
<tr>
<td>IP ip 2...ip n:</td>
<td>Multiple IP addresses (for example, if the server domain has multiple IP addresses).</td>
</tr>
<tr>
<td>ip6 ip</td>
<td>IPv6 address of the server for which transactions are to be logged.</td>
</tr>
<tr>
<td>IP ip NETMASK mask</td>
<td>IP addresses and netmask combination to be used on a subnet.</td>
</tr>
<tr>
<td>ON</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Table 1. Parameters for Creating a Filter

To create a filter

To create a filter, enter the following command in the log.conf file:

- `filter <filterName> <HOST name> | [IP<ip>] | [IP<ip 2...ip n>] | <IP ip NETMASK mask> [ON | OFF]`
- `filter <filterName> <HOST name> | [IP6/Ip<prefix length>] [ON | OFF]`

To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

`filter <filterName> <VirtualServer IP address>

Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

```
1 Filter F1 HOST www.netscaler.com ON
2 Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
3 Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
4 Filter F4 IP 192.168.100.151
5 Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
```
Specify log properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
logFormat ...
logFilenameFormat ...
logInterval ...
logFileSize ....
logExclude ....
logTime ....
END
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

  By default, the logformat property is w3c. To override, enter custom or NCSA in the configuration file, for example:

```
LogFormat NCSA
```

**Note:** For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.

```
**LogInterval** specifies the intervals at which new log files are created. Use one of the following values:

- Hourly: A file is created every hour.
- Daily: A file is created every day at midnight. Default value.
- Weekly: A file is created every Sunday at midnight.
- Monthly: A file is created on the first day of the month at midnight.
```
None: A file is created only once, when Web server logging starts.

Example:

```
LogInterval Daily
```

**LogFileSizeLimit** specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.

To override this behavior, specify the size as the loginterval property so that a file is created only when the log file size limit is reached.

The default LogFileSizeLimit is 10 MB.

Example:

```
LogFileSizeLimit 35
```

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: Specifies a constant string that contains the absolute path and file name.
  - Dynamic: Specifies an expression containing the following format:
    - Server IP address
    - Date (%{format}t)
    - URL suffix (%x)
    - Host name (%v)

Example:

```
LogFilenameFormat Ex%{\%m%\%d%\%y } t.log
```

This command creates the first file name as Exmmdyy.log, then every hour creates a file with file name: Exmmdyy.log.0, Exmmdyy.log.1,…, Exmmdyy.log.n.

Example:

```
LogInterval size
LogFileSize 100
LogFileFilenameFormat Ex%{\%m%\%d%\%y } t.log
```
Caution:
The date format %t specified in the LogFilenameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat.

- **LogExclude** prevents logging of transactions with the specified file extensions.

**Example:**

```plaintext
LogExclude .html
```

This command creates a log file that excludes log transactions for *.html files.

**LogTime** specifies log time as either GMT or LOCAL.

The defaults are:

```plaintext
1 - NCSA log file format: LOCAL
2 - W3C log file format: GMT.
```

**Understanding NCSA and W3C log formats**

The Citrix ADC supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

**NCSA Common Log Format**

If the log file format is NCSA, the log file displays log information in the following format:

```plaintext
Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object HTTP_version" HTTP_StatusCode BytesSent
```

To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client_IP_address</td>
<td>The IP address of the client computer.</td>
</tr>
<tr>
<td>User Name</td>
<td>The user name.</td>
</tr>
<tr>
<td>Date</td>
<td>The date of the transaction.</td>
</tr>
</tbody>
</table>
Argument Specifies

Time The time when the transaction was completed.

Time Zone The time zone (Greenwich Mean Time or local time).

Method The request method (for example; GET, POST).

Object The URL.

HTTP_version The version of HTTP used by the client.

HTTP_Status_Code The status code in the response.

Bytes Sent The number of bytes sent from the server.

W3C extended log format

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line may contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

```
1 %'{
2 '%%Y-%m-%d%H:%M:%S }
3 t %a %u %S %A %p %m %q %s %j %J %T %H %+
4 user-agent }
5 i +%{ 
6 cookie }
7 i%+
8 referer }
9 i
```

You can also change the order or remove some fields in this W3C log format. For example:

```
1 logFormat W3C %'{
2 '%%Y-%m-%d%H:%M:%S }
3 t %m %U
```

W3C log entries are created with the following format:
Entries

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space; Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.

Directives

Refer to the Directives table for information about the logging process. Lines beginning with the pound sign (#) contain directives.

Example:

The following sample log file shows the log entries in W3C Extended log format:

```
#Version: 1.0 #Fields: date time cs-method cs-uri #Date: 12-Jun-2001
12:34 2001-06-12 12:34:23 GET /sports/football.html 2001-06-12
12:34:30 GET /sports/football.html
```

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers may have one of the following forms:

- **identifier**: Relates to the transaction as a whole.
- **prefix-identifier**: Relates to information transfer between parties defined by the value prefix.
- **prefix(header)**: Specifies the value of the HTTP header field header for transfer between parties defined by the value prefix. Fields specified in this manner always have the type.

The following table describes defined prefixes.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>

</tr>
<tr>
<td>s</td>
<td>Server</td>
</tr>
</tbody>
</table>

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Prefix Specifies

r Remote

cs Client to server

sc Server to client

sr Server to remote server (prefix used by proxies)

rs Remote server to server (prefix used by proxies)

x Application-specific identifier

Examples:
The following examples are defined identifiers that use prefixes:

cs-method: The method in the request sent by the client to the server.

sc(Referer): The Referer field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date on which the transaction was done.</td>
</tr>
<tr>
<td>time</td>
<td>The time when the transaction is done.</td>
</tr>
<tr>
<td>time-taken</td>
<td>The time taken (in seconds) for the transaction to complete.</td>
</tr>
<tr>
<td>bytes</td>
<td>The number of bytes transferred.</td>
</tr>
<tr>
<td>cached</td>
<td>Records whether a cache hit has occurred. A zero indicates a cache miss.</td>
</tr>
</tbody>
</table>

Table 5. W3C Extended Log Format Identifiers (No Prefix Required)

The following table describes the W3C Extended log format identifiers that require a prefix.
### Table 6. W3C Extended Log Format Identifiers (Requires a Prefix)

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>The date on which the transaction is done.</td>
</tr>
<tr>
<td>Time</td>
<td>The time when the transaction is done.</td>
</tr>
<tr>
<td>Client IP</td>
<td>The IP address of the client.</td>
</tr>
<tr>
<td>User Name</td>
<td>The user name.</td>
</tr>
<tr>
<td>Service Name</td>
<td>The service name, which is always HTTP.</td>
</tr>
<tr>
<td>Server IP</td>
<td>The server IP address.</td>
</tr>
<tr>
<td>Server Port</td>
<td>The server port number</td>
</tr>
<tr>
<td>Method</td>
<td>The request method (for example; GET, POST).</td>
</tr>
<tr>
<td>Url Stem</td>
<td>The URL stem.</td>
</tr>
<tr>
<td>Url Query</td>
<td>The query portion of the URL.</td>
</tr>
<tr>
<td>Http Status</td>
<td>The status code in the response.</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>The number of bytes sent to the server (request size, including HTTP headers).</td>
</tr>
<tr>
<td>Bytes Received</td>
<td>The number of bytes received from the server (response size, including HTTP headers).</td>
</tr>
</tbody>
</table>
Table 7. W3C Extended Log File Format (Allows Log Fields)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time Taken</td>
<td>The time taken for transaction to complete, in seconds.</td>
</tr>
<tr>
<td>Protocol Version</td>
<td>The version number of HTTP being used by the client.</td>
</tr>
<tr>
<td>User Agent</td>
<td>The User-Agent field in the HTTP protocol.</td>
</tr>
<tr>
<td>Cookie</td>
<td>The Cookie field of the HTTP protocol.</td>
</tr>
<tr>
<td>Referer</td>
<td>The Referer field of the HTTP protocol.</td>
</tr>
</tbody>
</table>

Creating a custom log format

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.

Creating a custom log format by using the NSWL library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows**: The nswl.lib library located in \ns\bin directory on the system manager host computer.
- **Solaris**: The libnswl.a library located in /usr/local/netscaler/bin.

To create the custom log format by using the NSWL library

1. Add the following two C functions defined by the system in a C source file:
   - `ns_userDefFieldName()`: This function returns the string that must be added as a custom field name in the log record.
   - `ns_userDefFieldVal()`: This function implements the custom field value, then returns it as a string that must be added at the end of the log record.
2. Compile the file into an object file.
3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.
4. Add a %d string at the end of the logFormat string in the configuration file (log.conf).

**Example:**

```plaintext
########## # A new file is created every midnight or on reaching 20MB file size, # and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmddyy.log and create digital #signature field for each record. BEGIN CACHE_F logFormat custom "%a - "%
user-agent }
i" [%d/%B/%Y %T -%g] "%x" %s %b{
referrer }
i "%{
user-agent }
i" %{cookie }
i" %d " logInterval Daily logFileSizeLimit 20 logFilenameFormat /
datadisk5/netscaler/log/%v/NS%{
' %m%d%y }
t.log END CACHE_F
```

**Creating a Custom log format manually**

To customize the format in which log file data should appear, specify a character string as the argument of the LogFormat log property definition. The following is an example where character strings are used to create a log format:

```plaintext
LogFormat Custom "%a - "%{
user-agent }
i" [%d/%m/%Y]t %U %s %b %T
```

- The string can contain the “c” type control characters \n and \t to represent new lines and tabs.
- Use the Esc key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

```plaintext
"*/:<=>?\`
```

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:
%<ASCII value of character in hexadecimal>. 

For example, the character with ASCII value 22 is replaced by %16.

Caution:

If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open should be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache log formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

NCSA/combined: LogFormat custom %h %l %u [%t] “%r” %s %B “%{referer}i” “%{user-agent}i”

NCSA/Common: LogFormat custom %h %l %u [%t] “%r” %s %B

Referer Log: LogFormat custom “%{referer}i” -> %U

Useragent: LogFormat custom %{user-agent}i

Similarly, you can derive the other server log formats from the custom formats.

Arguments for defining a custom log format

Refer to the Custom log format pdf table for more information about defining a custom log format.

Note:

For instructions on how to export custom HTTP headers, see Configuring the Citrix ADC for Web Server Logging

For example, if you define the log format as %+{user-agent}i, and if the user agent value is Citrix ADC system Web Client, then the information is logged as Citrix ADC system+Web+Client. An alternative is to use double quotation marks. For example, “%{user-agent}i” logs it as “Citrix ADC system Web Client.” Do not use the <Esc> key on strings from %.. .r, %. .i and, %. .o. This complies with the requirements of the Common Log Format. Note that clients can insert control characters into the log. Therefore, you should take care when working with raw log files.

Time format definition

Refer to the Time format definition table to know about the format part of the %{format}t string described in the Custom Log Format table. Values within brackets ([ ]) show the range of values that
appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.</td>
</tr>
</tbody>
</table>

The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

### Displaying Server Logs

You can configure a Citrix ADC Web Logging (NSWL) feature to display server logs on the console or redirect server logs to a directory on the Citrix ADC appliance.

There are two ways to display logs on the console (standard output):
- **Option 1:** Display all logs on the console.
- **Option 2:** Display only selected logs on the console where filters with logfilenameformat as STDOUT.

1. **Citrix ADC**
2. **Citrix ADC 12.1**

### Call Home

January 25, 2019

Contributed by:

C

Appliances might sometimes fail to perform well because of software or hardware issues. In such cases, Citrix needs to collect data and perform issue resolution before a potential impact can occur at the customer site. By enabling Call Home on your Citrix ADC appliance, you can automate the error notification process. Not only you avoid calling Citrix Support, raising a service request, and uploading system data before Support team can troubleshoot the issue, but Support can identify and address an issue before it occurs. Call Home periodically monitors the appliance and automatically uploads data to the Citrix technical support server. In addition, the incoming Call Home data provide insights about Citrix ADC usage. Multiple teams within Citrix can use this data to better design, support, and implement Citrix ADC.
By default, Call Home is enabled on all platforms and all flavors of Citrix ADC (MPX, VPX, SDX). By having this feature enabled, you allow Citrix to collect Citrix ADC deployment and telemetry data for better implementation, and support service.

**Note**

You can also see the Call Home FAQ page for information pertaining to Call Home.

**Benefits**

Call Home provides the following benefits.

- Monitor hardware and software error conditions. For more information, see Monitor critical error conditions section.
- Notify critical events that impact your network.
- Send performance data and system usage details to Citrix to:
  - Analyze and improve product quality.
  - Provide real-time troubleshooting information for proactive issue identification, and faster issue resolution.

**Platform support**

Call Home feature is supported on all Citrix ADC platforms and all appliance models (MPX, VPX, and SDX).

- Citrix ADC MPX: All MPX models.
- Citrix ADC VPX: All VPX models, including VPX appliances that obtain their license from external or central licensing pools.
- Citrix ADC SDX: Monitors the disk drive and assigned SSL chips for any errors or failures. The VPX instances, however, do not have access to the Power Supply Unit (PSU) and therefore their status is not monitored. In an SDX platform, you can configure Call Home either directly on an individual instance or through the SVM.

**Prerequisites**

To use Call Home, Citrix ADC must have the following:

- **Internet connection.** Call Home requires an internet connection for Citrix ADC to connect to the Citrix support server for uploading a data archive.
**How Call Home works**

The following figure shows the basic workflow of Call Home in a Citrix ADC appliance deployed at a customer site.

Call Home workflow is as follows:

1. **Set up Internet Connectivity.** For Call Home to upload system data, your appliance must have an internet connectivity. If it does not, you can configure a proxy server configuration to provide internet connectivity. For more information, see Configuring Call Home section.

2. **Enable Call Home.** When upgrading your appliance to the latest software through either Citrix ADC command interface or GUI, Call Home is enabled by default and the system delays the registration process by 24 hours. During this period, you can choose to manually disable the feature, but Citrix recommends you to have it enabled.

   **Note:** If you are upgrading your appliance from an older version that explicitly has Call Home disabled, the system still enables the feature by default and displays a notification message on your first login.

   In addition, if you are doing any configuration changes for an internet connectivity, you must disable and enable Call Home. This enables Call Home to register with Citrix Insight Services (CIS) server without any failure errors.

3. **Register the Citrix ADC appliance on the Citrix Support Server.** When Call Home registers the appliance with the Citrix Support server, the server checks the database for the validity of appliance serial number. If the serial number is valid, the server registers the appliance for Call Home service and sends a successful registration response. Otherwise, the server sends back a registration failure message. The basic system information is sent as a separate message. The data includes memory and CPU usage details along with the throughput numbers. The data is sent periodically as part of the heartbeat message every 7 days, by default. However, a value of less than 5 days is not recommended, because frequent uploads are usually not very useful.

4. **Monitor critical error conditions.** Once registered, Call Home starts monitoring the appliance. The following table lists the conditions Call Home can monitor on the appliance.

<table>
<thead>
<tr>
<th>Critical Error Condition</th>
<th>Description</th>
<th>Call Home Monitoring Interval</th>
<th>Corresponding SNMP Alarm Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compact flash drive errors</td>
<td>The compact flash drive on the appliance encountered read or write failures.</td>
<td>24 hours</td>
<td>COMPACT-FLASH-ERRORS</td>
</tr>
</tbody>
</table>
## Critical Error Condition

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
<th>Call Home Monitoring Interval</th>
<th>Corresponding SNMP Alarm Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hard disk drive errors</td>
<td>The hard drives on the appliance encountered read or write failures.</td>
<td>24 hours</td>
<td>HARD-DISK-DRIVE-ERRORS</td>
</tr>
<tr>
<td>Power supply unit failure</td>
<td>One of the power supply units on the Citrix ADC appliance has failed.</td>
<td>7 seconds</td>
<td>POWER-SUPPLY-FAILURE</td>
</tr>
<tr>
<td>SSL card failure</td>
<td>One of the SSL cards on the Citrix ADC appliance has failed.</td>
<td>7 seconds</td>
<td>SSL-CARD-FAILED</td>
</tr>
<tr>
<td>Warm restart</td>
<td>The appliance has warm restarted due to a failure of a system process.</td>
<td>After every restart of the Citrix ADC appliance.</td>
<td>WARM-RESTART-EVENT</td>
</tr>
<tr>
<td>Memory anomaly error</td>
<td>Memory utilization progressively increases above its normal limit and exceeds the threshold.</td>
<td>1 day</td>
<td>No SNMP alarm</td>
</tr>
<tr>
<td>Rate limit packet drop</td>
<td>The throughput limits or packets-per-second (pps) limits is reached.</td>
<td>7 seconds</td>
<td>PF-RL-PPS-PKTS-DROPPED, PF-RL-RATE-PKTS-DROPPED</td>
</tr>
</tbody>
</table>

5. **Upload Call Home data.** If Call Home identifies any one of the above critical condition on the appliance, the feature notifies Citrix support by automatically uploading the support archive to the Citrix support server. Additionally, you can configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home upload happens. The SNMP alert notifies the local administrator about the critical event.

**Note**

Call Home creates the Call Home tar file and uploads it to the Citrix tech support server for only
the first occurrence of a particular error condition since the last reboot. If you want the appliance to send alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.

6. Create Service Request. For all critical hardware related events such as power supply failure, SSL card failure, hard disk drive errors, and compact flash errors Call Home automatically creates a service request. For other errors, after you review the System Logs, you can contact the Citrix support team to appear a service request for investigation. For more information, see http://support.citrix.com/article/CTX126172.

Configuring Call Home

To configure Call Home, verify the internet connectivity on the appliance and ensure a DNS nameserver is configured. If there is no internet connection, configure a proxy server or service. Then, enable Call Home on the appliance and verify the registration status of the appliance with Citrix support server. Once registered, Call Home can monitor and upload data. In addition, you can configure SNMP alarms to notify the administrator at the customer site.

To configure Call Home, you can use either the Citrix ADC command interface or GUI to do the following tasks:

- Enable Call Home.
- Configure Call Home for optional proxy server parameters.
- Verify Call Home Registration Status.
- View errors and timestamp details.
- Configure SNMP Alarms.

To configure Call Home by using Citrix ADC command interface

The Citrix ADC command interface enables you to do the following:

Enabling Call Home

At the command prompt, type:

```
enable
ns
feature
callhome
```

Configuring Call Home for optional proxy server parameters

Call Home enables you to configure the optional proxy server for internet connectivity. You can either configure a proxy server with IP address and port or configure a proxy authentication service with one-way or two-way authentication.

To configure optional proxy server with IP address and port

At the command prompt, type:
set callhome -proxyMode (YES | NO)[-IPAddress <ip_addr|ipv6_addr|*>] [-port <port |*]]

1 set callhome - proxyMode YES - IPAddress 10.102.167.33 - port 80

Note
Call Home uses the proxy server only when you set the proxy-mode parameter to YES. If you set it to NO, the proxy functionality does not work, even if the IP address and port are configured. The port number should be for an HTTP service, not for an HTTPS service.

To configure optional proxy authentication service

This mode provides two types of security authentication: one-way and two-way. To set up either type, you must configure an SSL service. For more information, see Configuring SSL Service topic.

In one-way authentication, only the Citrix ADC appliance authenticates the proxy server. In two-way authentication, the Citrix ADC appliance authenticates the proxy server and the proxy server, in turn, authenticates the appliance.

To configure proxy authentication service

At the command prompt, type:

set callhome -proxyMode (YES | NO)[-proxyAuthService <string>]

1 set callhome - proxyMode YES - proxyAuthService callhome_proxy

To configure one-way proxy server authentication

Do the following tasks to configure one-way proxy server authentication.

1. Create an SSL service.
2. Bind a CA certificate to the service.
3. Bind an HTTPS Monitor to the service.
4. Configure Call Home to use the SSL service.

To configure two-way proxy server authentication

Do the following tasks to configure two-way proxy server authentication.

1. Create an SSL service
2. Bind a CA certificate to the service.
4. Bind an HTTPS Monitor to the service.
5. Configure Call Home to use the SSL service.

Verifying Call Home Registration status

At the command prompt, type:
show callhome

Registration with Citrix upload server SUCCESSFUL

Mode: Default

Contact email address: exampleadmin@example.com

Heartbeat Custom Interval (days): 7

Proxy Mode: Yes

Proxy IP Address: 10.102.29.200

Proxy Authentication Service:

Proxy Port: 80

<table>
<thead>
<tr>
<th>Trigger event</th>

<tr>
<td>5) Power supply unit failure</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>6) Rate limit packet drops</td>
<td>Enabled</td>
<td>..</td>
<td>..</td>
</tr>
</tbody>
</table>
Enabling SNMP Alarms

The Citrix ADC appliance provides a set of error condition entities called SNMP alarms. When an error condition in a SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the SSL-CARD-FAILED alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a SSL card failure on the appliance. For more information, see SNMP.

At the command prompt, type:

```
enable snmp alarm <trapName>
show snmp alarm <trapName>
```

To configure Call Home by using GUI

To verify if Call Home feature is enabled by default in the GUI

1. Navigate to Configuration > System > Settings.
2. In the details pane, click Configure Advanced features link.
3. In the Configure Advanced Features page, Call Home option must display as enabled.

To enable Call Home by using GUI

1. Navigate to Configuration > System > Settings.
2. In the details pane, click Configure Advanced features link and select Callhome option.

To configure Call Home for optional proxy mode authentication by using GUI

1. You can use any of the two ways to access the Call Home page:
   a) Navigate to System > System Information.
   b) Navigate to System > Diagnostics.
      i. In the details pane, under Technical Support Tools, select Call Home.
2. On the Configure Call Home page, set the following parameters.
   a) Mode. Call Home mode of operation. Possible types: Default, Citrix Service Provider (CSP) deployment.
   b) Email address. Email address of the contact administrator at the customer site.
c) **CallHome Heartbeats Interval (days).** Monitoring interval (in days) between Call Home heartbeats. Minimum value=1 and Maximum value=7.

d) **Enable Call Home.** Enable or disable the Call Home feature to view the status of appliance registration on the Citrix support server.

e) **Proxy Mode.** If you do not have an internet connectivity, enable proxy mode and set the optional proxy parameters.

f) **Proxy Server.** If you set the proxy mode by using a proxy server, specify the server IP address.
   i. **Proxy Service.** If you set the proxy mode by using a proxy service. Specify the service name.
   ii. **IP Address.** IP address of the proxy server.
   iii. **Port.** Port number of the proxy server.
   iv. **Proxy Authentication SSL Service.** Name of the proxy service that provides proxy-mode authentication.

3. Click **OK** and **Done**.

To configure SSL service for proxy server authentication by using GUI

For information about configuring SSL service by using the GUI, see [Configuring SSL Service](#) topic.

To verify Call Home registration status by using GUI

1. You can use any of the two ways to access the **Call Home** page:
   a) Navigate to **System > System Information**.
   b) Navigate to **System > Diagnostics**.
      i. In the details pane, under **Technical Support Tools**, select **Call Home**.

2. In the **Configure Call Home** page, the **Registration with Citrix upload server** field shows the registration status.

To configure an SNMP alarms

1. Navigate to **System > SNMP > Alarms**.
2. In the details pane, select an alarm and configure its parameters.
3. Click **OK** and **Close**.

**Citrix Service Provider (CSP) deployment support**

In a Citrix Service Provider (CSP) environment where Citrix ADC services are deployed on VPX instances, Call Home can monitor and track the license-specific information and securely send the information to Citrix Insights Services (CIS). CIS in turn sends the information to the License Usage Insights (LUI) portal for accounting purposes and for CSP customers to review their license usage. Currently, CSP environments support Citrix ADC services on VPX instances only, not on MPX or SDX appliances. The VPX instances can be deployed in either standalone or high availability mode.
Use the Citrix® Citrix ADC® Reporting tool to view Citrix ADC performance statistics data as reports. Statistics data are collected by the nscollect utility and are stored in a database. When you want to view certain performance data over a period of time, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports as well as the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, nscollect, and stop or start its operation.

Using the reporting tool

The Reporting tool is a Web-based interface accessed from the Citrix® Citrix ADC® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports. You can create a custom report for any number of entities.

To invoke the reporting tool

1. Use the Web browser of your choice to connect to the IP address of the Citrix ADC (for example, http://10.102.29.170/). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the Citrix ADC.
3. In the Password text box, type the password.
4. In the Start in drop-down box, select Reporting. Click Login.

The following screen shots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. Report Toolbar
Figure 2. Chart Toolbar
Working with reports

You can plot and monitor statistics for the various functional groups configured on the Citrix ADC over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a tabular format. The graphical view consists of line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then clicking Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag-and-drop operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.

Using built-in reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, Citrix ADC Gateway, and Citrix ADC Application Firewall. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

Note:
You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report.

To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).
2. Click a report (for example, SSL > All Backend Ciphers).

Creating and deleting reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar.

By default, newly created custom reports contain one chart named System Overview that displays a CPU Usage counter plotted for the last day.

To create a custom report

1. In the Reporting tool, on the report toolbar, click Create, or if you want to create a new custom report based on an existing report, open the existing report, and then click Save As.
2. In Report Name box, type a name for the custom report.
3. Do one of the following:
   • To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click OK.
   • To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click OK.

   Note:
   You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to delete, and then click Delete.

   Note:
   When you delete a folder, all the contents of that folder are deleted.
Modifying the time interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click Duration, and then click a time interval.

Setting the data Source and time zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report’s time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the Reporting tool, on the report toolbar, click Settings.
2. In the Settings dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
   • If you want the tool to remember the time period for which a chart is plotted, select the Remember time selection for charts check box.
   • If you want the reports to use the time settings of your Citrix ADC appliance, select the Use Appliance’s time zone check box.

Exporting and importing custom reports

You can share reports with other Citrix ADC administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to export or import, and then click Export or Import.
Note:
When you export the file, it is exported in a .gz file format.

Working with charts

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats (for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day.

Note:
If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report.

Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.

Modifying a chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to Plot chart for, do one of the following:
   • To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
   • To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In Select group, click the desired entity.
6. Under Counters, in Available, click the counter name(s) that you want to plot, and then click the > button.
7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click the entity instance name(s) you want to plot, and then click the > button.
8. Click OK.

Viewing a chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.

To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click Customize.
3. On the Chart tab, under Category, click Plot type, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Zoom In, and do one or both of the following:
To refocus the chart to display data for a specific time window, drag and drop the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.

To refocus the chart to display data for a data point, simply click once on chart where you want to zoom in and get more detailed information.

3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click Graphical View.

Note: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Scroll, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, click and drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the background color, click Background Color, and then select the options for color, transparency, and effects.
   - To change the text color, click Text Color, and then select the options for color, transparency, and effects.

To customize the axes of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the scale of the left y-axis, click Left Y-Axis, and then select the scale you want.
• To change the scale of the right y-axis, click Right Y-Axis, in Data set to plot, select the date set, and then select the scale you want.

Note:
The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

• To plot each data set in its own hidden y-axis, click Multiple Axes, and then click Enable.

To change the background color, edge color, and gridlines for a plot area of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click Customize.
3. On the Plot Area tab, under Category, click one or more of the following:
   • To change the background color and edge color of the chart, click Background Color and Edge Color, and then select the options for color, transparency, and effects.
   • To change the horizontal or vertical grids of the chart, click Horizontal Grids or Vertical Grids, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

To change the color and graph type of a data set

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click Customize.
3. On the Data Set tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.
   Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.
4. Under Category, do one of more of the following:
   • To change the background color, click Color, and then select the options for color, transparency, and effects.
To change the graph type, click **Plot type**, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

**Exporting chart data to excel**

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click **Export**.

**Deleting a chart**

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the **Delete** icon.

**Examples**

**To display the trend report for CPU usage and memory usage for the last week**

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click **Duration**, and then click **Last Week**.

**To compare the bytes received rate and the bytes transmitted rate between two interfaces for the last week**

1. In the right pane, on the report toolbar, click **Create**.
2. In the **Report Name** box, type a name for the custom report (for example, Custom.Interfaces), and then click **OK**. The report is created with the default System Overview chart, which displays the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click **Counters**.
4. In the counter selection pane, in Title, type a name for the chart (for example, Interfaces bytes data).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the Entities tab, click the interface name(s) you want to plot (for example, 1/1 and 1/2), and then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the > button.
8. Click OK.
9. On the report toolbar, click Duration, and then click Last Week.

**Stopping and starting the data collection utility**

The data collection utility, nscollect, runs automatically when you start the Citrix ADC. This utility retrieves the application performance data and stores it in the form of data sources on the ADC. You can create up to 32 data sources. The default data source is /var/log/db/default.

The data collection utility creates databases for global counters and entity-specific counters, and uses this data to generate reports. Global-counter databases are created at /var/log/db/<DataSourceName>. The entity-specific databases are created based on the entities configured on the Citrix ADC, and a separate folder is created for each entity type in /var/log/db/<DataSourceName/EntityNameDB>.

Nscollect retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day, hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the reports display corrupted data.

**To stop nscollect**

At the command prompt, type:

```
/netscaler/nscollect stop
```

**To start nscollect on the current SSH session to the Citrix ADC:**

At the command prompt, type:

```
/netscaler/nscollect start
```

**To start nscollect on the local system:**

At the command prompt, type:

```
/netscaler/nscollect start &
```
CloudBridge Connector

January 25, 2019
Contributed by: C

Note: The current Citrix ADC 1000V release does not support this feature.

The CloudBridge Connector feature of the Citrix ADC appliance connects enterprise datacenters to external clouds and hosting environments, making the cloud a secure extension of your enterprise network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network. With Citrix CloudBridge Connector, you can augment your datacenters with the capacity and efficiency available from cloud providers.

The CloudBridge Connector enables you to move your applications to the cloud to reduce costs and increase reliability.

In addition to using CloudBridge Connector between a datacenter and a cloud, you can use it to connect two datacenters for a high-capacity secure and accelerated link.

Understanding CloudBridge Connector

To implement the Citrix CloudBridge Connector solution, you connect a datacenter to another datacenter or an external cloud by setting up a tunnel called the CloudBridge Connector tunnel.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between two Citrix ADC appliances, one in each datacenter.

To connect a datacenter to an external cloud (for example, Amazon AWS cloud), you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual appliance (VPX) that resides in the Cloud. The remote end point can be a CloudBridge Connector or a Citrix ADC VPX with platinum license.

The following illustration shows a CloudBridge Connector tunnel set up between a datacenter and an external cloud.

The appliances between which a CloudBridge Connector tunnel is set up are called the end points or peers of the CloudBridge Connector tunnel.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
A CloudBridge Connector tunnel uses the following protocols:

- Generic Routing Encapsulation (GRE) protocol
- Open-standard IPSec Protocol suite, in transport mode

The GRE protocol provides a mechanism for encapsulating packets, from a wide variety of network protocols, to be forwarded over another protocol. GRE is used to:

- Connect networks running non-IP and non-routable protocols.
- Bridge across a wide area network (WAN).
- Create a transport tunnel for any type of traffic that needs to be sent unchanged across a different network.

The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

The Internet Protocol security (IPSec) protocol suite secures communication between peers in the CloudBridge Connector tunnel.

In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the transport mode in which the GRE encapsulated packet is encrypted. The encryption is done by the Encapsulating Security Payload (ESP) protocol. The ESP protocol ensures the integrity of the packet by using a HMAC hash function, and ensures confidentiality by using an encryption algorithm. After the packet is encrypted and the HMAC is calculated, an ESP header is generated. The ESP header is inserted after the GRE IP header and, an ESP trailer is inserted at the end of the encrypted payload.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version (IKE) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

- The two peers mutually authenticate with each other, using one of the following authentication methods:
  - **Pre-shared key authentication.** A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
  - **Digital certificates authentication.** The initiator (sender) peer signs message interchange data by using its private key, and the other receiver peer uses the sender’s public key to verify the signature. Typically, the public key is exchanged in messages containing
an X.509v3 certificate. This certificate provides a level of assurance that a peer’s identity as represented in the certificate is associated with a particular public key.

- The peers then negotiate to reach agreement on:
  - An encryption algorithm.
  - Cryptographic keys for encrypting data in one peer and decrypting the data in the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when two peers, CB1 and CB2, are communicating through a Connector tunnel, CB1 has two Security Associations. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets.

SAs expire after a specified length of time, which is called the lifetime. The two peers use the Internet Key Exchange (IKE) protocol (part of the IPSec protocol suite) to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

The following table lists some IPSec properties supported by a Citrix ADC appliance:

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Types Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKE Versions</td>
<td>V1, V2</td>
</tr>
<tr>
<td>IKE Authentication Methods</td>
<td>Pre-shared key authentication, Digital certificates authentication</td>
</tr>
<tr>
<td>Encryption Algorithm</td>
<td>AES (128 bits), AES 256 (256 bits), 3DES</td>
</tr>
<tr>
<td>Hash Algorithm</td>
<td>HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5</td>
</tr>
</tbody>

Moni
Monitoring CloudBridge Connector tunnels

Monitoring CloudBridge Connector tunnels

January 23, 2019

You can display the statistics for monitoring the performance of a CloudBridge Connector tunnel. To display CloudBridge Connector tunnel statistics on a Citrix ADC appliance, use the GUI or the Citrix
ADC command line.

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a Citrix ADC appliance.

<table>
<thead>
<tr>
<th>Statistical counter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes Received</td>
<td>Total number of bytes received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>Total number of bytes sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Packets Received</td>
<td>Total number of packets received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Packets Sent</td>
<td>Total number of packets sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Bytes Received Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Bytes Sent Rate</td>
<td>Number of bytes per second sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Packets Received Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Packets Sent Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
</tbody>
</table>

All these counters are reset to 0 when the Citrix ADC appliance is restarted. They do not increment
during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.

To display CloudBridge Connector tunnel statistics by using the Citrix ADC command line

At the command prompt, type:

- `stat ipsec counters`

To display CloudBridge Connector tunnel statistics by using the GUI

1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance.
2. On the Configuration tab, navigate to System > CloudBridge Connector.
3. On the CloudBridge Connector page, click Create/Monitor CloudBridge Connector. The IPSec Bytes and IPSec Packets charts display the bytes received rate, bytes sent rate, packets received rate, and packets sent rate of all the CloudBridge Connector tunnels configured on the Citrix ADC appliance.

<table>
<thead>
<tr>
<th></th>
<th>Rate (/s)</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes Received</td>
<td>0</td>
<td>2811248</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>0</td>
<td>157460630</td>
</tr>
<tr>
<td>Packets Received</td>

**Configuring a CloudBridge Connector tunnel between two datacenters**

January 25, 2019

Contributed by: C

You can configure a CloudBridge Connector tunnel between two different datacenters to extend your network without reconfiguring it, and leverage the capabilities of the two datacenters. A CloudBridge
Connector tunnel between the two geographically separated datacenters enables you to implement redundancy and safeguard your setup from failure. The CloudBridge Connector tunnel helps achieve optimal utilization of infrastructure and resources across datacenters. The applications available across the two datacenters appear as local to the user.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in one datacenter and a Citrix ADC appliance in the other datacenter.

As an illustration of CloudBridge Connector tunnel between datacenters, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in datacenter DC1 and Citrix ADC appliance NS_Appliance-2 in datacenter DC2.

Both NS_Appliance-1 and NS_Appliance-2 function in L2 and L3 mode. They enable communication between private networks in datacenters DC1 and DC2. In L3 mode, NS_Appliance-1 and NS_Appliance-2 enable communication between client CL1 in datacenter DC1 and server S1 in the datacenter DC2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Because client CL1 and server S1 are on different private networks, L3 mode is enabled on NS_Appliance-1 and NS_Appliance-2, and routes are updated as follows:

- CL1 has a route to NS_Appliance-1 for reaching S1.
- NS_Appliance-1 has a route to NS_Appliance-2 for reaching S1.
- S1 has a route to NS_Appliance-2 for reaching CL1.
- NS_Appliance-2 has a route to NS_Appliance-1 for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-1 in datacenter DC1.
The following table lists the settings on Citrix ADC appliance NS_Appliance-2 in datacenter DC2.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>The NSIP address</td>
<td>198.51.100.12</td>
<td></td>
</tr>
<tr>
<td>SNIP address</td>
<td>198.51.100.15</td>
<td></td>
</tr>
</tbody>
</table>
Points to consider for configuring CloudBridge Connector tunnel

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Deploy and set up a Citrix ADC appliance in each of the two datacenters.
2. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Configuration procedure

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in one datacenter and another Citrix ADC appliance that resides in the other datacenter, use the GUI or the command line interface of one of the Citrix ADC appliances.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the first Citrix ADC appliance is automatically pushed to the other endpoint (the other Citrix ADC appliance) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI of the other Citrix ADC appliance to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on each of the Citrix ADC appliances consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the
CloudBridge Connector tunnel.

- **GRE tunnel**—An IP tunnel specifies the local IP address (a public SNIP address configured on the local Citrix ADC appliance), remote IP address (a public SNIP address configured on the remote Citrix ADC appliance), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.

- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the first datacenter and is destined to a server on the subnet in the second datacenter. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the first datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

```
add ipsec profile <name> [-ikeVersion ( V1 | V2 )] [-encAlgo ( AES | 3 DES )...] [-hashAlgo <hashAlgo>... ] [-lifetime <positive_integer>]( -psk | (-publickey<string> -privatekey <string>-peerPublickey <string>))[ -livenessCheckInterval <positive_integer>][ -replayWindowSize <positive_integer>][ -ikeRetryInterval <positive_integer>][ -retransmissiontime <positive_integer>] 
```

```
show ipsec profile <name>
```

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

```
add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol < protocol>] [-ipsecProfileName <string>] 
```

```
show ipTunnel <name>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

```
add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name> 
```

```
apply ns pbrs 
```

```
show ns pbr <pbr_name>
```

**Example**
To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI:

1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.
2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.
3. Navigate to **System > CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
   The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.
5. On the **Welcome** screen click **Get Started**.

**Note:**
If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the **CloudBridge Connector Setup** pane, click **Citrix ADC**.
2. In the Citrix ADC pane, provide your account credentials for the remote Citrix ADC appliance. Click **Continue**.
3. In the **CloudBridge Connector Setting** pane, set the following parameter:
   - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.
3. Under **Local Setting**, set the following parameter:
   - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel.

4. Under **Remote Setting**, set the following parameter:
   - **Subnet IP**—IP address of the peer endpoint of the CloudBridge Connector tunnel.

5. Under **PBR Setting**, set the following parameters:
   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - **Source IP Low**—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - **Destination IP Low**—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
   - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.

6. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:
   - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   - **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
     - **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
     - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
       * Pre Shared Security Key—The text string entered for pre-shared key based authentication.
     - **Upload Certificates**—Authentication based on digital certificates.
       * **Public Key**—A local digital certificate to be used to authenticate the local Citrix ADC appliance to the peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
       * **PrivateKey**—Private key of the local digital certificate.
       * **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer.
to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

7. Click Done.

The new CloudBridge Connector tunnel configuration on both the Citrix ADC appliances appears on the Home tab of the respective GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge Connectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring CloudBridge Connector between datacenter and AWS cloud

January 25, 2019
Contributed by: C

You can configure a CloudBridge Connector tunnel between a datacenter and AWS cloud to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.

To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a Citrix ADC virtual appliance (VPX) that resides in AWS cloud.

As an illustration of a CloudBridge Connector tunnel between a datacenter and Amazon AWS cloud, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-DC, in datacenter DC, and Citrix ADC virtual appliance (VPX) NS_VPX_Appliance-AWS.
Both NS_Appliance-DC and NS_VPX_Appliance-AWS function in L3 mode. They enable communication between private networks in datacenter DC and the AWS cloud. NS_Appliance-DC and NS_VPX_Appliance-AWS enable communication between client CL1 in datacenter DC and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

**Note:**
AWS does not support L2 mode, hence it is necessary to have only L3 mode enabled on both the endpoints.

For proper communication between CL1 and S1, L3 mode is enabled on NS_Appliance-DC and NS_VPX_Appliance-AWS and routes are updated as such:

- CL1 have a route to NS_Appliance-DC for reaching S1.
- NS_Appliance-DC have a route to NS_VPX_Appliance-AWS for reaching S1.
- S1 should have a route to NS_VPX_Appliance-AWS for reaching CL1.
- NS_VPX_Appliance-AWS have a route to NS_Appliance-DC for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-DC in datacenter DC.

<table>

</tr>
</tbody>
</table>

**Prerequisites**

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Install, configure, and launch an instance of Citrix ADC Virtual appliance (VPX) on AWS cloud. For instructions on installing Citrix ADC VPX on AWS, see [http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/nsvpx-aws-ns-vpxaws-con.html](http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/nsvpx-aws-ns-vpxaws-con.html).

2. Deploy and configure a Citrix ADC physical appliance, or provisioning and configuring a Citrix ADC virtual appliance (VPX) on a virtualization platform in the datacenter.
   - For instructions on installing Citrix ADC virtual appliances on VMware ESX or ESXi, see [http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-esx-wrapper-con.html](http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-esx-wrapper-con.html).

2. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.
Citrix ADC VPX license

After the initial instance launch, Citrix ADC VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: http://support.citrix.com/article/CTX122426.

You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a paid marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Configuration steps

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in a datacenter and a Citrix ADC virtual appliance (VPX) that resides on the AWS cloud, use the GUI of the Citrix ADC appliance.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on AWS) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI (GUI) of the Citrix ADC VPX on AWS to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on both peers (the Citrix ADC appliance that resides in the datacenter and the Citrix ADC virtual appliance (VPX) that resides on the AWS cloud) consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in both the peers of the CloudBridge Connector tunnel.

- **GRE tunnel**—An IP tunnel specifies a local IP address (a public SNIP address configured on the local peer), remote IP address (a public SNIP address configured on the remote peer), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.

- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the datacenter and is destined to a server on the subnet in the AWS cloud. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSec profile by using the command line interface
At the command prompt, type:

- `add ipsec profile <name> [-**ikeVersion** ( V1 | V2 )] [-**encAlgo** ( AES | 3DES )] [-**hashAlgo** <hashAlgo> ...] [-**lifetime** < positive_integer>] [-**psk** | -**publickey** <string> -**privatekey** <string> -**peerPublicKey** <string>] [-**livenessCheckInterval** <positive_integer>] [-**replayWindowSize** <positive_integer>] [-**ikeRetryInterval** <positive_integer>] [-**retransmissiontime** <positive_integer>]`

- `**show ipsec profile** <name>`

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- `add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol < protocol>] [-ipsecProfileName <string>]`

- `**show ipTunnel** <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- `add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name>`

- `**apply ns pbrs**`

- `**show ns pbr <pbr_name>**`

Example

```
1  > add ipsec profile CC_Tunnel_DC-AWS -encAlgo AES -hashAlgo HMAC_SHA1
2  Done
3  > add ipTunnel CC_Tunnel_DC-AWS 168.63.252.133 255.255.255.0
4  66.165.176.15 - protocol GRE -ipsecProfileName CC_Tunnel_DC-AWS
5  Done
6  > add ns pbr PBR-DC-AWS ALLOW - srcIP 66.165.176.15 - destIP 168.63.252.133 ipTunnel CC_Tunnel_DC-AWS
7  Done
8  > apply ns pbrs
9  Done
```

To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI
1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.

2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.

3. Navigate to System > CloudBridge Connector.

4. In the right pane, under Getting Started, click Create/Monitor CloudBridge.

5. The first time you configure a CloudBridge Connector tunnel on the appliance, a Welcome screen appears.

6. On the Welcome screen click Get Started.

Note:

If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the CloudBridge Connector Setup pane, click amazon web services

1. In the Amazon pane, provide your AWS account credentials: AWS Access Key ID and AWS Secret Access Key. You can obtain these access keys from the AWS GUI console. Click Continue.

   Note

   Earlier, the Setup wizard always connects to the same AWS region even when another region is selected. As a result, configuring CloudBridge Connector tunnel to a Citrix ADC VPX running on the selected AWS region used to fail. This issue has been fixed now.

2. In the Citrix ADC pane, select the NSIP address of the Citrix ADC virtual appliance running on AWS. Then, provide your account credentials for the Citrix ADC virtual appliance. Click Continue.

3. In the CloudBridge Connector Setting pane, set the following parameter:

   • CloudBridge Connector Name—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.

4. Under Local Setting, set the following parameter:

   • Subnet IP—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.

5. Under Remote Setting, set the following parameter:

   • Subnet IP—IP address of the CloudBridge Connector tunnel end point on the AWS side. Must be an IP address of type SNIP on the Citrix ADC VPX instance on AWS.
• **NAT**—Public IP address (EIP) in AWS that is mapped to the SNIP configured on the Citrix ADC VPX instance on AWS.

6. Under **PBR Setting**, set the following parameters:

   • **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   • **Source IP Low**—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
   • **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
   • **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   • **Destination IP Low**—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
   • **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.

7. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the Cloud-Bridge Connector tunnel:

   • **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   • **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   • **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
     - **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
     - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
       * **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.
     - **Upload Certificates**—Authentication based on digital certificates.
       * **Public Key**—A local digital certificate to be used to authenticate the local peer to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
       * **Private Key**—Private key of the local digital certificate.
       * **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

8. Click **Done**.

The new CloudBridge Connector tunnel configuration on the Citrix ADC appliance in the datacenter
appears on the Home tab of the GUI. The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC VPX appliance in the AWS cloud appears on the GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see [Monitoring CloudBridge Connector Tunnels](#).

2. Citrix ADC 12.1

**Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and virtual private gateway on AWS**

January 25, 2019

Contributed by: C

To connect a datacenter to Amazon Web Services (AWS), you can configure a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual private gateway on AWS. The Citrix ADC appliance and the virtual private gateway form the endpoints of the CloudBridge Connector tunnel and are called peers.

**Note:**

You can also set up a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and a Citrix ADC VPX instance (instead of a virtual private gateway) on AWS. For more information, see [Configuring CloudBridge Connector between Datacenter and AWS Cloud](#).

Virtual private gateways on AWS support the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.
example of CloudBridge Connector tunnel configuration and data flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in a datacenter and virtual private gateway gateway AWS-Virtual-Private-Gateway-1 on AWS cloud.

NS_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the AWS cloud through the CloudBridge Connector tunnel. As a router, NS_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named NS.AWS_IPSec_Profile, a CloudBridge Connector tunnel entity named NS.AWS_Tunnel, and a policy based routing (PBR) entity named NS.AWS_Pbr.

The IPSec profile entity NS.AWS_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. NS.AWS_IPSec_Profile is bound to IP tunnel entity NS.AWS_Tunnel.

CloudBridge Connector tunnel entity NS.AWS_Tunnel specifies the local IP address (a public IP—SNIP—address configured on the Citrix ADC appliance), the remote IP address (the IP address of the AWS-Virtual-Private-Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. NS.AWS_Tunnel is bound to policy based routing (PBR) entity NS.AWS_Pbr.

The PBR entity NS.AWS_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (NS.AWS_Tunnel). The source IP address range and the destination IP address range are the conditions for NS.AWS_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the AWS cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the AWS cloud matches the conditions in NS.AWS_Pbr. This packet is then considered for CloudBridge Con-
nector processing and is sent across the CloudBridge Connector tunnel (NS_AWS_Tunnel) bound to the PBR entity.

The following table lists the settings used in this example.

| IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in the datacenter side | 66.165.176.15 |
| IP address of the CloudBridge Connector tunnel end point (AWS-Virtual-Private-Gateway-1) in the AWS Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel | 168.63.252.133 10.102.147.0/24 |
| AWS Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel | 10.20.20.0/24 |

Settings on Amazon AWS

| Customer Gateway | AWS-Customer-Gateway-1 | Routing = Static, IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side = 66.165.176.15 |
| Virtual Private Gateway | AWS-Virtual-Private-Gateway-1 | Associated VPC = AWS-VPC-1 |
| VPN Connection | AWS-VPN-Connection-1 | Customer Gateway = AWS-Customer-Gateway-1, Virtual Private Gateway= Virtual-Private-Gateway-1, Routing Options: Type = Static, Static IP Prefixes = Subnets on the Citrix ADC side = 10.102.147.0/24 |

Settings on Citrix ADC appliance NS_Appliance-1 in Datacenter-1:

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, consider the following points:

1. AWS supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.
   - IKE version = v1
   - Encryption algorithm = AES
   - Hash algorithm = HMAC SHA1

2. You must configure the firewall at the Citrix ADC end to allow the following.
   - Any UDP packets for port 500
   - Any UDP packets for port 4500
   - Any ESP (IP protocol number 50) packets

3. You must configure Amazon AWS before specifying the tunnel configuration on the Citrix ADC, because the public IP address of the AWS end (gateway) of the tunnel and the PSK are automatically generated when you set up the tunnel configuration in AWS. You need this information for specifying the tunnel configuration on the Citrix ADC appliance.

4. AWS gateway supports static routes and the BGP protocol for route updates. The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.
Configuring Amazon AWS for the CloudBridge Connector tunnel

To create a CloudBridge Connector tunnel configuration on Amazon AWS, use the Amazon AWS Management Console, which is a web based graphical interface for creating and managing resources on Amazon AWS.

Before you begin the CloudBridge Connector tunnel configuration on AWS cloud, make sure that:

- You have a user account for Amazon AWS cloud.
- You have a virtual private cloud whose networks you want to connect to the networks at the Citrix ADC side through the CloudBridge Connector tunnel.
- You are familiar with the Amazon AWS Management Console.

Note:
The procedures for configuring Amazon AWS for a CloudBridge Connector tunnel might change over time, depending on the Amazon AWS release cycle. Citrix recommends you refer Amazon AWS documentation for the latest procedures.

To configure a CloudBridge connector tunnel between a Citrix ADC and AWS gateway perform the following tasks on the AWS Management Console:

- **Create a Customer Gateway.** A customer gateway is an AWS entity that represents a CloudBridge Connector tunnel endpoint. For a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, the customer gateway represents the Citrix ADC appliance on AWS. The customer gateway specifies a name, the type of routing (static or BGP) used in the tunnel, and the CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

- **Create a Virtual Private Gateway and attach it to a VPC.** A virtual private gateway is a CloudBridge Connector tunnel endpoint at the AWS side. When you create a virtual private gateway, you assigned it a name or allow AWS to assign the name. You then associate the virtual private gateway with a VPC. This association enables the subnets of the VPC to connect to the subnets at the Citrix ADC side through the CloudBridge Connector tunnel.

- **Create a VPN Connection.** A VPN connection specifies a customer gateway and a virtual private gateway between which a CloudBridge Connector tunnel is to be created. It also specifies an IP prefix for the networks at the Citrix ADC side. Only IP prefixes that are known to the virtual private gateway (through static route entry) can receive traffic from the VPC through the tunnel. Also, the virtual private gateway does not route any traffic not destined to the specified IP prefixes through the tunnel. After configuring a VPN connection, you might have to wait few minutes for it to be created.

- **Configure Routing Options.** For the VPC’s network to reach the networks at the Citrix ADC side through the CloudBridge Connector tunnel, you must configure the VPC’s routing table to
include routes for the networks at the Citrix ADC side and point those routes to the virtual private gateway. You can include routes in a VPC’s routing table in one of the following ways:

- **Enable Route Propagation.** You can enable route propagation for your routing table, so that routes are automatically propagated to the table. The static IP prefixes that you specify for VPN configuration are propagated to the routing table after you’ve created the VPN connection.

- **Enter Static Routes Manually.** If you do not enable route propagation, you must manually enter the static routes for the networks at the Citrix ADC side.

- **Download Configuration.** After the CloudBridge Connector tunnel (VPN connection) configuration is created on AWS, download the configuration file of the VPN connection to your local system. You might need the information in the configuration file for configuring the CloudBridge Connector tunnel on the Citrix ADC appliance.

To create a customer gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Navigate to **VPN Connections > Customer Gateways** and click on **Create Customer Gateway.**
3. In the Create Customer Gateway dialog box, set the following parameters and then click **Yes, Create:**
   - **Name tag.** A name for the customer gateway.
   - **Routing list.** Type of routing between Citrix ADC appliance and AWS virtual private gateway for advertising routes to each other through the CloudBridge Connector tunnel. Select **Static Routing** from the Routing list. **Note:** The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.
   - **IP Address.** Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

To create a virtual private gateway and attach it to a VPC

1. Navigate to **VPN Connections > Virtual Private Gateways**, and then click Create Virtual Private Gateway.
2. Enter a name for the virtual private gateway, and then click Yes, Create.

   1. Select the virtual private gateway that you created, and then click Attach to VPC.
   2. In the Attach to VPC dialog box, select your VPC from the list, and then choose Yes, Attach.

**To create a VPN connection:**

1. Navigate to VPN Connections > VPN Connections and then click Create VPN Connection.
2. In the Create VPN Connection dialog box set the following parameters and then choose Yes,
Create:

- **Name tag.** A name for the VPN connection.
- **Virtual Private Gateway.** Select the virtual private gateway that you created earlier.
- **Customer Gateway.** Select Existing. Then, from the drop down list, select the customer gateway that you created earlier.
- **Routing Options.** Type of routing between the virtual private gateway and customer gateway (Citrix ADC appliance). Select Static. In the Static IP Prefixes field, specify the IP prefixes for the subnet on the Citrix ADC side, separated by commas.

**To enable route propagation:**

1. Navigate to **Route Tables** and select the routing table that's associated with the subnet whose traffic is to traverse the CloudBridge Connector tunnel.

   **Note**
   
   By default, this is the main routing table for the VPC.

2. On the **Route Propagation** tab in the details pane, choose **Edit**, select the virtual private gateway, and then choose **Save**.

**To manually enter static routes:**

1. Navigate to **Route Tables** and select your routing table.
2. On the **Routes** tab, click **Edit**.
3. In the **Destination** field, enter the static route used by your CloudBridge Connector tunnel (VPN connection).
4. Select the virtual private gateway ID from the **Target** list, and then click **Save**.

**To download the configuration file:**

1. Navigate to **VPN Connection**, select a VPN connection, and then click **Download Configuration**.
2. In the **Download Configuration** dialog box, set the following parameters, and then click **Yes, Download**.
   
   - **Vendor.** Select **Generic**.
   - **Platform.** Select **Generic**.
   - **Software.** Select **Vendor Agnostic**.

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a virtual private gateway on AWS cloud, perform the following tasks on the Citrix ADC appliance.
You can use either the Citrix ADC command line or the GUI.
• **Create an IPsec profile.** An IPsec profile entity specifies the IPsec protocol parameters, such as IKE version, encryption algorithm, hash algorithm and PSK to be used by the IPsec protocol in the CloudBridge Connector tunnel.

• **Create an IP tunnel that uses IPsec protocol and associate the IPsec profile with it.** An IP tunnel specifies the local IP address (a SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the virtual private gateway in AWS), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPsec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

• **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to traverse the tunnel, and set the destination IP address range to specify the AWS VPC subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet that originates from a client in the subnet on the Citrix ADC side and is destined to a server in the AWS cloud subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the Citrix ADC command line

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion** v1`
- `show ipsec profile** <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the Command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the Command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP** <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbr <pbrName>`

The following commands create all settings of Citrix ADC appliance NS_Appliance-1 used in “Example of CloudBridge Connector Configuration and Data Flow.”
To create an IPSEC profile by using the GUI

1. Navigate to **System > CloudBridge Connector > IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version (select V1)
4. Select the **Pre-shared Key Authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System > CloudBridge Connector > IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click Add.
3. In the **Add IP Tunnel** dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
   - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3905
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** dialog box, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters.

For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see **Monitoring CloudBridge Connector Tunnels**.

**Configuring a CloudBridge Connector tunnel between a datacenter and Azure cloud**

January 30, 2019
The Citrix ADC appliance provides connectivity between your enterprise datacenters and the Microsoft cloud hosting provider, Azure, making Azure a seamless extension of the enterprise network. Citrix ADC encrypts the connection between the enterprise datacenter and Azure cloud so that all data transferred between the two is secure.

How CloudBridge Connector tunnel works

To connect a datacenter to Azure cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a gateway that resides in the Azure cloud. The Citrix ADC appliance in the datacenter and the gateway in Azure cloud are the end points of the CloudBridge Connector tunnel and are called peers of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel between a datacenter and Azure cloud uses the open-standard Internet Protocol security (IPSec) protocol suite, in tunnel mode, to secure communications between peers in the CloudBridge Connector tunnel. In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the tunnel mode in which the complete IP packet is encrypted and then encapsulated. The encryption uses the Encapsulating Security Payload (ESP) protocol, which ensures the integrity of the packet by using a HMAC hash function and ensures confidentiality by using an encryption algorithm. The ESP protocol, after encrypting the payload and calculating the HMAC, generates an ESP header and inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and inserts it at the end of the packet.

The IPSec protocol then encapsulates the resulting packet by adding an IP header before the ESP header. In the IP header, the destination IP address is set to the IP address of the CloudBridge Connector peer.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version 1 (IKEv1) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

1. The two peers mutually authenticate with each other, using pre-shared key authentication, in which the peers exchange a text string called a pre-shared key (PSK). The pre-shared keys are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.

2. The peers then negotiate to reach agreement on:
• An encryption algorithm
• Cryptographic keys for encrypting data on one peer and decrypting it on the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when a CloudBridge Connector tunnel is set up between a Citrix ADC appliance in a datacenter and a gateway in an Azure cloud, both the datacenter appliance and the Azure gateway have two SAs. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets. SAs expire after a specified interval of time, which is called the lifetime.

**Example of CloudBridge Connector tunnel configuration and data flow**

As an illustration of CloudBridge Connector Tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance CB_Appliance-1 in a datacenter and gateway Azure_Gateway-1 in Azure cloud.

CB_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the Azure cloud through the CloudBridge Connector tunnel. As a router, CB_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the Azure cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On CB_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named CB_Azure_IPSec_Profile, a CloudBridge Connector tunnel entity named CB_Azure_Tunnel, and a policy based routing (PBR) entity named CB_Azure_Pbr.

The IPSec profile entity CB_Azure_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. CB_Azure_IPSec_Profile is bound to IP tunnel entity CB_Azure_Tunnel.

CloudBridge Connector tunnel entity CB_Azure_Tunnel specifies the local IP address (a public IP address configured on the Citrix ADC appliance), the remote IP address (the IP address of the Azure_Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. CB_Azure_Tunnel is bound to the PBR entity CB_Azure_Pbr.

The PBR entity CB_Azure_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (CB_Azure_Tunnel). The source IP address range and the destination IP address range are the conditions for CB_Azure_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the Azure cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the Azure cloud matches the conditions in CB_Azure_Pbr. This packet is then considered for CloudBridge processing and is sent across the CloudBridge Connector tunnel (CB_Azure_Tunnel) bound to the PBR entity.
On Microsoft Azure, the CloudBridge Connector tunnel configuration includes a local network entity named My-Datacenter-Network, a virtual network entity named Azure-Network-for-CloudBridge-Tunnel, and a gateway named Azure_Gateway-1.

The local (local to Azure) network entity My-Datacenter-Network specifies the IP address of the Citrix ADC appliance on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network entity Azure-Network-for-CloudBridge-Tunnel defines a private subnet named Azure-Subnet-1 in Azure. The traffic of the subnet traverses the CloudBridge Connector tunnel. The server S1 is provisioned in this subnet.

The local network entity My-Datacenter-Network is associated with the virtual network entity Azure-Network-for-CloudBridge-Tunnel. This association defines the remote and local network details of the CloudBridge Connector tunnel configuration in Azure. Gateway Azure_Gateway-1 was created for this association to become the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel.

For more information about the settings, refer to the CloudBridge Connector Tunnel Settings pdf.

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Microsoft Azure, consider the following points:

1. The Citrix ADC appliance must have a public facing IPv4 address (type SNIP) to use as a tunnel end-point address for the CloudBridge Connector tunnel. Also, the Citrix ADC appliance should not be behind a NAT device.
2. Azure supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings while configuring the Citrix ADC for the CloudBridge Connector tunnel.
   • IKE version = v1
   • Encryption algorithm = AES
   • Hash algorithm = HMAC SHA1
3. You must configure the firewall in the datacenter edge to allow the following.
   • Any UDP packets for port 500
   • Any UDP packets for port 4500
   • Any ESP (IP protocol number 50) packets
4. IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge Connector tunnel end points to establish new SAs, is not supported. When the Security Associations (SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for the lifetimes of SAs.
5. You must configure Microsoft Azure before specifying the tunnel configuration on the Citrix ADC, because the public IP address of the Azure end (gateway) of the tunnel, and the PSK, are auto-
matically generated when you set up the tunnel configuration in Azure. You need this information for specifying the tunnel configuration on the Citrix ADC.

**Configuring the CloudBridge Connector tunnel**

For setting up a CloudBridge Connector tunnel between your datacenter and Azure, you must install CloudBridge VPX/MPX in your datacenter, configure Microsoft Azure for the CloudBridge Connector tunnel, and then configure the Citrix ADC appliance in the data center for the CloudBridge Connector tunnel.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Microsoft Azure consists of the following tasks:

1. **Setting up the Citrix ADC appliance in the datacenter.** This task involves deploying and configuring a Citrix ADC physical appliance (MPX), or provisioning and configuring a Citrix ADC virtual appliance (VPX) on a virtualization platform in the datacenter.

2. **Configuring Microsoft Azure for the CloudBridge Connector tunnel.** This task involves creating local network, virtual network, and gateway entities in Azure. The local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC appliance) on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network defines a network on Azure. Creating the virtual network includes defining a subnet whose traffic is to traverse the CloudBridge Connector tunnel to be formed. You then associate the local network with the virtual network. Finally, you create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel.

3. **Configuring the Citrix ADC appliance in the datacenter for the CloudBridge Connector tunnel.** This task involves creating an IPSec profile, an IP tunnel entity, and a PBR entity in the Citrix ADC appliance in datacenter. The IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used in the CloudBridge Connector tunnel. The IP tunnel specifies the IP address of both the CloudBridge Connector tunnel end points (the Citrix ADC appliance in datacenter and the gateway in Azure) and the protocol to be used in the CloudBridge Connector tunnel. You then associate the IPSec profile entity with the IP tunnel entity. The PBR entity specifies the two subnets, in the datacenter and in the Azure cloud, that are to communicate with each other through the CloudBridge Connector tunnel. You then associate the IP tunnel entity with the PBR entity.

**Configuring Microsoft Azure for the CloudBridge Connector tunnel**

To create a CloudBridge Connector tunnel configuration on Microsoft Azure, use the Microsoft Windows Azure Management Portal, which is a web based graphical interface for creating and managing resources on Microsoft Azure.
Before you begin the CloudBridge Connector tunnel configuration on Azure cloud, make sure that:

- You have a user account for Microsoft Azure.
- You have a conceptual understanding of Microsoft Azure.
- You are familiar with the Microsoft Windows Azure Management Portal.

**Note:**
The procedures for configuring Microsoft Azure for a CloudBridge Connector tunnel might change over time, depending on the Microsoft Azure release cycle. Citrix recommends the following Microsoft Azure documentation for the latest procedures.

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on Microsoft Azure by using the Microsoft Windows Azure Management Portal:

- **Create a local network entity.** Create a local network entity in Windows Azure for specifying the network details of the datacenter. A local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC) on the datacenter side and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel.

- **Create a Virtual Network.** Create virtual network entity that defines a network on Azure. This task includes defining a private address space, where you provide a range of private addresses and subnets belonging to the range specified in the address space. The traffic of the subnets will traverse the CloudBridge Connector tunnel. You then associate a local network entity with the virtual network entity. This association lets Azure create a configuration for a CloudBridge Connector tunnel between the virtual network and the data center network. A gateway (to be created) in Azure for this virtual network will be the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel. You then define a private subnet for the gateway to be created. This subnet belongs to the range specified in the address space in the virtual network entity.

- **Create a gateway in Windows Azure.** Create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel. Azure, from its pool of public IP addresses, assigns an IP address to the gateway created.

- **Gather the public IP address of the gateway and the pre-shared key.** For a CloudBridge Connector tunnel configuration on Azure, the public IP address of the gateway and the pre-shared Key (PSK) are automatically generated by Azure. Make a note of this information. You will need it for configuring the CloudBridge Connector tunnel on the Citrix ADC in datacenter.

To specify a local network by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + NEW.
3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click REGISTER LOCAL NETWORK.
4. In the ADD A LOCAL NETWORK wizard, in the specify your local network details screen, set the following parameters:
   - NAME
   - VPN DEVICE IP ADDRESS

5. In the lower right corner of the screen, click -> (forward arrow mark).

6. On the Specify the address space screen, set the following parameter:
   - ADDRESS SPACE

7. In the lower right corner of the screen, click the check mark.

8. The local network entity is created in Windows Azure. You can verify it on the portal’s LOCAL NETWORK tab.

To create a virtual network in Azure by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.

2. In the lower left-hand corner of the screen, click + New.

3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click CUSTOM CREATE.

4. In the CREATE A VIRTUAL NETWORK wizard, in the Virtual Network Details screen, set the following parameters:
   - NAME
   -AFFINITY GROUP
   - REGION
   - AFFINITY GROUP NAME

5. Click -> (forward arrow mark) in the lower right-hand corner of the screen.

6. In the DNS Servers and VPN Connectivity screen, in SITE-TO-SITE CONNECTIVITY, select Configure Site-To-Site VPN and set the following parameter:
   - LOCAL NETWORK

7. In the Address Space and Subnets screen, set the following parameters:
   a) Address space
   b) Subnets
   c) Gateway

8. Click the check mark in the lower right-hand corner of the screen.

9. The virtual network is created in Windows Azure and is listed on the VIRTUAL NETWORK tab.
To create a gateway by using the Microsoft Windows Azure Management Portal

1. In the left pane, click **NETWORKS**.

2. On the **Virtual Network** tab, in the Name column, click the virtual network entity for which you want to create a gateway.

3. On the **DASHBOARD** page of the virtual network, at the bottom of the page, click **+ Create Gateway**.

4. When prompted to confirm you want the gateway created, click **YES**. Creating the gateway can take up to 15 minutes.

5. When the gateway is created, the **DASHBOARD** page displays the gateway IP address, which is a public IP address.

To gather public IP address of the gateway and the pre-shared key information by using the Microsoft Windows Azure Management Portal

1. In the left pane, click **NETWORKS**.

2. On the **Virtual Network** tab, in the Name column, click **virtual network entity**.

3. On the **DASHBOARD** page of the virtual network, copy the **Gateway IP Address**.

4. For the Pre Shared Key (PSK), at the bottom of the page, click **MANAGE KEY**.

5. In the **MANAGE SHARED KEY** dialog box, copy the **SHARED KEY**.

**Configuring the Citrix ADC Appliance in the datacenter for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on the Citrix ADC in the datacenter. You can use either the Citrix ADC command line or the GUI:

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel with IPSec protocol and associate the IPSec profile to it.** An IP tunnel specifies the local IP address (a public SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the gateway in Azure), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate the IP tunnel to it.** A PBR entity specifies a set of conditions and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address
range to specify the datacenter subnet whose traffic is to traverse the tunnel, and the destina-
tion IP address range to specify the Azure subnet whose traffic is to traverse the CloudBridge
Connector tunnel. Any request packet originated from a client in the subnet on the datacenter
and destined to a server in the subnet on the Azure cloud matches the source and destination IP
range of the PBR entity. This packet is then considered for CloudBridge Connector tunnel pro-
cessing and is sent across sent across the CloudBridge Connector tunnel associated with the
PBR entity.

The GUI combines all these tasks in a single wizard called the CloudBridge Connector wizard.
To create an IPSEC profile by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipsec profile <name> -psk <string> -ikeVersion v1
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line
```
add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> ipTunnel <tunnelName> apply pbrs
```

Sample Configuration

The following commands create all settings of Citrix ADC appliance CB_Appliance-1 used in “Example
of CloudBridge Connector Configuration and Data Flow”.

```
1 > add ipsec profile CB_Azure_IPSec_Profile -psk DkiMgMdcbqvYREEuIvxsbKkWOF0yDiLM -ikeVersion v1 -lifetime 31536000
   Done
2
3
4
5
6
7 > add iptunnel CB_Azure_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 -protocol IPSEC -ipsecProfileName CB_Azure_IPSec_Profile
   Done
8
9
10
11 > apply pbrs
   Done
```

To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI
1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance in the datacenter.

2. Navigate to **System > CloudBridge Connector**.

3. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.

4. Click **Get Started**.

   **Note:** If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

5. In the CloudBridge Setup pane, click **Microsoft Windows Azure**.

6. In the Azure Settings pane, in the Gateway IP Address* field, type the IP address of the Azure gateway. The CloudBridge Connector tunnel is then set up between the Citrix ADC appliance and the gateway. In the Subnet (IP Range)* text boxes, specify a subnet range (in Azure cloud), the traffic of which is to traverse the CloudBridge Connector tunnel. Click **Continue**.

7. In the Citrix ADC Settings pane, from the Local Subnet IP* drop-down list, select a publicly accessible SNIP address configured on the Citrix ADC appliance. In Subnet (IP Range)* text boxes, specify a local subnet range, the traffic of which is to traverse the CloudBridge Connector tunnel. Click **Continue**.

8. In the **CloudBridge Setting** pane, in the CloudBridge Name text box, type a name for the CloudBridge that you want to create.

9. From the Encryption Algorithm and Hash Algorithm drop-down lists, select the AES and HMAC_SHA1 algorithms, respectively. In the Pre Shared Security Key text box, type the security key.

10. Click **Done**.

### Monitoring the CloudBridge Connector tunnel

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the Citrix ADC appliance in the datacenter and Microsoft Azure. To view CloudBridge Connector tunnel statistics on the Citrix ADC appliance, use GUI or Citrix ADC command line. To view CloudBridge Connector tunnel statistics in Microsoft Azure, use the Microsoft Windows Azure Management Portal.

### Displaying CloudBridge Connector tunnel Statistics in the Citrix ADC appliance

For information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see

**Monitoring CloudBridge Connector Tunnels.**
Displaying CloudBridge Connector tunnel Statistics in Microsoft Azure

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels in Microsoft Azure.

<table>
<thead>
<tr>
<th>Statistical counter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA IN</td>
<td>Total number of kilobytes received by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.</td>
</tr>
<tr>
<td>DATA OUT</td>
<td>Total number of kilobytes sent by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.</td>
</tr>
</tbody>
</table>

To display CloudBridge Connector tunnel statistics by using the Microsoft Windows Azure Management Portal

1. Log on to the Windows Azure Management Portal by using your Microsoft Azure account credentials.
2. In the left pane, click NETWORKS.
3. On the Virtual Network tab, in the Name column, select the virtual network entity associated with a CloudBridge Connector tunnel whose statistics you want to display.
4. On the DASHBOARD page of the virtual network, view the DATA IN and DATA OUT counters for the CloudBridge Connector tunnel.

Configuring CloudBridge Connector tunnel between datacenter and softlayer enterprise cloud

January 25, 2019

Contributed by:
C

The GUI includes a wizard that helps you to easily configure a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and Citrix ADC VPX instances on the SoftLayer enterprise cloud.
When you use the wizard of the Citrix ADC appliance in the datacenter, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on SoftLayer) of the CloudBridge Connector tunnel.

Using the wizard of the Citrix ADC appliance in the datacenter, you perform the following steps to configure a CloudBridge Connector tunnel.

1. Connect to the Softlayer enterprise cloud by providing the user log on credentials.
2. Select the Citrix XenServer that is running the Citrix ADC VPX appliance.
3. Select the Citrix ADC VPX appliance.
4. Provide CloudBridge Connector tunnel parameters to:
   - Configure a GRE Tunnel.
   - Configure IPsec on the GRE tunnel.
   - Create a netbridge, which is a logical representation of the CloudBridge connector, by specifying a name.
   - Bind the GRE Tunnel to the netbridge.

To configure a CloudBridge Connector tunnel by using the GUI

1. Log on to the GUI of the Citrix ADC appliance in the datacenter by using your account credentials for the appliance.
2. Navigate to System > CloudBridge Connector.
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge Connector.
4. Click Get Started.
   
   **Note:**
   
   If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.
5. In the CloudBridge Connector Setup pane, click Softlayer, and then follow the instructions in the wizard.

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

1.
Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device

January 25, 2019

Contributed by: C

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco device to connect two datacenters or extend your network to a Cloud provider. The Citrix ADC appliance and the Cisco IOS device form the end points of the CloudBridge Connector tunnel and are called peers.

Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco IOS device Cisco-IOS-Device-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco_Tunnel, and policy based routing (PBR) entity NS_Cisco_Pbr.

For more information, refer to the CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device settings pdf.

Points to Consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, consider the following points:
The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec mode</td>
<td>Tunnel mode</td>
</tr>
<tr>
<td>IKE version</td>
<td>Version 1</td>
</tr>
<tr>
<td>IKE authentication method</td>
<td>Pre-Shared Key</td>
</tr>
<tr>
<td>IKE encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>IKE hash algorithm</td>
<td>HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5</td>
</tr>
<tr>
<td>ESP encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>ESP hash algorithm</td>
<td>HMAC SHA1, HMAC SHA256, HMAC SHA256, HMAC MD5</td>
</tr>
</tbody>
</table>

You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco IOS device at the two ends of the CloudBridge Connector.

Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another, and a common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore on the Cisco device, you must specify the same hash algorithm and same encryption algorithm for IKE (while creating IKE policy) and ESP (while creating IPSec transform set).

You must configure the firewall at the Citrix ADC end and Cisco device end to allow the following.
- Any UDP packets for port 500
- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

Configuring Cisco IOS device for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a Cisco IOS device, use the Cisco IOS command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco devices.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco IOS device, make sure that:
- You have a user account with administrator credentials on the Cisco IOS device.
- You are familiar with the Cisco IOS command line interface.
The Cisco IOS device is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

Note:

The procedures for configuring CloudBridge Connector tunnel on a Cisco IOS device might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco product documentation for more information, see Configuring IPSec VPN tunnels topic.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Cisco device’s IOS command line:

- **Create an IKE Policy.** An IKE policy defines a combination of security parameters to be used during the IKE negotiation. For example, parameters such as hash algorithm, encryption algorithm, Diffie-Hellman group, and authentication method to be used in the IKE negotiation are set in this task.

- **Configure a Pre-shared key for IKE authentication.** A pre-shared key is a text string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco device and the Citrix ADC appliance.

- **Define a transform set and configure IPSec in tunnel mode.** A transform set defines a combination of security parameters to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful. Parameters such as hash algorithm and encryption algorithm are set in this task. This task also specifies that IPSec in tunnel mode be used for the CloudBridge tunnel.

- **Create a crypto access List.** Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco device side and Citrix ADC side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from a device in the Cisco device side subnet and is destined to a device in the Citrix ADC side subnet, and that matches the source and destination parameters of the access list, is sent across the CloudBridge Connector tunnel.

- **Create a crypto map.** Crypto maps define the IPSec parameters to be negotiated with peer. They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (Citrix ADC) identification by IP address, and transform set to match the peer security settings.

- **Apply the crypto Map to an interface.** In this task, you apply a crypto map to an interface through which CloudBridge Connector tunnel traffic will flow. Applying the crypto map to an interface instructs the Cisco IOS device to evaluate all the interface traffic against the crypto map set, and to use the specified policy during connection or SA negotiation on behalf of subnet’s...
traffic to be protected.

The examples in the following procedures create settings of Cisco IOS device Cisco-IOS-Device-1 used in “Example of CloudBridge Connector Configuration and Data Flow.”

To create an IKE policy, refer to the IKE policy pdf.

To configure a pre-shared key by using the Cisco IOS command line

At the Cisco IOS device’s command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto isakmp identity address</td>
<td>Cisco-ios-device-1(config)# crypto isakmp identity address</td>
<td>Specify the ISAKMP identity (address) for the Cisco IOS device to use when communicating with the peer (Citrix ADC appliance) during IKE negotiations. This example specifies the address keyword, which uses IP address 203.0.113.200 (Gigabit Ethernet interface 0/1 of Cisco-IOS-Device-1) as the identity for the device.</td>
</tr>
<tr>
<td>crypto isakmp key keystringaddress peer-address</td>
<td>Cisco-ios-device-1(config)# crypto isakmp key examplepresharedkey address 198.51.100.100</td>
<td>Specify a pre-shared key for the IKE authentication. This example configures shared key examplepresharedkey to be used with the Citrix ADC appliance NS_Appliance-1 (198.51.100.100). The same pre-shared key must be configured on the Citrix ADC appliance for IKE authentication to be successful between the Cisco IOS device and the Citrix ADC appliance.</td>
</tr>
</tbody>
</table>
To create a crypto access list by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following command in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-list access-list-number permit IP source wildcard destination wildcard</td>
<td>Cisco-ios-device-1(config)# access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255</td>
<td>Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-IOS-Device-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).</td>
</tr>
</tbody>
</table>

To define a transform and configure IPSec tunnel mode by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ipsec transform-set name ESP_Authentication_Transform ESP_Encryption_Transform</td>
<td>Cisco-ios-device-1(config)# crypto ipsec transform-set NS-CISCO-TS esp-sha256-hmac esp-3des</td>
<td>Define a transform set and specify the ESP hash algorithm (for authentication) and the ESP encryption algorithm to be used during exchange of data between the CloudBridge Connector tunnel peers. This example defines transform set NS-CISCO-TS and specifies ESP authentication algorithm as esp-sha256-hmac, and ESP encryption algorithm as esp-3des.</td>
</tr>
<tr>
<td>mode tunnel</td>
<td>Cisco-ios-device-1 (config-crypto-trans)# mode tunnel</td>
<td>Set IPSec in tunnel mode.</td>
</tr>

<td>Cisco-ios-device-1 (config)# exit, Cisco-ios-device-1 (config)#</td>
<td>Exit back to global configuration mode.</td>
</tr>
</tbody>
</table>

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such
as IKE version, encryption algorithm, hash algorithm, and authentication method (Pre-Shared key) to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the Cisco IOS device), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the Cisco IOS device side subnet whose traffic is to be protected over the tunnel. Any request packet that originates from a client in the subnet on the Citrix ADC side and is destined to a server in the Cisco IOS device side subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity. Apply the PBR rule to make it functional.

To create an IPSEC profile by using the Citrix ADC command line

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the Command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `add ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the Command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbrs <pbrName>`

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of CloudBridge Connector Configuration and Data Flow.”
To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
   - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR dialog box, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click Create, and then click Close.

To apply a PBR by using the GUI

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector Tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

3. Citrix ADC 12.1
Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and Fortinet FortiGate appliance

January 25, 2019
Contributed by: C

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Fortinet FortiGate appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the FortiGate appliance form the end points of the CloudBridge Connector tunnel and are called peers.

Example of a CloudBridge Connector Tunnel Configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- FortiGate appliance FortiGate-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and FortiGate-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and FortiGate-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Fortinet_IPSec_Profile, CloudBridge Connector tunnel entity NS_Fortinet_Tunnel, and policy based routing (PBR) entity NS_Fortinet_Pbr.

For more information, see CloudBridge Connector tunnel configuration table pdf.

For information about Settings on Fortinet FortiGate-Appliance-1 in Datacenter-2, see table.

Points to consider for a CloudBridge Connector tunnel configuration

The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Setting</th>
</tr>
</thead>
</table>

<td>HMAC SHA1</td>
</tr>
</tbody>
</table>

- You must specify the same IPSec settings on the Citrix ADC appliance and the FortiGate appliance at the two ends of the CloudBridge Connector.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore in the FortiGate appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).
- You must configure the firewall at the Citrix ADC end and FortiGate end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets
- FortiGate appliance supports two types of VPN tunnels: Policy-based and Route-based. Only policy-based VPN tunnel is supported between a FortiGate appliance and a Citrix ADC appliance.

**Configuring FortiGate appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel on a FortiGate appliance, use the Fortinet Web-based Manager, which is the primary user interface for configuring, monitoring, and maintaining FortiGate appliances.

Before you begin the CloudBridge Connector tunnel configuration on a FortiGate appliance, make sure that:

- You have a user account with administrator credentials on the FortiGate appliance.
- You are familiar with the Fortinet Web-based Manager.
- The FortiGate appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
Note
The procedures for configuring CloudBridge Connector tunnel on a FortiGate appliance might change over time, depending on the Fortinet release cycle. Citrix recommends that you follow the official Fortinet product documentation for Configuring IPSec VPN tunnels.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a FortiGate appliance, perform the following tasks on the FortiGate appliance by using the Fortinet Web-based manager:

- **Enable Policy-based IPSec VPN feature.** Enable this feature for creating policy-based VPN tunnels on the FortiGate appliance. Only policy-based type of VPN tunnel is supported between a FortiGate appliance and a Citrix ADC appliance. A policy-based VPN tunnel configuration on a FortiGate appliance includes phase 1 settings, phase 2 settings, and an IPSec security policy.
- **Define phase 1 parameters.** Phase 1 parameters are used by the FortiGate appliance for IKE Authentication before forming a secure tunnel to the Citrix ADC appliance.
- **Define phase 2 parameters.** Phase 2 parameters are used by the FortiGate appliance for forming a secure tunnel to the Citrix ADC appliance by establishing IKE security associations (SA).
- **Specify private subnets.** Define the FortiGate-side and the Citrix ADC-side private subnets whose IP traffic is to be transported through the tunnel.
- **Define an IPSec security policy for the tunnel.** A security policy allow IP traffic to pass between interfaces on a FortiGate appliance. An IPSec security policy specifies the interface to the private subnet and the interface connecting the Citrix ADC appliance through the tunnel.

To enable Policy-based IPSec VPN feature by using the Fortinet Web-based Manager

1. Navigate to **System > Config > Features**.
2. On the **Feature Settings** page, select **Show More** and turn on **Policy-based IPSec VPN**.

To define phase 1 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN > IPsec > Auto Key (IKE)** and click **Create Phase1**.
2. On the **New Phase 1** page, set the following parameters:
   - Name: Enter a name for this phase 1 configuration.
   - Remote Gateway: Select **Static IP Address**.
   - Mode: Select **Main (ID Protection)**.
   - Authentication Method: Select **Preshared Key**.
   - Pre-Shared Key: Enter a pre-shared key. The same pre-shared key must be configured on the Citrix ADC appliance.
   - Peer Options: Set the following IKE paramters for authenticating a Citrix ADC appliance.
     - IKE Version: Select **1**.
     - Mode Config: Clear this option if it is selected.
     - Local Gateway IP: Select **Main Interface IP**.
— P1 Proposal: Select the encryption and authentication algorithms for IKE Authentication before forming a secure tunnel to the Citrix ADC appliance.
  * 1 - Encryption: Select AES128.
  * Authentication: Select SHA1.
  * Keylife: Enter an amount of time (in seconds) for the phase 1 key life.
  * DH Group: Select 2.
— X-Auth: Select Disable.
— Deed Peer Detection: Select this option.
3. Click OK.

To specify private subnets by using the Fortinet Web-based Manager
1. Navigate to Firewall Objects > Address > Addresses and select Create New.
2. On the New Address page, set the following parameters:
   • Name: Enter a name for FortiGate-side subnet.
   • Type: Select Subnet.
   • Subnet / IP Range: Enter the address of the FortiGate-side subnet.
   • Interface: Select the local interface to this subnet.
3. Click OK.
4. Repeat steps 1-3 to specify the Citrix ADC-side subnet.

To define phase 2 parameters by using the Fortinet Web-based Manager
1. Navigate to VPN > IPsec > Auto Key (IKE) and click Create Phase 2.
2. On the New Phase 2 page, set the following parameters:
   • Name: Enter a name for this phase 2 configuration.
   • Phase 1: Select the Phase 1 configuration from the drop-down list.
3. Click Advanced and set the following parameters:
   • P2 Proposal: Select the encryption and authentication algorithms for forming a secure tunnel to the Citrix ADC appliance.
     – 1 - Encryption: Select AES128.
     – Authentication: Select SHA1.
     – Enable replay detection: Select this option.
     – Enable perfect forward secrecy (PFS): Select this option.
   • Keylife: Enter an amount of time (in seconds) for the phase 2 key life.
   • Autokey Keep Alive: Select this option.
   • Auto-negotiate: Select this option.
   • Quick Mode Selector: Specify the FortiGate-side and the Citrix ADC-side private subnets whose traffic is to be traversed through the tunnel.
     – Source Address: Select the FortiGate-side subnet from the drop-down list.
     – Source Port: Enter 0.
To define an IPSec security policy by using the Fortinet Web-based Manager

1. Navigate to Policy > Policy > Policy and click Create New.
2. On the Edit Policy page, set the following parameters:
   • Policy Type: Select VPN.
   • Policy Subtype: Select IPSec.
   • Local Interface: Select the local interface to the internal (private) network.
   • Local Protected Subnet: Select the FortiGate-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   • Outgoing VPN Interface: Select the local interface to the external (public) network.
   • Remote Protected Subnet: Select the Citrix ADC-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   • Schedule: Keep the default setting (always) unless changes are needed to meet specific requirements.
   • Service: Keep the default setting (ANY) unless changes are needed to meet your specific requirements.
   • VPN Tunnel: Select Use Existing and select the tunnel from the drop-down list.
   • Allow traffic to be initiated from the remote site: Select if traffic from the remote network will be allowed to initiate the tunnel.
3. Click OK.

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

• Create an IPSec profile. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.

• Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the FortiGate appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
• **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the FortiGate appliance-side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```bash
• add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE
• show ipsec profile <name>
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

```bash
• add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName** <string>
• show ipTunnel <name>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

```bash
• add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
• apply pbrs
• show pbr <pbrName>
```

To create an IPSEC profile by using the GUI

1. Navigate to **System > CloudBridge Connector > IPSec Profile.**
2. In the details pane, click **Add.**
3. In the **Add IPSec Profile** page, set the following parameters:
   • Name
   • Encryption Algorithm
   • Hash Algorithm
   • IKE Protocol Version
   • Perfect Forward Secrecy (Enable this parameter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click **Create**, and then click **Close.**
To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System > CloudBridge Connector > IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select *Subnet IP*).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select *IP Tunnel*)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

```
1 The following commands create settings of Citrix ADC appliance
   NS_Appliance-1 in "Example of a CloudBridge Connector Configuration.

   > add ipsec profile NS_Fortinet_IPSec_Profile -psk
     examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo
     HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
```
Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

3. Citrix ADC 12.1

CloudBridge Connector tunnel diagnostics and troubleshooting

January 25, 2019
Contributed by: C

If you have problems with a CloudBridge Connector tunnel configuration, make sure that all prerequisites were observed before the tunnel was set up. If they were, the problem might be with the tunnel end-point IP addresses, a NAT configuration, the way the tunnel was set up, or with the data traffic.

Troubleshooting a CloudBridge Connector tunnel

If your CloudBridge Connector tunnel does not function properly, the issue could be with tunnel establishment or with the data traffic. If you are unsure which type of problem you have, look for an
error message in the log file and see if the error message is in the list of tunnel-establishment issues. If you do not find your error message, check the list of possible issues related to data traffic.

**Issues Related to tunnel establishment**

After the requirements for configuring the IPSec tunnel are met and the CloudBridge Connector tunnel is configured, if the status of the tunnel is not UP, look for debugging information in the ikeh.log file on one or both Citrix ADC appliances configured as the tunnel end points.

On either appliance, type the following command at the Citrix ADC shell prompt:

```
cat /tmp/iked.debug tee /var/iked.log
```

The Troubleshooting pdf lists some common errors and their solutions.

**Issues related to data traffic**

If the data in the CloudBridge Connector tunnel are not exchanged properly between the tunnel end points, do the following.

- For a CloudBridge Connector tunnel that uses GRE and IPSec protocols:
  - Make sure that L2 mode is enabled on both of the CloudBridge Connector tunnel end points. To enable L2 mode, type the following command at the Citrix ADC command line interface:
    
    ```
    enable mode L2
    ```
  - If one of the CloudBridge Connector tunnel end points is a CloudBridge virtual appliance (VPX) and is provisioned on a VMware ESXi hypervisor, make sure that Promiscuous mode is set to Accept for the vSwitch associated with the CloudBridge VPX appliance.
  - If a VLAN is extended through a CloudBridge Connector tunnel, verify one-to-one mapping on the extended VLAN entity on each of the tunnel end points.
  - Make sure that the IP tunnel entity is bound to the correct netbridge entity in each of the tunnel end points.
  - Verify that the ARP entry for the peer CloudBridge Connector tunnel end point exists on the local tunnel end point, by typing the following command at the Citrix ADC command line interface:
    
    ```
    show arp
    ```
  - If the output shows an incomplete ARP entry, bidirectional traffic is not flowing through the tunnel. If bidirectional traffic is flowing, the ARP entry shows the name of tunnel interface for the devices on the other side of the tunnel.
Citrix ADC 12.1

- Remove the IP tunnel entities from both tunnel end points and add them again with the same parameters, but with the IPSec profile set to NONE, so that the tunnel uses only the GRE protocol.
  
  After verifying the following in the IP tunnel (that uses GRE protocol), configure the tunnel with IPSec parameters by specifying a valid IPSec profile to the respective IP tunnel entities on each of the tunnel end points.
  
  Proper PING or TCP flow through the tunnel.
  
  Proper flow of data traffic through the tunnel.

  After the configured tunnel (that uses GRE and IPSec protocols) is in UP state, if the data traffic does not flow properly through the tunnel, and if a NAT device was deployed in front of any or both of the tunnel end points, analyze the ingress and egress packets on the NAT devices.

- If a Citrix ADC appliance is used as Router or Gateway.
  
  - Make sure that L3 mode is enabled on the Citrix ADC appliance. To enable L3 mode, run the following command in the CloudBridge command line.
    
    `enable mode L3`

  - If subnets are bound to a netbridge entity, make sure that correct IP tunnel entity is also bound to the netbridge.

  - Run the following command in the Citrix ADC command line to see where the packets (Input and Output) are getting dropped:

    `stat ipsec counters`

  - Make sure that the correct routes are configured on both the tunnel end points.

  - If no NAT device is deployed in front of the Citrix ADC appliance, make sure that the firewalls are configured to allow any ESP (IP protocol number 50) packets and any UDP packets for port 4500.

If none of the above measures result in successful exchange of traffic between the tunnel end points, contact Citrix Technical Support.

**Checklist before contacting Citrix technical Support**

For a speedy resolution, make sure that you have the following items ready before contacting Citrix Technical Support.

- Details of the deployment and network topology.

- Log file collected by typing the following command at the Citrix ADC shell prompt.

  `cat /tmp/iked.debug | tee /var/log/iked.log`

- Tech support bundle captured by typing the following command at the Citrix ADC command line.

  `show techsupport`
Packet traces captured on both CloudBridge Connector tunnel end points. To start a packet trace, type the following command at the Citrix ADC command line.

```
start nstrace -size 0
```

To stop packet trace, type the following command at the Citrix ADC command line.

```
stop nstrace
```

Output of the following command typed at the Citrix ADC command prompt.

```
show arp
```

CloudBridge Connector interoperability – StrongSwan

January 25, 2019

Contributed by:

C

StrongSwan is an open source IPsec implementation for Linux platforms. You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the StrongSwan appliance form the end points of the CloudBridge Connector tunnel and are called peers.

Example of a CloudBridge Connector tunnel configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- StrongSwan appliance StrongSwan-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPsec profile entity NS_StrongSwan_IPSec_Profile, CloudBridge Connector tunnel entity NS_StrongSwan_Tunnel, and policy based routing (PBR) entity NS_StrongSwan_Pbr.
The following table lists the settings used in this example.

Main settings of the CloudBridge Connector tunnel setup

<table>
<thead>
<tr>
<th>Entity</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in Datacenter-1</td>
<td>198.51.100.100</td>

Points to consider for a CloudBridge Connector tunnel configuration

Before you begin configuring CloudBridge connector tunnel, make sure that:

- You have a basic knowledge about Linux configurations.
- You have a basic knowledge about IPSec protocol suite.
- The StrongSwan appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
  - IKE encryption algorithm: AES
  - IKE hash algorithm: HMAC SHA1
  - ESP encryption algorithm: AES
  - ESP hash algorithm: HMAC SHA1
- You must specify the same IPSec settings on the Citrix ADC appliance and the StrongSwan appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the StrongSwan appliance, you must specify the same hash algorithm and same encryption algorithm in IKE and ESP parameters in the IPSec.conf file.
- You must configure the firewall at the Citrix ADC end and StrongSwan end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
Configure StrongSwan for the CloudBridge Connector tunnel

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the StrongSwan appliance:

- **Specify IPsec connection information in ipsec.conf file.** ipsec.conf file defines all control and configuration information for IPsec connections in the strongSwan appliance.
- **Specify pre-shared key in ipsec.secrets file.** ipsec.secrets file defines secrets for IKE/IPsec authentication for IPsec connections in the strongSwan appliance.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on a StrongSwan appliance might change over time, depending on the StrongSwan release cycle. Citrix recommends that you follow the official StrongSwan documentation for Configuring IPSec VPN tunnels.

Following sample excerpt of ipsec.conf file specifies IPsec information for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic. For more information, see CloudBridge Connector Configuration pdf.

Following sample excerpt of ipsec.secrets file specifies the IKE authentication pre-shared key for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic.

```
/etc/ipsec.secrets
PSK 'examplepresharedkey' #pre-shared key for IPsec IKE authentication
```

Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel endpoint IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the StrongSwan appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address...
range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the StrongSwan side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

- add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1
- show ipsec profile <name>

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
- show ipTunnel <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

- add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
- apply pbrs
- show pbr <pbrName>

To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel page, set the following parameters:
To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select **IP Tunnel**)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration:

```
add ipsec profile NS_StrongSwan_IPSec_Profile -psk examplepreshtaredkey -ikeVersion v1 -encAlgo AES -hashalgo HMAC_SHA1
Done

add iptunnel NS_StrongSwan_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 -protocol IPSEC -ipsecProfileName NS_StrongSwan_IPSec_Profile
```
Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

2. Citrix ADC 12.1

CloudBridge Connector interoperability – F5 BIG-IP

January 25, 2019

Contributed by: C

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the F5 BIG-IP appliance form the end points of the CloudBridge Connector tunnel and are called peers.
Example of a CloudBridge Connector tunnel configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- F5 BIG-IP appliance F5-BIG-IP-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_F5-BIG-IP_IPSec_Profile, CloudBridge Connector tunnel entity NS_F5-BIG-IP_Tunnel, and policy based routing (PBR) entity NS_F5-BIG-IP_Pbr.

For more information, refer to F5 big IP pdf.

Points to consider for a CloudBridge Connector tunnel configuration

- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The F5 BIG-IP appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
  - IKE encryption algorithm: AES
  - IKE hash algorithm: HMAC SHA1
  - ESP encryption algorithm: AES
  - ESP hash algorithm: HMAC SHA1
- You must specify the same IPSec settings on the Citrix ADC appliance and the F5 BIG-IP appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the F5 BIG-IP appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).
You must configure the firewall at the Citrix ADC end and F5 BIG-IP end to allow the following:
- Any UDP packets for port 500
- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

Configuring F5 BIG-IP for the CloudBridge Connector tunnel

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance, perform the following tasks on the F5 BIG-IP appliance:

- **Create a forwarding virtual server for IPsec.** A forwarding virtual server intercepts IP traffic for the IPsec tunnel.
- **Create an IKE peer.** An IKE peer specifies the local and remote IPsec tunnel endpoints. It also specifies algorithms and credentials to be used for IPsec IKE phase 1.
- **Create a custom IPsec policy.** A policy specifies the IPsec protocol (ESP) and the mode (tunnel) to be used for forming the IPsec tunnel. It also specifies the algorithms and security parameters to be used for IKE IPsec phase 2.
- **Create a bidirectional IPsec traffic selector.** A traffic selector specifies the F5 BIG-IP side and Citrix ADC side subnets whose IP traffic is to be traversed through the IPsec tunnel.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on an F5 BIG-IP appliance might change over time, depending on the F5 release cycle. Citrix recommends that you follow the official F5 BIG-IP documentation for configuring IPSec VPN tunnels, at:

https://f5.com

To create a forwarding virtual server for IPsec by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Local Traffic > Virtual Servers**, and then click **Create**.
2. On the **New Virtual Server List** screen, set the following parameters:
   - **Name.** Type a unique name for the virtual server.
   - **Type.** Select **Forwarding (IP)**.
   - **Destination Address.** Type a wildcard network address in CIDR format, for example, 0.0.0.0/0 for IPv4 to accept any traffic.
   - **Service Port.** Select **All Ports** from the list.
   - **Protocol list.** Select **All Protocols** from the list.
   - **VLAN and Tunnel Traffic.** Retain the default selection, **All VLANs and Tunnels**.
3. Click **Finished**.

To create a custom IPsec policy by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network > IPsec > IPsec Policies**, and then click **Create**.
2. On the **New Policy** screen, set the following parameters:
   - **Name.** Type a unique name for the policy.
• **IPsec Protocol.** Retain the default selection, ESP.

• **Mode.** Select Tunnel. The screen refreshes to show additional related settings.

• **Tunnel Local Address.** Type the local IPsec tunnel endpoint IP address (Configured on the F5 BIG-IP appliance).

• **Tunnel Remote Address.** Type the remote IPsec tunnel endpoint IP address (Configured on the Citrix ADC appliance).

3. For the IKE Phase 2 parameters, retain the default values, or select the options that are appropriate for your deployment.

4. Click **Finished.**

To create a bidirectional IPsec traffic selector by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network > IPsec > Traffic Selectors,** and then click **Create.**

2. On the **New Traffic Selector** screen, set the following parameters:
   - **Name.** Type a unique name for the traffic selector.
   - **Order.** Retain the default value (First). This setting specifies the order in which the traffic selector appears on the Traffic Selector List screen.

3. From the **Configuration** list, select **Advanced,** and set the following parameters:
   - **Source IP Address.** Click **Host** or **Network,** and in the **Address** field, type the address of the F5 BIG-IP side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Source Port.** Select *All Ports.*
   - **Destination IP Address.** Click **Host,** and in the **Address** field, type the address of the Citrix ADC side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Destination Port.** Select *All Ports.*
   - **Protocol.** Select *All Protocols.*
   - **Direction.** Select **Both.**
   - **Action.** Select **Protect.** The **IPsec Policy Name** setting appears.
   - **IPsec Policy Name.** Select the name of the custom IPsec policy that you created.

4. Click **Finished.**

### Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

• **Create an IPsec profile.** An IPsec profile entity specifies the IPsec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPsec protocol in the CloudBridge Connector tunnel.

• **Create an IP tunnel that uses IPsec protocol, and associate the IPsec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of
type SNIP) configured on the Citrix ADC appliance, remote IP address (CloudBridge Connector
tunnel endpoint IP address configured on the F5 BIG-IP appliance), protocol (IPSec) used to set
up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity
is also called the CloudBridge Connector tunnel entity.

• **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules
and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the
destination IP address range are the conditions for the PBR entity. Set the source IP address
range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and
set the destination IP address range to specify the F5 BIG-IP side subnet whose traffic is to be
protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

- add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -
  hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE
- show ipsec profile** <name>

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol
  IPSec -ipsecProfileName <string>
- show ipTunnel <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

- add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -
  ipTunnel <tunnelName>
- apply pbtrs
- show pbr <pbrName>

To create an IPSEC profile by using the GUI

1. Navigate to **System > CloudBridge Connector > IPSecProfile.**
2. In the details pane, click **Add.**
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tun-
   nel peers to mutually authenticate: Select the **Pre-shared key authentication method** and set
the Pre-Shared Key Exists parameter.

5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select Subnet IP).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click Create, and then click Close.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.”:
Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector interoperability – Cisco ASA

January 25, 2019

Contributed by:
C
You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the Cisco ASA appliance form the end points of the CloudBridge Connector tunnel and are called peers.

**Example of a CloudBridge Connector tunnel configuration**

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following appliances:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco ASA appliance Cisco-ASA-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco-ASA_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco-ASA_Tunnel, and policy based routing (PBR) entity NS_Cisco-ASA_Pbr.

**Points to consider for a CloudBridge Connector tunnel configuration**

Before you begin configuring CloudBridge connector tunnel, make sure that:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec mode</td>
<td>Tunnel mode</td>
</tr>
<tr>
<td>IKE version</td>
<td>Version 1</td>
</tr>
<tr>
<td>IKE authentication method</td>
<td>Pre-Shared Key</td>
</tr>
<tr>
<td>IKE encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>IKE hash algorithm</td>
<td>HMAC SHA1, HMAC MD5</td>
</tr>
<tr>
<td>ESP encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>ESP hash algorithm</td>
<td>HMAC SHA1, HMAC MD5</td>
</tr>
</tbody>
</table>
You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco ASA appliance at the two ends of the CloudBridge Connector tunnel.

Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the Cisco ASA appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).

You must configure the firewall at the Citrix ADC end and Cisco ASA end to allow the following.

- Any UDP packets for port 500
- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

**Configuring Cisco ASA for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel on a Cisco ASA appliance, use the Cisco ASA command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco ASA appliances.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco ASA appliance, make sure that:

- You have a user account with administrator credentials on the Cisco ASA appliance.
- You are familiar with the Cisco ASA command line interface.
- The Cisco ASA appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

**Note**

The procedures for configuring CloudBridge Connector tunnel on a Cisco ASA appliance might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco ASA product documentation for Configuring IPSec VPN tunnels, at:

- [http://www.cisco.com](http://www.cisco.com)

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Cisco ASA appliance’s command line:

- **Create an IKE Policy.** An IKE policy defines a combination of security parameters to be used during the IKE negotiation (phase 1). For example, parameters such as hash algorithm, encryption algorithm, and authentication method to be used in the IKE negotiation are set in this task.

- **Enable IKE on the outside interface.** Enable IKE on the outside interface through which the tunnel traffic will flow to the tunnel peer.

- **Create a tunnel group.** A tunnel group specifies the type of tunnel and the pre-shared key. The tunnel type must be set to ipsec-l2l, which stands for IPsec LAN to LAN. A pre-shared key is a text
string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco ASA appliance and the Citrix ADC appliance.

- **Define a transform set.** A transform set defines a combination of security parameters (phase 2) to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful.

- **Create an access List.** Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco appliance side and Citrix ADC side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from an appliance in the Cisco appliance side subnet and is destined to an appliance in the Citrix ADC side subnet, and that matches the source and destination parameters of the access list, is sent across the CloudBridge Connector tunnel.

- **Create a crypto map.** Crypto maps define the IPSec parameters for security associations (SAs). They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (Citrix ADC) identification by IP address, and transform set to match the peer security settings.

- **Apply the crypto Map to the outside interface.** In this task, you apply the crypto map to the outside interface through which the tunnel traffic will flow to the tunnel peer. Applying the crypto map to an interface instructs the Cisco ASA appliance to evaluate all interface traffic against the crypto map set and to use the specified policy during connection or security association negotiations.

The examples in the following procedures create settings of Cisco ASA appliance Cisco-ASA-Appliance-1 used in Example of CloudBridge Connector Configuration and Data Flow.

To create an IKE policy by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following commands, starting in global configuration mode, in the order shown:
<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ikev1 policy priority</td>
<td>Cisco-ASA-appliance-1(config)# crypto</td>
<td>Enter IKE policy</td>
</tr>
<tr>
<td></td>
<td>ikev1 policy 1</td>
<td>configuration mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and identify the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>policy to create.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(Each policy is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>uniquely identified</td>
</tr>
<tr>
<td></td>
<td></td>
<td>by the priority</td>
</tr>
<tr>
<td></td>
<td></td>
<td>number you assign.)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This example configures policy 1.</td>

<td></td>
<td>algorithm.</td>
</tr>
<tr>
<td>hash (sha)</td>
<td>md5)</td>
<td>Specify the hash</td>
</tr>
<tr>
<td></td>
<td></td>
<td>algorithm.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This example configures SHA.</td>
</tr>
<tr>
<td>authentication pre-share</td>
<td>Cisco-ASA-appliance-1(config-ikev1-policy) # authentication pre-share</td>
<td>Specify the pre-share authentication method.</td>
</tr>
<tr>
<td>group 2</td>
<td>Cisco-ASA-appliance-1(config-ikev1-policy)# group 2</td>
<td>Specify 1024-bit Diffie-Hellman group identifier (2).</td>
</tr>
<tr>
<td>lifetime seconds</td>
<td>Cisco-ASA-appliance-1(config-ikev1-policy)# lifetime 28800</td>
<td>Specify the security association’s lifetime in seconds. This example configures 28800 seconds, which is the default value of lifetime in a Citrix ADC appliance.</td>
</tr>
</tbody>
</table>
To enable IKE on the outside interface by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ikev1 enable outside</td>
<td>Cisco-ASA-appliance-1(config)# crypto ikev1 enable outside</td>
<td>Enable IKEv1 on the interface through which the tunnel traffic flows to the tunnel peer. This example enables IKEv1 on the interface named outside.</td>
</tr>
</tbody>
</table>

To create a tunnel group by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following commands, starting in global configuration mode, as show in the attached pdf Tunnel Group using Cisco ASA command line:

To create a crypto access list by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following command in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-list access-list-number permit IP source source-wildcard destination destination-wildcard</td>
<td>Cisco-ASA-appliance-1(config)# access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255</td>
<td>Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-ASA-Appliance-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).</td>

</tr>
</tbody>
</table>
Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- Create an IPSec profile.
- Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.
- Create a PBR rule and associate it with the IP tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```
add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE
show ipsec profile <name>
```

**To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line**

**At the command prompt, type:**

```
add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
show ipTunnel <name>
```

**To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line**

**At the command prompt, type:**

```
**add pbr** <pbrName> **ALLOW** -**srcIP** <subnet-range> -**destIP** <subnet-range> -**ipTunnel** <tunnelName>
**apply pbrs**
**show pbr** <pbrName>
```

To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
   - Perfect Forward Secrecy (Enable this parameter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (in the Local IP Type drop-down list, select Subnet IP).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop
     down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click Create, and then click Close.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.”:

```
1 > add ipsec profile NS_Cisco-ASA_IPSec_Profile -psk examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
2
3 Done
```
Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

2. Citrix ADC
3. Citrix ADC 12.1

High Availability

January 25, 2019
Contributed by: C

A high availability (HA) deployment of two Citrix ADC appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.
The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.

With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.

The following figure shows a network configuration with an HA pair.

Figure 1. Citrix ADC Appliances in a High Availability Configuration

To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept Citrix ADC gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Points to consider for a high availability setup

January 23, 2019

Contributed by:
C

1. Citrix ADC
2. Citrix ADC
3. Citrix ADC 12.1
Note

The following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary Citrix ADC appliances should be of the same model. Different Citrix ADC models are not supported in an HA pair (for example, you cannot configure a 10010 model and a 7000 model as an HA pair).

- In an HA setup, both nodes must run the same version of Citrix ADC, for example, nCore/nCore or classic/classic. If the nodes are running Citrix ADC classic and you want to migrate to Citrix ADCs nCore of the same Citrix ADC release, prop and sync are not supported during the migration process. Once migration is complete, prop and sync are auto-enabled. The same applies if you migrate from Citrix ADC nCore to Citrix ADC classic.

- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
  - The primary and the secondary systems must each be configured with their own unique IP addresses (NSIPs.)
  - In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.

- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.

- Initially, all Citrix ADC appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

  One RPC node exists on each Citrix ADC. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each Citrix ADC requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

  RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

  Note:

  If the Citrix ADC appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.
For an IPv6 HA configuration, the following considerations apply:

- You must install the IPv6PT license on both Citrix ADC appliances.
- After installing the IPv6PT license, enable the IPv6 feature by using the GUI or the command line interface.
- Both Citrix ADC appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

2. Citrix ADC 12.1

Configuring high availability

January 25, 2019

Contributed by: C

To set up a high availability configuration, you create two nodes, each of which defines the other’s Citrix ADC IP (NSIP) address as a remote node. Begin by logging on to one of the two Citrix ADC appliances that you want to configure for high availability, and add a node. Specify the other appliance’s Citrix ADC IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

Note:
The Citrix ADC GUI provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

Figure 1. Two Citrix ADC Appliances Connected in a High Availability Configuration

 Adding a remote node

To add a remote Citrix ADC appliance as a node in a high availability setup, you specify a unique node ID and the appliance’s NSIP. The maximum number of node IDs in an HA setup is 64. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.
Note:
To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress>
- `show ha node

Example

```
1 > add ha node 10 203.0.113.32
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [-haMonitor ( ON | OFF )]
- `show interface <ifNum>

Example

```
1 > set interface 1/3 -haMonitor OFF
2  Done
```

To add a remote node by using the GUI

Navigate to System > High Availability and, on the Nodes tab, add a new remote node, or edit an existing node.

Disabling or Enabling a Node

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.
**To disable or enable a node by using the command line interface**

At the command prompt, type one of the following commands:

- `set ha node -hastatus DISABLED`
- `set ha node -hastatus ENABLED`

**To disable or enable a node by using the GUI**

1. Navigate to **System > High Availability** and, on the **Nodes** tab, open the node.
2. In the **High Availability Status** list, select **ENABLED (Actively Participate in HA)** or **DISABLED (Do not participate in HA)**.

**Removing a Node**

If you remove a node, the nodes are no longer in high availability configuration.

**To remove a node by using the command line interface**

At the command prompt, type:

```bash
rm ha node <id>
```

Example

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; rm ha node 10</td>
</tr>
<tr>
<td>2</td>
<td>Done</td>
</tr>
</tbody>
</table>

**To remove a node by using the GUI**

Navigate to **System > High Availability** and, on the **Nodes** tab, delete the node.

1. 
2. **Citrix ADC**
3. **Citrix ADC 12.1**

**Configuring the communication intervals**

January 23, 2019
The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair. Dead interval must be set as a multiple of hello interval.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- `set HA node [-helloInterval <msecs>] [-deadInterval <secs>]`
- `show HA node <id>`

To set the hello and dead intervals by using the GUI

1. Navigate to **System > High Availability** and, on the **Nodes** tab, open the node.
2. Set the following parameters:
   - Hello Interval (msecs)
   - Dead Interval (secs)

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.
Automatic synchronization is enabled by default. You can also force synchronization.

**Disabling or enabling synchronization**

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

**To disable or enable automatic synchronization by using the command line interface**

At the command prompt, type:

- `set HA node -haSync DISABLED`
- `set HA node -haSync ENABLED`

**To disable or enable synchronization by using the GUI**

1. Navigate to System > High Availability.
2. Under HA Synchronization, clear or select the Secondary node will fetch the configuration from Primary option.

**Forcing the secondary node to synchronize with the primary node**

In addition to automatic synchronization, the Citrix ADC supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.
- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.

**To force synchronization by using the command line interface**

At the command prompt, type:

`force HA sync`
To force synchronization by using the GUI

1. Navigate to System > High Availability.
2. On the Nodes tab, in the Action list, click Force Synchronization.

Synchronizing configuration files in a high availability setup

January 23, 2019
Contributed by: C

In a high availability setup, all configuration files are synchronised automatically from the primary node to the secondary node at an interval of one minute. Synchronizing configuration files can be performed manually by using the command line interface or the GUI at either the primary or the secondary node.

Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type:

```
sync HA files <mode>
```

Example

```
1 > sync HA files all
2   Done
```

```
1 > sync HA files ssl
2   Done
```

Parameter descriptions (of the command listed in the CLI procedure)

```
sync ha files <mode>
```
Specify one of the following modes of synchronization.

- **all** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, and Application Firewall XML objects.
- **bookmarks** - Synchronize all Access Gateway bookmarks.
- **ssl** - Synchronize all certificates, keys, and CRLs for the SSL feature.
- **htmlinjection** - Synchronize all scripts configured for the HTML injection feature.
- **imports** - Synchronize all XML objects (for example, WSDLs, schemas, error pages) configured for the application firewall.
- **misc** - Synchronize all license files and the rc.conf file.
- **all_plus_misc** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, application firewall XML objects, licenses, and the rc.conf file.

To synchronize files in a high availability setup by using the GUI

Navigate to **System > Diagnostics** and, in the **Utilities** group, click **Start HA files synchronization**.

1. Citrix ADC
2. Citrix ADC 12.1

Configuring command propagation

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.
**Note**

After reenabling propagation, remember to force synchronization.

If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.

**To disable or enable command propagation by using the command line interface**

At the command prompt, type:

- `set HA node -haProp DISABLED`
- `set HA node -haProp ENABLED`

**To disable or enable command propagation by using the GUI**

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

**Restricting high availability synchronization traffic to a VLAN**

February 21, 2019

Contributed by: C

In a high availability (HA) deployment, traffic related to maintaining the HA configuration flows between the two HA nodes. This traffic is of the following types:

- Config synchronization
- Config propagation
- Connection mirroring
- Load balancing persistency config synchronization
- Persistent session synchronization
- Session state synchronization
Proper flow of this HA related traffic between the two nodes is critical for the functioning of the HA deployment. Typically, the HA related traffic is small in volume but can become very high during a failover. It becomes very high if stateful connection failover is enabled and the node that was primary before the failover was handling a large number of connections.

By default, the HA related traffic flows through the VLANs to which the NSIP address is bound. To accommodate a potential surge in this traffic, you can separate the HA related traffic from the management traffic and restrict its flow to a separate VLAN. This VLAN is called the HA SYNC VLAN.

**Points to consider before Configuring an HA SYNC VLAN**

- The configuration of an HA SYNC VLAN is neither propagated nor synchronized. In other words, the HA SYNC VLAN is node specific and is configured independently on each node.
- HA SYNC VLAN configuration is removed when you clear the configuration in only FULL mode.
- HA MON must be set to OFF for interfaces that are part of the HA SYNC VLAN, to avoid a situation in which both nodes function as the primary node.
- Management interfaces (for example, 0/1 and 0/2) must not be part of the HA SYNC VLAN, so that HA related traffic does not flow through management interfaces.
- Citrix recommends disabling high availability heartbeat messages on management interfaces and enabling on HA SYNC VLAN interfaces. After meeting these recommendations, high availability heartbeat messages can also be enabled on data interfaces.

  For more information on disabling high availability heartbeat messages on interfaces, see [Managing high availability heartbeat messages on a Citrix ADC appliance](#).

To configure an HA SYNC VLAN on a Citrix ADC node, specify a configured VLAN with the HA SYNC VLAN parameter of the local node entity.

To configure an HA SYNC VLAN on a local node by using the command line

At the command prompt, type:

- `set node -hasyncvlan <VLANID>
- `show node`

**Parameter Description**

- **Hasyncvlan (Sync VLAN)**

  VLAN on which HA related traffic is sent. This includes traffic for synchronization, propagation, connection mirroring, load balancing persistency, configuration synchronization, persistent session synchronization, and session state synchronization. However, HA heartbeats can use any interface.

To configure an HA SYNC VLAN on a node by using the GUI
Configuring fail-safe mode

January 23, 2019

Contributed by:
C

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.

<table>
<thead>
<tr>
<th>Node A (Primary) Health State</th>
<th>Node B (Secondary) Health State</th>
<th>Default HA Behavior</th>
<th>Fail-Safe Enabled HA Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT_UP (failed last)</td>
<td>NOT_UP (failed first)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If both nodes fail, one after the other, the node that was the last primary remains primary.</td>
</tr>
<tr>
<td>NOT_UP (failed first)</td>
<td>NOT_UP (failed last)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Secondary), B (Primary)</td>
<td>If both nodes fail, one after the other, the node that was the last primary remains primary.</td>
</tr>
</tbody>
</table>
Citrix ADC 12.1

### Fail-Safe Mode

<table>
<thead>
<tr>
<th>Node A Health State</th>
<th>Node B Health State</th>
<th>Default HA Behavior</th>
<th>Fail-Safe Enabled HA Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UP</td>
<td>UP</td>
<td>A (Primary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If both nodes pass the health check, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>UP</td>
<td>NOT_UP</td>
<td>A (Primary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If only the secondary node fails, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>NOT_UP</td>
<td>UP</td>
<td>A (Secondary), B (Primary)</td>
<td>A (Secondary), B (Primary)</td>
<td>If only the primary fails, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>NOT_UP</td>
<td>UP (STAYSECONDARY)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If the secondary is configured as STAYSECONDARY, the primary remains primary even if it fails.</td>
</tr>
</tbody>
</table>

### To enable fail-safe mode by using the command line interface

At the command prompt, type:

```bash
set HA node ['-failSafe ( **ON** | **OFF** )]
```

**Example**

```bash
1 set ha node -failsafe ON
```
To enable fail-safe mode by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under Fail-Safe Mode, select the Maintain one Primary node even when both nodes are unhealthy option.

Configuring Virtual MAC Addresses

January 25, 2019
Contributed by: C

A Virtual MAC address (VMAC) is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node’s MAC address.

When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the Citrix ADC appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a VMAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a VMAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a VMAC with the VRID as the last octet.

This section includes the following details:

- Configuring IPv4 VMACs
- Configuring IPv6 VMAC6s
Configuring IPv4 VMACs

When you create a IPv4 VMAC address and bind it to a interface, any IPv4 packet sent from the interface uses the VMAC address that is bound to the interface. If there is no IPv4 VMAC bound to an interface, the interface's physical MAC address is used.

The generic VMAC is of the form 00:00:5e:00:01:<VRID>. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting VMAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

Creating or modifying an IPv4 VMAC

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then bind the VMAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the VMAC configuration, you should display and examine the VMACs and the interfaces bound to the VMACs.

To add a VMAC by using the command line interface

At the command prompt, type:

- add vrID
- bind vrid <id> -ifnum <interface_name>
- show vrID

Example

```
1 > add vrID 100
2 Done
3 > bind vrid 100 -ifnum 1/1 1/2 1/3
4 Done
```

To unbind interfaces from a VMAC by using the command line interface

At the command prompt, type:

- unbind vrid <id> -ifnum <interface_name>
- show vrID

To configure a VMAC by using the GUI

Navigate to System > Network > VMAC and, on the VMAC tab, add a new VMAC, or edit an existing VMAC.
Removing an IPv4 VMAC

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove an IPv4 VMAC by using the command line interface

At the command prompt, type:

```
rm vrid <id>
```

Example

```
1 rm vrid 100
```

To remove an IPv4 VMAC by using the GUI

Navigate to System > Network > VMAC and, on the VMAC tab, delete the IPv4 VMAC.

Configuring IPv6 VMAC6s

The Citrix ADC supports VMAC6 for IPv6 packets. You can bind any interface to a VMAC6, even if an IPv4 VMAC is bound to the interface. Any IPv6 packet sent from the interface uses the VMAC6 bound to that interface. If there is no VMAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a VMAC6

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then bind the VMAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the VMAC6 configuration, you should display and examine the VMAC6s and the interfaces bound to the VMAC6s.

To add a VMAC6 by using the command line interface

At the command prompt, type:

```
• add vrID6 <id>
• bind vrID6 <id> -ifnum <interface_name>
• show vrID6
```

Example

```
1 > add vrID6 100
2 Done
3 > bind vrID6 100 -ifnum 1/1 1/2 1/3
4 Done
```
To unbind interfaces from a VMAC6 by using the command line interface

At the command prompt, type:

- `unbind vrID6 <id> -ifnum <interface_name>`
- `show vrID6`

To configure a VMAC6 by using the GUI

Navigate to System > Network > VMAC and, on the VMAC6 tab, add a new VMAC6, or edit an existing VMAC6.

Removing a VMAC6

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove a VMAC6 by using the command line interface

At the command prompt, type:

`rm vrid6 <id>`

Example

```
1  rm vrid6 100s
```

To remove a VMAC6 by using the GUI

Navigate to System > Network > VMAC and, on the VMAC6 tab, delete the virtual router ID.

2. Citrix ADC
3. Citrix ADC 12.1

Configuring high availability nodes in different subnets

January 25, 2019

Contributed by: C

The following figure shows an HA deployment with the two systems located in different subnets:
Figure 1. High Availability over a Routed Network

In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The Citrix ADC appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

**Note:**

If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as SNIPs, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.

<table>
<thead>
<tr>
<th>NetScaler entities</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPs (NSIP/SNIPs)</td>
<td>Node-specific. Active only on that node.</td>
</tr>
<tr>
<td>VIPs</td>
<td>Floating.</td>
</tr>
<tr>
<td>VLANs</td>
<td>Node-specific. Active only on that node.</td>
</tr>
<tr>
<td>Routes</td>
<td>Node-specific. Active only on that node. Link load balancing routes are floating.</td>
</tr>
<tr>
<td>ACLs</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>Dynamic routing</td>
<td>Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.</td>
</tr>
<tr>
<td>L2 mode</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>L3 mode</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>Reverse NAT (RNAT)</td>
<td>Node-specific. RNAT with VIP, because NATIP is floating.</td>
</tr>
</tbody>
</table>

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two Citrix ADC appliances and add a remote node representing the other appliance.
Adding a Remote Node

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress> -inc ENABLED`
- `show ha node`

Example

```
1 > add ha node 3 10.102.29.170 -inc ENABLED
2  Done
3 > add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
4  Done
```

To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [-haMonitor ( **ON** | **OFF** )]`
- `show interface <ifNum>`

Example

```
1 > set interface 1/3 -haMonitor OFF
2  Done
```

To add a remote node by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.
Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

```
rm ha node <id>
```

Example

```
1 > rm ha node 2
2   Done
```

To remove a node by using the GUI

Navigate to **System > High Availability** and, on the **Nodes** tab, delete the node.

**Note:**

You can use the Network Visualizer to view the Citrix ADC appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks.

3. Citrix ADC 12.1

Configuring route monitors

January 25, 2019

Contributed by: C

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a Citrix ADC appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes.
MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

<table>
<thead>
<tr>
<th>Route Monitors in HA in non-INC mode</th>
<th>Route Monitors in HA in INC mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Route monitors are propagated by nodes and exchanged during synchronization.</td>
<td>Route monitors are neither propagated by nodes nor exchanged during synchronization.</td>
</tr>
<tr>
<td>Route monitors are active only in the current primary node.</td>
<td>Route monitors are active on both the primary and the secondary node.</td>
</tr>
<tr>
<td>The Citrix ADC appliance always displays the state of a route monitor as UP irrespective of whether the route entry is present or not in the internal routing table.</td>
<td>The Citrix ADC appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.</td>
</tr>
<tr>
<td>A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: reboot, failover, set route6 command for v6 routes, set route msr enable/disable command for v4 routes, adding a new route monitor.</td>
<td>-</td>
</tr>
</tbody>
</table>

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-Inc mode HA setup in a two-arm topology that has Citrix ADC appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

Figure 1.

With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1’s internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.
2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges
heartbeat messages through switch SW3 at regular intervals.

3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

**Adding a route monitor to a high availability node**

A single procedure creates a route monitor and binds it to an HA node.

**To add a route monitor by using the command line interface**

At the command prompt, type:

- `bind HA node <id> (routeMonitor <ip_addr|ipv6_addr> [netmask])`
- `show HA node`

**Example**

```
1  > bind HA node 0 routeMonitor 10.102.71.0 255.255.255.0
2    Done
3  > bind HA node 0 routeMonitor 1000:0000:0000:0000:0005:0600:700a:8888
4    Done
```

**To add a route monitor by using the GUI**

Navigate to System > High Availability and, on the Route Monitors tab, click Configure.

**Removing route monitors**

**To remove a route monitor by using the command line interface**

At the command prompt, type:

- `unbind HA node <id> (routeMonitor <ip_addr|ipv6_addr> [netmask])`
- `show ha node`

**Example**

```
1  unbind HA node 3 routeMonitor 10.102.71.0 255.255.255.0
2  unbind HA node 3 routeMonitor 1000:0000:0000:0000:0005:0600:700a:8888
```
To remove a route monitor by using the GUI

Navigate to **System > High Availability** and, on the **Route Monitors** tab, delete the route monitor.

Limiting failovers caused by route monitors in non-INC mode

January 25, 2019
Contributed by: C

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.

However, for a node, you can limit the number of failovers for a given interval by setting the **Maximum Number of Flips** and **Maximum Flip Time** parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary (but node state as NOT UP) even if any route monitor fails on that node. This combination of HA state as Primary and Node state as NOT UP is called Stick Primary state.

If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the **Maximum Number of Flips** and **Maximum Flip Time** parameters on the node and starting the time specified in the **Maximum Flip Time** parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

- **Parameters for limiting the number of failovers**
  
  **Maximum Number of Flips (maxFlips)**
  
  Maximum number of failovers allowed, within the **Maximum Flip Time** interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

  **Maximum Flip Time (maxFlipTime)**
  
  Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:
• set HA node [-maxFlips < positive_integer>] [-maxFlipTime <positive_integer>]
  
• show HA node [<id>]

To limit the number of failovers by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, open the local node.
2. Set the following parameters:
   - Maximum Number of Flips
   - Maximum Flip Time

```bash
> set ha node -maxFlips 30 -maxFlipTime 60
Done
> sh ha node
1) Node ID: 0
   IP: 10.102.169.82 (NS)
   Node State: UP
   Master State: Primary
   Fail-Safe Mode: OFF
   INC State: DISABLED
   Sync State: ENABLED
   Propagation: ENABLED
   Enabled Interfaces : 1/1
   Disabled Interfaces : None
   HA MON ON Interfaces : 1/1
   Interfaces on which heartbeats are not seen :None
   Interfaces causing Partial Failure:None
   SSL Card Status: NOT PRESENT
   Hello Interval: 200 msecs
   Dead Interval: 3 secs
   Node in this Master State for: 0:4:24:1 (days:hrs:min:sec)

2) Node ID: 1
   IP: 10.102.169.81
   Node State: UP
   Master State: Secondary
   Fail-Safe Mode: OFF
   INC State: DISABLED
   Sync State: SUCCESS
   Propagation: ENABLED
   Enabled Interfaces : 1/1
   Disabled Interfaces : None
   HA MON ON Interfaces : 1/1
   Interfaces on which heartbeats are not seen : None
   Interfaces causing Partial Failure: None
```
SSL Card Status: NOT PRESENT

- Configured/Completed Flips: 30/0
- Configured Flip Time: 60
- Critical Interfaces: 1/1

Done

SNMP Alarm for Sticky Primary State

Enable HA-STICKY-PRIMARY SNMP alarm in a node of a high availability set up if you want to be alerted of the node becoming sticky primary. When the node becomes sticky primary, it alerts by generating a trap message (stickyPrimary (1.3.6.1.4.1.5951.1.1.0.138)) and sends it to all the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see configuring the Citrix ADC to Generate SNMPv1 and SNMPv2 Traps.

Frequently Asked Questions

Consider an example of a high availability setup of two Citrix ADC appliances NS-1 and NS-2 in non-INC mode. Maximum numbers of flips and maximum flip time in both the nodes have been set with the same values.

The following table lists the settings used in this example:

<table>
<thead>
<tr>
<th>Entity</th>
<th>Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of NS-1</td>
<td>10.102.173.211</td>
</tr>
<tr>
<td>IP address of NS-2</td>
<td>10.102.173.212</td>
</tr>
<tr>
<td>Maximum number of flips</td>
<td>2</td>
</tr>
<tr>
<td>Maximum flip time</td>
<td>200</td>
</tr>
</tbody>
</table>

For information about the maximum number of flips and maximum flip time settings, refer to the pdf.

Configuring failover interface set

January 23, 2019
A Failover Interface Set (FIS) is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. A FIS can also be configured for the nodes of a Citrix ADC cluster.

HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

**Note:**
An FIS does not create an active and standby configuration. It also does not prevent bridging loops when connecting to links to the same VLAN.

**Creating or Modifying an FIS**

**To add an FIS and bind interfaces to it by using the command line interface**

At the command prompt, type:

- `add fis <name>`
- `bind fis <name> <ifnum> ...`
- `show fis <name>`

**Example**

```
1 > add fis fis1
2 Done
3 > bind fis fis1 1/3 1/5
4 Done
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

**To unbind an interface from an FIS by using the command line interface**

At the command prompt, type:

- `unbind fis <name> <ifnum> ...`
- `show fis <name>`

**Example**

```
To configure an FIS by using the GUI

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Removing an FIS

When the FIS is removed, its interfaces are marked as critical interfaces.

To remove an FIS by using the command line interface

At the command prompt, type:

```
rm fis <name>
```

Example

```
1 > rm fis fis1
2   Done
```

To remove an FIS by using the GUI

Navigate to System > High Availability and, on the Failover Interface Set tab, delete the FIS.

Understanding the causes of failover

January 25, 2019

Contributed by:

C

The following events can cause failover in an high availability configuration:
1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note: 1.)

2. The primary node experiences a hardware failure of its SSL card.

3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.

4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note: 2.)

5. On the primary node, all interfaces in an FIS fail. (See Note: 2.)

6. On the primary node, an LA channel with HAMON enabled fails. (See Note: 2.)

7. On the primary node, all interfaces fail (see Note: 2). In this case, failover occurs regardless of the HAMON configuration.

8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.

9. You force a failover by issuing the force failover command on either node.

10. A route monitor that is bound to the primary node goes DOWN.

Note:
For more information about setting the dead interval, see Configuring the Communication Intervals. Possible causes for a node not receiving heartbeat packets from a peer node include:

- A network configuration problem prevents heartbeats from traversing the network between the HA nodes.

- The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.

Note:
In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the GUI. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

2. Citrix ADC
3. Citrix ADC 12.1
Forcing a node to fail over

January 23, 2019
Contributed by: C

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The Citrix ADC appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node.**

  If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.

  If the secondary node is DOWN, the force failover command returns the following error message: “Operation not possible due to invalid peer state. Rectify and retry.”

  If the secondary system is in the claiming state or inactive, it returns the following error message: “Operation not possible now. Please wait for system to stabilize before retrying.”

- **Forcing Failover on the Secondary Node.**

  If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node’s health is good and it is not configured to stay secondary.

  If the secondary node cannot become the primary node, or if secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message: “Operation not possible as my state is invalid. View the node for more information.”

- **Forcing Failover When Nodes Are in Listen Mode.**
When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

Before upgrading the system software on both nodes, you should test the new version on one of the nodes. To do this, you need to force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections need to be re-established.

To force failover on a node by using the command line interface

At the command prompt, type:

```
force HA failover
```

To force failover on a node by using the GUI

Navigate to **System > High Availability** and, on the **Nodes** tab, select the node, in the Action list, select **Force Failover**.

2.  Citrix ADC  
3.  Citrix ADC 12.1

### Forcing the secondary node to stay secondary

January 23, 2019

Contributed by: C

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the secondary node to take over; you want it to remain the secondary node even if it detects a failure in the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the
new node, the existing node continues to function as the primary node, and the new node becomes the secondary node.

**Note:**

When you force a system to remain secondary, the forcing process is not propagated or synchronized. It affects only the node on which you run the command.

**To force the secondary node to stay secondary by using the command line interface**

At the command prompt, type:

```
set ha node -hastatus STAYSECONDARY
```

**To force the secondary node to stay secondary by using the GUI**

Navigate to **System > High Availability**, on the **Nodes** tab, open the local node, and select **STAY SECONDARY**.

1.  
2.  Citrix ADC
3.  Citrix ADC 12.1

**Forcing the primary node to stay primary**

January 23, 2019

Contributed by: C

In an HA setup, you can force the primary node to remain primary even after a failover. You can enable this option either on a primary node in an HA pair or on a standalone system.

On a standalone system, you must run this command before you can add a node to create an HA pair. When you add the new node, it becomes the primary node. The existing node stops processing traffic and becomes the secondary node in the HA pair.

**To force the primary node to stay primary by using the command line interface**

At the command prompt, type:

```
set ha node -hastatus STAYPRIMARY
```
To force the primary node to stay primary by using the GUI

Navigate to **System > High Availability**, on the **Nodes** tab, open the local node, and select **STAY PRIMARY**.

High Availability FAQs

May 7, 2019
Contributed by:

1. What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

In an HA configuration, both nodes use the following ports to exchange HA related information:

- UDP Port 3003, to exchange heartbeat packets.
- Port 3010, for synchronization and command propagation.

2. What are the conditions that trigger config synchronization?

Synchronization is triggered by any of the following conditions:

- The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
  
  Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:

  a) All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.

  b) All Interface related commands. For example, set interface and unset interface.

  c) All channel-related commands. For example, add channel, set channel, and bind channel.

- The secondary node comes up after a restart.
- The primary node becomes secondary after a failover.

3. What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?

The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
• All channel related configuration commands. For example, add channel, set channel, and bind channel.

4. What configurations are not synced nor propagated in an HA configuration in INC mode?

The following configurations are not synced or propagated. Each node has its own.

• SNIPs
• VLANs
• Routes (except LLB routes)
• Route monitors
• RNAT rules (except any RNAT rule with VIP as the NAT IP)
• Dynamic routing configurations.

5. Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

6. What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

7. Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

• The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
• After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
• Similar considerations apply to any time related decisions on the nodes.

8. What are the conditions for failure of the force HA sync command?

Forced synchronization fails in any of the following circumstances:

• You force synchronization when synchronization is already in progress.
• You force synchronization on a standalone Citrix ADC appliance.
• The secondary node is disabled.
• HA synchronization is disabled on the current secondary node.
• HA propagation is disabled on the current primary node and you force synchronization from the primary.

9. What are the conditions for failure of the sync HA files command?

Synchronizing configuration files fail in either of the following circumstances:
• On a standalone system.
• With the secondary node disabled.

10. In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the `forcefailover` command.

11. What are the conditions for failure of the force failover command?

A forced failover fails in any of the following circumstances:

• You force failover on a standalone system.
• The secondary node is disabled.
• The secondary node is configured to remain secondary.
• The primary node is configured to remain primary.
• The state of the peer node is unknown.

12. What types of traffic flows between the nodes of a high availability set-up?

In a high availability set-up, traffic related to maintaining the high availability configuration flows between the two nodes. This traffic is of the following types:

• Config synchronization
• Config propagation
• Data connection mirroring (For features that have connection failover enabled. For more information see, `Connection failover`.)
• Load balancing persistent session synchronization
• Session state synchronization
• Session state ICA sessions (If ICA session reliability is enabled. For more information, see `Session reliability`.)

Troubleshooting high availability issues

January 23, 2019
Contributed by: C
The most common high availability issues involve the high availability feature not working at all, or working only intermittently. Following are common high availability issues, and probable causes and resolutions.

- **Issue**
  The inability of the Citrix ADC appliances to pair the Citrix ADC appliances in a high availability setup.
  - **Cause**
    Network connectivity
  - **Resolution**
    Verify that both the appliances are connected to the switch and the interfaces are enabled.
  - **Cause**
    Mismatch in the Password for the default Administrator account
  - **Resolution**
    Verify that the password on both the appliances is the same.
  - **Cause**
    IP conflict
  - **Resolution**
    Verify that both the appliances have unique Citrix ADC IP (NSIP) address. The appliances should not have the same NSIP address.
  - **Cause**
    Node ID mismatch
  - **Resolution**
    Verify that the Node ID Configuration on both the appliances is unique. The appliances should not have the same Node ID configuration. Additionally, you must assign value for a Node ID between 1 and 64.
  - **Cause**
    Mismatch in the password of the RPC node
  - **Resolution**
    Verify that both the nodes have the same RPC node password.
  - **Cause**
    An administrator has disabled the remote node
  - **Resolution**
    Enable the remote node.
  - **Cause**
    The Firewall application has blocked the heartbeat packets
  - **Resolution**
    Verify that the UDP port 3003 is allowed.

- **Issue**
  Both the appliances claim to be the primary appliance.
- **Cause**
  Missing heartbeat packets between the appliances

  **Resolution**
  Verify that the UDP port 3003 is not blocked for communication between the appliances.

- **Issue**
  The Citrix ADC appliance is not able to synchronize the configuration.

  - **Cause**
    A Firewall application is blocking the required port.

  - **Resolution**
    Verify that the UDP port 3010 (or UDP port 3008 with secure synchronization) is not blocked for communication between the appliances.

  - **Cause**
    An administrator has disabled synchronization.

  - **Resolution**
    Enable synchronization on the appliance that has the issue.

  - **Cause**
    Different Citrix ADC releases or builds are installed on appliances.

  - **Resolution**
    Upgrade the appliances to the same Citrix ADC release or build.

- **Issue**
  Command propagation fails between the appliances.

  - **Cause**
    A Firewall application is blocking the port.

  - **Resolution**
    Verify that the UDP port 3011 (or UDP port 3009 with secure propagation) is not blocked for communication between the appliances.

  - **Cause**
    An administrator has disabled command propagation.

  - **Resolution**
    Enable command propagation on the appliance that has the issue.

  - **Cause**
    Different Citrix ADC releases or builds are installed on appliances.

  - **Resolution**
    Upgrade the appliances to the same Citrix ADC release or build.

- **Issue**
  The Citrix ADC appliances in the high availability pair are unable to run the force failover process.

  - **Cause**
    The Secondary node is disabled.

  - **Resolution**
Enable the secondary node.

- **Cause**
  The Secondary node is configured to stay secondary.

**Resolution**
Set the secondary high availability status of the secondary node to Enable from Stay Secondary.

- **Issue**
The secondary appliance does not receive any traffic after the failover process.

  - **Cause**
    The upstream router does not understand GARP messages of Citrix ADC appliance.

  **Resolution**
Configure Virtual MAC (VMAC) address on the secondary appliance.

**Managing high availability heartbeat messages on a Citrix ADC appliance**

February 20, 2019

Contributed by:
C

The two nodes in a high availability configuration send and receive heartbeat messages to and from each other on all interfaces that are enabled. The heartbeat messages flow regardless of the HA MON setting on these interfaces. If NSVLAN or both (NSVLAN and SYNC) are configured on an appliance, the heartbeat messages flow only through the enabled interfaces that are part of the NSVLAN and SYNCVLAN.

If a node does not receive the heartbeat messages on an enabled interface, it sends critical alerts to the specified Command Center and SNMP managers. These critical alerts give false alarms and draw unnecessary attention from the administrators for interfaces that are not configured as part of the connections to the peer node.

To resolve this issue, the HAAHeartBeat option for interfaces and channels is used for enabling or disabling HA heartbeat-message flow on them.

To manage the high availability heartbeat messages on an interface by using the command line interface

At the command prompt, type:
To manage the high availability heartbeat messages on a channel by using the command line interface

At the command prompt, type:

- `set interface <ID> [-HAHeartBeat ( ON | OFF )]
- `show interface <ID>

To manage the high availability heartbeat messages for an interface by using the GUI

1. Navigate to **System > Network > Interfaces**.
2. Enable or disable the **HA Heart Beat** parameter.

To manage the high availability heartbeat messages on a channel by using the GUI

1. Navigate to **System > Network > Channels**.
2. Enable or disable the **HA Heart Beat** parameter.

# Remove and Replace a Citrix ADC in a High Availability Setup

January 25, 2019

Contributed by:

C

This topic helps you to address RMA replacements. Also, this topic has instructions on how to backup configurations, upgrade or downgrade shipped software version, and setup of RPC password on ADC.

## Points to Consider

The following configurations are not synchronized or propagated in a high availability configuration in INC (Independent Network Configuration) or non-INC mode:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.
- All Interface HA Monitoring configuration commands.

The following configurations are not synced nor propagated in an HA configuration in INC mode (Independent Network Configuration):

- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations

**Instructions**

Complete the following steps to replace a Citrix ADC in high availability setup:

- Remove an Active Citrix ADC secondary node
- Configure Replacement secondary node
- Verify and Update the Software Build on Replacement ADC
- Set Password on New secondary to Match primary
- Add Licenses to Replacement ADC
- Creating HA Pair between primary and New secondary node

**Remove an Active Secondary Node**

1. Log on to both ADCs and run the following command to confirm which node is primary and which node is secondary:

   1. `show ha node`

2. Log on to the primary ADC, backup the configurations on the primary node, and copy the files off of the ADC prior to the changes. These files are located under “/var/ns Sys_backup/” directory.

   The steps are as follows:

   a) Save the ADC running configurations to memory:

   1. `save ns config`

   b) Create the full backup file package:

   1. `create system backup -level full`

   c) Create the basic backup file package:
3. After all backup files have been generated, be sure to copy them off of the device before proceeding.

From a windows terminal, open a Command Prompt and copy the backup files off of the ADC and onto your local hard drive. This can be done using the following command:

```bash
pscp <username>@<NSIP>:<Target file source> <Target file destination>
```

Example:

```bash
pscp nsroot@10.125.245.78:/var/ns_sys_backup/backup_basic_10.125.245.78_2016_09_14_15_08.tgz c:\nsbackup\backup_basic_10.125.245.78_2016_09_14_15_08.tgz
```

When prompted, enter the password for the specified administrator account, then hit Enter. Repeat these steps until all backup bundles are copied to the local PC before proceeding.

4. SSH into the secondary ADC, and set the unit to the “STAYSECONDARY” status. This will force the unit to not attempt to assume the primary role in the event of a detected failure during the swap. Confirm that you are connected to the secondary ADC before executing this step.

```bash
set ha node -haStatus <state>
set ha node -haStatus STAYSECONDARY
```

5. Once the secondary ADC's Node State successfully displays STAYSECONDARY, switch to the primary ADC and delete the secondary node and run the following command:

```bash
save ns config
```

While logged into the primary ADC, run the following commands:

a) Run the following command to identify which numerical value represents the secondary HA node:

```bash
show ha node
```

b) Run the following command to remove the secondary ADC from the primary HA pair;

```bash
rm ha node <node ID>
```

c) Run the following command to save the configuration:

```bash
save ns config
```
d) With the secondary ADC now removed, shutdown, disconnect, and remove the secondary ADC from the network.

**Note.** Be sure to label all connections before disconnecting.

### Configure Replacement Secondary Node

1. With the replacement ADC in place, power up the new device. DO NOT CONNECT the network connections at this point.

2. With boot-up complete, use the console port to connect to the ADC and configure the NSIP that you will use to connect to the unit.

   **Note.** In this example, we are using a different NSIP for the replacement ADC. If you wish to use the original secondary unit's IP, you may change it on the replacement before binding the new ADC to the primary HA unit.

4. The ADC should now be booted. Now connect the network interface that will be used for Management traffic, and confirm that the IP address is reachable from your network.

### Verify and Update the Software Build on Replacement ADC

Before syncing the new unit to the primary ADC, we need to ensure that both ADCs are running the same build.

1. To verify the version on ADC run the following command:

   ```
   show version
   ```

2. While on the new secondary ADC, create a subfolder in `/var` to be used for the upgrade.

3. Go to [Citrix Downloads](https://www.citrix.com/downloads) and download the appropriate package that matches the build version running on the primary ADC.

4. Download and extract the .tgz file:

   ```
   tar -xvzf "file.tgz"
   ```

5. Copy the extracted files to the secondary ADC. On your windows terminal, open a “Command Prompt” and navigate to the directory containing the extracted .tgz build package and run the following pscp command:
After the file has been transferred, return to the secondary ADC and upgrade. For detailed instructions, see Upgrading a Citrix ADX Standalone Appliance.

7. Once the new secondary has rebooted, SSH back into the unit and confirm that the upgrade is successful and the build matches that of the primary.

Set Password on Replacement Secondary Node to Match Primary

**Note:** If at this point you want to change the management IP (NSIP) address of the new secondary ADC, you may do so before moving forward.

Change the password on the new secondary ADC to match the password that is currently on the primary ADC.

1. Make that the default administrator (nsroot) account password is the same as the primary ADC. This is accomplished using the following command while logged in through SSH into the new secondary unit:

```
set system user <user> <password>
```

This command set/resets the password for the specified user.

2. SSH into the primary and new secondary ADC and confirm that passwords match.

Add Licenses to Replacement Secondary Node

With the new ADC updated and ready for pairing, download and install the appropriate licensing for the replacement node.

1. Navigate to [https://www.mycitrix.com](https://www.mycitrix.com) to request and download licenses for the new replacement unit.

2. Once you have all appropriate licenses downloaded, SSH into the new secondary ADC and type the following command to see the current state of licensing:

```
show license
```
3. From the Windows terminal command prompt you must now upload the license files to the new secondary ADC using the following command:

**Note.** If you have multiple licenses, repeat this step until all licenses are uploaded.

```
pscp <Target file source> <username>@<NSIP>:<Target file destination>
```

Example:

```
C:\inetpub>pscp c:\inetpub\NS-VPX-3K-LIC-020030ad024.lic
nsroot@10.125.245.80:/nsconfig/license/NS-VPX-3K-LIC-020030ad024.lic
```

4. SSH into the new secondary ADC and perform a warm reboot using the following command:

```
reboot -w
```

After the unit is restarted, SSH into the unit and run show license command once again. At this point, the licenses should be applied.

**Set up High Availability between primary and New Secondary Node**

At this point, we are now ready to join the Citrix ADC units into a high availability pair. For more information, see Configuring high availability.

**TCP optimization**

April 12, 2019

Contributed by:

C

TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.
**Congestion Control Strategies**

The Transmission Control Protocol (TCP) has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

**Proportional Rate Recovery (PRR) algorithm**

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

**TCP Fast Open (TFO)**

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP’s initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a Citrix ADC appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the Citrix ADC appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using the TFO mechanism, you can reduce an application’s network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

**How TFO works**

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the Citrix ADC appliance can include data in the SYN-ACK segment even though it has not received the final ACK segment of the three-way handshake. This saves up to one full round-trip compared to a normal TCP connection, which requires a three-way handshake before any data can be exchanged.

A client and a backend server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the Citrix ADC appliance.
2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client’s IP address under a secret key) and responds to the client with a SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.
4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached Fast Open Cookie (as a TCP option) along with HTTP data.
5. The Citrix ADC appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with a SYN-ACK, TFO Cookie, and HTTP Response.

**Note:**
If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the Citrix ADC appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.
2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the backend server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same backend server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the backend server.
6. The backend server acknowledges the event with both data and a SYN.

**Note:** If the server acknowledges the event with only a SYN segment, the Citrix ADC appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.

**Configuring TCP fast open**

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

**To enable or disable TFO by using the command line**

At the command prompt, type one of the following commands to enable or disable TFO in a new or
existing profile.

**Note:** The default value is DISABLED.

<p>| | |</p>
<table>
<thead>
<tr>

<tr>
<td>4</td>
<td><strong>Examples</strong></td>
</tr>
<tr>
<td>5</td>
<td>add tcpprofile Profile1 - tcpFastOpen</td>
</tr>
<tr>
<td>6</td>
<td>Set tcpprofile Profile1 - tcpFastOpen Enabled</td>
</tr>
<tr>
<td>7</td>
<td>unset tcpprofile Profile1 - tcpFastOpen</td>
</tr>
</tbody>
</table>

**To set TCP Fast Open cookie timeout value by using the command line interface**

At the command prompt, type:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>set tcpparam - tcpfastOpenCookieTimeout &lt;Timeout Value&gt;</td>
</tr>
<tr>
<td>2</td>
<td><strong>Example</strong></td>
</tr>
<tr>
<td>3</td>
<td>set tcpprofile - tcpfastOpenCookieTimeout 30secs</td>
</tr>
</tbody>
</table>

**To configure the TCP Fast Open by using the GUI**

1. Navigate to **Configuration > System > Profiles** and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **TCP Fast Open** checkbox.
3. Click **OK** and then **Done**.

**To Configure the TCP Fast Cookie timeout value by using the GUI**

Navigate to **Configuration > System > Settings > Change TCP Parameters** and then **Configure TCP Parameters** page to set the TCP Fast Open Cookie timeout value.

**TCP Hystart**

A new TCP profile parameter, hystart, enables the Hystart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

If congestion is detected, Hystart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.
Configuring TCP Hystart

To use the Hystart feature, enable the Cubic Hystart option in the relevant TCP profile.

To configure Hystart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable Hystart in a new or existing TCP profile.

```
1 add tcpprofile <profileName> -hystart ENABLED
2 set tcpprofile <profileName> -hystart ENABLED
3 unset tcpprofile <profileName> -hystart
```

Examples:

```
1 add tcpprofile profile1 -hystart ENABLED
2 set tcpprofile profile1 -hystart ENABLED
3 unset tcpprofile profile1 -hystart
```

To configure Hystart support by using the GUI

1. Navigate to Configuration > System > Profiles > and click Edit to modify a TCP profile.
2. On the Configure TCP Profile page, select the Cubic Hystart check box.
3. Click OK and then Done.

TCP burst rate control

It is observed that TCP control mechanisms can lead to a bursty traffic flow on high speed mobile networks with a negative impact on the overall network efficiency. Due to mobile network conditions such as congestion or Layer-2 retransmission of data, TCP acknowledgements arrive clumped at the sender triggering a burst of transmission. These group of consecutive packets sent with a short inter-packet gaps it is called TCP packet burst. To overcome traffic burst, the Citrix ADC appliance uses a TCP Burst Rate Control technique. This technique evenly spaces data into the network for an entire round-trip-time so that the data is not sent into a burst. By using this burst rate control technique, you can achieve better throughput and lower packet drop rates.

How TCP burst rate control works

In a Citrix ADC appliance, this technique evenly spreads the transmission of a packets across the entire duration of the round-trip-time (RTT). This is achieved by using a TCP stack and network packet
scheduler that identifies the various network conditions to output packets for ongoing TCP sessions in order to reduce the bursts.

At the sender, instead of transmitting packets immediately upon receipt of an acknowledgment, the sender can delay transmitting packets to spread them out at the rate defined by scheduler (Dynamic configuration) or by the TCP profile (Fixed configuration).

**Configuring TCP burst rate control**

To use the TCP Burst Rate Control option in the relevant TCP profile and set the burst rate control parameters.

**To set TCP burst rate control by using the command line**

At the command prompt, set one of the following TCP Burst Rate Control commands are configured in a new or existing profile.

**Note:** The default value is DISABLED.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add tcpProfile &lt;TCP Profile Name&gt; -burstRateControl Disabled</td>
<td>Set the Burst Rate Control to Disabled. If the Burst rate control is disabled, then a Citrix ADC appliance does not perform burst management other than the maxBurst setting.</td>
</tr>
<tr>
<td>set tcpProfile &lt;TCP Profile Name&gt; -burstRateControl Dynamic</td>
<td>Set the Burst Rate Control to Dynamic. If the Burst Rate Control is Dynamic, the connection is being regulated based on various network conditions to reduce TCP bursts. This mode works only when the TCP connection is in END-POINT mode. When Dynamic Burst Rate control is enabled the maxBurst parameter of the TCP profile is not in effect.</td>
</tr>
</tbody>
</table>

where,

**Disabled** – If the Burst rate control is disabled, then a Citrix ADC appliance does not perform burst management other than the maxBurst setting.

**Fixed** – If the TCP burst rate control is Fixed, the appliance uses the TCP Connection Payload Send Rate value mentioned in the TCP Profile.

**Dynamic** – If the Burst Rate Control is “Dynamic” the connection is being regulated based on various network conditions to reduce TCP bursts. This mode works only when the TCP connection is in END-POINT mode. When Dynamic Burst Rate control is enabled the maxBurst parameter of the TCP profile is not in effect.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add tcpProfile profile1 -burstRateControl Disabled</td>

1. Navigate to Configuration > System > Profiles > and then click Edit to modify a TCP profile.
2. On the Configure TCP Profile page, select TCP Burst Control option from the drop-down list:
   a) BurstRateCntrl
   b) CreditBytePrms
   c) RateBytePerms
   d) RateSchedulerQ
3. Click OK and then Done.

Protection against wrapped sequence (PAWS) algorithm

If you enable the TCP timestamp option in the default TCP profile, the Citrix ADC appliance uses the Protection Against Wrapped Sequence (PAWS) algorithm to identify and reject old packets whose sequence numbers are within the current TCP connection’s receive window because the sequence has “wrapped” (reached its maximum value and restarted from 0).

If network congestion delays a non-SYN data packet and you open a new connection before the packet arrives, sequence-number wrapping might cause the new connection to accept the packet as valid, leading to data corruption. But if the TCP timestamp option is enabled, the packet is discarded.

By default, the TCP timestamp option is disabled. If you enable it, the appliance compares the TCP timestamp (SEG.TSval) in a packet’s header with the recent timestamp (Ts.recent) value. If SEG.TSval is
equal to or greater than Ts.recent, the packet is processed. Otherwise, the appliance drops the packet and sends a corrective acknowledgement.

**How PAWS works**

The PAWS algorithm processes all the incoming TCP packets of a synchronized connection as follows:

1. If SEG.TSval < Ts.recent: The incoming packet is not acceptable. PAWS sends an acknowledgement (as specified in RFC-793) and drops the packet. Note: Sending an ACK segment is necessary in order to retain TCP’s mechanisms for detecting and recovering from half-open connections.
2. If packet is outside the window: PAWS rejects the packet, as in normal TCP processing.
3. If SEG.TSval > Ts.recent: PAWS accepts the packet and processes it.
4. If SEG.TSval <= Last.ACK.sent (arriving segment satisfies): PAWS must copies SEG.TSval value to Ts.recent (is it copied to Ts.Recent field in the db?).
5. If packet is in sequence: PAWS accepts the packet.
6. If packet is not in sequence: The packet is treated as a normal in-window, out-of-sequence TCP segment. For example, it might be queued for later delivery.
7. If Ts.recent value is idle for more than 24 days: The validity of Ts.recent is checked if the PAWS timestamp check fails. If the Ts.recent value is found to be invalid, the segment is accepted and the PAWS rule updates Ts.recent with the TSval value from the new segment.

**To enable or disable TCP timestamp by using the command line interface**

At the command prompt, type:

```
set nstcpprofile nstcp_default_profile -TimeStamp (ENABLED | DISABLED)
```

**To enable or disable TCP timestamp by using the GUI**

Navigate to System > Profile > TCP Profile, select the default TCP profile, click Edit, and select or clear the TCP timestamp check box.

**Optimization Techniques**

TCP uses the following optimization techniques and methods for optimized flow controls.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Policy based TCP Profile Selection

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server’s traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

For information about using subscriber attributes to perform TCP optimization, see Policy-based TCP Profile.

Configuring policy based TCP profile selection

Configuring policy based TCP profile selection consists of the following tasks:

• Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.
• Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
• Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your Citrix ADC ADC can distinguish the connections and bind the correct AppQoE action to each policy.
• Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

• enable ns feature appqoe
• show ns feature

To bind a TCP profile while creating an AppQoE action using the command line interface

At the command prompt, type the following AppQoE action command with tcpprofiletobind option.

To configure an AppQoE policy by using the command line interface

At the command prompt, type:
add appqoe policy <name> -rule <expression> -action <string>

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:
bind cs vserver <name> -policyName <appqoe_policy_name> -priority <priority>
bind lb vserver <name> -policyName <appqoe_policy_name> -priority <priority>
bind cr vserver <name> -policyName <appqoe_policy_name> -priority <priority>

Example

1  add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle ENABLED -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 500 -slowStartIncr 1 -bufferSize 4194304 -flavor BIC -KA ENABLED -sendBuffsize 4194304 -rstWindowAttenuate ENABLED -spooﬁnDrop ENABLED -dsack enabled -frto ENABLED -maxcwnd 4000000 -fack ENABLED -tcpmode ENDPOINT
2  add appqoe action appact1 -priority HIGH -tcpprofile tcp1
3  add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -action appact1
4  bind lb vserver lb2 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST
5  bind cs vserver cs1 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST
Configuring policy based TCP profiling using the GUI

To enable AppQoE by using the GUI

1. Navigate to **System > Settings**.
2. In the details pane, click **Configure Advanced Features**.
3. In the **Configure Advanced Features** dialog box, select the **AppQoE** check box.
4. Click **OK**.

To configure AppQoE policy by using the GUI

1. Navigate to **App-Expert > AppQoE > Actions**.
2. In the details pane, do one of the following:
   a. To create a new action, click **Add**.
   b. To modify an existing action, select the action, and then click **Edit**.
3. In the **Create AppQoE Action** or the **Configure AppQoE Action** screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring the AppQoE Action” as follows (asterisk indicates a required parameter):
   a) Name—name
   b) Action type—respondWith
   c) Priority—priority
   d) Policy Queue Depth—polqDepth
   e) Queue Depth—priqDepth
   f) DOS Action—dosAction
4. Click **Create**.

To bind AppQoE policy by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select a server and then click **Edit**.
2. In the **Policies** section and click (+) to bind an AppQoE policy.
3. In the **Policies** slider, do the following:
   a) Select a policy type as AppQoE from the drop-down list.
   b) Select a traffic type from the drop-down list.
4. In the **Policy Binding** section, do the following:
   a) Click **New** to create a new AppQoE policy.
   b) Click **Existing Policy** to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click **Bind** to the policy to the virtual server.
6. Click **Done**.
**SACK block generation**

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgement (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

**Note:** A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

**Client reneging**

A Citrix ADC appliance can handle client reneging during SACK based recovery.

**Memory checks for marking end_point on PCB is not considering total available memory**

In a Citrix ADC appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

**Unnecessary retransmissions due to missing SACK blocks**

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers additional retransmissions from the server.

**SNMP for number of connections bypassed optimization because of overload**

The following SNMP ids have been added to a Citrix ADC appliance to track number of connections bypassed TCP optimization due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.131 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.
Dynamic receive buffer

To maximize TCP performance, a Citrix ADC appliance can now dynamically adjust the TCP receive buffer size.

How to record a packet trace on Citrix ADC

January 30, 2019
Contributed by: C

This troubleshooting article explains how an administrator can record a network packet trace using the Citrix ADC GUI.

Points to remember

- Citrix recommends you to use the recent Wireshark version from the “automated build section” available in the following web page: http://www.wireshark.org/download/automated.
• In Citrix ADC software release 10.5 and later, to decrypt the capture, ensure that ECC (Elliptic Curve Cryptography), Session Reuse and DH Param are disabled/removed from the virtual server before the trace is captured. Refer to the Additional Resources section of this article before making these changes.

Record packet trace on NetScaler 11.1 appliance

To record a packet trace on a NetScaler 11.1 appliance, you must complete the following procedure:

1. Sign into NetScaler GUI and navigate to System > Diagnostics page.
2. Click the Start new trace link in the Diagnostic page, as shown in the following screenshot.
3. Update the packet size to 0 in the Packet size field.
4. Click Start to start recording the network packet trace.
5. Click Stop and Download to stop recording the network packet trace after the test is complete.
6. Select the required file and click Select and click Download.
7. Open the network packet trace file with the Wireshark utility to display the content of the file.

Record packet trace on NetScaler 10.5 appliance

To record a packet trace on a NetScaler 10.5 appliance, you must complete the following procedure:

1. Sign into NetScaler GUI and navigate to System > Diagnostics page.
2. Click the Start new trace link under Technical Support Tools as shown in the following screenshot.
3. Update the packet size to 0 in the Packet Size field.
   
   Note: If NetScaler headers are not required then select Capture trace in .pcap format.
4. Click Start to start recording the network packet trace.
5. Click OK to stop recording the network packet trace after the test is complete.
   
   An nstrace.cap file is generated, which contains the network packet trace.
6. Highlight the required file and click Download.
7. Specify a destination and save the packet trace.
8. Open the network packet trace file with the Wireshark utility to display the content of the file.
Note: Select Decrypted SSL packets (SSLPLAIN) to decrypt the packet trace without the private key.

Capture SSL master keys

In the latest 11.0 and 11.1 version and above there is an option to capture the session keys which will be valid for only for that particular session/nstrace and this option can be used if you donot want to share the private key or use SSLPLAIN mode. For more information please refer to How to use the new “capsslkeys” option when trying to capture nstrace on Netscaler.

Export Session Keys without sharing Private key

In most of the scenarios the private key is not available or shared. In such scenarios we can suggest to export the SSL session keys instead of the private key. Please refer to the below article for more information.
How to Export and Use SSL Session Keys to Decrypt SSL Traces Without Sharing the SSL Private Key.

Filters

Additionally, it is always recommended to add IP based filters while taking traces. This will ensure that you will capture only interested traffic which will further ease your troubleshooting. Adding filters will also decrease the load on NetScaler while taking traces.

You will find the option to configure filters on the same page:

```
1 screenshot
```

Simple IP based filters are enough to get the right captures. For a detailed list of filters and examples, refer to Citrix Documentation - nstrace.

Use case to capture a packet trace with virtual server IP filter (both frontend and backend)

With a filter of the virtual server IP address and enabling the option “-link” in CLI or select the option “Trace filtered connection peer traffic” in GUI (available 10.1 and above), you will be able to capture both the front end and backend traffic for that particular IP address. With this option it is not recommended to mention a source IP or destination IP filter.

```
1 start nstrace -size 0 -filter "CONNECTION.IP.EQ(1.1.1.1)" -link ENABLED
2
3 show nstrace
```
Capturing cyclic traces

It is always challenging to troubleshoot an intermittent issue. Cyclic tracing is best suited for issues which are intermittent. These traces can be run over a span of few hours or days based on the occurrence of the issue. Also a specific filter can be used as mentioned above. Please evaluate the size of the trace files that are being generated before running it for a longer time (as this can fill up the var space)

Run the following command from CLI:

```
1 start nstrace -nf 60 -time 30 -size 0
2 This particular trace will create 60 files each of them for 30 sec. This means the files will start getting overwritten after 60 trace files or 30 mins
3 Show nstrace à To check the status of the nstrace
4 Stop nstrace à To stop the nstrace.
```

Best Practices

On a unit handling gigabytes of traffic per second, capturing traffic is a very resource intensive process. The impact to resources is mainly in terms of CPU and Disk Space. Disk Space impact can be reduced by using filtering expressions (capturing traffic only related to a particular IP). However the impact on CPU remains despite using expressions and in some cases might cause a slight further increase as NetScaler now needs to process packets according to the filter before capturing them.

The best practice with regards to tracing are:

1. The duration for which the trace is run should be as limited as possible while still ensuring the packets of interest are captured.
2. Schedule the tracing activity to happen at a time when the number of users (and hence the traffic) is greatly reduced, such as during off hours.
Additional resources

Disable session reuse on virtual server from NetScaler GUI

Session reuse is disabled while capturing a trace in order to capture a complete SSL handshake in the
trace. When it is enabled it is likely that you will only capture a partial handshake in the trace. Ensure
to enable the option after trace collection.
Do not disable SSL session reuse when the persistence method is sssl, as it will break the persist-
tence for existing connections. For more information refer to CTX121925- SSL Renegotiation Process
and Session Reuse on NetScaler appliance.

1. Open the virtual server and navigate to SSL Parameters.
2. Disable Enable Session Reuse if enabled.

Disable session reuse on virtual server from NetScaler CLI

1. SSH to the NetScaler.
2. Run the following command to disable DH Param from the virtual server:

   set ssl vserver "vServer_Name"-sessReuse DISABLED

Disable DH parameter on virtual server from NetScaler GUI

Refer to CTX213335 - How do I setup a Diffie-Hellman key on NetScaler? to understand about DH Pa-
rameter.

1. Open the virtual server and navigate to SSL Parameters.
2. Disable DH Param if enabled.

Disable DH parameter on virtual server from NetScaler CLI

1. SSH to the NetScaler.
2. Run the following command to disable DH Param from the virtual server:

   set ssl vserver "vServer_Name"-dh DISABLED

Disable ECC curve on virtual server from NetScaler GUI

ECC curve are disabled in order to decrypt the captured SSL trace with private key. These keys should
not be disabled if the related SSL ciphers are used. For more information on ECC curve refer to CTX20
- How Do I Setup ECC on NetScaler?
1. Open the virtual server and navigate to ECC Curve.

2. If no ECC Curve is bound to the virtual server then no other action is required.

3. If any ECC Curve is bound to the virtual server then click the ECC Curve and Unbind it from the virtual server.

**Disable ECC curve on virtual server from NetScaler CLI**

1. SSH to the NetScaler.

2. Run the following command for each ECC Curve bound to the virtual server:

   ```bind ssl vserver "vServer_Name"-eccCurveName "ECC_Curve_Name"```

**How to free space on /var directory for logging issues with a Citrix ADC appliance**

January 23, 2019

Contributed by: C

This troubleshooting article explains how an administrator can free space from the /var directory of a Citrix ADC appliance when you are unable to log on to the Citrix GUI.

When the amount of disk space is low in /var directory of the appliance, you might not be able to sign in to the Citrix GUI. In this scenario, you can remove the old log files to create free space in /var directory.

**Points to remember**

- Ensure that you back up the files before removing the files from the appliance.

To free space in the /var directory of a NetScaler appliance, complete the following procedure:

1. Log on to the Command Line Interface (CLI) of NetScaler by using SSH. For more information to complete this task, refer to Citrix ADC Documentation.

2. After you log on to NetScaler CLI, switch to the shell prompt using the following command.

3. Run the following command to see the availability of space on NetScaler appliance.
4. If the capacity of the /var directory is less than 90 percent or very low, then you must delete few files from this directory.

- Run the following commands to view the contents of the /var directory:
  
  ```bash
cd /var
ls -l
```  

The directories that are usually of interest are as follows:

- `/var/nstrace` - This directory contains trace files. This is the most common reason for HDD being filled on the NetScaler. This is due to an nstrace being left running for indefinite amount of time. All traces that are not of interest can and should be deleted. To stop an nstrace, go back to the CLI and issue stop nstrace command.

- `/var/log` - This directory contains system specific log files.

- `/var/nslog` - This directory contains NetScaler log files.

- `/var/tmp/support` - This directory contains technical support files, also known as, support bundles. All files not of interest should be deleted.

- `/var/core` - Core dumps are stored in this directory. There will be directories within this directory and they will be labeled with numbers starting with 1. These files can be quite large in size. Clear all files unless the core dumps are recent and investigation is required.

- `/var/crash` - Crash files, such as process crashes are stored in this directory. Clear all files unless the crashes are recent and investigation is required.

- `/var/nsinstall` - Firmware is placed in this directory when upgrading. Clear all files, except the firmware that is currently being used.

- Verify if any of the directories are using more space:

  ```bash
du -hs*
```
989M crash
4.0k cron
2.0k dev
6.0k download
2.0k gui
2.0k install
2.0k krb
2.0k learnt_data
122M log
366M netscaler
14k ns_gui
86k ns_sys_backup
631M nsinstall
883M nslog
32k nsprofllog
2.0k nssynclog
16k nstemplates
36k nstemplats
4.5G nstrace
8.1M opt
6.0k pubkey
52k run
28M safenet
72M tmp
2.0k vmtools
14k vpn

- Delete the files which are not required:

  1. `rm -r nstrace/*`

For more help on deleting files refer to FreeBSD Man Pages.

- If the log or nslog directory is using more space, then run the following commands to open the log directory and view its contents:
- Delete the files which are not required.

  1. `rm -r nstrace/*`

For more help on deleting files refer to FreeBSD Man Pages.

- If the log or nslog directory is using more space, then run the following commands to open the log directory and view its contents:

  1. `cd /var/log`
1. Ensure that all files are compressed. This is indicated by the .tar.gz file extension.
2. If you are using NetScaler MAS or Command Center, then verify the /var/ns_system_backup directory. Ensure that NetScaler MAS or Command Center clears the backup files it creates.

How to download core or crashed files from Citrix ADC appliance

January 25, 2019
Contributed by:
C

This troubleshooting article explains how an administrator can download core or crash files from the Citrix ADC GUI.

Download core or crash files from Citrix ADC appliance

To download files, you must complete the following procedure.

1. Sign into NetScaler GUI and navigate to System > Diagnostics page.
2. click the Download core files link in the Diagnostic page, as shown in the following screenshot.
   
   **Note:** You must download the latest core or crash files generated by the appliance that are relevant to the time-stamp of your issue. The files can be located either in the core or crash directory.
3. Select the relevant file and click Download.
Download core or crash files from Citrix ADC appliance using SFTP client

To download the core or crash files from a NetScaler appliance, complete the following procedure:

1. Open WinSCP and log on to the NetScaler Management IP.
2. Navigate to the `/var/core/1` to download the files.

Reference Material

January 23, 2019

Contributed by:

Use this reference information to get an in-depth understanding of the following Citrix ADC components:

Citrix ADC SNMP OIDs - Details of the SNMP OIDs that can be used to obtain information from a Citrix ADC appliance.

Citrix ADC Syslog Messages - Details of the Syslog messages given by the Citrix ADC appliance.

Citrix ADC CLI Commands - Details of the commands that can be used to configure the Citrix ADC appliance through the CLI. You can also view the details of each command in the CLI, by entering the “man <ns-command-name>” command.

API Reference - Details of all operations that can be performed on the Citrix ADC appliance by using the REST API.

Citrix ADC Advanced Policy Expressions - Details of the expressions that can be used to define advanced policies.
