**sessionTicket**: Use of session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the **ENABLED** setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

**sessionTicketKeyData**: Contains the session ticket name (0–15 bytes), the session AES key used to encrypt or decrypt the session ticket (16–31 bytes), and the session HMAC key used to compute the digest of the ticket (32–63 bytes). Externally generated by an administrator and added to a Citrix ADC appliance.

Maximum length: 64 bytes

**Example:**

```
1 set ssl profile ns_default_ssl_profile_frontend -sessionticket ENABLED
2
3 Done
4
5 set ssl profile ns_default_ssl_profile_frontend -sessionticketkey
   1111111111111111111111111111111111111111111111111111111111111111
6
7 Done
```
show ssl profile ns_default_ssl_profile_frontend

1) Name: ns_default_ssl_profile_frontend (Front-End)

ECC Curve: P_256, P_384, P_224, P_521

1) Cipher Name: DEFAULT Priority :4
Description: Predefined Cipher Alias

1) Internal Service Name (Front-End): nsrnatsip-127.0.0.1-5061
Type SSL session ticket data manually by using the GUI

1. Navigate to System > Profiles, and select SSL Profile.
2. Select ns_default_ssl_profile_frontend and click Edit.
3. In the Basic Settings section, click the pencil icon and set the following parameters:
   - Session Ticket
   - Session Ticket Key Data
   - Confirm Session Ticket Key Data
4. Click OK.

Load an old configuration

Enabling the default profiles is not reversible. However, if you decide that your deployment does not require the default profiles, you can load an older configuration that you saved before you enabled the default profiles. The changes are effective after you restart the appliance.

Load an old configuration by using the CLI

At the command prompt, type:

```
shell
root@ns# clear config
root@ns# cd /nsconfig
root@ns# cp ns.conf.NS.11.0.jun.16 ns.conf
root@ns# reboot
```
Secure front-end profile

April 23, 2019

In addition to a default front-end and a default back-end profile, a new default secure front-end profile is available from release 12.1. The settings required for an A+ rating (as of May 2018) from Qualys SSL Labs are preloaded into this profile. Earlier, you had to explicitly set each of the parameters required for an A+ rating on an SSL front-end profile or an SSL virtual server. Now you can bind the ns_default_ssl_profile_secure_frontend profile to your SSL virtual server and the required parameters are automatically set on your SSL virtual server.

Note:
The secure front-end profile is not editable.

When you enable the default profile, the default front-end profile is automatically bound to all the SSL virtual servers. To get an A+ rating, you must explicitly bind the ns_default_ssl_profile_secure_frontend profile and also bind an SHA2/SHA256 server certificate to your SSL virtual server.

Secure front-end profile parameters

The parameters with their default settings are listed below:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLv3</td>
<td>DISABLED</td>
</tr>
<tr>
<td>TLSv1.0</td>
<td>DISABLED</td>
</tr>
<tr>
<td>TLSv1.1</td>
<td>DISABLED</td>
</tr>
<tr>
<td>TLSv1.2</td>
<td>ENABLED</td>
</tr>
<tr>
<td>TLSv1.3</td>
<td>DISABLED</td>
</tr>
<tr>
<td>Deny SSL Renegotiation</td>
<td>NONSECURE</td>
</tr>
<tr>
<td>HSTS</td>
<td>ENABLED</td>
</tr>
<tr>
<td>HSTS IncludeSubDomains</td>
<td>YES</td>
</tr>
<tr>
<td>HSTS Max-Age</td>
<td>15552000</td>
</tr>
<tr>
<td>Cipher Name</td>
<td>SECURE</td>
</tr>
<tr>
<td>Priority</td>
<td>1</td>
</tr>
</tbody>
</table>

Secure cipher alias

A new secure cipher alias is added and bound to the secure front-end profile. To list the ciphers that are part of this alias, at the command prompt type: show cipher SECURE

```
show cipher SECURE
```
1) Cipher Name: TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 Priority : 1
   Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES-GCM(256)
   Mac=AEAD HexCode=0xc030
2) Cipher Name: TLS1.2-ECDHE-RSA-AES128-GCM-SHA256 Priority : 2
   Description: TLSv1.2 Kx=ECC-DHE Au=RSA Enc=AES-GCM(128)
   Mac=AEAD HexCode=0xc02f
3) Cipher Name: TLS1.2-ECDHE-ECDSA-AES256-GCM-SHA384
   Priority : 3
   Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES-GCM(256)
   Mac=AEAD HexCode=0xc02c
4) Cipher Name: TLS1.2-ECDHE-ECDSA-AES128-GCM-SHA256
   Priority : 4
   Description: TLSv1.2 Kx=ECC-DHE Au=ECDSA Enc=AES-GCM(128)
   Mac=AEAD HexCode=0xc02b

Done

Configuration

Perform the following steps:

1. Add a load balancing virtual server of type SSL.
2. Bind a SHA2/SHA256 certificate.
3. Enable the default profile.
4. Bind the secure front-end profile to the SSL virtual server.

Get an A+ rating for an SSL virtual server by using the CLI

At the command prompt, type:

```
1  add lb vserver <name> <serviceType> <IPAddress> <port>
2  bind ssl vserver <vServerName> -certkeyName <string>
3  set ssl parameter -defaultProfile ENABLED
4  set ssl vserver <vServerName> -
                sslProfile ns_default_ssl_profile_secure_frontend
5  show ssl vserver [/<vServerName>]
```

Example:

```
1  add lb vserver ssl-vsvr SSL 192.0.2.240 443
2  bind ssl vserver ssl-vsvr -certkeyName letras
3
4
```

Legacy SSL profile

April 23, 2019

Note:
Citrix recommends using the enhanced profiles instead of legacy profiles. For information about the enhanced profile infrastructure, see SSL profile infrastructure.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Important:

You must bind an SSL profile to an SSL virtual server. Do not bind a DTLS profile to an SSL virtual server. For information about DTLS profiles, see DTLS Profiles.

You can use an SSL profile to specify how a Citrix ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.
- Backend profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiples entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

<table>
<thead>
<tr>
<th>Front end profile</th>
<th>Backend profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>cipherRedirect, cipherURL</td>
<td>denySSLReneg</td>
</tr>
<tr>
<td>clearTextPort*</td>
<td>encryptTriggerPktCount</td>
</tr>
<tr>
<td>clientAuth, clientCert</td>
<td>nonFipsCiphers</td>
</tr>
<tr>
<td>denySSLReneg</td>
<td>pushEncTrigger</td>
</tr>
<tr>
<td>dh, dhFile, dhCount</td>
<td>pushEncTriggerTimeout</td>
</tr>
<tr>
<td>dropReqWithNoHostHeader</td>
<td>pushFlag</td>
</tr>
<tr>
<td>encryptTriggerPktCount</td>
<td>quantumSize</td>
</tr>
<tr>
<td>eRSA, eRSACount</td>
<td>serverAuth</td>
</tr>
<tr>
<td>insertionEncoding</td>
<td>commonName</td>
</tr>
<tr>
<td>nonFipsCiphers</td>
<td>sessReuse, sessTimeout</td>
</tr>
<tr>
<td>pushEncTrigger</td>
<td>SNIEnable</td>
</tr>
<tr>
<td>pushEncTriggerTimeout</td>
<td>ssl3</td>
</tr>
<tr>
<td>pushFlag</td>
<td>sslTriggerTimeout</td>
</tr>
<tr>
<td>quantumSize</td>
<td>strictCAChecks</td>
</tr>
<tr>
<td>redirectPortRewrite</td>
<td>tls1</td>
</tr>
</tbody>
</table>
An error message appears if you try to set a parameter that is not part of the profile (for example, if you try to set the clientAuth parameter in a backend profile).

Some SSL parameters, such as CRL memory size, OCSP cache size, UndefAction Control, and UndefAction Data, are not part of any of the above profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- Add—Creates an SSL profile on the Citrix ADC. Specify whether the profile is front end or backend. Front end is the default.
- Set—Modifies the settings of an existing profile.
- Unset—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- Remove—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- Show—Displays all the profiles that are available on the Citrix ADC. If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.

Create an SSL profile by using the CLI

- To add an SSL profile, type:

```
1 add ssl profile <name> [-sslProfileType (BackEnd | FrontEnd )]
```
To modify an existing profile, type:

```
set ssl profile <name>
```

To unset an existing profile, type:

```
unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA]...
```

To unset an existing profile from an entity, type:

```
unset ssl vserver <vServerName> -sslProfile
```

To remove an existing profile, type:

```
m sl ssl profile <name>
```

To display an existing profile, type:

```
sh ssl profile <name>
```

Create an SSL profile by using the GUI

Navigate to **System > Profiles**, select the SSL Profiles tab, and create an SSL profile.

Enable stricter control on client certificate validation

The Citrix ADC appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCACertificate setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root
certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the Citrix ADC appliance

Enable stricter control on client certificate validation by using the CLI

At the command prompt, type:  
```
set ssl profile <name> -ClientAuthUseBoundCAChain Enabled
```  

Enable stricter control on client certificate validation by using the GUI

1. Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile, or select an existing profile.
2. Select Enable Client Authentication using bound CA Chain.

Certificate revocation lists

April 23, 2019

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA may revoke the issued certificate before the expiration date (for example, when an owner’s private key is compromised, a company’s or individual’s name changes, or the association between the subject and the CA changes).

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs on a regular basis. You can configure the Citrix ADC appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the Citrix ADC appliance. You can configure refresh options. You can also configure the Citrix ADC to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The appliance supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the Citrix ADC appliance.

If you have used the Citrix ADC as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the Citrix ADC are not used either in a production environment or beyond a particular date.

Note:
By default, CRLs are stored in the /var/netscaler/ssl directory on the Citrix ADC appliance.

Create a CRL on the ADC

Since you can use the Citrix ADC appliance to act as a certificate authority and create self-signed certificates, you can also revoke certificates that you have created and certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

Revoke a certificate or create a CRL by using the CLI

At the command prompt, type the following command:

```
create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>)
```

Example:

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```

Revoke a certificate or create a CRL by using the GUI

1. Navigate to Traffic Management > SSL and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the Choose Operation list, select Revoke Certificate or Generate CRL.

Add an existing CRL to the ADC

Before you configure the CRL on the Citrix ADC appliance, make sure that the CRL file is stored locally on the Citrix ADC appliance. In the case of an HA setup, the CRL file must be present on both Citrix ADC appliances, and the directory path to the file must be the same on both appliances.
Add a CRL on the Citrix ADC by using the CLI

At the command prompt, type the following commands to add a CRL on the Citrix ADC and verify the configuration:

```
1  add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]
2  show ssl crl [<crlName>]
```

Example:

```
1  > add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM
2  Done
3  > show ssl crl crl-one
4  Name: crl-one  Status: Valid,  Days to expiration: 29
5  CRL Path: /var/netscaler/ssl/CRL-one
6  Format: PEM   CAcert: samplecertkey
7  Refresh: DISABLED
8  Version: 1
9  Signature Algorithm: sha1WithRSAEncryption
10 Issuer: C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,
11   OU=SSL Acceleration,CN=www.ns.com/emailAddress=support@Citrix
12   ADC appliance.com
13  Last_update:Jun 15 10:53:53 2010 GMT
14  Next_update:Jul 15 10:53:53 2010 GMT
15 1)  Serial Number: 00
16  Revocation Date:Jun 15 10:51:16 2010 GMT
17  Done
```

Add a CRL on the Citrix ADC by using the GUI

Navigate to Traffic Management > SSL > CRL, and add a CRL.

Configure CRL refresh parameters

A CRL is generated and published by a Certificate Authority periodically or, in some cases, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the Citrix ADC appliance regularly, for protection against clients trying to connect with certificates that are not valid.
The Citrix ADC appliance can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you execute the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. You must explicitly specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

Configure CRL autorefresh by using the CLI

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration:

```
1 set ssl crl <crlName> [-refresh ( ENABLED | DISABLED )] [-CAcert <string>] [-url <URL | -server <ip_addr|ipv6_addr>] [-method HTTP | (LDAP [-baseDN <string>] [-bindDN <string>] [-scope ( Base | One )] [-password <string>] [-binary ( YES | NO )]) [-port <port>] [-interval <interval>]
2
3 show ssl crl [<crlName>]
```

Example:

```
1 set CRL crl1 -refresh enabled -method ldap -inform DER -CAcert ca1 -server 10.102.192.192 -port 389 -scope base -baseDN "cn=clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01
2
3 set ssl crl crl1 -refresh enabled -method http -cacert ca1 -port 80 -time 00:10 -url http://10.102.192.192/crl/ca1.crl
4
5
6 > sh crl
7
8 1) Name: crl1 Status: Valid, Days to expiration: 355
9     CRL Path: /var/netscaler/ssl/crl1
10     Format: PEM CAcert: ca1
11     Refresh: ENABLED Method: HTTP
12     URL: http://10.102.192.192/crl/ca1.crl
13     Port:80
14     Refresh Time: 00:10
15     Last Update: Successful, Date: Tue Jul 6 14:38:13 2010
```
Configure CRL autorefresh using LDAP or HTTP by using the GUI

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, and select Enable CRL Auto Refresh.

Note: If the new CRL has been refreshed in the external repository before its actual update time as specified by the Last Update time field of the CRL, you should immediately refresh the CRL on the Citrix ADC appliance.

To view the last update time, select the CRL, and click Details.

Synchronize CRLs

The Citrix ADC appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the Citrix ADC appliance needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the appliance to update CRLs automatically at a specified refresh interval.

The appliance maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated, connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

Note: If CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, all client-authentication connections with the same issuer as the CRL are rejected as REVOKED until the CRL is successfully refreshed.

You can specify the interval at which the CRL refresh should be carried out. You can also specify the exact time.

Synchronize CRL autorefresh by using the CLI

At the command prompt, type the following command:

```
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <HH:MM>]
```

Example:
Synchronize CRL refresh by using the GUI

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, select enable CRL Auto Refresh, and specify the interval.

Perform client authentication by using a certificate revocation list

If a certificate revocation list (CRL) is present on a Citrix ADC appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional.

The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

Table 1. Result of a Handshake with a Client Using a Revoked Certificate

<table>
<thead>
<tr>
<th>Rule for CRL Check</th>
<th>Rule for Client Certificate Check</th>
<th>State of the CRL Configured for the CA certificate</th>
<th>Result of a Handshake with a Revoked Certificate</th>

</tr>
<tr>
<td>Optional/Mandatory</td>
<td>Mandatory</td>
<td>Expired</td>
<td>Failure</td>
</tr>
</tbody>
</table>
Note:

- The CRL check is optional by default. To change from optional to mandatory or vice-versa, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.

- In the output of the sh ssl vserver command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the sh ssl vserver command only if CRL check is set to mandatory. If CRL check is set to optional, the CRL check details do not appear.

To configure CRL check by using the CLI

At the command prompt, type the following command:

```
bind ssl vserver <vServerName> -certkeyName <string> [(-CA -crlCheck (Mandatory | Optional ))]
```

Example:

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
> sh ssl vs v1

Advanced SSL configuration for VServer v1:

DH: DISABLED
DH Private-Key Exponent Size Limit: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED
Push Encryption Trigger: Always
```
Configure CRL check by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. Click in the Certificates section.
3. Select a certificate and, in the OCSP and CRL Check list, select CRL Mandatory.

Monitor certificate status with OCSP

April 23, 2019

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. Citrix ADC appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. Citrix ADC implementation of OCSP includes request batching and response caching.

OCSP implementation

OCSP validation on a Citrix ADC appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the appliance creates an OCSP request and forwards it to the OCSP responder. To do so, the appliance uses a locally configured URL. The transaction is in a suspended state until the appliance evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the appliance will allow the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.
The appliance supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

**OCSP request batching**

Each time the appliance receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the appliance can query the status of more than one client certificate in the same request. For this to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

**OCSP response caching**

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the appliance caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the appliance first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the appliance sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

**Note:** From release 12.1 build 49.x, the cache timeout limit is now increased to a maximum of 43200 minutes (30 days). Earlier the limit was 1440 minutes (one day). The increased limit helps reduce the lookups on the OCSP server and avoid any SSL/TLS connection failures in case the OCSP server is not reachable due to network or other problems.

**OCSP responder configuration**

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

**Add an OCSP responder by using the CLI**

At the command prompt, type the following commands to configure OCSP and verify the configuration:
add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED ) [-cacheTimeout <positive_integer>] [-batchingDepth < positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce ( YES | NO )][-insertClientCert( YES | NO )]

bind ssl certKey [ <certkeyName> ] [-ocspResponder <string>] [-priority < positive_integer>]

bind ssl vserver <vServerName>@ (-certkeyName <string> ( CA [-ocspCheck ( Mandatory | Optional )]))

show ssl ocspResponder [ <name>]

Example:

add ssl ocspResponder ocsp_responder1 -url "http://www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -batchingDelay 100 -resptimeout 100 -responderCert responder_cert -producedAtTimeSkew 300 -signingCert sign_cert -insertClientCert YES

bind ssl certKey ca_cert -ocspResponder ocsp_responder1 -priority 1

bind ssl vserver vs1 -certkeyName ca_cert -CA -ocspCheck Mandatory

sh ocspResponder ocsp_responder1

1) Name: ocsp_responder1

Caching: Enabled  Timeout: 30 minutes

Batching: 8  Timeout: 100 mS

HTTP Request Timeout: 100mS

Request Signing Certificate: sign_cert

Response Verification: Full, Certificate: responder_cert

ProducedAt Time Skew: 300 s

Nonce Extension: Enabled

Client Cert Insertion: Enabled

Done

show certkey ca_cert
Modify an OCSP responder by using the CLI

You cannot modify the responder name. All other parameters can be changed using the set ssl ocspResponder command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED) ] [-cacheTimeout <positive_integer>] [-batchingDepth <
positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [ -responderCert <string> | -trustResponder][-
producedAtTimeSkew <positive_integer>][ -signingCert <string>] [-
useNonce ( YES | NO )]
unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <
positive_integer>]
show ssl ocspResponder [<name>]
```
Configure an OCSP responder by using the GUI

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select OCSP Mandatory.

OCSP stapling

April 23, 2019

The Citrix ADC implementation of CRL and OCSP reports the revocation status of client certificates only. To check the revocation status of a server certificate received during an SSL handshake, a client must send a request to a certificate authority.

For web sites with heavy traffic, many clients receive the same server certificate. If each client sent a query for the revocation status of the server certificate, the certificate authority would be inundated with OCSP requests to check the validity of the certificate.

OCSP stapling solution

To avoid unnecessary congestion, the Citrix ADC appliance now supports OCSP stapling. That is, the appliance can now send the revocation status of a server certificate to a client, at the time of the SSL handshake, after validating the certificate status from an OCSP responder. The revocation status of a server certificate is “stapled” to the response the appliance sends to the client as part of the SSL handshake. To use the OCSP stapling feature, you must enable it on an SSL virtual server and add an OCSP responder on the appliance.

Note:

- Citrix ADC appliances support OCSP stapling as defined in RFC 6066.
- OCSP stapling is supported only on the front-end of Citrix ADC appliances.

Important:

Citrix ADC support for OCSP stapling is limited to handshakes using TLS protocol version 1.0 or higher.
OCSP response caching of server certificates

During the SSL handshake, when a client requests the revocation status of the server certificate, the appliance first checks its local cache for an entry for this certificate. If a valid entry is found, it is evaluated and the server certificate and its status are presented to the client. If a revocation status entry is not found, the appliance sends a request for the revocation status of the server certificate to the OCSP responder. If it receives a response, it sends the certificate and the revocation status to the client. If the next update field is present in the OCSP response, the response is cached for the configured length of time (value specified in timeout field.)

**Note:** From release 12.1 build 49.x, you can clear the cached response, of the server certificate, from the OCSP responder even before the timeout expires. Earlier, you could not discard the cached status in the certificate-key pair until the configured timeout was over.

To clear the cached status by using the CLI, at the command prompt, type:

```
1 clear ssl certKey <cert key name> -ocspstaplingCache
```

**Example:**

```
1 clear ssl certKey s1 -ocspstaplingCache
```

To clear the cached status by using the GUI

1. In the GUI, navigate to Traffic Management > SSL > Certificates > CA Certificates.
2. In the details pane, select a certificate.
3. In the Select Action list, select Clear. If prompted to confirm, click Yes.

OCSP stapling configuration

Configuring OCSP stapling involves enabling the feature and configuring OCSP. To configure OCSP, you must add an OCSP responder, bind the OCSP responder to a CA certificate, and bind the certificate to an SSL virtual server.

**Note:**

OCSP responders with only HTTP based URL are supported.

Enable OCSP stapling by using the CLI

At the command prompt, type:

```
1 set ssl vserver <name> -ocspstapling [ENABLED | DISABLED]
```
Example:

```
1 set ssl vserver vip1 -ocspStapling ENABLED
2 Done
3
4 sh ssl vserver vip1
5
6   Advanced SSL configuration for VServer vip1:
7     DH: DISABLED
8     DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA:
9       ENABLED Refresh Count: 0
10    Session Reuse: ENABLED Timeout: 120 seconds
11    Cipher Redirect: DISABLED
12    SSLv2 Redirect: DISABLED
13    ClearText Port: 0
14    Client Auth: DISABLED
15    SSL Redirect: DISABLED
16    Non FIPS Ciphers: DISABLED
17    SNI: ENABLED
18    OCSP Stapling: ENABLED
19    SSLv2: DISABLED SSLv3: DISABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED
20    Push Encryption Trigger: Always
21    Send Close-Notify: YES
22
23     ECC Curve: P_256, P_384, P_224, P_521
24
25     1) CertKey Name: server_certificate1 Server Certificate
26
27     1) Cipher Name: DEFAULT
28     Description: Default cipher list with encryption strength >= 128 bit
29
30 Done
```

Enable OCSP stapling by using the GUI

1. Navigate to Traffic Management > SSL > Virtual Server.
2. Open a virtual server and, in SSL Parameters, select OCSP Stapling.

OCSP configuration

An OCSP responder is added dynamically or manually to send OCSP stapling requests. An internal responder is dynamically added when you add a server certificate and its issuer certificate based on
the OCSP URL in the server certificate. A manual OCSP responder is added from the CLI or GUI. To send an OCSP request for a server certificate, the Citrix ADC appliance selects an OCSP responder based on the priority assigned to it when binding it to an issuer certificate. If a responder fails to send an OCSP stapling request, the responder with the next highest priority is selected for sending the request. For example, if only one responder is manually configured and it fails and a dynamically bound responder exists, it is selected for sending the OCSP request.

If the OCSP URL is other than HTTP, an internal OCSP responder is not created.

**Note**
A manually added OCSP responder takes precedence over a dynamically added responder.

**Difference between a manually created OCSP responder and an internally created OCSP responder**

<table>
<thead>
<tr>
<th>Manually created OCSP responder</th>
<th>Internally (dynamically) created OCSP responder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created manually and explicitly bound to the issuer certificate with a priority.</td>
<td>Created and bound by default, while adding a server certificate and its issuer certificate (CA certificate). Name starts with “ns_internal_“.</td>
</tr>
<tr>
<td>Priority between 1 and 127 is reserved for configured responder.</td>
<td>Priority is automatically assigned from 128 onwards.</td>
</tr>
<tr>
<td>URL and batching depth can be changed.</td>
<td>URL and batching depth cannot be changed.</td>
</tr>
<tr>
<td>Deleted directly.</td>
<td>Deleted only when you delete the server certificate or the CA certificate.</td>
</tr>
<tr>
<td>Can be bound to any CA certificate.</td>
<td>Bound by default to one CA certificate. Cannot be bound to any other CA certificate.</td>
</tr>
<tr>
<td>Saved in the configuration (ns.conf).</td>
<td>Add commands are not saved in the configuration; only set commands are saved.</td>
</tr>
</tbody>
</table>
If you bind three OCSP responders to the same issuer certificate with priorities 1, 2, and 3 respectively, and later unbind priority 2, the other priorities are not affected.

Three OCSP responders are automatically bound to an issuer certificate with priorities 128, 129, and 130 respectively. If you remove the server certificate that was used to create a responder bound with priority 129, then that responder is deleted. Also, the priority for the next responder (priority 130) is automatically changed to 129.

Example of request handling:

1. Add a virtual server (VIP1).
2. Add issuer certificate (CA1) and bind it to VIP1.
3. Add three certificates S1, S2, and S3. Internal responders resp1, resp2, and resp3 respectively are created by default.
4. Bind S3 to VIP1.
5. A request comes to VIP1. Responder resp3 is selected.

To create an internal OCSP responder dynamically, the appliance needs the following:

- Certificate of the issuer of the server certificate (usually the CA certificate).
- Certificate-key pair of the server certificate. This certificate must contain the OCSP URL provided by the CA. The URL is used as the name of the dynamically added internal responder.

An internal OCSP responder has the same default values as a manually configured responder.

**Note:**

Caching is disabled by default on an internal responder. Use the “set ssl ocspResponder” command to enable caching.

**Configure OCSP by using the CLI**

At the command prompt, type the following commands to configure OCSP and verify the configuration:

```
add ssl certKey <certkeyName> (-cert <string> [ -password ]) [ -key <string> | -fipsKey <string> | -hsmKey <string> ] [-inform <inform>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]
```
Parameters:

**httpMethod:**

HTTP method used to send OCSP requests. For requests, less than 255 bytes long, you can configure the HTTP GET method for queries to an OCSP server. If you specify the GET method but the length is greater than 255 bytes, the appliance uses the default method (POST).

Possible values: GET, POST

Default value: POST

**ocspUrlResolveTimeout:**

Time, in milliseconds, to wait for an OCSP URL resolution. After this time elapses, the responder with the next higher priority is selected. If all the responders fail, an error message appears or the connection is dropped, depending on the settings on the virtual server.

Minimum value: 100

Maximum value: 2000

**Example:**

```bash
add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )] [-cacheTimeout <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>] [-useNonce ( YES | NO )] [-insertClientCert ( YES | NO )]
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
show ssl ocspResponder [<name>]
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Modify OCSP by using the CLI

You cannot modify the name of an OCSP responder, but you can use the `set ssl ocspResponder` command to change any of the other parameters.

At the command prompt, type the following commands to set the parameters and verify the configuration:

```bash
set ssl ocspResponder <name> [-url <URL>] [-cache (ENABLED | DISABLED)] [-cacheTimeout <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder][-producedAtTimeSkew <positive_integer>] [-signingCert <string> ] [-useNonce (YES | NO)]
unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
show ssl ocspResponder [<name>]
```

Configure OCSP by using the GUI

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select OCSP Mandatory.
Note:
The insert client certificate parameter in the “add ssl ocspResponder” and the “set ssl ocspResponder” commands is no longer valid. That is, the parameter is ignored during configuration.

Ciphers available on the Citrix ADC appliances

September 25, 2019

Your Citrix ADC appliance ships with a predefined set of cipher groups. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see Configure user-defined cipher groups on the ADC appliance.

Note:
RC4 cipher is not included in the default cipher group on the Citrix ADC appliance. However, it is supported in the software on the N3-based appliances. RC4 encryption, including the handshake, is done in software.

Citrix recommends that you do not use this cipher because it is considered insecure and deprecated by RFC 7465.

Use the ‘show hardware’ command to identify whether your appliance has N3 chips.

```sh
cpu hardware
Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100
Manufactured on: 8/19/2013
CPU: 2900MHZ
Host Id: 1006665862
Serial no: EUNK6298FT
Encoded serial no: EUNK6298FT
```

- To display information about the cipher suites bound by default at the front end (to a virtual server), type: `sh cipher DEFAULT`
- To display information about the cipher suites bound by default at the back end (to a service), type: `sh cipher DEFAULT_BACKEND`
To display information about all the cipher groups (aliases) defined on the appliance, type: `sh cipher`
To display information about all the cipher suites that are part of a specific cipher group, type: `sh cipher aliasname`. For example, `sh cipher ECDHE`.

The following links list the cipher suites supported on different Citrix ADC platforms and on external hardware security modules (HSMs):

- **Citrix ADC MPX/SDX (N3) appliance**: Cipher support on a Citrix ADC MPX/SDX (N3) appliance
- **Citrix ADC MPX/SDX Intel Coletto appliance**: Cipher support on a Citrix ADC MPX/SDX Intel Coletto SSL chip based appliance
- **Citrix ADC VPX appliance**: Cipher support on a Citrix ADC VPX appliance
- **Citrix ADC MPX/SDX 14000 FIPS appliance**: Cipher support on a Citrix ADC MPX/SDX 14000 FIPS appliance
- **External HSM (Thales/Safenet)**: Cipher supported on an External HSM (Thales/Safenet)
- **Citrix ADC MPX/SDX (N2) appliance**: Cipher support on a Citrix ADC MPX/SDX (N2) appliance
- **Citrix ADC MPX 9700 FIPS appliance**: Cipher support on a Citrix ADC MPX 9700 FIPS with firmware 2.2

**Note:**
For DTLS cipher support, see [DTLS cipher support on Citrix ADC VPX, MPX, and SDX appliances](#).

</table>
For the detailed list of ECDSA ciphers supported, see [ECDSA Cipher Suites support](#).

**Note**
- TLS-Fallback_SCSV cipher suite is supported on all appliances from release 10.5 build 57.x
- HTTP Strict Transport Security (HSTS) support is policy-based.
• All SHA-2 signed-certificates (SHA256, SHA384, SHA512) are supported on the front end of all appliances. In release 11.1 build 54.x and later, these certificates are also supported on the back-end of all appliances. In release 11.0 and earlier, only SHA256 signed-certificates are supported on the back end of all appliances.

• In release 11.1 build 52.x and earlier, the following ciphers are supported only on the front-end of the MPX 9700 and MPX/SDX 14000 FIPS appliances:
  – TLS1.2-ECDHE-RSA-AES-256-SHA384
  – TLS1.2-ECDHE-RSA-AES256-GCM-SHA384 From release 11.1 build 53.x, and in release 12.0, these ciphers are also supported on the back end.

• All ChaCha20-Poly1035 ciphers use a TLS pseudo random function (PSF) with the SHA-256 hash function.

ECDHE ciphers

April 23, 2019

All Citrix ADC appliances support the ECDHE cipher group on the front end and the back end. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

For more information about the builds and platforms that support these ciphers, see Ciphers available on the Citrix ADC appliances.

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A Citrix ADC appliance supports the following ECC curves:

• P_256
• P_384
• P_224
• P_521

Note: If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers or front end services. The curves are bound by default to any virtual servers or front end services that you create after the upgrade.

You can bind an ECC curve to SSL front-end entities only. By default all four curves are bound, in the following order: P_256, P_384,P_224,P_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.
Unbind and bind ECC curves to an SSL virtual server by using the CLI

At the command prompt, type:

```
1 unbind ssl vserver <vServerName> -eccCurveName ALL
2
3 bind ssl vserver <vServerName> -eccCurveName <eccCurveName>
```

Example:

```
1 unbind ssl vs v1 -eccCurvename ALL
2
3 bind ssl vserver v1 -eccCurveName P_224
4
5 sh ssl vserver v1
6
7 Advanced SSL configuration for VServer v1:

Diffie-Hellman parameters generation and achieving PFS with DHE

April 23, 2019

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction to agree
upon a shared secret over an insecure channel. These parties have no prior knowledge about each other. This secret can be converted into cryptographic keying material for symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default. Configured the feature to support ciphers that use DH as the key exchange algorithm.

**Note:**
Generating 2048-bit DH parameters might take a long time (up to 30 minutes).

**Generate DH parameters by using the CLI**

At the command prompt, type the following command:

```
create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]
```

**Example:**

```
create ssl dhparam Key-DH-1 512 -gen 2
```

**Generate DH parameters by using the GUI**

Navigate to **Traffic Management > SSL** and, in the **Tools** group, select **Create Diffie-Hellman (DH) key**, and **Configure SSL DH Param**.

**Note:**
For information about DH parameters, see [Diffie-Hellman parameters](#).

**Achieve perfect forward secrecy with DHE**

Generating DH parameters is a CPU-intensive operation. In earlier releases, parameter generation, on a VPX appliance, took a long time because it was done in the software. Parameter generation is optimized by setting the `dhKeyExpSizeLimit` parameter. You can set this parameter for an SSL virtual server or an SSL profile and then bind the profile to a virtual server.

You can maintain perfect forward secrecy (PFS) on Citrix ADC MPX appliances by setting DH count equal to zero. As a result, DH parameters are generated for each transaction (minimum `DHcount` is 0) on Citrix ADC MPX appliances. The parameters are generated without a significant drop in performance, because the operation is optimized. Earlier, the minimum DH count allowed was 500. That is, you could not regenerate the key for up to 500 transactions.
On a Citrix ADC VPX appliance, you can generate DH parameters for every 500 transaction at the minimum (DHcount = 500). If you set DHcount equal to 0, then the DH parameters are not regenerated.

**Limitation:**
You cannot achieve PFS in VPX today with DH ciphers.

### Optimize DH parameters generation by using the CLI

At the command prompt, type commands 1 and 2, or type command 3:

1. `add ssl profile <name> [-sslProfileType (BackEnd | FrontEnd)] [-dhCount <positive_integer>] [-dh (ENABLED | DISABLED) -dhFile <string>] [-dhKeyExpSizeLimit (ENABLED | DISABLED)]`

2. `set ssl vserver <vServerName> [ -dh ( ENABLED | DISABLED ) -dhFile <string>] [ -dhCount <positive_integer>] [ -dhKeyExpSizeLimit ( ENABLED | DISABLED )]`

### Optimize DH parameters generation by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable DH Key Expire Size Limit.

### Cipher redirection

April 23, 2019

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client do not match those configured on the SSL server, the SSL handshake fails, and the failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When SSL handshake fails, the Citrix ADC appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.
Configure cipher redirection by using the CLI

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

```
1 - set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED> -cipherURL < URL>
2 - show ssl vserver <vServerName>
```

**Example:**

```
1 set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://redirectURL
2
3 Done
4
5 show ssl vserver vs-ssl
6
7 Advanced SSL configuration for VServer vs-ssl:
8 DH: DISABLED

Configure cipher redirection by using the GUI

2. In the **SSL Parameters** section, select **Enable Cipher Redirect**, and specify a redirect URL.

**Leverage hardware and software to improve ECDHE and ECDSA cipher performance**

April 23, 2019

**Note:**
This enhancement is applicable only to the following platforms:
- MPX/SDX 11542
- MPX/SDX 14000
- MPX 22000, MPX 24000, and MPX 25000
- MPX/SDX 14000 FIPS

Previously, ECDHE and ECDSA computation on a Citrix ADC appliance was performed only on the hardware (Cavium chips), which limited the number of SSL sessions at any given time. With this enhancement, some operations are also performed in the software. That is, processing is done both on the Cavium chips and on the CPU cores to improve ECDHE and ECDSA cipher performance.

The processing is first performed in software, up to the configured software crypto threshold. After this threshold is reached, the operations are offloaded to the hardware. Therefore, this hybrid model leverages both hardware and software to improve SSL performance. You can enable the hybrid model by setting the “softwareCryptoThreshold” parameter to suit your requirement. To disable the hybrid model, set this parameter to 0.

Benefits are greatest if the current CPU utilization is not too high, because the CPU threshold is not exclusive to ECDHE and ECDSA computation. For example, if the current workload on the Citrix ADC appliance consumes 50% of the CPU cycles, and the threshold is set to 80%, ECDHE and ECDSA computation can use an additional 30% of the cycles. After the configured software crypto threshold of 80% is reached, further ECDHE and ECDSA computation is offloaded to the hardware. In that case, actual CPU utilization might exceed 80%, because performing ECDHE and ECDSA computations in hardware consumes some CPU cycles.

**Enable the hybrid model by using the CLI**

At the command prompt, type:

```
1  set ssl parameter -softwareCryptoThreshold <positive_integer>
2
3  Synopsis:
```
softwareCryptoThreshold:

Citrix ADC CPU utilization threshold (as a percentage) beyond which crypto operations are not done in software. A value of zero implies that CPU is not utilized for doing crypto in software.

Default = 0
Min = 0
Max = 100

Example:

> set ssl parameter - softwareCryptoThreshold 80
Done

> show ssl parameter
Advanced SSL Parameters

SSL quantum size : 8 KB
Max CRL memory size : 256 MB
Strict CA checks : NO
Encryption trigger timeout : 100 ms
Send Close-Notify : YES
Encryption trigger packet c : 45
Deny SSL Renegotiation : ALL
Subject/Issuer Name Insertion Format : Unicode
OCSP cache size : 10 MB
Push flag : 0x0 (Auto)
Strict Host Header check for SNI enabled SSL sessions : NO
PUSH encryption trigger timeout : 1 ms
Crypto Device Disable Limit : 0
Global undef action for control policies : CLIENTAUTH
Global undef action for data policies : NOOP
Default profile : DISABLED
Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors : NO
Disable TLS 1.1/1.2 for dynamic and VPN services : NO
Software Crypto acceleration CPU Threshold : 80
Signature and Hash Algorithms supported by TLS1.2 : ALL
Enable the hybrid model by using the GUI

1. Navigate to Traffic Management > SSL > Change advanced SSL settings.
2. Enter a value for Software Crypto Threshold (%).

ECDSA cipher suites support

June 11, 2019

ECDSA cipher suites use elliptical curve cryptography (ECC). Because of its smaller size, it is helpful in environments where processing power, storage space, bandwidth, and power consumption are constrained.

The following Citrix ADC appliances now support the elliptical curve digital signature algorithm (ECDSA) cipher group:

- Citrix ADC MPX and SDX appliances with N3 chips
- Citrix ADC MPX 5900/8900/15000/26000
- Citrix ADC SDX 8900/15000
- Citrix ADC VPX appliances

When the ECDHE_ECDSA cipher group is used, the server’s certificate must contain an ECDSA-capable public key.

Example:

```
1   sh ssl cipher ECDSA
2
3   1) Cipher Name: TLS1-ECDHE-ECDSA-AES256-SHA          Priority : 1
4       Description: SSLv3 Kx=ECC-DHE   Au=ECDSA Enc=AES(256) Mac=SHA1
5                HexCode=0xc00a
6   2) Cipher Name: TLS1-ECDHE-ECDSA-AES128-SHA          Priority : 2
7       Description: SSLv3 Kx=ECC-DHE   Au=ECDSA Enc=AES(128) Mac=SHA1
8                HexCode=0xc009
9   3) Cipher Name: TLSv1.2-ECDHE-ECDSA-AES256-SHA384    Priority : 3
10      Description: TLSv1.2 Kx=ECC-DHE   Au=ECDSA Enc=AES(256) Mac=SHA-384
11             HexCode=0xc024
12  4) Cipher Name: TLSv1.2-ECDHE-ECDSA-AES128-SHA256    Priority : 4
13      Description: TLSv1.2 Kx=ECC-DHE   Au=ECDSA Enc=AES(128) Mac=SHA-256
14             HexCode=0xc023
15  5) Cipher Name: TLSv1.2-ECDHE-ECDSA-AES256-GCM-SHA384 Priority : 5
16      Description: TLSv1.2 Kx=ECC-DHE   Au=ECDSA Enc=AES-GCM(256) Mac=AEAD
17             HexCode=0xc02c
```
The following table lists the ECDSA ciphers that are supported on the Citrix ADC MPX and SDX appliances with N3 chips, Citrix ADC VPX appliances, MPX 5900/26000, and MPX/SDX 8900/15000 appliances.

### Important

Use the **show ns hardware** command to find out if your appliance has N3 chips.

#### Example:

```bash
1  sh ns hardware
2  Platform: NSMPX=22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100
3  Manufactured on: 8/19/2013
4  CPU: 2900MHZ
5  Host Id: 1006665862
6  Serial no: ENUK6298FT
7  Encoded serial no: ENUK6298FT
8  Done
```

### ECDSA/RSA cipher and certificate selection

You can bind both ECDSA and RSA server certificates at the same time to an SSL virtual server. When both ECDSA and RSA certificates are bound to the virtual server, it automatically selects the appropriate server certificate to present to the client. If the client cipher list includes RSA ciphers, but does not include ECDSA ciphers, the virtual server presents the RSA server certificate. If both ciphers are present in the client’s list, then the server certificate presented depends on the cipher priority set on the virtual server. That is, if RSA has a higher priority, the RSA certificate is presented. If ECDSA has a higher priority, the ECDSA certificate is presented to the client.
Client authentication by using an ECDSA or an RSA certificate

For client authentication, the CA certificate bound to the virtual server can be ECDSA or RSA signed. The appliance supports a mixed certificate chain. For example, the following certificate chain is supported.

Client certificate (ECDSA) <-> CA certificate (RSA) <-> Intermediate certificate (RSA) <-> Root certificate (RSA)

Note
ECDSA certificates with only the following curves are supported:
- prime256v1
- secp384r1
- secp521r1 (VPX only)
- secp224r1 (VPX only)

Create an ECDSA certificate-key pair

You can create an ECDSA certificate-key pair directly on a Citrix ADC appliance by using the CLI or the GUI. Earlier, you could install and bind an ECC certificate-key pair on the appliance, but you had to use OpenSSL to create a certificate-key pair.

Only P_256 and P_384 curves are supported.

Note
This support is available on all platforms except MPX 9700/1050/12500/15500.

To create an ECDSA certificate-key pair by using the CLI:

At the command prompt, type:

```
1 create ssl ecdsaKey <keyFile> -curve (P_256 | P_384) [-keyform (DER | PEM)] [-des | -des3] { -password }
2 [-pkcs8]
```

Example:

```
1 create ecdsaKey ec_p256.ky -curve P_256 -pkcs8
2 Done
3 create ecdsaKey ec_p384.ky -curve P_384
4 Done
```

To create an ECDSA certificate-key pair by using the GUI:
Configure user-defined cipher groups on the ADC appliance

April 23, 2019

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the Citrix ADC appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create an SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

**Note:** If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

Binding a cipher group to an SSL virtual server, service, or service group, appends the ciphers to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity. Then bind the specific cipher group to the entity. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.

   ```
   1 unbind ssl service <service name> -cipherName ALL
   ```

2. Bind the AES cipher group to the service

   ```
   1 bind ssl service <Service name> -cipherName AE
   ```

   If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

   ```
   1 bind ssl service <service name> -cipherName DES
   ```
Note: The free Citrix ADC virtual appliance supports only the DH cipher group.

Configure a user-defined cipher group by using the CLI

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

1. add ssl cipher <cipherGroupName>
2. bind ssl cipher <cipherGroupName> -cipherName <string>
3. show ssl cipher <cipherGroupName>

Example:

1. add ssl cipher test
2. Done
3. bind ssl cipher test -cipherName ECDHE
4. Done
5. show ssl cipher test

**Unbind ciphers from a cipher group by using the CLI**

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:
Remove a cipher group by using the CLI

**Note:** You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

```plaintext
1 rm ssl cipher <userDefCipherGroupName> [cipherName] ...
2 show ssl cipher <cipherGroupName>
```

**Example:**

```plaintext
1 rm ssl cipher test Done
2 sh ssl cipher test ERROR: No such resource [cipherGroupName, test]
```

Configure a user-defined cipher group by using the GUI

Navigate to **Traffic Management > SSL > Cipher Groups**, and configure a cipher group.

To bind a cipher group to an SSL virtual server, service, or service group by using the CLI:

At the command prompt, type one of the following:

```plaintext
1 bind ssl vserver <vServerName> -cipherName <string>
2 bind ssl service <serviceName> -cipherName <string>
3 bind ssl serviceGroup <serviceGroupName> -cipherName <string>
```

**Example:**

```plaintext
1 bind ssl vserver ssl_vserver_test -cipherName test Done
2 bind ssl service nshttps -cipherName test Done
```
To bind a cipher group to an SSL virtual server, service, or service group by using the GUI:

   For service, replace virtual servers with services. For service groups, replace virtual servers with service groups.
   Open the virtual server, service, or service group.

2. In Advanced Settings, select SSL Ciphers.

3. Bind a cipher group to the virtual server, service, or service group.

Binding individual ciphers to an SSL virtual server or service

You can also bind individual ciphers, instead of a cipher group, to a virtual server or service.

To bind a cipher by using the CLI:
At the command prompt, type:

```
bind ssl vserver <vServerName> -cipherName <string>
bind ssl service <serviceName> -cipherName <string>
```

Example:

```
bind ssl vserver v1 -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done
bind ssl service sslsvc -cipherName TLS1.2-ECDHE-RSA-AES256-GCM-SHA384
Done
```

To bind a cipher to an SSL virtual server by using the GUI:

2. Select an SSL virtual server and click Edit.
3. In Advanced Settings, select SSL Ciphers.
4. In Cipher Suites, select Add.
5. Search for the cipher in the available list and click the arrow to add it to the configured list.
6. Click OK.
7. Click Done.

To bind a cipher to an SSL service, repeat the preceding steps after replacing virtual server with service.
Server certificate support matrix on the ADC appliance

August 12, 2019

From release 13.0 build 41.x, the Citrix ADC appliance supports server certificate messages that are fragmented into more than one record so long as the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

The Citrix ADC appliance supports the following server certificates.

Table 1: Support on front-end (FE) and back-end (BE) service

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Note:

- In release 11.1 and earlier, a Citrix ADC appliance supports the following “signature algorithms” extensions in the back end client hello message: RSA-MD5, RSA-SHA1, and RSA-SHA256. Because the Citrix ADC appliance does not support SHA 384 and SHA 512 signature algorithms extensions, some servers, such as Windows IIS servers, reset the connection.
- Starting release 12.0, a Citrix ADC appliance supports all the signature_algorithms extensions.

Client authentication

August 12, 2019

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server. Do so, it checks the server’s certificate before initiating the SSL transaction. Sometimes, however, you might want to configure the server to authenticate the client that is connecting to it.

Note: From release 13.0 build 41.x, the Citrix ADC appliance supports certificate request messages that are fragmented into more than one record provided the total size is within 32 KB. Earlier, the maximum supported size was 16 KB and fragmentation was not supported.

With client authentication enabled on an SSL virtual server, the Citrix ADC appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

Note: For the appliance to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the appliance and bound to the virtual server that the client is transacting.
If the certificate is valid, the appliance allows the client to access all secure resources. But if the certificate is invalid, the appliance drops the client request during the SSL handshake.

The appliance verifies the client certificate by first forming a chain of certificates, starting with the client certificate and ending with the root CA certificate for the client (for example, Verisign). The root CA certificate might contain one or more intermediate CA certificates (if the root CA does not directly issue the client certificate).

Before you enable client authentication on the Citrix ADC appliance, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that handles the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the appliance.

**Note:** A Citrix ADC MPX appliance supports a certificate-key pair size from 512 bits to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A Citrix ADC virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 4096-bit certificate on the physical server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

**Provide the client certificate**

Before you configure client authentication, a valid client certificate must be installed on the client. A client certificate includes details about the specific client system that creates secure sessions with the Citrix ADC appliance. Each client certificate is unique and should be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the Citrix ADC appliance, you must convert the certificate to the correct format. On
the Citrix ADC appliance, certificates are stored in either the PEM or DER format and must be converted
to PKCS#12 format before they are installed on the client system. After converting the certificate and
transferring it to the client system, make sure that it is installed on that system and configured for the
client application that will be part of the SSL transactions (for example, the web browser).

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Import
and convert SSL files.

For instructions on how to generate a client certificate, see Create a certificate.

**Enable client-certificate based authentication**

By default, client authentication is disabled on the Citrix ADC appliance, and all SSL transactions pro-
ceed without authenticating the client. You can configure client authentication to be either optional
or mandatory as part of the SSL handshake.

If client authentication is optional, the appliance requests the client certificate but proceeds with the
SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory,
the appliance terminates the SSL handshake if the SSL client does not provide a valid certificate.

**Caution:** Citrix recommends that you define proper access control policies before changing client-
certificate-based authentication check to optional.

**Note:** Client authentication is configured for individual SSL virtual servers, not globally.

**Enable client-certificate based authentication by using the CLI**

At the command prompt, type the following commands to enable the client-certificate-based authen-
tication and verify the configuration:

```
1 set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-
   clientCert (MANDATORY | OPTIONAL)]
2 show ssl vserver <vServerName>
```

**Example:**

```
1 set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
2 Done
3 show ssl vserver vssl
4
5 Advanced SSL configuration for VServer vssl:
6   DH: DISABLED
7   Ephemeral RSA: ENABLED Refresh Count: 0
8   Session Reuse: ENABLED Timeout: 120 seconds
```
Enable client-certificate based authentication by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

Note:
If client authentication is set to mandatory and if the client certificate contains policy extensions, certificate validation fails. From release 12.0-56.x, you can set a parameter in the front-end SSL profile to skip this check. The parameter is disabled by default. That is, the check is performed by default.

Skip the policy extension check during client authentication by using the CLI

At the command prompt, type:

```
set ssl profile ns_default_ssl_profile_frontend -clientauth ENABLED -skipClientCertPolicyCheck ENABLED
```
**skipClientCertPolicyCheck**

Control policy extension check, **if** present inside the X509 certificate chain. Applicable only **if** client authentication is enabled and client certificate is set to mandatory. Possible values functions as follows:

- **ENABLED**: Skip the policy check during client authentication.
- **DISABLED**: Perform policy check during client authentication.

Possible values: **ENABLED**, **DISABLED**

Default: **DISABLED**

---

**Skip the policy extension check during client authentication by using the GUI**

1. Navigate to **System > Profiles > SSL Profiles**.
2. Create a new front-end profile or edit an existing front-end profile.
3. Verify that client authentication is enabled and client certificate is set to mandatory.
4. Select **Skip Client Certificate Policy Check**.

**Bind CA certificates to the virtual server**

A CA whose certificate is present on the Citrix ADC appliance must issue the client certificate used for client authentication. Bind this certificate to the Citrix ADC virtual server that carries out client authentication.

Bind the CA certificate to the SSL virtual server in such a way that the appliance can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The appliance forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by **CA_A**, where **CA_A** is an intermediate CA whose certificate is issued by **CA_B**, whose certificate is in turn issued by a trusted root CA, **Root_CA**, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the Citrix ADC appliance.

For instructions on binding one or more certificates to the virtual server, see **Bind the certificate-key pair to the SSL virtual server**.
For instructions on creating a chain of certificates, see Create a chain of certificates.

**Stricter control on client certificate validation**

The Citrix ADC appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the **ClientAuthUseBoundCACChain** setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCACChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCACChain is enabled, only clientcert1 is accepted by the Citrix ADC appliance.

**Enable stricter control on client certificate validation by using the CLI**

At the command prompt, type:

```
set ssl profile <name> -ClientAuthUseBoundCACChain Enabled
```

**Enable stricter control on client certificate validation by using the GUI**

1. Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile, or select an existing profile.
2. Select Enable Client Authentication using bound CA Chain.

**Server authentication**

April 23, 2019

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Since the Citrix ADC appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server’s certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the appliance becomes the SSL client, carries out a secure transaction with the SSL server, verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, you must first enable server authentication and then bind the certificate of the CA that signed the server’s certificate to the SSL service on the Citrix ADC appliance. When binding the certificate, you must specify the bind as CA option.

**Enable (or disable) server certificate authentication**

You can use the CLI and the GUI to enable and disable server certificate authentication.

**Enable (or disable) server certificate authentication using the CLI**

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

```
1 set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
2 show ssl service <serviceName>
```

**Example:**

```
1 set ssl service ssl-service-1 -serverAuth ENABLED
2 show ssl service ssl-service-1
```

```
Advanced SSL configuration for Back-end SSL Service ssl-service-1:

1)  Cipher Name: ALL
    Description: Predefined Cipher Alias

   DH: DISABLED
   Ephemeral RSA: DISABLED
   Session Reuse: ENABLED         Timeout: 300 seconds
   Cipher Redirect: DISABLED
   SSLv2 Redirect: DISABLED
   Server Auth: ENABLED
   SSL Redirect: DISABLED
   Non FIPS Ciphers: DISABLED
   SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED
```
Enable (or disable) server certificate authentication by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

Bind the CA certificate to the service by using the CLI

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

```
bind ssl service <serviceName> -certkeyName <string> -CA
show ssl service <serviceName>
```

Example:

```
binding ssl service ssl-service-1 -certkeyName samplecertkey -CA
```

```
show ssl service ssl-service-1

Advanced SSL configuration for Back-end SSL Service ssl-service-1:

DH: DISABLED
Ephemeral RSA: DISABLED
Session Reuse: ENABLED           Timeout: 300 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
Server Auth: ENABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED   TLSv1: ENABLED
1) CertKey Name: samplecertkey    CA Certificate
   CRLCheck: Optional
   1) Cipher Name: ALL
   Description: Predefined Cipher Alias
```

Done
Configure a common name for server certificate authentication

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful.

If the common names do not match, the common name specified for the service or service group is compared to values in the subject alternative name (SAN) field in the certificate. If it matches one of those values, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

**Note:** Only domain name, URL, and email ID DNS entries in the SAN field are compared.

Configure common-name verification for an SSL service or service group by using the CLI

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure common name in a service, type:

   ```
   1 set ssl service <serviceName> -commonName <string> -serverAuth ENABLED
   2 show ssl service <serviceName>
   ```

2. To configure common name in a service group, type:

   ```
   1 set ssl serviceGroup <serviceGroupName> -commonName <string> -serverAuth ENABLED
   2 show ssl serviceGroup <serviceGroupName>
   ```

**Example:**

```
1 > set ssl service svc1 -commonName xyz.com -serverAuth ENABLED
2
3 Advanced SSL configuration for Back-end SSL Service svc1:
4     DH: DISABLED
5     Ephemeral RSA: DISABLED
6     Session Reuse: ENABLED Timeout: 300 seconds
7     Cipher Redirect: DISABLED
8     SSLv2 Redirect: DISABLED
```
Configure common-name verification for an SSL service or service group by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services or Navigate to Traffic Management > Load Balancing > Service Groups, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

SSL actions and policies

April 23, 2019

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.

Note: Users who are not experienced in configuring policies at the CLI usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.
Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the Citrix ADC appliance.

SSL policies

April 23, 2019

Policies on the Citrix ADC appliance help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through any virtual server configured on the Citrix ADC appliance.

The Citrix ADC appliance SSL feature supports default syntax (advanced) policies. For a complete description of default syntax expressions, how they work, and how to configure them manually, see Policies and Expressions.

Note:

Users who are not experienced in configuring policies at the CLI will usually find using the configuration utility considerably easier.

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies.

In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see SSL built-in actions and user-defined actions.

SSL default syntax policies

An SSL default syntax policy, also known as advanced policy, defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy.** A control policy uses a control action, such as forcing client authentication.
  Note: In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.
- **Data policy.** A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed.
You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an additional action, called an UNDEF action, to be performed in the event that applying the expression to a request has an undefined result.

**SSL policy configuration**

You can configure an SSL default syntax policy by using the CLI and the GUI.

**Configure an SSL policy by using the CLI**

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -Action <string> [-undefAction <string>] [-comment <string>]
```

**Configure an SSL policy by using the GUI**

Navigate to Traffic Management > SSL > Policies and, on the Polices tab, click Add.

**SSL built-in actions and user-defined actions**

June 17, 2019

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies. Then, you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- **DOCLIENTAUTH**—Perform client certificate authentication.
- **NOCLIENTAUTH**—Do not perform client certificate authentication.

The built-in data actions are:

- **RESET**—Close the connection by sending a RST packet to the client.
- **DROP**—Drop all packets from the client. The connection remains open until the client closes it.
- **NOOP**—Forward the packet without performing any operation on it.
You can create user-defined data actions. If you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying DOCLIENTAUTH or NOCLIENTAUTH.

Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the Citrix ADC appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
1 add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction DOCLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction NOOP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction DROP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```
1 add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction RESET
```

Client certificate verification with policy based client authentication

You can set client certificate verification to mandatory or option when you have configured policy based client authentication. Default is mandatory.
Set client certificate verification to optional using the CLI

At the command prompt, type:

```
1   add ssl action <name> ((-clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH ) [ -
            clientCertVerification ( Mandatory | Optional )])
```

Example:

```
1   add ssl action sslact -clientauth DOCLIENTAUTH -clientcertverification
    OPTIONAL
```

Set client certificate verification to optional using the GUI

1. Navigate to Traffic Management > SSL > Policies.
2. On the SSL Actions tab, click Add.
3. Specify a name and in the Client Certificate Verification list, select Optional.

User-defined SSL actions

In addition to built-in actions, you can also configure other SSL actions depending on your deployment. These actions are called user-defined actions.

Configure a user-defined SSL action by using the CLI

At the command prompt, type the following commands to configure an action and verify the configuration:

```
1   add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -
    clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <
    string> -clientCertSerialNumber (ENABLED | DISABLED) -
    certSerialHeader <string> -clientCertSubject (ENABLED | DISABLED) -
    certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -
    certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -
    certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -
    sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader
    <string> -clientCertNotBefore (ENABLED | DISABLED) -
    certNotBeforeHeader <string> -clientCertNotAfter (ENABLED | DISABLED)
    ) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
```
show ssl action [<name>]  

Example:

add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X-Client-Cert"

show ssl action Action-SSL-ClientCert
1) Name: Action-SSL-ClientCert
   Data Insertion Action:
   Cert Header: ENABLED  Cert Tag: X-Client-Cert
Done

Configure a user-defined SSL action by using the GUI

Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.

Configure an SSL action to forward client traffic to another virtual server

Admins can configure an SSL action to forward the client traffic received on an SSL virtual server to another virtual server to avoid SSL offloading or for terminating the connection on the ADC appliance. This virtual server can be of type: SSL, TCP, or SSL_BRIDGE. For example, admins can choose to forward the request to another virtual server for further action instead of terminating the connection if any of the following cases:

- The appliance does not have a certificate.
- The appliance does not support a specific cipher.

To achieve the above, a new bind point ‘CLIENTHELLO_REQ’ is added to evaluate client traffic when a client hello is received. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, the traffic is forwarded to another virtual server. If this virtual server is of type SSL, it performs the handshake. If this virtual server is of type TCP or SSL_BRIDGE, the back-end server performs the handshake.

In release 12.1-49.x, only the forward and reset actions are supported for CLIENTHELLO_REQ bind point. The following expression prefixes are available:

- CLIENT.SSL.CLIENT_HELLO.CIPHERS_HAS_HEXCODE
- CLIENT.SSL.CLIENT_HELLO.CLIENT_VERSION
- CLIENT.SSL.CLIENT_HELLO.IS_RENEGOTIATE
- CLIENT.SSL.CLIENT_HELLO.IS_REUSE
- CLIENT.SSL.CLIENT_HELLO.IS_SCSV
• CLIENT.SSL.CLIENT_HELLO.IS_SESSION_TICKET
• CLIENT.SSL.CLIENT_HELLO.LENGTH
• CLIENT.SSL.CLIENT_HELLO.SNI

For a description of these prefixes, see Advanced policy expressions: parsing SSL.

A new parameter forward is added to the add SSL action command and a new bind point CLIENTHELLO_REQ is added to the bind ssl vserver command.

Configuration using the CLI

At the command prompt, type:

```
1 add ssl action <name> -forward <virtual server name>
2 add ssl policy <name> -rule <expression> -action <string>
3 bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>
```

**EXAMPLE:**

```
1 add ssl action act1 -forward v2
2 add ssl policy poll -rule client.ssl.client_hello.ciphers.has_hexcode(0x002f) -action act1
3 bind ssl vserver v1 -policyName poll -priority 1 -type CLIENTHELLO_REQ
```

Configuration using the GUI

Navigate to Traffic Management > SSL > Policies.

Create SSL action:

1. In SSL Actions, click Add.
2. In Create SSL Action, specify a name for the action.
3. In Forward Action Virtual Server, select an existing virtual server or add a new virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click Create.

Create SSL policy:

1. In SSL Policies, click Add.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action that you created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

**Create or add a virtual server and bind policy:**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSLPolicies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

For the end-to-end configuration for the most popular use cases, see the following topics:

- Configure SSL action to forward client traffic if the appliance does not have a domain specific (SNI) certificate.
- Configure SSL action to forward client traffic if a cipher is not supported on the ADC.

**SSL action to selectively pick CAs based on SNI for client authentication**

You can send only the list of CAs based on SNI (domain) in the client certificate request rather than the list of all the CAs bound to an SSL virtual server. For example, when a client hello is received, only the CA certificates based on the SSL policy expression (for example, SNI) are sent. To send a specific set of certificates, you must create a CA certificates group. Then, bind this group to an SSL action, and bind the action to an SSL policy. If the policy bound to the virtual server receiving client traffic evaluates to true after parsing the client hello, only a specific CA certificates group is sent in the client request certificate.

Earlier, you had to bind CA certificates to an SSL virtual server. With this enhancement, you can simply add CA certificate groups and associate them to an SSL action.

**Note:** Enable client authentication and SNI on the SSL virtual server. Bind the correct SNI certificates to the virtual server.

Perform the following steps:

1. Add a CA certificate group.
2. Add certificate-key pairs.
3. Bind the certificate-key pairs to this group.

4. Add an SSL action.

5. Add an SSL policy. Specify the action in the policy.

6. Bind the policy to an SSL virtual server. Specify the bind point as CLIENTHELLO_REQ.

**Configuration using the CLI**

At the command prompt, type the following commands in a sequence:

```
1 add ssl caCertGroup <caCertGroupName>
2 add ssl certkey <certkey_name> -cert <cert> -key <key>
3 bind ssl caCertGroup <caCertGroupName> <certkey_name>
4 add ssl action <name> -caCertGrpName <string>
5 add ssl policy <name> -rule <expression> -action <string>
6 bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type CLIENTHELLO_REQ
```

**Example:**

```
1 add ssl cacertGroup ca_cert_group
2
3 add ssl certkey ca_certkey1 -cert cacert1 -key cakey1
4 add ssl certkey ca_certkey2 -cert cacert2 -key cakey2
5 add ssl certkey snicert -cert snicert -key snikey
6
7 bind ssl cacertGroup ca_cert_group ca_certkey1
8 bind ssl caCertGroup ca_cert_group ca_certkey2
```

```
1 sh ssl caCertGroup ca_cert_group
2
3 CA GROUP NAME: ca_cert_group
4 ACTIONS REFERRING: 1
5
6 1) CertKey Name: ca_certkey1  CA Certificate  CRLCheck: Optional
   CA_Name Sent
7 2) CertKey Name: ca_certkey2  CA Certificate  CRLCheck: Optional
   CA_Name Sent
```

```
1 add ssl action pick_ca_group -cacertGrpName ca_cert_group
```

```
1 sh ssl action pick_ca_group
2 1) Name: sniaction
```
Type: Data Insertion
PickCaCertGroup: ca_cert_group
Hits: 0
Undef Hits: 0
Action Reference Count: 1

```
1 add ssl policy snipolicy -rule client.ssl.client_hello.sni.contains("abc") -action pick_ca_group
2 bind ssl vserver v_SSL -policyName snipolicy -type CLIENTHELLO_REQ -priority 10
```

```
1 sh ssl policy snipolicy
2 Name: pol1
3 Rule: client.ssl.client_hello.sni.contains("abc")
4 Action: pick_ca_group
5 UndefAction: Use Global
6 Hits: 0
7 Undef Hits: 0
8
9 Policy is bound to following entities
10 1) Bound to: CLIENTHELLO_REQ VSERVER v_SSL
11 Priority: 10
```

```
1 set ssl vserver v_SSL -clientauth ENABLED -SNIEnable ENABLED
2 bind ssl vserver v_SSL -certkeyName snicert -sniCert
```

```
1 sh ssl vserver v_SSL
2
3 Advanced SSL configuration for VServer v_SSL:

   Cipher Name: DEFAULT
   Description: Default cipher list with encryption strength >= 128bit

Configuration using the GUI

Create CA certificates group and bind certificates to the group:
1. Navigate to Traffic Management > SSL > CA Certificates Group.
2. Click Add and specify a name for the group.
3. Click Create.
4. Select the CA certificate group and then click Show Bindings.
5. Click Bind.
6. In the CA Certificate Binding page, select an existing certificate or click Add to add a new certificate.
7. Click Select and then click Bind.
8. To bind another certificate, repeat steps 5 through 7.
9. Click Close.

Navigate to Traffic Management > SSL > Policies.

Create SSL action:
1. In SSL Actions, click Add.
2. In Create SSL Action, specify a name for the action.
3. In **Forward Action Virtual Server**, select an existing virtual server or add a virtual server to forward the traffic to.
4. Optionally, set other parameters.
5. Click **Create**.

**Create SSL policy:**
1. In **SSL Policies**, click **Add**.
2. In **Create SSL Policy**, specify a name for the policy.
3. In **Action**, select the action created earlier.
4. In **Expression Editor**, enter the rule to evaluate.
5. Click **Create**.

**Create or add a virtual server and bind policy:**
1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Add or select a virtual server.
3. In **Advanced Settings**, click **SSL Policies**.
4. Click in the SSL Policy section.
5. In **Select Policy**, select the policy that you created earlier.
7. In **Type**, select **CLIENTHELLO_REQ**.
8. Click **Bind**.
9. Click **Done**.

**Unbind a CA certificate group by using the GUI**
1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Show Bindings**.
3. Select the certificate to remove from the group and click **Unbind**.
4. If prompted for confirmation, click **Yes**.
5. Click **Close**.

**Remove a CA certificate group by using the GUI**
1. Navigate to **Traffic Management > SSL > CA Certificates Group**.
2. Select a certificate group and click **Delete**.
3. If prompted for confirmation, click **Yes**.
SSL policy binding

June 17, 2019

You can bind SSL policies globally or to an SSL virtual server. Globally bound policies are evaluated after all policies bound to services, virtual servers, or other Citrix ADC bind points are evaluated. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered, and the action associated with it is carried out.

When binding an SSL policy to a virtual server, you must select from one of the following bind points:

- REQUEST (Default bind point. Policy evaluation is done in the HTTP layer after the SSL handshake is completed.)
- INTERCEPT_REQ (This option applies to a Citrix Secure Web Gateway setup. For more information, see SSL policy infrastructure for SSL interception).
- CLIENTHELLO_REQ

Similarly, when unbinding a policy from a virtual server, you must specify the bind point.

If you specify CLIENTHELLO_REQ as the bind point, the policy is evaluated when a client hello message is received. The allowed actions are RESET, FORWARD, and caCertGrpName. The reset action terminates the connection. The forward action forwards the request to a load balancing virtual server for processing. The caCertGrpName action selectively picks CAs based on SNI for client authentication. For more information about SSL actions, see SSL built-in actions and user-defined actions.

Bind an SSL policy globally by using the CLI

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

```
1 bind ssl global -policyName <string> [-priority <positive_integer>]
2 show ssl global
```

Example:

```
1 bind ssl global -policyName Policy-SSL-2 -priority 90
2 Done
3
4 sh ssl global
5 1) Name: Policy-SSL-2 Priority: 90
6 2) Name: Policy-SSL-1 Priority: 100
7 Done
8
```
Bind an SSL policy globally by using the GUI

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind SSL Policies to Global dialog box, click Insert Policy.
4. In the Policy Name list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click OK. A message appears in the status bar, stating that the policy has been bound successfully.

Bind or unbind an SSL policy to a virtual server by using the CLI

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

```
1 bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>
2
3 unbind ssl vserver <vServerName> -policyName <string> -priority <positive_integer> -type <type>
```

Example:

```
1 bind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ

2 unbind ssl vserver v1 -policyName pol1 -priority 1 -type CLIENTHELLO_REQ
```

Advanced SSL configuration for VServer vs-server:

```
1 show ssl vserver vs-server
2
3 Advanced SSL configuration for VServer vs-server:
4
5 DH: DISABLED
6
7 Ephemeral RSA: ENABLED Refresh Count: 1000
8
9 Session Reuse: ENABLED Timeout: 120 seconds
10
11 Cipher Redirect: DISABLED
12
13 SSLv2 Redirect: DISABLED
```
Bind an SSL policy to a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. In Advanced Settings, select SSL Policy. Click in the SSL policy section to bind a policy to the virtual server.
3. In the Policy Binding page, select an existing policy or add a new policy.
4. Specify priority and type (bind point) for the policy.
5. Select Bind.
6. Select Done.

SSL policy labels

April 23, 2019

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy
bank, you bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the CLI, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

**Create an SSL policy label and bind policies to the label by using the CLI**

At the command prompt, type:

```plaintext
1  add ssl policylabel <labelName> -type ( CONTROL | DATA )
2  bind ssl policylabel <labelName> <policyName> <priority> [ <
gotoPriorityExpression> ] [ -invoke (<labelType> <labelName>) ]
```

**Example:**

```plaintext
1  add ssl policylabel cpl1 -type CONTROL
2  add ssl policylabel dpl1 -type DATA
3  bind ssl policylabel cpl1 -policyName ctrlpol -priority 1
4  bind ssl policylabel dpl1 -policyName datapol -priority 1
```

**Configure an SSL policy label and bind policies to the label by using the GUI**

Navigate to Traffic Management > SSL > Policy Labels, and configure an SSL policy label.

**Selective SSL logging**

April 23, 2019

In a large deployment comprising thousands of virtual servers, all SSL-related information is logged. Earlier, filtering the client authentication and SSL handshake successes and failures for a few critical virtual servers was not easy. Perusing through the entire log to get this information was a time-consuming and tedious task because the infrastructure did not offer the control to filter the logs. Now, you can log SSL-related information in `ns.log`, for a specific virtual server or for a group of virtual servers. This information is especially helpful in debugging failures. To log this information, you must add an SSL log profile.

See sample `ns.log` output for successful client authentication at the end of this page.
**SSL log profile**

An SSL log profile provides control over logging the following events for a virtual server or a group of virtual servers:

- Client authentication success and failures, or only failures.
- SSL handshake success and failures, or only failures.

By default, all the parameters are disabled.

An SSL log profile can be set on an SSL profile, or on an SSL action. If set to an SSL profile, you can log both client authentication and SSL handshake success and failure information. If set to an SSL action, you can only log client authentication success and failure information because the handshake is complete before the policy is evaluated.

Client authentication and SSL handshake success and failures are logged even if you do not configure an SSL log profile. However, selective logging is possible only if SSL log profile is used.

**Note:**

SSL log profile is supported in high availability and cluster setups.

### Add an SSL log profile by using the CLI

At the command prompt, type:

```
1 add ssl logprofile <name> [-sslLogClAuth ( ENABLED | DISABLED )] [-ssllogClAuthFailures ( ENABLED | DISABLED )] [-sslLogHS ( ENABLED | DISABLED )] [-sslLogHSfailures ( ENABLED | DISABLED )]
```

**Parameters:**

**Name:**

Name for the SSL log profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the profile is created.

Name is a mandatory argument. Maximum Length: 127

**sslLogClAuth:**

Log all client authentication events. Includes both success and failure events.

Possible values: ENABLED, DISABLED

Default value: DISABLED

**ssllogClAuthFailures:**

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Log all client authentication failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

**sslLogHS:**
Log all SSL handshake related events. Includes both success and failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

**sslLogHSfailures:**
Log all SSL handshake related failure events.
Possible values: ENABLED, DISABLED
Default value: DISABLED

**Example:**

```
> add ssl logprofile ssllog10 -sslLogClAuth ENABLED -sslLogHS ENABLED
Done

sh ssllogprofile ssllog10
1) Name: ssllog10
   SSL log ClientAuth [Success/ Failures] : ENABLED
   SSL log ClientAuth [Failures] : DISABLED
   SSL log Handshake [Success/ Failures] : ENABLED
   SSL log Handshake [Failures] : DISABLED
Done
```

**Add an SSL log profile by using the GUI**

Navigate to **System > Profiles > SSL Log Profile** and add a profile.

**Modify an SSL log profile by using the CLI**

At the command prompt type:
Modify an SSL log profile by using the GUI

1. Navigate to **System > Profiles > SSL Log Profile, select a profile, and click **Edit.
2. Make changes and click **OK.

View all the SSL log profiles by using the CLI

At the command prompt, type:

```
sh ssl logprofile
```

Example:
View all the SSL log profiles by using the GUI

Navigate to System > Profiles > SSL Log Profile. All the profiles are listed.

Attach an SSL log profile to an SSL profile

You can attach (set) an SSL log profile on an SSL profile when you are creating an SSL profile, or later by editing the SSL profile. You can log both client authentication and handshake successes and failures.

Important:

The default SSL profile must be enabled before you can attach an SSL log profile.

Attach an SSL log profile on an SSL profile by using the CLI

At the command prompt, type:

```
set ssl profile <name> [-ssllogProfile <string>]
```

Example:

```
set ssl profile fron_1 -ssllogProfile ssllog10
```
Attach an SSL log profile to an SSL profile by using the GUI

1. Navigate to System > Profiles > SSL Profile.
2. Click Edit and in SSL Log Profile, specify a profile.

Attach an SSL log profile to an SSL action

You can set an SSL log profile only while creating an SSL action. You cannot modify an SSL action to set the log profile. Associate the action to a policy. You can only log client authentication successes and failures.

Attach an SSL log profile to an SSL action by using the CLI

At the command prompt, type:

```
add ssl action <name> -clientAuth (DOCLIENTAUTH | NOCLIENTAUTH) -ssllogProfile <string>
```

Example:

```
> add ssl action act1 -clientAuth DoCLIENTAUTH -ssllogProfile ssllog10
Done
> sh ssl action act1
  1) Name: act1
     Type: Client Authentication (DOCLIENTAUTH)
     Hits: 0
     Undef Hits: 0
     Action Reference Count: 0
     SSLlogProfile: ssllog10
Done
```

Attach an SSL log profile to an SSL action by using the GUI

1. Navigate to Traffic Management > SSL > Policies and click SSL Actions.
2. Click Add.
3. In Client Authentication, select ENABLED.
4. In SSL Log Profile, select a profile from the list, or click “+” to create a profile.
5. Click Create.
Sample output from the log file

The following is a sample log output from ns.log for successful client authentication.

1 Jan 24 16:24:25 <local0.debug> 10.102.57.80 01/24/2019:10:54:25 GMT 0-PPE-0 : default SSLLOG SSL_HANDSHAKE_SUCCESS 158 0 : SPCBId 671 - ClientIP 10.102.1.98 - ClientPort 49451 - VserverServiceIP 10.102.57.82 - VserverServicePort 443 - ClientVersion TLSv1.2 - CipherSuite "AES-256-CBC-SHA TLSv1.2 Non-Export 256-bit" - Session New - CLIENT_AUTHENTICATED -SerialNumber "2A" - SignatureAlgorithm "sha1WithRSAEncryption" - ValidFrom "Sep 22 09:15:20 2008 GMT" - ValidTo "Feb 8 09:15:20 2036 GMT" - HandshakeTime 10 ms

Support for DTLSv1.0 protocol

June 17, 2019

Notes:

• DTLSv1.0 protocol is supported on Citrix ADC MPX/SDX (N2 and N3 based), VPX, and MPX 14000 FIPS appliances. It is not supported on external HSMs.
Support for Intel Coleto based appliances is added in build 12.1-50.x and later. The following appliances ship with Intel Coleto chips:

- MPX 5901/5905/5910
- MPX 8905/8910/8920/8930
- MPX/SDX 26100-100G/26160-100G/26100-200G

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is slow. Also, TLS cannot handle lost or reordered packets.

UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

Create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (nsdtls_default_profile) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4 ciphers are not supported on a DTLS virtual server.

**DTLS configuration**

You can use the command line (CLI) or the configuration utility (GUI) to configure DTLS on your ADC appliance.

**Create a DTLS configuration by using the CLI**

At the command prompt, type:

```
1 add lb vserver <vserver_name> DTLS <IPAddress> <port>
2 add service <service_name> <IPAddress> UDP 443
3 bind lb vserver <vserver_name> <udp_service_name>
```

The following steps are optional:

```
1 add dtlsProfile dtls1 -maxretryTime <positive_integer>
2 set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
```
Create a DTLS configuration by using the GUI

2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a profile, click the plus (+) next to DTLS Profile.

Support for SNI on a DTLS virtual server

From release 12.1 build 49.x, SNI is supported on a DTLS virtual server. For information about SNI, see Configure an SNI virtual server for secure hosting of multiple sites.

Configure SNI on a DTLS virtual server by using the CLI

At the command prompt, type:

```
1 set dtls vserver <vServerName> -SNIEnable ENABLED
2 bind dtls vserver <vServerName> -certkeyName <string> -SNICert
3 show dtls vserver <vServerName>
```

Example:

```
1 set ssl vserver v1 -sniEnable ENABLED
2 bind ssl vserver v1 -certkeyName san2 -sniCert
3 bind ssl vserver v1 -certkeyName san3 -sniCert
4 bind ssl vserver v1 -certkeyName san17 -sniCert

1 sh ssl vserver v1
2
3 Advanced SSL configuration for VServer v1:
4 DH: DISABLED
5 DH Private-Key Exponent Size Limit: DISABLED
6 Ephemeral RSA: ENABLED
7 Refresh Count: 0
8 Session Reuse: ENABLED
9 Timeout: 1800 seconds
10 Cipher Redirect: DISABLED
11
12 ClearText Port: 0
13 Client Auth: DISABLED
14 SSL Redirect: DISABLED
```
Non FIPS Ciphers: DISABLED
SNI: ENABLED
OCSP Stapling: DISABLED
HSTS: DISABLED
HSTS IncludeSubDomains: NO
HSTS Max-Age: 0
DTLSv1: ENABLED
Send Close-Notify: YES
Strict Sig-Digest Check: DISABLED
Zero RTT Early Data: DISABLED
DHE Key Exchange With PSK: NO
Tickets Per Authentication Context: 1
DTLS profile name: nsdtls_default_profile
ECC Curve: P_256, P_384, P_224, P_521
1) CertKey Name: ca
CA Certificate OCSPCheck: OptionalCA_Name Sent
2) CertKey Name: san2 Server Certificate for SNI
3) CertKey Name: san17 Server Certificate for SNI
4) CertKey Name: san13 Server Certificate for SNI
1) Cipher Name: DEFAULT
Description: Default cipher list with encryption strength >= 128bit
Done

Configure SNI on a DTLS virtual server by using the GUI

2. Open a DTLS virtual server and, in Certificates, click Server Certificate.
3. Add a certificate or select a certificate from the list and select Server Certificate for SNI.
4. In Advanced Settings, click SSL Parameters.
5. Select SNI Enable.

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
Citrix ADC 13.0

- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL

**Parameters not used by a DTLS virtual server**

A DTLS virtual server ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

**Configure renegotiation on a DTLS service**

Non-secure renegotiation is supported on a DTLS service. You can use the CLI or the GUI to configure this setting.

**Configure renegotiation on a DTLS service by using the CLI**

At the command prompt, type:

```
1 set ssl parameter -denysslreneg NONSECURE
```

**Example:**

```
1 set ssl parameter -denysslreneg NONSECURE
```

```
1 sh ssl parameter
2 Advanced SSL Parameters
3 -----------------------
4 SSL quantum size : 8 KB
5 Max CRL memory size : 256 MB
6 Strict CA checks : NO
7 Encryption trigger timeout : 100 ms
8 Send Close-Notify : YES
9 Encryption trigger packet count : 45
```
Configure renegotiation on a DTLS service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Select a DTLS service and click Edit.
3. Navigate to SSL > Advanced Settings.
4. Select Deny SSL Renegotiation.

Features not supported by a DTLS service

The following options cannot be enabled on a DTLS service:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation
Parameters not used by a DTLS service

A DTLS service ignores the following SSL parameters, even if set:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

Note:
SSL session reuse handshake fails on a DTLS service because session reuse is not currently supported on DTLS services.

Workaround: Manually disable session reuse on a DTLS service. At the CLI, type:

```
set ssl service <dtls-service-name> -sessReuse DISABLED
```

DTLS profile

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a DTLS profile with specific settings to suit your requirement.

Use a DTLS profile with a DTLS virtual server or a VPN DTLS virtual server. You cannot use an SSL profile with a DTLS virtual server.

Create a DTLS profile by using the CLI

```
1 add ssl dtlsProfile <name>
2
3 show ssl dtlsProfile <name>
```

Example:

```
1 add dtlsProfile dtls1 -helloVerifyRequest ENABLED -maxretryTime 4
2
3 Done
4
5 show dtlsProfile dtls1
6
7 1) Name: dtls1
8    PMTU Discovery: DISABLED
9    Max Record Size: 1460 bytes
10   Max Retry Time: 4 sec
```
Hello Verify Request: ENABLED
Terminate Session: DISABLED
Max Packet Count: 120 bytes

Create a DTLS profile by using the GUI

Navigate to System > Profiles > DTLS Profiles and configure a new profile.

Example for an end-to-end DTLS configuration

```
enable ns feature SSL LB
add server s1 198.51.100.2
en ns mode usnip
add service svc_dtls s1 DTLS 443
add lb vserver v1 DTLS 10.102.59.244 443
bind ssl vserver v1 -ciphertextname ALL
add ssl certkey servercert -cert servercert_aia_valid.pem -key serverkey_aia.pem
bind ssl vserver v1 -certkeyname servercert
bind lb vserver lb1 svc_dtls
sh lb vserver v1
```

```

1) Name: nstdtls_default_profile
**DTLS cipher support**

By default, a DTLS cipher group is bound when you create a DTLS virtual server or service. DEFAULT_DTLS contains the ciphers that a front-end DTLS entity supports. This group is bound by default when you create a DTLS virtual server. DEFAULT_DTLS_BACKEND contains the ciphers that are supported to a back-end DTLS entity. This group is bound by default to a DTLS back-end service. DTLS_FIPS contains the ciphers that are supported on the Citrix ADC FIPS platform. This group is bound by default to a DTLS virtual server or service created on a FIPS platform.

**DTLS cipher support on Citrix ADC VPX, MPX/SDX (N2 and N3 based) appliances**

**How to read the tables:**

Unless a build number is specified, a cipher suite is supported for all builds in a release.

**Example:**

- **10.5, 11.0, 11.1, 12.0, 12.1, 13.0:** All builds of 10.5, 11.0, 11.1, 12.0, 12.1, 13.0 releases.
- **-NA-:** not applicable.

**DTLS cipher support on Citrix ADC VPX, MPX/SDX (N2 and N3 based) appliances**

Support for Intel Coleto SSL chip based platforms

July 29, 2019

The following appliances ship with Intel Coleto chips:

• MPX 5901/5905/5910
• MPX 8905/8910/8920/8930
• MPX/SDX 26100-100G/26160-100G/26200-100G
• MPX/SDX 15020-50G/15030-50G/15040-50G/15060-50G/15080-50G/15100-50G

Use the ‘show hardware’ command to identify whether your appliance has Coleto (COL) chips.

```
1  >  sh hardware
2  Platform: NSMPX-8900 8*CPU+4*F1X+6*E1K+1*E1K+1*COL 8955 30010
3    Manufactured on: 10/18/2016
4    CPU: 2100MHZ
5    Host Id: 0
6    Serial no: CRAC5CR8UA
7    Encoded serial no: CRAC5CR8UA
8  Done
```

Note: Secure renegotiation is supported on the back end for these platforms.

Limitations:

• DH 512 cipher is not supported.
• SSLv3 protocol is not supported.
• GnuTLS is not supported.
• ECDSA certificates with ECC curves P_224 and P521 are not supported (Not supported on platforms with Cavium chips also.)
• DNSSEC offload is not supported. (DNSSEC is supported in software but offload to hardware is not supported.)
The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The Citrix ADC FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—and a Cavium CN1620-NFBE3-2.0-G on the MPX 9700/10500/12500/15500 FIPS appliances—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server’s private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

The following table summarizes the differences between standard Citrix ADC and Citrix ADC FIPS appliances.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Citrix ADC appliance</th>
<th>Citrix ADC FIPS appliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key storage</td>
<td>On the hard disk</td>
<td>On the FIPS card</td>
</tr>
<tr>
<td>Cipher support</td>
<td>All ciphers</td>
<td>FIPS approved ciphers</td>
</tr>
<tr>
<td>Accessing keys</td>
<td>From the hard disk</td>
<td>Not accessible</td>
</tr>
</tbody>
</table>

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you should export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability (HA) setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard HA setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1, and you can reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a Citrix ADC FIPS appliance.

HSM configuration

Before you can configure the HSM of your Citrix ADC FIPS appliance, you must complete the initial hardware configuration. For more information about MPX appliances, see Initial Configuration.
information about SDX appliances, click here.

Configuring the HSM of your Citrix ADC FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser (nsroot account). The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM. The maximum length allowed for the password is 14 alphanumeric characters. Symbols are not allowed.

**Important:** Do not perform the set ssl fips command without first resetting the FIPS card and restarting the MPX FIPS appliance.

Although the FIPS appliance can be used with the default password values, you should modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

**Important:** Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. Should you need to reinitialize the HSM, you will need to specify this password as the old SO password.

Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see [Upgrading or Downgrading the System Software](#).

After upgrading, verify that the /nsconfig/fips directory has been successfully created on the appliance.

**Configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the CLI**

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

```
1  show ssl fips
2  reset ssl fips
3  reboot
4  set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <userPassword> [-hsmLabel <string>]
5  save ns config
6  reboot
7  show ssl fips
```

**Example:**

```
1  show ssl fips
2  reset ssl fips
3  reboot
4  set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <userPassword> [-hsmLabel <string>]
5  save ns config
6  reboot
7  show ssl fips
```
```
show fips
FIPS Card is not configured

reset fips
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]: y

set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel cavium
This command will erase all data on the FIPS card. You must save the configuration
(saveconfig) after executing this command.

Do you want to continue?(Y/N)y
Done

save ns config
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]: y

show fips
FIPS HSM Info:
HSM Label : Citrix ADC FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 2.1G1008-IC000021
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Firmware Version : 1.1
Firmware Release Date : Jun04,2010
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3994
Total SRAM Memory : 467348
Free SRAM Memory : 62564
Total Crypto Cores : 3
Enabled Crypto Cores : 1
Done
```
Note: If you upgrade the firmware to version 2.2, the firmware release date is replaced with the firmware build.

> show fips

FIPS HSM Info:

```
HSM Label : Citrix ADC FIPS
Initialization : FIPS-140-2 Level-2
HSM Serial Number : 3.0G1235-ICM000264
HSM State : 2
HSM Model : NITROX XL CN1620-NFBE
Hardware Version : 2.0-G
Firmware Version : 2.2
Firmware Build : NFBE-FW-2.2-130009
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3958
Total SRAM Memory : 467348
Free SRAM Memory : 50524
Total Crypto Cores : 3
Enabled Crypto Cores : 3
Done
```

Configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the GUI

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Infotab, click Reset FIPS.
3. In the navigation pane, click System.
4. In the details pane, click Reboot.
5. In the details pane, on the FIPS Info tab, click Initialize HSM.
6. In the Initialize HSM dialog box, specify values for the following parameters:
   - Security Officer (SO) Password*—new SO password
   - Old SO Password*—old SO password
   - User Password*—user password
   - Level—initHSM (Currently set to Level2 and cannot be changed)
   - HSM Label—hsmLabel

*A required parameter
7. Click OK.

8. In the details pane, click Save.

9. In the navigation pane, click System.

10. In the details pane, click Reboot.

11. Under FIPS HSM Info, verify that the information displayed for the FIPS HSM that you just configured is correct.

Create and transfer FIPS keys

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance’s HSM. You can then export the FIPS key to the appliance’s CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance. You must enable SIM between two standalone nodes before you export and transfer the keys. In an HA setup, if one of the nodes is replaced with a new appliance, you must enable SIM between this new appliance and the existing appliance of the HA setup before you export or import FIPS keys.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

**Note:** If you are planning an HA setup, make sure that the FIPS appliances are configured in an HA setup before creating a FIPS key.

Create FIPS keys

Before creating a FIPS key, make sure that the HSM is configured.

You must specify the key type (RSA or ECDSA) and specify the curve for ECDSA keys.

Create a FIPS key by using the GUI

1. Navigate to Traffic Management > SSL > FIPS.

2. In the details pane, on the FIPS Keys tab, click Add.

3. In the Create FIPS Key dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - Modulus*—modulus
   - Exponent*—exponent
Create a FIPS key by using the CLI

At the command prompt, type the following commands to create a FIPS key and verify the settings:

```
1 create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent ( 3 | F4 )]
2 3 show ssl fipsKey [<fipsKeyName>]
```

Example:

```
1 create fipskey Key-FIPS-1 -keytype RSA -modulus 2048 -exponent 3
2 3 show ssl fipsKey Key-FIPS-1
4 5 FIPS Key Name: Key-FIPS-1 Key Type: RSA Modulus: 2048
Public Exponent: F4 (Hex: 0x10001)
```

Export FIPS keys

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the /nsconfig/ssl folder on the appliance’s CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

Export a FIPS key by using the CLI

At the command key prompt, type:

```
1 export ssl fipsKey <fipsKeyName> -key <string>
```

Example:
Export a FIPS key by using the GUI

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Export.
3. In the Export FIPS key to a file dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify
     the complete path or click the Browse button and navigate to a location.)
   *A required parameter
4. Click Export, and then click Close.

Import an existing FIPS key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard
disk of the appliance into its HSM.

Note: To avoid errors when importing a FIPS key, make sure that the name of the key imported is the
same as the original key name when it was created.

Import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the CLI

At the command prompt, type the following commands to import a FIPS key and verify the settings:

```
1 export fipskey Key-FIPS-1 -key Key-FIPS-1.key
```

Example:

```
1 import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
2 show ssl fipskey Key-FIPS-2
3 FIPS Key Name: Key-FIPS-2 Modulus: 2048 Public Exponent: F4 (Hex value 0x10001)
```
Import a FIPS key by using the GUI

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Import.
3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
   - Exponent*  
* A required parameter
4. Click Import, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

Import an external key

In addition to transferring FIPS keys that are created within the Citrix ADC appliance’s HSM, you can transfer external private keys (such as those created on a standard Citrix ADC, Apache, or IIS) to a FIPS Citrix ADC appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance’s flash drive under /nsconfig/ssl.

On the MPX 9700/10500/12500/15500 FIPS appliances, the -exponent parameter in the import ssl fipskey command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The Citrix ADC FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```plaintext
openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
```

**Note:** If you import an RSA key as a FIPS key, Citrix recommends that you delete the RSA key from the appliance for security purposes.
Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the CLI

1. Copy the external key to the appliance’s flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:

   ```bash
   convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx file name> -password <password>
   ```

3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:

   ```bash
   import ssl fipsKey <fipsKeyName> -key <string> -informPEM
   show ssl fipskey <fipsKeyName>
   ```

Example:

```bash
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx
import fipskey Key-FIPS-2 -key iis.pem -inform PEM
show ssl fipskey key-FIPS-2
FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0 x10001)
```

Import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the GUI

1. If the key is in .pfx format, you must first convert it to PEM format.
   a) Navigate to Traffic Management > SSL.
   b) In the details pane, under Tools, click Import PKCS#12.
   c) In the Import PKCS12 File dialog box, set the following parameters:
      - Output File Name*
      - PKCS12 File Name*—Specify the .pfx file name.
      - Import Password*
      - Encoding Format
      *A required parameter

2. Navigate to Traffic Management > SSL > FIPS
3. In the details pane, on the FIPS Keys tab, click Import.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.

* A required parameter

5. Click Import, and then click Close.

6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

Configure FIPS appliances in a high availability setup

April 23, 2019

You can configure two appliances in a high availability (HA) pair as FIPS appliances. For information about configuring an HA setup, see High availability.

Note: Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause inconsistency that requires that the appliance be restarted. In addition, if you use the CLI, the create ssl fipskey command is not propagated to the secondary node. When you execute the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not identical. You have to create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

Important: On the MPX 9700/10500/12500/15500 FIPS appliances, the HA setup should be completed within six minutes. If the process takes longer than six minutes, the internal timer of the FIPS card expires and the following error message appears:

ERROR: Operation timed out or repeated, please wait for 10 mins and redo the SIM/HA configuration steps.

If this message appears, restart the appliance or wait for 10 minutes, and then repeat the HA setup procedure.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.
Configure FIPS appliances in a high availability setup by using the CLI

1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:
   ```
   1 init ssh fipsSIMsource <certFile>
   ```
4. Copy this `<certFile>` file to appliance B, in the `/nconfig/ssl` folder.
5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:
   ```
   1 init ssh fipsSIMtarget <certFile> <keyVector> <targetSecret>
   ```
8. Copy this `<targetSecret>` file to appliance A.
9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:
   ```
   1 enable ssh fipsSIMSource <targetSecret> <sourceSecret>
   ```
10. Copy this `<sourceSecret>` file to appliance B.
11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:
    ```
    1 enable ssh fipsSIMtarget <keyVector> <sourceSecret>
    ```
12. **On appliance A**, create a FIPS key, as described in Create a FIPS key.
13. Export the FIPS key to the appliance’s hard disk, as described in Export a FIPS key.
14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in Import an existing FIPS key.

Configure FIPS appliances in a high availability setup by using the GUI

1. On the appliance to be configured as the source appliance, navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Info tab, click Enable SIM.
3. In the Enable HA Pair for SIM dialog box, in the Certificate File Name text box, type the file name, with the path to the location at which the FIPS certificate should be stored on the source appliance.

4. In the Key Vector File Name text box, type the file name, with the path to the location at which the FIPS key vector should be stored on the source appliance.

5. In the Target Secret File Name text box, type the location for storing the secret data on the target appliance.

6. In the Source Secret File Name text box, type the location for storing the secret data on the source appliance.

7. Click OK. The FIPS appliances are now configured in HA mode.

8. Create a FIPS key, as described in Create a FIPS key. The FIPS key is automatically transferred from the primary to the secondary.

The following diagram summarizes the transfer process.

Figure 1. Transfer the FIPS key—summary

**Update the firmware to version 2.2 on a FIPS card**

April 23, 2019

FIPS firmware version 2.2 supports TLS protocol versions 1.1 and 1.2. From the command line, you can update the firmware version of the FIPS card of a Citrix ADC MPX 9700/10500/12500/15500 FIPS appliance from version 1.1 to version 2.2.

For successful SIM key propagation from primary to secondary in a high availability (HA) pair, the Cavium firmware version on each appliance should be identical. Perform the firmware update on the secondary appliance first. If executed on the primary appliance first, the long-running update process causes a failover.

**Limitations**

- Secure renegotiation is supported only on SSL virtual servers and front-end SSL services.
- Creating a certificate signing request by using a key that was created on firmware version 1.1 and updated to firmware version 2.2 fails.
- You cannot create a 1024-bit RSA key on firmware version 2.2. However, if you have imported or created a 1024-bit FIPS key on firmware version 1.1 and you then update to firmware version 2.2, you can use that FIPS key on firmware version 2.2.
- 1024-bit RSA keys are not supported.
- Secure renegotiation using SSLv3 protocol is not supported.
• After you upgrade the firmware, TLSv1.1 and TLSv1.2 are disabled by default on the existing virtual server, internal, front end, and backend services. To use TLS 1.1/1.2, you must explicitly enable these protocols, on the SSL entities, after the upgrade.
• FIPS keys that are created in firmware version 2.2 are not available if you downgrade the firmware to version 1.1.

Prerequisites

Download the following files from the download page on www.citrix.com. The files must be stored in the /var/nsinstall directory on the appliance.

• FW 2.2 File: FW-2.2-130013
• FW 2.2 Signature File: FW-2.2-130013.sign

FW-2.2-130013 is the recommended firmware version. It includes fixes to improve DRBG.

Update the FIPS firmware to version 2.2 on a standalone appliance

1. Log on to the appliance by using the administrator credentials.
2. At the prompt, type the following command to confirm that the FIPS card is initialized.

```
1  show fips
2  FIPS HSM Info:
3    HSM Label : Citrix ADC FIPS
4    Initialization : FIPS-140-2 Level-2
5    HSM Serial Number : 3.0G1235-ICM000264
6    HSM State : 2
7    HSM Model : NITROX XL CN1620-NFBE
8  Hardware Version : 2.0-G
9  Firmware Version : 1.1
10 Firmware Release Date : Jun04,2010
11 Max FIPS Key Memory : 3996
12 Free FIPS Key Memory : 3992
13 Total SRAM Memory : 467348
14 Free SRAM Memory : 62512
15 Total Crypto Cores : 3
16 Enabled Crypto Cores : 1
17 Done
```

3. Save the configuration. At the prompt, type:
1 save config

4. Perform the update. At the prompt, type:

   1 update ssl fips -fipsFW <path to the extracted contents>/CN16XX-NFBE-FW-2.2-1300013

Press Y when the following prompt appears:

   1 This command will update compatible version of the FIPS firmware. You must save the current configuration (saveconfig) before executing this command. You must reboot the system after execution of this command, for the firmware update to take effect. Do you want to continue? (Y/N) Y

   2 Done

Note: You only need to specify the firmware file, because the firmware signature file is placed in the same location.

The update takes up to ten seconds. The update command is blocking, which means that no other actions are executed until the command finishes. The command prompt reappears when execution of the command is completed.

1. Restart the appliance. At the prompt, type:

   1 reboot

   2 Are you sure you want to restart NetScaler (Y/N)? [N]: Y

2. Verify that the update is successful. At the prompt, type:

   1 show fips

   The firmware version displayed in the output should be 2.2. For example:

   1 sh fips
   2   FIPS HSM Info:
   3       HSM Label : Citrix ADC FIPS
   4       Initialization : FIPS-140-2 Level-2
   5       HSM Serial Number : 2.1G1207-IC002429
   6       HSM State : 2
   7       HSM Model : NITROX XL CN1620-NFBE
   8       Hardware Version : 2.0-G
Update the FIPS firmware to version 2.2 on appliances in a high availability pair

1. Log on to the secondary node and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

   Force the secondary node to become primary. At the prompt, type:

   ```
   force failover
   ```

   Press Y at the confirmation prompt.

2. Log on to the new secondary node (old primary) and perform the update as described in “Update the FIPS firmware to version 2.2 on a standalone appliance”.

3. Force the new secondary node to become primary again. At the prompt, type:

   ```
   force failover
   ```

   Press Y at the confirmation prompt.

Update the FIPS firmware to version 1.1 on a standalone appliance

1. Download the nfb_firmware-r1235_100604 and nfb_firmware-r1235_100604.sign files, to the same directory on the appliance, from the download page on www.citrix.com.

2. Log on to the appliance by using the administrator credentials.

3. At the prompt, type:

   ```
   update ssl fips -fipsFW /<full path to the file>/nfb_firmware-r1235_100604
   ```
Reset a locked HSM

April 23, 2019

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. This is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

**Important:** To avoid this situation, save the configuration after initializing the HSM.

If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

**Caution:** Do not reset the HSM unless it has become locked.

Reset a locked HSM by using the CLI

At the command prompt, type the following commands to reset and re-initialize a locked HSM:

```
1 reset ssl fips
2 reboot -warm
3 set ssl fips -initHSM Level=2 <new SO password> <old SO password> <user password> [-hsmLabel <string>]
4 save ns config
5 reboot -warm
```

**Example:**

```
1 reset fips
2
3 reboot -warm
4
5 set fips -initHSM Level=2 newsopin123 sopin123 userpin123 -hsmLabel NSFIPS
6
7 saveconfig
8
9 reboot -warm
10
11 Note: By default the HSM passwords are preconfigured. The <Old_SO_Password> = so12345, <User_Password> = user123, <New_SO_Password> = sopin12345, <New_User_Password> = userpin123.
```
Reset a locked HSM by using the GUI

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in Configuring the HSM.
4. In the details pane, click Save.

MPX 14000 FIPS appliances

April 23, 2019

Important:

Configuration steps for Citrix ADC MPX 14000 FIPS and Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances are different.

A FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0 build 56.x). The Critical Security Parameters (CSPs), primarily the server’s private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (ns-root) can perform operations on the keys stored inside the HSM.

Before configuring a FIPS appliance, you must check the state of the FIPS card and then initialize the card. Create a FIPS key and server certificate, and add any additional SSL configuration.

For information about the FIPS ciphers supported, see FIPS Approved Algorithms and Ciphers.

For information about configuring FIPS appliances in a high availability setup, see Configuring FIPS Appliances in a High Availability Setup.

Limitations

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an MPX FIPS appliance.
2. 1024-bit and 4096-bit keys and exponent value of 3 are not supported.

Configure the HSM

Before configuring the HSM on an MPX 14000 FIPS appliance, you must check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.
At the command prompt, type:

```
1 show fips
2
3 FIPS Card is not configured
4 Done
```

The message “ERROR: Operation not permitted - no FIPS card present in the system” appears if the driver is not loaded correctly.

**Initialize the FIPS card**

The appliance must be restarted three times for proper initialization of the FIPS card.

---

**Important**

- Verify that the /nsconfig/fips directory has been successfully created on the appliance.
- Do not save the configuration before you restart the appliance for the 3rd time.

---

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.
   
   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance.
7. Verify that the password encrypted key for the default partition (default_pek.key) has been created in the /nsconfig/fips/ directory.
8. Restart the appliance.
9. Verify that the FIPS card is UP.

**Initialize the FIPS card by using the CLI**

At the command prompt, type the following commands:

```
1 reset fips
2 Done
3
4 reboot
5
6 set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS
```
This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. Do you want to continue? (Y/N) y

Note: The following message appears when you run the setfips command:

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue? (Y/N) y

clear
Done

FIPS HSM Info:

    HSM Label : NSFIPS
    Initialization : FIPS-140-2 Level-2
    HSM Serial Number : 3.0G1501-ICM000083
    HSM State : 2
    HSM Model : No Model Info
    Hardware Version : 0.0-G
    Firmware Version : 1.0
    Firmware Build : NFBE-FW-1.0-39
    Max FIPS Key Memory : 102235
    Free FIPS Key Memory : 102233
    Total SRAM Memory : 557396
    Free SRAM Memory : 255456
    Total Crypto Cores : 63
    Enabled Crypto Cores : 63

Done
Create FIPS keys

You can create a FIPS key on your MPX 14000 FIPS appliance or import an existing FIPS key to the appliance. The MPX 14000 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your appliance.

You must specify the key type (RSA or ECDSA) and specify the curve for ECDSA keys.

**Note**

1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

Create a FIPS key by using the CLI

At the command prompt, type:

```
create ssl fipsKey <fipsKeyName> -keytype (RSA | ECDSA) [-exponent (3 | F4)] [-modulus <positive_integer>] [-curve (P_256 | P_384)]
```

**Example:**

```
create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4
Done
```

Import a FIPS key by using the CLI

At the command prompt, type:

```
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv <string>] -exponent F4
```

**Example:**

```
import fipskey Key=FIPS-2 -key Key=FIPS-2.key -inform SIM -exponent F4
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
**Create a certificate signing request by using the CLI**

At the command prompt, type:

```plaintext
create ssl certReq <reqFile> [-keyFile <input_filename> | -fipsKeyName <string>] [-keyform ( DER | PEM ) {  
-PEMPassPhrase } [-countryName <string> -stateName <string> -organizationName <string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] {  
-challengePassword } [-companyName <string>] [-digestMethod ( SHA1 | SHA256 )]
```

**Example:**

```plaintext
>create certreq f1.req -fipsKeyName f1 -countryName US -stateName CA  
-organizationName Citrix -companyName Citrix -commonName ctx -emailAddress test@example.com
```

**Create a server certificate by using the CLI**

At the command prompt, type:

```plaintext
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM ) {  
-PEMPassPhrase } [-days <positive_integer>] [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CACertForm ( DER | PEM )] [-CAkey <input_filename>] [-CAkeyForm ( DER | PEM )] [-CAserial <output_filename>]
```

**Example:**
The above example creates a server certificate using a local root CA on the appliance.

**Add a certificate-key pair by using the CLI**

At the command prompt, type:

```
1 add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <
    string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>][-
    expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <
    positive_integer>]] [-bundle ( YES | NO )]
```

Example:

```
1 add certkey cert1 -cert f1.cert -fipsKey f1
2 Done
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server. Save the configuration.

```
1 enable ns feature SSL LB
2 Done
3
4 add server s1 10.217.2.5
5 Done
6
7 add service sr1 s1 HTTP 80
8 Done
9
10 add lb vserver v1 SSL 10.217.2.172 443
11 Done
12
13 bind ssl vserver v1 -certkeyName cert1
14 Done
15
16 bind lb vserver v1 sr1
17 Done
18
19 saveconfig
```
The basic configuration of your MPX 14000 FIPS appliance is now complete.

For information about configuring secure HTTPS, click here.

For information about configuring secure RPC, click here.

**Support for hybrid FIPS mode on the MPX 14000 FIPS and SDX 14000 FIPS platforms**

**Note:**

This feature is supported only on the new MPX/SDX 14000 FIPS platform containing one primary FIPS card and one or more secondary cards. It is not supported on a VPX platform or a platform containing only one type of hardware card.

On a FIPS platform, all the encryption and decryption (asymmetric and symmetric) is performed on the FIPS card for security reasons. However, you can perform part of this activity (asymmetric) on a FIPS card and offload the bulk encryption and decryption (symmetric) to another card without compromising the security of your keys.

The new MPX/SDX 14000 FIPS platform contains one primary card and one or more secondary cards. If you enable the hybrid FIPS mode, the pre-master secret decryption commands are run on the primary card because the private key is stored on this card, but the bulk encryption and decryption is offloaded to the secondary card. This significantly increases the bulk encryption throughput on an MPX/SDX 14000 FIPS platform as compared to non-hybrid FIPS mode and the existing MPX 9700/10500/12500/15000 FIPS platform. Enabling the hybrid FIPS mode also improves the SSL transaction per second on this platform.

The hybrid FIPS mode is disabled by default to meet the strict certification requirements where all the crypto-computation must be done inside a FIPS certified module. You must enable the hybrid mode to offload the bulk encryption and decryption to the secondary card.

**Note:**

On an SDX 14000 FIPS platform, you must first assign an SSL chip to the VPX instance before you enable the hybrid mode.

**Enable hybrid FIPS mode by using the CLI**

At the command prompt, type:

```bash
1 set SSL parameter -hybridFIPSMode { ENABLED | DISABLED }
2
3
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Arguments

hybridFIPSMode

When this mode is enabled, system will use additional crypto hardware to accelerate symmetric crypto operations.

Possible values: ENABLED, DISABLED

Default value: DISABLED

Example:

```
set SSL parameter -hybridFIPSMode ENABLED
show SSL parameter
Advanced SSL Parameters
-----------------------------
.......
Hybrid FIPS Mode : ENABLED
.......
Done
```

Enable hybrid FIPS mode by using the GUI

1. Navigate to Traffic Management > SSL.
2. In the details pane, under Settings, click Change advanced SSL settings.
3. In the Change Advanced SSL Settings dialog box, select Hybrid FIPS Mode.

Limitations:

1. Renegotiation is not supported.
2. The “stat ssl parameter” command on an SDX 14000 platform does not display the correct secondary card utilization percentage. It always displays 0.00% utilization.

```
stat ssl
SSL Summary
# SSL cards present 1
# SSL cards UP 1
# Secondary SSL cards present 4
# Secondary SSL cards UP 4
SSL engine status 1
SSL sessions (Rate) 963
```
SDX 14000 FIPS appliances

April 23, 2019

A Citrix ADC SDX appliance is a multitenant platform on which you can provision and manage multiple virtual Citrix ADC instances. The SDX appliance addresses cloud computing and multitenancy requirements by allowing a single administrator to configure and manage the appliance and delegate the administration of each hosted instance to tenants.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance provides the capabilities of an SDX appliance with FIPS functionality. It is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 12.0 build 56.x). The Critical Security Parameters (CSPs), primarily the server’s private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

A Citrix ADC SDX 14030/14060/14080 FIPS appliance contains one FIPS HSM module with 63 cores. The FIPS HSM module can be partitioned up to a maximum of 32 partitions. The SDX administrator can assign dedicated key storage, cryptographic resources, and number of crypto SSL FIPS cores to each partition. Keys and resources allocated to a partition are dedicated and secure and cannot be accessed or shared by another partition.

The FIPS HSM partition that you create can be assigned or attached to a VPX instance at the time of provisioning the instance, or later by editing the instance. The FIPS partition created and attached to an instance acts like a virtual HSM module for that particular instance.

The VPX instances on an SDX 14030/14060/14080 FIPS appliance are assigned a FIPS virtual function (VF) partition, which is treated as an isolated FIPS virtual card or HSM. Therefore, the steps to configure a FIPS partition inside a VPX instance are similar to the steps to configure an MPX FIPS appliance. For compliance details, see the security policy details on the U.S. National Institute of Standards and Technology (NIST) website.

For information about configuring FIPS appliances in a high availability setup, see FIPS Appliances in a High Availability Setup.

Important
Each key includes a private and a public key. As a result, it occupies two key spaces. Therefore, the maximum number of keys is limited to one less than half the key store size.

The SDX 14000 FIPS platform supports a hybrid FIPS mode. In this mode, you can offload part of the encryption and decryption activity to a non-FIPS card. For more information, see Hybrid FIPS mode.

Limitations

April 23, 2019

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an SDX FIPS appliance.
2. 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.
3. Backup and restore is not supported.
4. Cluster and administrative domains are not supported.
5. You can attach only one FIPS partition to an instance.
6. An instance with a FIPS partition can be assigned only one CPU core.
7. You can assign either a FIPS partition or an SSL core to an instance, but not both.

Terminology

April 23, 2019

Zeroize: Reset the HSM. All the data on the HSM is deleted. This is a mandatory step before the HSM is initialized.

Initialize: Set the HSM capabilities. The Citrix ADC SDX FIPS appliance complies with FIPS-140-2 level 2. You can create partitions after you initialize the chip.

Key store size: Number of keys that can be stored on a partition. A maximum of 102235 keys can be specified. The maximum number of keys that can be stored is one less than half the number specified. For example, if you specify 100, you can create only 49 keys because one of the keys is the RSA key pair that consumes 2 key stores.

Crypto Core Capacity: Number of crypto cores assigned to a partition. A maximum of 63 cores are available.

SSL Context: Number of concurrent SSL connections that can be created on a partition.
Initialize the HSM

April 23, 2019

Before initializing the HSM, you must first zeroize it.

Zeroize the HSM by using the Management Service

1. Open a browser and log on to the appliance.
2. On the Configuration tab, navigate to System > HSM Administration, and in the details plane, click Zeroize.

All data is wiped from the FIPS chip, and the state appears as “Zeroized.” Any HSM partitions created earlier are deleted.

Initialize the HSM by using the Management Service

1. On the Configuration tab, navigate to System > HSM Administration, and in the details plane, click Initialize.
2. Type a new user name, specify a password, and click OK.

The card state appears as “Initialized.”

Create partitions

April 23, 2019

Create partitions for different tenants and specify the cryptographic resources for each partition. Each instance is assigned one partition, and a partition can be assigned to only one instance. Deleting an instance deletes the partition assigned to the instance. As a result, the partition data is also deleted and not left unsecured or accessible later. Number of keys and SSL context assignment depends on your application. For information about number of cores to assign, see the Citrix ADC datasheet.

Important

After you assign a key store size and cores to an HSM partition, you cannot change them at runtime. You must first detach the partition from the instance.
Create a partition by using the Management Service

1. On the Configuration tab, navigate to System > HSM Administration > Partitions, and in the details plane, click Add.
2. Specify a name for the partition, and the resources to be assigned to this partition.
3. Click OK.

The summary page displays all the partitions that were created. Some partitions are assigned an instance while some are free partitions.

Provision a new instance or modify an existing instance and assign a partition

September 13, 2019

After creating the partitions, you must assign them to instances.

Important:

- You can attach only one FIPS partition to an instance.
- An instance with a FIPS partition can be assigned only one CPU core.

Provision a new instance or modify an existing instance

1. On the Configuration tab, navigate to NetScaler > Instances, and add or modify an instance.
2. Select Enable FIPS, and from the Partitions list, select a partition to attach to this instance.

You can verify that the partition is attached to an instance by using either the GUI or the CLI.

In the GUI, navigate to System > HSM Administration > Partitions. The instance name attached to the partition is displayed.

To unassign a FIPS partition, navigate to NetScaler > Instances. Edit the instance and clear the Enable FIPS check box.

In the CLI, at the command prompt, type the following commands:

```
1 show fips
2
3 FIPS Card is not configured
4 Done
```
If you see the following output, see the troubleshooting section for debugging.

**ERROR: Operation not permitted - no FIPS card present in the system**

## Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance

April 23, 2019

You must first check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

```plaintext
1 show fips
2
3 FIPS Card is not configured
4
5 Done
```

If the driver is not loaded correctly, the message “ERROR: Operation not permitted - no FIPS card present in the system” appears.

### Initialize the FIPS card

**Important:**

Verify that the `/nsconfig/fips` directory has successfully been created on the appliance.

Do not save the configuration before you restart the appliance for the third time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.
   - Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the `/nsconfig/fips/` directory.
6. Restart the appliance.
7. Verify that the FIPS card is UP.
**Initialize the FIPS card by using the CLI**

At the command prompt, type the following commands:

```
reset fips
reboot
set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -hsmLabel <string>
```

**Note**: The following message appears when you run the `set fips` command:

```
This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y
```

```
saveconfig
reboot
set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS
```

**Example:**

```
reset fips
Done
reboot
set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS
```

```
This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y
Done
saveconfig
```
Create a FIPS key for an instance on an SDX 14030/14060/14080 FIPS appliance

April 23, 2019

You can create a FIPS key on your instance or import an existing FIPS key into the instance. An SDX 14030/14060/14080 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your instance.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024-bit and 4096-bit keys and an exponent value of 3 are not supported.</td>
</tr>
</tbody>
</table>

Create a FIPS key by using the CLI

At the command prompt, type:
**Create SSL FIPS Key**

Create an SSL FIPS key with the following command:

```bash
create ssl fipsKey <fipsKeyName> -keytype (RSA | ECDSA) [-exponent (3 | F4)] [-modulus <positive_integer>] [-curve (P_256 | P_384)]
```

**Example:**

```bash
create fipsKey f1 -keytype RSA -modulus 2048 -exponent F4
Done
show ssl fipskey ddvws
FIPS Key Name: f1  Key Type: RSA  Modulus: 2048  Public Exponent: F4  (Hex: 0x10001)
Done
```

**Import a FIPS Key by using the CLI**

To import a FIPS key, use the following command:

```bash
import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv <string>] [-exponent F4]
```

**Example:**

```bash
import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
Done
import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM
Done
```

Verify that the FIPS key is created or imported correctly by running the `show fipskey` command.

```bash
show fipskey
1)  FIPS Key Name: Key-FIPS-2
Done
```

**Create a Certificate Signing Request by using the CLI**

To create a certificate signing request, use the following command:

```bash
create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform (DER | PEM)]
```
Example:

```
1 create certreq f1.req -fipsKeyName f1 -countryName US -stateName CA -organizationName Citrix -companyName Citrix -commonName ctx -emailAddress test@example.com'
2 'Done
```

Create a server certificate by using the CLI

At the command prompt, type:

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM )] 
   -PEMPassPhrase } 
2 ] [ -days <positive_integer> ] [-certForm ( DER | PEM )] [-CAcert <input_filename>] [-CAcertForm ( DER | PEM )] [-CAsignature <input_filename>] [-CAsignatureForm ( DER | PEM )] [-CAserial <output_filename>]
```

Example:

```
1 create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAsignature ns-root.srl -days 1000 
2 Done
```

The above example creates a server certificate using a local root CA on the appliance.

Add a certificate-key pair by using the CLI

At the command prompt, type:

```
1 add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]] [-bundle ( YES | NO )]
```
Example:

```
1 add certkey cert1 -cert f1.cert -fipsKey f1
2 Done
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server, and save the configuration.

```
1 enable ns feature SSL LB
2 Done
3 add server s1 10.217.2.5
4 Done
5 add service sr1 s1 HTTP 80
6 Done
7 add lb vserver v1 SSL 10.217.2.172 443
8 Done
9 bind ssl vserver v1 -certkeyName cert1
10 Done
11 bind lb vserver v1 sr1
12 Done
13 saveconfig
14 Done
```

For information about configuring secure HTTPS and secure RPC, click here.

### Upgrade the FIPS firmware

April 23, 2019

FIPS firmware updates are released from time to time. Download the latest firmware from the Citrix download page and upload it to the appliance. The upgrade process might take up to 10 minutes to complete. The instance is restarted after the upgrade.

#### Upgrade the FIPS firmware

1. Navigate to System > HSM Administration > Firmware Images.
2. Select Upload.
3. Navigate to the folder that contains the firmware image and select the file.
4. Navigate to System > HSM Administration, and select Upgrade Firmware.
5. Select the firmware image to upgrade to, and click OK.

Support for Thales nShield® HSM

April 23, 2019

A non-FIPS Citrix ADC appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a Thales nShield® Connect external HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS appliances.

Thales nShield® Connect is an external FIPS-certified network-attached HSM. With a Thales HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the Thales HSM only.

If you are already using a Thales HSM, you can now use a Citrix ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

Note:

- Thales HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the Thales HSM. Only the Hardserver can read the response from the HSM to the Citrix ADC appliance, because it is encrypted.

Supported versions matrix

<table>
<thead>

</table>
The three entities that are part of a Citrix ADC-Thales deployment are a Thales nShield Connect module, a remote file server (RFS), and a Citrix ADC.

The Thales nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

Hardserver, a proprietary daemon provided by Thales, is used for communication between the client (ADC), the Thales HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the Hardserver Gateway, is used to communicate between the Citrix ADC packet engine and the Hardserver.

**Note:** The terms Thales nShield Connect, Thales HSM, and HSM are used interchangeably in this documentation.

The following figure illustrates the interaction between the different components.

In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the GUI or command line to load the keys to the HSM. A virtual server on the ADC uses Thales to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

**Note:** The terms keys and application key tokens are used interchangeably in this documentation.

The following figure illustrates the packet flow in the SSL handshake with the Thales HSM.

**Figure 1. SSL Handshake Packets Flow Diagram with Citrix ADC Using Thales HSM**

**Note:** The communication between the ADC and the HSM uses a Thales proprietary communication protocol, called IMPATH.

**Prerequisites**

Before you can use a Thales nShield Connect with a Citrix ADC, make sure that the following prerequisites are met:

- A Thales nShield Connect device is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.
A usable Security World exists. Security World is a unique key management architecture used by the Thales nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Thales. You can also find the guide in the CD provided with the Thales HSM module at CipherTools-linux-dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf.

Note: Softcard or token/OCS protected keys are currently not supported on the Citrix ADC.

Licenses are available to support the number of clients that will be connected to the Thales HSM. The ADC and RFS are clients of the HSM.

A remote file server (RFS) is installed in the network and is accessible to the Citrix ADC.

The Thales nShield Connect device, the RFS, and the Citrix ADC can initiate connections with each other through port 9004.

You are using NetScaler release 10.5 build 52.1115.e or later.

The Citrix ADC appliance does not contain a FIPS Cavium card.

Important: Thales HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

**Configure the ADC-Thales integration**

April 23, 2019

The following flowchart depicts the tasks that you need to perform to use Thales HSM with a Citrix ADC:

As shown in the above flowchart, you perform the following tasks:

1. Enable remote configuration push on the HSM.
2. Configure the ADC to use the Thales HSM.
   - Add the NSIP address on the HSM.
   - Configure access permission for the ADC on the RFS.
   - Configure automatic start of the Hardserver at boot time.
   - Enroll the HSM on the ADC.
   - Add RFS details on the ADC.
   - Synchronize the ADC to the RFS.
   - Verify that Thales HSM is successfully enrolled on the ADC.
3. (Optional) Create an HSM RSA key.
4. Configure the entities on the Citrix ADC.
   - Add the HSM key.
   - Add a certificate-key pair by using the HSM key.
   - Add a virtual server.
   - Add a server object.
• Add a service.
• Bind the service to the virtual server.
• Bind the certificate-key pair to the virtual server.
• Verify the configuration.

Configure the Thales HSM

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

Specify the IP address of a remote computer on the Thales HSM

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

Enable remote configuration push on the HSM

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

Specify the IP address of a remote computer on the Thales HSM

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

Configure the ADC to use the Thales HSM

Sample values used in this documentation:

NSIP address=10.217.2.43
Thales HSM IP address=10.217.2.112
RFS IP address=10.217.2.6
Add the NSIP address on the HSM

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.

Alternately, use the RFS to add the ADC as a client to the HSM. To do this, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can do this, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

```
1 root@ns# /opt/nfast/bin/anonkneti <Thales HSM IP address>
```

Example:

```
1 root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
2 BD17-C807-58D9 5e30a698f7bab3b2068ca90a9488dc4e6c78d822
```

The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

```
1 vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

In the hs_clients section, add the following entries:

```
1 # Amount of data in bytes to encrypt with a session key before session
   key# renegotiation, or 0 for unlimited. (default=1024*1024*8=8Mb).
2 # datalimit=INT
3 addr=10.217.2.43
4 clientperm=unpriv
5 keyhash=0000000000000000000000000000000000000000
6 esn=
7 timelimit=86400
8 datalimit=8388608
9 -----
```

**Note:** Include one or more hyphens as delimiters to add multiple entries in the same section.

To push the configuration to the HSM, run the following command on the RFS:

```
1 /opt/nfast/bin/cfg-pushnethsm --address=<Thales HSM IP address> --force
   /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

Example:
Configure access permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:

```
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP address>
```

Example:

```
[root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-noauth 10.217.2.43
Adding read-only remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local exists
Adding new writable remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
Saving the new config file and configuring the hardserver
Done
```

Verify that the ADC can reach both the RFS and Thales HSM by using port 9004.

**Configure automatic start of the hardserver at boot time**

Create a file and then restart the appliance. Now, whenever you restart the appliance, and if this file is found, the Hardserver is automatically started.

At the shell prompt, type:

```
touch /var/opt/nfast/bin/thales_hsm_is_enrolled
```

At the command prompt, type:

```
reboot
```

**Enroll the HSM on the ADC**

Change directory to /var/opt/nfast/bin.

To add HSM details into the ADC configuration, run the following command on the ADC:

```
/opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
```

```
/opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti < Thales_nShield_Connect_ip_address>)

Example:

```
1  root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)
2  OK configuring hardserver's nethsm imports
```

This step adds the following entries after the line # ntoken_esn=ESN in the nethsm_imports section of the /var/opt/nfast/kmdata/config/config file.

```
1 ...
2  local_module=0
3  remote_ip=10.217.2.112
4  remote_port=9004
5  remote_esn=BD17-C807-58D9
6  keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822
7  timelimit=86400
8  datalimit=8388608
9  privileged=0
10 privileged_use_high_port=0
11 ntoken_esn=
```

Change directory to /var/opt/nfast/bin and run the following command on the ADC:

```
1  touch "thales_hsm_is_enrolled"
```

**Note:** To remove an HSM that is enrolled on the ADC, type:

```
1  ./nethsmenroll -remove <NETHSM-IP>
```

**Add RFS details on the ADC**

To add RFS details, change directory to /var/opt/nfast/bin/ and then run the following command:

```
1  ./rfs-sync --no-authenticate --setup <rfs_ip_address>
```

**Example:**

```
1  ./rfs-sync --no-authenticate --setup 10.217.2.6
2  No current RFS synchronization configuration.
3  Configuration successfully written; new config details:
4  Using RFS at 10.217.2.6:9004: not authenticating.
```
This step adds the following entries after the # local_esn=ESN line in the rfs_sync_client section of the /var/opt/nfast/kmdata/config/config file.

```plaintext
1 ... ...
2 remote_ip=10.217.2.6
3 remote_port=9004
4 use_kneti=no
5 local_esn=
```

**Note:** To remove an RFS that is enrolled on the ADC, type:

```plaintext
1 ./rfs_sync - remove
```

**Synchronize the ADC to the RFS**

To synchronize all the files, change directory to /var/opt/nfast/bin and then run the following command on the ADC:

```plaintext
1 ./rfs-sync -update
```

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdatalocal directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module_XXXX_XXXX_XXXX files, where XXXX_XXXX_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

**Verify that the Thales HSM is successfully enrolled on the ADC**

After you synchronize the ADC to the RFS, do the following:

- Verify that the local Hardserver is UP and running. (nCipher server running).
- Get the state of the configured HSMs, and verify that the values for the n_modules (number of modules) field and the km info fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state 0x2 Usable) by the ADC.
- Load tests using sigtest run properly.

Change directory to /
/var/opt/nfast/bin, and at the shell prompt, run the following commands:

```plaintext
1 root@ns#./chkserv root@ns#./nfkminfo root@ns#./sigtest
```

See Appendix for an example.
Create an HSM RSA Key

Only RSA keys are supported as HSM keys.

**Note:** Skip this step if keys are already present in the /opt/nfast/kmdata/local folder on the RFS.

Create an RSA key, a self-signed certificate, and a Certificate Signing Request (CSR). Send the CSR to a certificate authority to get a server certificate.

The following files are created in the example below:

- Embed RSA key: key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78
- Self-Signed Certificate: example_selfcert
- Certificate Signing Request: example_req

**Note:** The `generatekey` command is supported in strict FIPS 140-2 Level 3 Security World. An administrator card set (ACS) or an operator card set (OCS) is needed to control many operations, including the creation of keys and OCSs. When you run the `generatekey` command, you are prompted to insert an ACS or OCS card. For more information about strict FIPS 140-2 Level 3 Security World, see the nShield Connect User Guide.

The following example uses Level-2 Security World. In the example, the commands are in boldface type.

**Example:**

```bash
1 [root@localhost bin]# ./generatekey embed
2 size: Key size? (bits, minimum 1024) [1024] > 2048
3 OPTIONAL: pubexp: Public exponent for RSA key (hex)? []
4 >
5 embedsavefile: Filename to write key to? []
6 > example
7 plainname: Key name? [] > example
8 x509country: Country code? [] > US
9 x509province: State or province? [] > CA
10 x509locality: City or locality? [] > Santa Clara
11 x509org: Organisation? [] > Citrix
12 x509orgunit: Organisation unit? [] > NS
13 x509dnscommon: Domain name? [] > www.citrix.com
14 x509email: Email address? [] > example@citrix.com
15 nvram: Blob in NVRAM (needs ACS)? (yes/no) [no] >
16 digest: Digest to sign cert req with? (md5, sha1, sha256, sha384, sha512)
17   [default sha1] > sha512
18 key generation parameters:
```
<table>
<thead>
<tr>
<th>Operation</th>
<th>Application</th>
<th>Verify</th>
<th>Key type</th>
<th>Key size</th>
<th>Public exponent for RSA key (hex)</th>
<th>Filename to write key to</th>
<th>Key name</th>
<th>Country code</th>
<th>State or province</th>
<th>City or locality</th>
<th>Organisation</th>
<th>Organisation unit</th>
<th>Domain name</th>
<th>Email address</th>
<th>Blob in NVRAM (needs ACS)</th>
<th>Digest to sign cert req with</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate</td>
<td>Embed</td>
<td>Yes</td>
<td>RSA</td>
<td>2048</td>
<td>ed5428aaeae1e159bdbd63f25292c7113ec2c78</td>
<td>example</td>
<td>example</td>
<td>US</td>
<td>CA</td>
<td>Santa Clara</td>
<td>Citrix</td>
<td>NS</td>
<td><a href="http://www.citrix.com">www.citrix.com</a></td>
<td><a href="mailto:example@citrix.com">example@citrix.com</a></td>
<td>no</td>
<td>sha512</td>
</tr>
</tbody>
</table>

**Result:**

You have created a CSR (example_req), a self-signed certificate (example_selfcert), and an application key token file in embed format (/opt/nfast/kmdatalocal/key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78)

Because the ADC supports keys in simple format only, you must convert the embed key to a simple key.

**To convert the embed key to a simple key, run the following command on the RFS:**

```
[root@localhost bin]# .generatekey -r simple
```

```
from-application: Source application? (embed, simple) [embed] > embed
```

```
from-ident: Source key identifier? (c6410ca00af7e394157518cb53b2db46ff18ce29,
2
   ed5428aaeae1e159bdbd63f25292c7113ec2c78)
```

```
[default c6410ca00af7e394157518cb53b2db46ff18ce29]
```

```
> 2ed5428aaeae1e159bdbd63f25292c7113ec2c78
```

```
ident: Key identifier? [] > examplersa2048key
plainname: Key name? [] > examplersa2048key
```

```nvr
```
12 verify Verify security of key yes
13 from-application Source application embed
14 from-ident Source key identifier 2
   ed5428aaeae1e159bdbd63f25292c7113ec2c78
15 ident Key identifier examplersa2048key
16 plainname Key name examplersa2048key
17 Key successfully retargetted.
18 Path to key: /opt/nfast/kdata/local/key_simple_examplersa2048key

Important:
When prompted for the source key identifier, enter 2ed5428aaeae1e159bdbd63f25292c7113ec2c78 as the embed key.

Result:
A key with the prefix key_simple (for example key_simple_examplersa2048key) is created.

Note: examplersa2048key is the key identifier (ident) and is referred to as the HSM key name on the ADC. A key identifier is unique. All the simple files have the prefix key_simple.

Configure the Entities on the ADC

Before the ADC can process traffic, you must do the following:

1. Enable features.
2. Add a subnet IP (SNIP) address.
3. Add the HSM key to the ADC.
4. Add a certificate-key pair by using the HSM key.
5. Add a virtual server.
6. Add a server object.
7. Add a service.
8. Bind the service to the virtual server.
9. Bind the certificate-key pair to the virtual server.
10. Verify the configuration.

Enable features on the ADC

Licenses must be present on the ADC before you can enable a feature.

Enable a feature by using the CLI

At the command prompt, run the following commands:
Enable a feature by using the GUI

Navigate to System > Settings and, in the Modes and Features group, select Configure basic features ••, and then select ••SSL Offloading.

Add a subnet IP address

For more information about subnet IP addresses, see Configuring Subnet IP Addresses.

Add a SNIP address and verify the configuration by using the CLI

At the command prompt, run the following commands:

```
1 add ns ip <IPAddress> <netmask> -type SNIP
2 show ns ip
```

Example:

```
1 add ns ip 192.168.17.253 255.255.248.0 -type SNIP
2 Done
3 show ns ip
4 Ipaddress  Traffic Domain  Type  Mode  Arp
          Icmp       Vserver   State
 1) 192.168.17.251  0 NetScaler IP  Active
    Enabled  Enabled NA   Enabled
 2) 192.168.17.252  0 VIP  Active
    Enabled -enabled NA   Enabled
 3) 192.168.17.253  0 SNIP  Active
    Enabled  Enabled NA   Enabled
5 Done
```

Add a SNIP address and verify the configuration by using the GUI

Navigate to System > Network > IPs, add an IP address, and select the IP Type as Subnet IP.
Copy the HSM key and certificate to the ADC

Use a secure file transfer utility to securely copy the key (key_simple_examplersa2048key) to the /var/opt/nfast/kmdata/local folder, and the certificate (example_selfcert) to the /nsconfig/ssl folder on the ADC.

Add the key on the ADC

All the keys have a key-simple prefix. When adding the key to the ADC, use the ident as the HSM key name. For example, if the key that you added is key_simple_XXXX, the HSM key name is XXXX.

Important:

- The HSM key name must be the same as the ident that you specified when you converted an embed key to a simple key format.
- The keys must be present in the /var/opt/nfast/kmdata/local/ directory on the ADC.

Add an HSM key by using the CLI

At the shell prompt, run the following command:

```
1 add ssl hsmKey <hsmKeyName> -key <string>
```

Example:

```
1 add ssl hsmKey examplersa2048key -key key_simple_examplersa2048key
2 Done
```

Add an HSM key by using the GUI

Navigate to Traffic Management > SSL > HSM, and add an HSM key.

Add a certificate-key pair on the ADC

For information about certificate-key pairs, see Add or update a certificate-key pair.

Add a certificate-key pair by using the CLI

At the command prompt, run the following command:

```
1 add ssl certKey <certKeyName> -cert <string> -hsmKey <string>
```
Example:
```
1  add ssl certKey key22 -cert example_selfcert -hsmKey examplersa2048key
2  Done
```

**Add a certificate-key pair by using the GUI**

Navigate to Traffic Management > SSL > Certificates, and add a certificate-key pair.

**Add a virtual server**

For information about a virtual server, see

SSL virtual server configuration.

**Configure an SSL-based virtual server by using the CLI**

At the command prompt, run the following command:
```
1  add lb vserver <name> <serviceType> <IPAddress> <port>
```

Example:
```
1  add lb vserver v1 SSL 192.168.17.252 443
```

**Configure an SSL-based virtual server by using the GUI**

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

**Add a server object**

Before you can add a server object on the ADC, make sure that you have created a backend server. The following example uses the built-in python HTTP Server module on a Linux system.

Example:
```
1  %python -m SimpleHTTPServer 80
```
Add a server object by using the CLI

At the command prompt, run the following command:

```
add server <name> <IPAddress>
```

Example:

```
add server s1 192.168.17.246
```

Add a server object by using the GUI

Navigate to Traffic Management > Load Balancing > Servers, and add a server.

Add a service

For more information, see Configuring services.

Configure a service by using the CLI

At the command prompt, run the following command:

```
add service <name> <serverName> <serviceType> <port>
```

Example:

```
add service srl s1 HTTP 80
```

Configure a service by using the GUI

Navigate to Traffic Management > Load Balancing > Services, and create a service.

Bind the service to the virtual server

For more information, see Bind services to the SSL virtual server.
Bind a service to a virtual server by using the CLI

At the command prompt, run the following command:

```
binding lb vserver <name> <serviceName>
```

**Example:**

```
binding lb vserver v1 srv1
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the Services pane to bind a service to the virtual server.

Bind the certificate-key pair to the virtual server on the ADC

For more information, see **Bind the certificate-key pair to the SSL virtual server**.

Bind a certificate-key pair to a virtual server by using the CLI

At the command prompt, run the following command:

```
binding ssl vserver <vServerName> -certkeyName <string>
```

**Example:**

```
binding ssl vserver v1 -certkeyName key22
```

**Warning:** Current certificate replaces the previous binding

Bind a certificate-key pair to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open an SSL virtual server and, in **Advanced Settings**, click **SSL Certificate**.
3. Bind a server certificate to the virtual server.

Verify the configuration

**To view the configuration by using the CLI:**

At the command prompt, run the following commands:
1 show lb vserver <name>
2 show ssl vserver <vServerName>

Example:

1 show lb vserver v1
   v1 (192.168.17.252:443) - SSL  Type: ADDRESS
   State: UP
   Last state change was at Wed Oct 29 03:11:11 2014
   Time since last state change: 0 days, 00:01:25.220
   Effective State: UP
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Appflow logging: ENABLED
   No. of Bound Services : 1 (Total) 1 (Active)
   Configured Method: LEASTCONNECTION
   Current Method: Round Robin, Reason: Bound service’s state changed to UP
   Mode: IP
   Persistence: NONE
   Vserver IP and Port insertion: OFF
   Push: DISABLED  Push VServer:
   Push Multi Clients: NO
   Push Label Rule: none
   L2Conn: OFF
   Skip Persistency: None
   IcmpResponse: PASSIVE
   RHIsate: PASSIVE
   New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
   Mac mode Retain Vlan: DISABLED
   DBS_LB: DISABLED
   Process Local: DISABLED
   Traffic Domain: 0

1) sr1 (192.168.17.246:80) - HTTP State: UP  Weight: 1

Done

1 sh ssl vserver v1
   Advanced SSL configuration for VServer v1:
   DH: DISABLED
   Ephemeral RSA: ENABLED  Refresh Count: 0
   Session Reuse: ENABLED  Timeout: 120 seconds
To view the configuration by using the GUI:

Navigate to Traffic Management > Load Balancing > Virtual Servers, and double-click an SSL virtual server to open it and view the configuration.

Limitations

April 23, 2019

- SSL version 3 (SSLv3) is not supported on an MPX appliance but is supported on a VPX virtual appliance. A VPX instance provisioned on an SDX appliance supports SSLv3 only if an SSL chip is not assigned to the instance.
- Export ciphers are not supported.
- SSL server key exchange using HSM keys is not supported.
- If you have added or removed keys after you last saved the configuration, you must save the configuration before you perform a warm restart. If you do not save the configuration, there will be a key mismatch between the ADC and the HSM.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot bind a certificate-key pair that is created by using an HSM key to an SSL service.
- You cannot use the GUI to enroll the ADC as a client of the HSM or check the status of the HSM from the configuration utility.
• From release 11 build 62.x, SSL renegotiation is supported.
• You cannot sign OCSP requests by using a certificate-key pair that is created by using an HSM key.
• A certificate bundle with HSM keys is not supported.
• An error does not appear if the HSM key and certificate do not match. Therefore, while adding a certificate-key pair, you need to make sure that the HSM key and certificate match.
• Clustering and admin partitions are not supported.

Appendix

Support for Gemalto SafeNet Network hardware security module

May 10, 2019

A non-FIPS Citrix ADC appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted with special FIPS approved ciphers.

Only the Citrix ADC MPX 9700/10500/12500/15500 FIPS appliances and the MPX/SDX 14000 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX/SDX appliances, or on the Citrix ADC VPX appliances. This limitation is addressed by supporting a SafeNet network HSM on all Citrix ADC MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS and the MPX/SDX 14000 FIPS appliances.

A SafeNet network HSM is designed to protect critical cryptographic keys and to accelerate sensitive cryptographic operations across a wide range of security applications.
**Supported versions matrix**

<table>
<thead>
<tr>
<th>Citrix ADC Version</th>
<th>Software Appliance Version</th>
<th>Firmware Version</th>

</tbody>
</table>

**Prerequisites**

April 23, 2019

Before you can use a SafeNet network HSM with a Citrix ADC, make sure that the following prerequisites are met:

- A SafeNet network HSM is installed in the network, ready to use, and accessible to the Citrix ADC. That is, the NSIP address is added as an authorized client on the HSM.
- Licenses are available to support the required number of partitions on the HSM.
- The SafeNet network HSM and the Citrix ADC can initiate connections with each other through port 1792.
- You are using NetScaler release 11.1 or later.
- The Citrix ADC appliance does not contain a FIPS Cavium card.

**Important**

SafeNet network HSMs are not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

**Configure a SafeNet client on the ADC**

May 10, 2019

After you have configured the SafeNet HSM and created the required partitions, you must create clients and assign them to partitions. Begin by configuring the SafeNet clients on the Citrix ADC and setting up the network trust links (NTLs) between the SafeNet clients and the SafeNet HSM. A sample configuration is given in the Appendix.

1. Change directory to /var/safenet and install the Safenet client. At the shell prompt, type:
To install Safenet client version 6.0.0, type:

```
install_client.sh -v 600
```

To install Safenet client version 6.2.2, type:

```
install_client.sh -v 622
```

To install Safenet client version 7.2.2, type:

```
install_client.sh -v 722
```

2. Configure the NTLs between SafeNet client (ADC) and HSM.

After the ‘/var/safenet/’ directory is created, perform the following tasks on the ADC.

a) Change directory to ‘/var/safenet/config/’ and run the ‘safenet_config’ script. At the shell prompt,
type:

```
sh safenet_config
```

This script copies the “Chrystoki.conf” file into the /etc/ directory. It also generates a symbolic link ‘libCryptoki2_64.so’ in the ‘/usr/lib/’ directory.

b) Create and transfer a certificate and key between the ADC and the SafeNet HSM.

In order to communicate securely, the ADC and the HSM must exchange certificates. Create a certificate and key on the ADC and then transfer it to the HSM. Copy the HSM certificate to the ADC.

i) Change directory to /var/safenet/safenet/lunaclient/bin.

ii) Create a certificate on the ADC. At the shell prompt, type:

```
vtl createCert -n <ip address of Citrix ADC>
```

This command also adds the certificate and key path to the “/etc/Chrystoki.conf” file.

iii) Copy this certificate to the HSM. At the shell prompt, type:

```
scp /var/safenet/safenet/lunaclient/cert/client/<ip address of NS>.pem
<LunaSA_HSM account>@<IP address of Luna SA>
```

iv) Copy the HSM certificate to the Citrix ADC. At the shell prompt, type:
To list the HSM servers configured on the ADC, type:

```
./vtl listServer
```

Note:

Before removing the HSM by using vtl, make sure all the keys for that HSM are manually removed from the appliance. HSM keys cannot be deleted after the HSM server is removed.
5) Verify the network trust links (NTLs) connectivity between the ADC and HSM. At the shell prompt, type:

```
1 ./vtl verify
```

If verification fails, review all the steps. Errors are generally due to an incorrect IP address in the client certificates.

6) Save the configuration.

The above steps update the “/etc/Chrystoki.conf” configuration file. This file is deleted when the ADC is started. Copy the configuration to the default configuration file, which is used when an ADC is restarted.

At the shell prompt, type:

```
1 root@ns# cp /etc/Chrystoki.conf /var/safenet/config/
```

Recommended practice is to run this command every time there is a change to the SafeNet-related configuration.

7) Start the SafeNet gateway process.

At the shell prompt, type:

```
1 sh /var/safenet/gateway/start_safenet_gw
```

8) Configure automatic start of the gateway daemon at boot time.

Create the “safenet_is_enrolled” file, which indicates that SafeNet HSM is configured on this ADC. Whenever the ADC restarts and this file is found, the gateway is automatically started.

At the shell prompt, type:

```
1 touch /var/safenet/safenet_is_enrolled
```

## Configure Safenet HSMs in a high availability setup on the ADC

May 8, 2019

Configuring SafeNet HSMs in a high availability (HA) ensures uninterrupted service even if all but one of the devices are unavailable. In an HA setup, each HSM joins an HA group in active-active mode. SafeNet HSMs in an HA setup provide load balancing of all the group members to increase performance and response time while providing the assurance of high availability service. For more information, contact SafeNet Sales and Support.
Prerequisites:

• Minimum two SafeNet HSM devices. All the devices in an HA group must have either PED (trusted path) authentication or password authentication. A combination of trusted path authentication and password authentication in an HA group is not supported.
• Partitions on each HSM device must have the same password even if the label (name) is different.
• All partitions in HA must be assigned to the client (Citrix ADC appliance).

After configuring a SafeNet client on the ADC as described in Configure a SafeNet client on the ADC, perform the following steps to configure Safenet HSMs in HA:

1. On the Citrix ADC shell prompt, launch “lunacm” (/usr/safenet/lunaclient/bin)

Example:

```bash
root@ns# cd /var/safenet/safenet/lunaclient/bin/
root@ns# ./lunacm
```

2. Identify the slot IDs of the partitions. To list the available slots (partitions), type:

Example:

```bash
lunacm:> slot list
```

<table>
<thead>
<tr>
<th>Slot Id</th>
<th>HSM Label</th>
<th>HSM Serial Number</th>
<th>HSM Model</th>
<th>HSM Firmware Version</th>
<th>HSM Configuration</th>
<th>HSM Status</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

3. Create the HA group. The first partition is called the primary partition. You can add more than one secondary partitions.

```
lunacm:> hagroup createGroup -slot <slot number of primary partition> -label <group name> -password <partition password>
lunacm:> hagroup createGroup -slot 1 -label gp12 -password ******
```

4. Add the secondary members (HSM partitions). Repeat this step for all partitions to be added to the
HA group.

```
lunacm:> hagroup addMember -slot <slot number of secondary partition to be added> -group <group name> -password <partition password>
```

**Code:**

```
lunacm:> hagroup addMember -slot 2 -group gp12 -password ******
```

5. Enable HA only mode.

```
lunacm:> hagroup HAOnly - enable
```

6. Enable active recovery mode.

```
lunacm:> hagroup recoveryMode - mode active
```

7. Set auto recovery interval time (in seconds). Default is 60 seconds.

```
lunacm:> hagroup interval - interval <value in seconds>
```

**Example:**

```
lunacm:> hagroup interval - interval 120
```

8. Set recovery retry count. A value of -1 allows infinite number of retries.

```
lunacm:> hagroup retry - count <xxx>
```

**Example:**

```
lunacm:> hagroup retry - count 2
```

9. Copy the configuration from Chrystoki.conf to the Safenet configuration directory.

```
cp /etc/Chrystoki.conf /var/safenet/config/
```

10. Restart the ADC appliance.

```
reboot
```

After configuring SafeNet HSM in HA, see Additional ADC configuration for further configuration on the ADC.
Additional ADC configuration

April 23, 2019

1) Generate a key on the HSM.
   Use third party tools to create keys on the HSM.

2) Add an HSM key on the ADC.
   **Important!**: The # character is not supported in a key name. If the key name include this character, the load key operation fails.

**To add a Safenet HSM key by using the CLI:**

At the command prompt, type:

```
add ssl hsmkey <KeyName> -hsmType SAFENET -serialNum <serial #> -password
```

where:
- **KeyName** is the key created on the HSM by using third party tools.
- **serialNum** is the serial number of the partition on the HSM on which the keys are generated.

**Note:** For HSM in a high availability setup, use the serial number of the high availability group.
- **password** is the password of the partition on which the keys are present.

**To add a Safenet HSM key by using the GUI:**

Navigate to **Traffic Management > SSL > HSM** and add an HSM key. You must specify the HSM Type as **SAFENET**.

3) Add a certificate-key pair on the ADC. You must first use a third party tool to generate a certificate associated with the key. Then, copy the certificate to the /nsconfig/ssl/ directory on the ADC.

**Note:** The key must be an HSM key.

**To add a certkey pair on the ADC by using the CLI:**

At the command prompt, type:

```
add ssl certkey <CertkeyName> -cert <cert name> -hsmkey <KeyName>
```

**To add a certkey pair on the ADC by using the GUI:**

1. Navigate to **Traffic Management > SSL**.
2. In **Getting Started**, select **Install Certificate (HSM)** and create a certificate-key pair using an HSM key.
4) Create a virtual server and bind the certificate-key pair to this virtual server.
For information about creating a virtual server, click SSL virtual server configuration.
For information about adding a certificate-key pair, click Add or update a certificate-key pair.
For information about binding a certificate-key pair to an SSL virtual server, click Bind the certificate-key pair to the SSL virtual server.

**Citrix ADC appliances in a high availability setup**

April 23, 2019

You can configure a high availability (HA) setup on the Citrix ADC appliances with a SafeNet HSM configuration in either of the following two ways:

- First, configure a SafeNet HSM on the two nodes, using the same HSM and partition. Then create an HA pair. Finally, add the Citrix ADC configuration, such as keys, certificate-key pairs, and virtual servers, on the primary node.
- If a SafeNet HSM is already configured on one node with the Citrix ADC configuration, add a similar configuration on the other node. Copy “/var/safenet/sfgw_ident_file” from the first node to the other and restart the safenet_gw binary. After the gateway is up and running, add the nodes in an HA setup.

**Limitations**

May 10, 2019

1. For any changes to the HSM-related configuration in an existing setup, such as adding or removing an HSM, or creating a high availability setup, you must copy ‘/etc/Chrystoki.conf’ to ‘/var/safenet/config’.

2. After adding, removing, or restarting an HSM, you must restart the ‘/var/safenet/gateway/safenet_gw’ binary. If you don’t restart the gateway binary, the HSM will not serve any traffic after it is added back or after it restarts.

3. To reboot or stop the current ‘/var/safenet/gateway/safenet_gw’ binary, use

```
1  kill -SIGTERM <PID>
2  kill -SIGINT  <PID>
```
Important! Do not use *kill* -9 <PID> or *kill* -6 <PID>

4. Before removing an existing HSM from the ADC, remove, from the ADC, all the keys and certificate-key pairs that are associated with that HSM. You cannot delete these files from the ADC after you remove the HSM.

5. On a standalone Citrix ADC appliance, SafeNet HSMs in HA are supported for Luna version 6.2 and later.

6. EXPORT ciphers are not supported.

7. Update certificate-key pair operation is not supported.

8. When you generate an HSM key on a third-party tool, the private and public key names must be the same. When you add the HSM key on the appliance, provide this name as the key name.

9. The # character is not supported in a key name.

10. Cluster and admin partitions are not supported.

Appendix

April 23, 2019

Sample commands with their outputs are given below.

**Run the script**

```bash
1    root@ns# pwd
2    /var/safenet/config
3    root@ns# sh safenet_config
```

**Create a certificate**

```bash
1    root@ns# cd /var/safenet/safenet/lunaclient/bin
2    root@ns# ./vtl createcert -n 10.102.59.175
3    Private Key created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175Key.pem
4    Certificate created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175.pem
```
Copy the certificate to the HSM

```
rroot@ns# scp /var/safenet/safenet/lunaclient/cert/client
     /10.102.59.175.pem admin@10.217.2.7:
admin@10.217.2.7's password:
10.102.59.175.pem    100%  818   0.8KB/s   00:00
```

Copy the certificate and key from the HSM to the Citrix ADC appliance

```
rroot@ns# scp admin@10.217.2.7:server.pem /var/safenet/safenet/
lunaclient/server.2.7.pem
admin@10.217.2.7's password:
server.pem     100% 1164   1.1KB/s   00:01
```

Use SSH to connect to the SafeNet HSM

```
ssh admin@10.217.2.7
Connecting to 10.217.2.7:22...
Connection established.
To escape to local shell, press 'Ctrl+Alt+]'.

Last login: Thu Jun 23 02:20:29 2016 from 10.252.243.11

[Safenet1] lunash:>hsm login

Please enter the HSM Administrators’ password:
> ******

'hsm login’ successful.

Command Result : 0 (Success)
[Safenet1] lunash:>
Register the Citrix ADC on the SafeNet HSM

```bash
[Safenet1] lunash:>client register -client ns175 -ip 10.102.59.175
'client register' successful.
Command Result : 0 (Success)
[Safenet1] lunash:
```

Assign the client a partition from the partition list

```bash
[Safenet1] lunash:>client assignPartition -client ns175 -partition p2
'client assignPartition' successful.
Command Result : 0 (Success)
[Safenet1] lunash:
```

Register the HSM with its certificate on the Citrix ADC

```bash
root@ns# ./vtl addserver -n 10.217.2.7 -c /var/safenet/safenet/lunaclient/server.2.7.pem
New server 10.217.2.7 successfully added to server list.
```

Verify the network trust links (NTLs) connectivity between the ADC and HSM

```bash
root@ns# ./vtl verify
The following Luna SA Slots/Partitions were found:

<table>
<thead>
<tr>
<th>Slot</th>
<th>Serial #</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>477877010</td>
<td>p2</td>
</tr>
</tbody>
</table>
```
Save the configuration

```bash
root@ns# cp /etc/Chrystoki.conf /var/safenet/config/
```

Configure automatic start of the gateway daemon at boot time

```bash
touch /var/safenet/safenet_is_enrolled
```

FAQ

April 23, 2019

- **How do I check that the SafeNet process is running?**
  
  At the Citrix ADC shell prompt, type:

  ```bash
  ps -aux | grep safenet_gw
  ```

- **How do I verify the network trust links (NTLs) connectivity between the ADC and HSM?**

  After configuring SafeNet, change directory to “/var/safenet/safenet/lunaclient/bin” and type:

  ```bash
  ./vtl verify
  ```

Support for Azure Key Vault

September 12, 2019

The Citrix ADC appliance integrates with external HSMs (SafeNet and Thales) for on premises deployments. For cloud deployments, the ADC appliance integrates with Azure Key Vault. The appliance stores its private keys in the Key Vault for ease of management and security of the private key in the public cloud domain. You no longer have to store and manage keys in different locations for ADC appliances deployed across multiple data centers and cloud providers.

Using ADC with the Azure Key Vault Premium pricing tier, which provided HSM backed keys, provides FIPS 140-2 level 2 compliance.

Azure Key Vault is a standard offering from Microsoft. For more information about Azure Key Vault, see the Microsoft Azure documentation.
**Note:** The Citrix ADC integration with Azure Key Vault is supported with TLS 1.3 protocol.

**Architecture overview**

Azure Key Vault is a service for storing secrets securely in the Azure cloud. By storing your keys in Azure Key Vault, you reduce the chances of keys being stolen. Once the Key Vault is set up, you can store your keys in it. Configure virtual servers on the ADC appliance to perform private key operations in the Key Vault. The ADC appliance accesses the key for each SSL handshake.

The following diagram illustrates the process to get an access token from the Azure Active Directory after authentication. This token is used with REST API calls for crypto operations using private keys.

The following diagram shows a typical RSA handshake. The client key exchange (CKE) message that is encrypted using the public key is decrypted using the private key stored in the Key Vault.

In an ECDHE handshake, the server key exchange (SKE) message sent by the Citrix ADC appliance is signed by using the private key stored in the Key Vault.

**Prerequisites**

1. You must have an Azure subscription.
3. Complete the configuration on the Azure portal before configuring entities on the ADC appliance.

**Configure the ADC Azure Key Vault integration**

First perform the configuration on the Azure portal followed by configuration on the ADC appliance.

**Perform the following steps on the Azure portal**

The following flowchart shows the high-level flow for configuration required on the Azure portal.

1. Create app and service principal in Azure Active Directory.
2. Create Key Vault in a resource group.
3. Configure the app and service principal to perform sign and decrypt operations on the Key Vault.
4. Create keys in Key Vault using one of the following ways:
   a) By importing a key file.
b) By generating a certificate.

For information about the commands to configure the preceding steps, see the Azure documentation at https://docs.microsoft.com/en-us/azure/active-directory/develop/app-objects-and-service-principals.

Perform the following steps on the ADC appliance

The following flowchart shows the high-level flow for configuration required on the ADC appliance.

1. Configure a DNS server.
2. Configure root certificates to verify the certificates presented by Azure.
3. Create an Azure application.
4. Create Azure Key Vault entity.
5. Create HSM key.
6. Create a certificate-key pair.
7. Bind the certificate-key pair to a virtual server.

Configure a DNS server

A DNS server is required for the name resolution of Key Vault host and Azure Active Directory end point.

To configure a DNS server by using the CLI

At the command prompt, type:

```
1 add dns nameserver <IP address>
```

Example:

```
1 add dns nameserver 192.0.2.150
```

To configure a DNS server by using the GUI

1. Navigate to Traffic Management > DNS > Name Servers. Click Add.

2. Enter values for the following parameters:

   - **IP Address** - IP address of an external name server or, if the Local parameter is set, IP address of a local DNS server (LDNS).
   - **Protocol** - Protocol used by the name server. UDP_TCP is not valid if the name server is a DNS virtual server configured on the appliance.

3. Click Create.
**Add and bind a root certificate**

Download the root certificates of the certificate presented by Azure Key Vault [https://<vault_name>.vault.azure.net](https://<vault_name>.vault.azure.net) and Azure Active Directory (AAD) [https://login.microsoftonline.com](https://login.microsoftonline.com) and load it on the ADC appliance. These certificates are required to validate the certificate presented by Azure Key Vault and AAD. Bind one or more certificates to the CA certificate group `ns_callout_certs`.

To add a root certificate by using the CLI

At the command prompt, type:

```
1 add ssl certkey <certkeyname> -cert <certname>
2 bind ssl caCertGroup <caCertGroupName> <certkeyName>
```

**Example:**

In the following example, the root certificate presented by Azure Key Vault and AAD is the same.

```
1 add ssl certKey rootcert -cert RootCyberTrustRoot.crt
2 bind ssl cacertGroup ns_callout_certs rootcert
```

To add a root certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates** > **CA Certificates**.
2. Enter values for the following parameters:
   - Certificate-key pair name
   - Certificate file name
3. Click **Install**.
4. Navigate to **Traffic Management > SSL > CA Certificates Group**.
5. Select **ns_callout_certs** and click **Show Bindings**.
6. Click **Bind**.
7. Select the CA certificate created earlier and click **Select**.
8. Click **Bind**, and then click **Close**.

**Configure an Azure application**

The Azure application entity contains the credentials required to authenticate to Azure Active Directory and obtain the access token. That is, to get authorization access to Key Vault resources and APIs, add the Azure Application ID, secret (password) and tenant ID on the ADC appliance.

When configuring the Azure Application entity using the CLI, you must enter the password. If you use
the GUI, the Azure application entity contains the credentials required to authenticate to Azure Active Directory and obtain the access token.

To configure an Azure application by using the CLI

At the command prompt, type:

```
1 add azure application <name> -clientID <string> -clientSecret -tenantID <string> [-tokenEndpoint <URL>]
2 show azure application
```

Example:

```
1 add azure application app1 -clientID 12345t23aaa5 -clientsecret csHz0oEzmuY -tenantID 33583ee9ca5b
2 Done
3 sh azure application
4 1) Name: app1
5 2) ClientID: 12345t23aaa5
6 3) TokenEndpoint: "https://login.microsoftonline.com/33583ee9ca5b/"
7 4) TenantID: 33583ee9ca5b
8 Done
```

To configure an Azure application by using the GUI

1. Navigate to Traffic Management > SSL > Azure > Application.
2. In the details pane, click Add.
3. Enter values for the following parameters:
   - Name – Name for the application object on the Citrix ADC appliance.
   - Client ID – Application ID that is generated when an application is created in Azure Active Directory using either the Azure CLI or the Azure portal (GUI).
   - Client Secret – Password for the application configured in Azure Active Directory. The password is specified in the Azure CLI or generated in the Azure portal (GUI).
   - Tenant ID – ID of the directory inside Azure Active Directory in which the application was created.
   - Token Endpoint – URL from where the access token can be obtained. If the token endpoint is not specified, the default value is `https://login.microsoftonline.com/<tenant id>`.

**Configure Azure Key Vault**

Create an Azure Key Vault object on the ADC appliance.
To configure Azure Key Vault by using the CLI

At the command prompt, type:

```
1  add azure keyVault <name> -azureVaultName <string> -azureApplication <string>
2     show azure keyVault
```

Example:

```
1  add azure keyvault kv1 -azureapplication app1 -azurevaultName nsssltestvault3
2  show azure keyVault
3  1) Name:   kv1               AzureVaultName:  SSLDevTest
4     AzureApplication: app1  State:  "Access token obtained"
5  Done
```

The following table lists the different values that the state of Azure Key Vault can take along with a brief description about each state.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Initial state of the Key Vault object. Authentication has not been attempted.</td>
</tr>
<tr>
<td>Could not reach token end point</td>
<td>Indicates one of the following: DNS server not configured, issuer certificate not bound to a CA certificate group, or network issues.</td>
</tr>
<tr>
<td>Authorization failed</td>
<td>Incorrect application credentials.</td>
</tr>
<tr>
<td>Token parse error</td>
<td>Response from Azure Active Directory is not in the expected format.</td>
</tr>
<tr>
<td>Access token obtained</td>
<td>Successfully authenticated by Azure Active Directory.</td>
</tr>
</tbody>
</table>

To configure Azure Key Vault by using the GUI

1. Navigate to **Traffic Management > SSL > Azure > Key Vault**.

2. Enter values for the following parameters:

   - **Name** - Name for the Key Vault.
   - **Azure Key Vault Name** - Name of the Key Vault configured in Azure cloud using either the Azure CLI or the Azure portal (GUI).
   - **Azure Application Name** - Name of the Azure Application object created on the ADC appli-
The Azure Application object with this name is used for authentication with Azure Active Directory.

**Add HSM key**

Storing your private key in the HSM provides FIPS 140-2 level 2 compliance.

To add an HSM key by using the CLI

At the command prompt, type:

```
1 add ssl hsmKey <hsmKeyName> [-hsmType <hsmType>] [-key <string> | -serialNum <string>] { -password } [-keystore <string>]
```

**Example:**

```
1 add ssl hsmKey h1 -keystore kv1 -key san15key -hsmType KEYVAULT
2
3 > sh ssl hsmKey h1
4    HSM Key Name: h1                  Type: KEYVAULT
5    Key: san15key
6    Key store: kv1
7    State: "Created"
8 Done
```

The following table lists the different values that the state of an HSM key can take along with a brief description about each state.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>The HSM key is added on the ADC appliance. A key operation is not yet attempted.</td>
</tr>
<tr>
<td>Access token unavailable</td>
<td>Access token not available when key operation was attempted.</td>
</tr>
<tr>
<td>Unauthorized</td>
<td>Configured Azure application does not have permission to perform the key operation.</td>
</tr>
<tr>
<td>Does not exist</td>
<td>The key does not exist in the Azure Key Vault.</td>
</tr>
<tr>
<td>Unreachable</td>
<td>The Key Vault host is not reachable on the network.</td>
</tr>
</tbody>
</table>
State Description

Marked down The HSM key is marked DOWN on the ADC appliance due to threshold errors during key operation.

Key operations successful Success response received from the Key Vault for key operation.

Key operations failed Failure response received from Key Vault for key operation.

Key operation throttled The key operation request is throttled by the Key Vault.

To add an HSM key by using the GUI

1. Navigate to Traffic Management > SSL > HSM.

2. Enter values for the following parameters.
   - HSM key name - Name of the key.
   - HSM type - Type of HSM.
   - Key store - Name of key store object representing HSM where the key is stored. For example, name of Key Vault object or Azure Key Vault authentication object. Applies only to KEYVAULT type HSM.

3. Click Add

Add a certificate-key pair

Add a certificate-key pair using the HSM key created earlier.

To add a certificate-key pair by using the CLI

At the command prompt, type:

```
1 add ssl certKey <certkeyName> (-cert <string> [-password]) -hsmKey <string>
2 show ssl certkey
```

Example:

```
1 add ssl certKey serverrsa_2048 -cert /nsconfig/ssl/san_certs/san15.pem -hsmKey h1
2 > sh ssl certkey serverrsa_2048
```
To add a certificate-key pair by using the GUI

1. Navigate to Traffic Management > SSL > Install Certificate (HSM).

2. Enter values for the following parameters:
   - Certificate-Key Pair Name
   - Certificate File Name
   - HSM Key

3. Click Install.

Bind the certificate-key pair to a virtual server

The certificate used for processing SSL transactions must be bound to the virtual server that receives the SSL data.

To bind the SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
show ssl vserver <vServerName>
```

Example:

```
bind ssl vserver v1 -certkeyName serverrsa_2048
sh ssl vserver v1
Advanced SSL configuration for VServer v1:
```
To bind an SSL certificate-key pair to a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and open an SSL virtual server. Click inside the Certificate section.

2. Click the arrow to select the certificate-key pair.

3. Select the certificate-key pair from the list.

4. Bind the certificate-key pair to the virtual server.
Limitations

- The number of concurrent calls to Azure Key Vault for key operations is limited. Performance of the ADC appliance depends on the Key Vault limits. For Azure Key Vault service limits, see https://docs.microsoft.com/en-us/azure/key-vault/key-vault-service-limits.
- EC keys are not supported.
- EDT and DTLS protocols are not supported.
- ADC appliances with Intel Coleto SSL chips are not supported.
- Clustering and admin partitions are not supported.
- You cannot update the Azure Application entity, Azure Key Vault object, and the HSM certificate-key pair after you have added them to the ADC appliance.

FAQ

When integrated with Azure Key Vault, are private keys stored in the ADC appliance memory?

No, private keys are not be stored in ADC appliance memory. For each SSL transaction, the appliance sends a request to Key Vault.

Is the integration FIPS 140-2 level 2 complaint?

Yes, the integrated solution provides FIPS 140-2 Level 2 support.

Which key types are supported?

Only RSA key types are supported.

What key sizes are supported?

1024-bit, 2048-bit, and 4096-bit RSA keys are supported.

Which ciphers are supported?

All ciphers supported on the ADC appliance, including TLSv1.3 ciphers with ECDHE and SHA256 are supported.
Are transactions logged?

The ADC appliance logs each transaction it makes with the Key Vault. Details such as, time, vault IP address, port, success or failure of connection, and errors are logged. The following is a sample SSL log output.

```
1 Apr 9 16:35:30 <local0.debug> 10.102.57.30 04/09/2019:16:35:30 GMT 0-PPE-0 : default SSLLOG SSL_HANDSHAKE_SUCCESS 896 0 :
  Backend SPCHId 30894 - ServerIP 104.211.224.186 - ServerPort 443

Troubleshooting

September 12, 2019

If the SSL feature does not work as expected after configuration, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

For best results, use the following resources to troubleshoot an SSL issue on a Citrix ADC appliance:

- The relevant ns.log file
- The latest ns.conf file
- The messages file
- The relevant newnslog file
- Trace files
- A copy of the certificate files, if possible
- A copy of the key file, if possible
The error message, if any

In addition to these resources, you can use the Wireshark application customized for the Citrix ADC trace files to expedite troubleshooting.

Troubleshooting SSL issues

To troubleshoot an SSL issue, proceed as follows:

• Verify that the Citrix ADC appliance is licensed for SSL Offloading and load balancing.
• Verify that SSL Offloading and load balancing features are enabled on the appliance.
• Verify that the status of the SSL virtual server is not displayed as DOWN.
• Verify that the status of the service bound to the virtual server is not displayed as DOWN.
• Verify that a valid certificate is bound to the virtual server.
• Verify that the service is using an appropriate port, preferably port 443.

Decrypting TLS1.3 traffic from packet trace

To troubleshoot protocols that run over TLS1.3, you must first decrypt the TLS1.3 traffic. To decrypt TLS 1.3 in Wireshark, the secrets must be exported in the NSS key log format. For more information about the key log format, see NSS Key Log Format.

For information about how to capture a packet trace, see Capturing SSL Session Keys During a Trace.

Note: Citrix ADC automatically logs each connection’s secrets in the appropriate format for the TLS/SSL protocol version in use.

CRL refresh does not happen on the secondary node in an HA setup

The refresh does not happen because the CRL server is accessible only to the primary node through a private network.

Workaround: Add a service on the primary node with the IP address of the CRL server. This service acts as a proxy for the CRL server. When the configuration is synchronized between the nodes, CRL refresh works for both primary and secondary nodes through the service configured on the primary node.

SSL FAQs

July 29, 2019
Basic questions

HTTPS access to the GUI fails on a VPX instance. How do I gain access?

A certificate-key pair is required for HTTPS access to the GUI. On a Citrix ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Citrix recommends that you install a certificate-key pair of at least 1024 bytes and bind it to the internal service for HTTPS access to the configuration utility or update the ns-server-certificate to 1024 bytes. You can use HTTP access to the configuration utility or the CLI to install the certificate.

If I add a license to an MPX appliance, the certificate-key pair binding is lost. How do I resolve this problem?

If a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding. You must reinstall the certificate and bind it to the internal service

Citrix recommends that you install an appropriate license before starting the appliance.

What are the various steps involved in setting up a secure channel for an SSL transaction?

Setting up a secure channel for an SSL transaction involves the following steps:

1. The client sends an HTTPS request for a secure channel to the server.
2. After selecting the protocol and cipher, the server sends its certificate to the client.
3. The client checks the authenticity of the server certificate.
4. If any of the checks fail, the client displays the corresponding feedback.
5. If the checks pass or the client decides to continue even if a check fails, the client creates a temporary, disposable key called the pre-master secret and encrypts it by using the public key of the server certificate.
6. The server, upon receiving the pre-master secret, decrypts it by using the server’s private key and generates the session keys. The client also generates the session keys from the pre-master secret. Thus both client and server now have a common session key, which is used for encryption and decryption of application data.
I understand that SSL is a CPU-intensive process. What is the CPU cost associated with the SSL process?

The following two stages are associated with the SSL process:

- The initial handshake and secure channel setup by using the public and private key technology.
- Bulk data encryption by using the asymmetric key technology.

Both of the preceding stages can affect server performance, and they require intensive CPU processing for the following reasons:

1. The initial handshake involves public-private key cryptography, which is very CPU intensive because of large key sizes (1024bit, 2048bit, 4096bit).
2. Encryption/decryption of data is also computationally expensive, depending on the amount of data that needs to be encrypted or decrypted.

What are the various entities of an SSL configuration?

An SSL configuration has the following entities:

- Server certificate
- Certificate Authority (CA) certificate
- Cipher suite that specifies the protocols for the following tasks:
  - Initial key exchange
  - Server and client authentication
  - Bulk encryption algorithm
  - Message authentication
- Client authentication
- CRL
- SSL Certificate Key Generation Tool that enables you to create the following files:
  - Certificate request
  - Self signed certificate
  - RSA and DSA keys
  - DH parameters

I want to use the SSL offloading feature of the Citrix ADC appliance. What are the various options for receiving an SSL certificate?

You must receive an SSL certificate before you can configure the SSL setup on the Citrix ADC appliance. You can use any of the following methods to receive an SSL certificate:

- Request a certificate from an authorized CA.
- Use the existing server certificate.
- Create a certificate-key pair on the Citrix ADC appliance.

**Note:** This is a test certificate signed by the test Root-CA generated by the Citrix ADC appliance. Test certificates signed by this Root-CA are not accepted by browsers. The browser throws a warning message stating that the server's certificate cannot be authenticated.
- For anything other than test purposes, you must provide a valid CA certificate and CA key to sign the server certificate.

**What are the minimum requirements for an SSL setup?**

The minimum requirements for configuring an SSL setup are as follows:
- Obtain the certificates and keys.
- Create a load balancing SSL virtual server.
- Bind HTTP or SSL services to the SSL virtual server.
- Bind certificate-key pair to the SSL virtual server.

**What are the limits for the various components of SSL?**

SSL components have the following limits:
- Bit size of SSL certificates: 4096.
- Number of SSL certificates: Depends on the available memory on the appliance.
- Maximum linked intermediate CA SSL certificates: 9 per chain.
- CRL revocations: Depends on the available memory on the appliance.

**What are the various steps involved in the end-to-end data encryption on a Citrix ADC appliance?**

The steps involved in the server-side encryption process on a Citrix ADC appliance are as follows:

1. The client connects to the SSL VIP configured on the Citrix ADC appliance at the secure site.
2. After receiving the secure request, the appliance decrypts the request, applies layer 4-7 content switching techniques and load balancing policies, and selects the best available backend Web server for the request.
3. The Citrix ADC appliance creates an SSL session with the selected server.
4. After establishing the SSL session, the appliance encrypts the client request and sends it to the Web server by using the secure SSL session.
5. When the appliance receives the encrypted response from the server, it decrypts and re-encrypts the data, and sends the data to the client by using the client side SSL session.

The multiplexing technique of the Citrix ADC appliance enables the appliance to reuse SSL sessions that have been established with the Web servers. Therefore, the appliance avoids the CPU intensive key exchange, known as *full handshake*. This process reduces the overall number of SSL sessions on the server and maintains end-to-end security.

**Certificates and Keys**

*Can I place the certificate and key files at any location? Is there any recommended location to store these files?*

You can store the certificate and key files on the Citrix ADC appliance or a local computer. However, Citrix recommends that you store the certificate and key files in the /nsconfig/ssl directory of the Citrix ADC appliance. The /etc directory exists in the flash memory of the Citrix ADC appliance. This provides portability and facilitates backup and restoration of the certificate files on the appliance.

**Note:** Make sure that the certificate and the key files are stored in the same directory.

**What is the maximum size of the certificate key supported on the Citrix ADC appliance?**

A Citrix ADC appliance running a software release earlier than release 9.0 supports a maximum certificate key size of 2048 bits. Release 9.0 and later support a maximum certificate key size of 4096 bits. This limit is applicable to both RSA and DSA certificates.

An MPX appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A virtual appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server from release 12.0-56.x. Older releases support 2048-bit certificates.
• 4096-bit client certificate (if client authentication is enabled on the virtual server) from release 12.0-56.x. Older releases support 2048-bit certificates.

**What is the maximum size of the DH parameter supported on the Citrix ADC appliance?**

The Citrix ADC appliance supports a DH parameter of maximum 2048 bits.

**What is the maximum certificate-chain length, that is, the maximum number of certificates in a chain, supported on a Citrix ADC appliance?**

A Citrix ADC appliance can send a maximum of 10 certificates in a chain when sending a server certificate message. A chain of the maximum length includes the server certificate and nine intermediate CA certificates.

**What are the various certificate and key formats supported on the Citrix ADC appliance?**

The Citrix ADC appliance supports the following certificate and key formats:

- Privacy Enhanced Mail (PEM)
- Distinguished Encoding Rule (DER)

**Is there a limit for the number of certificates and keys that I can install on the Citrix ADC appliance?**

No. The number of certificates and keys that can be installed is limited only by the available memory on the Citrix ADC appliance.

**I have saved the certificate and key files on the local computer. I want to transfer these files to the Citrix ADC appliance by using the FTP protocol. Is there any preferred mode for transferring these files to the Citrix ADC appliance?**

Yes. If using the FTP protocol, you should use binary mode to transfer the certificate and key files to the Citrix ADC appliance.

**Note:** By default, FTP is disabled. Citrix recommends using the SCP protocol for transferring certificate and key files. The configuration utility implicitly uses SCP to connect to the appliance.

**What is the default directory path for the certificate and key?**

The default directory path for the certificate and key is `/nsconfig/ssl`.
When adding a certificate and key pair, what happens if I do not specify an absolute path to the certificate and key files?

When adding a certificate and key pair, if you do not specify an absolute path to the certificate and key files, the Citrix ADC appliance searches the default directory, /nsconfig/ssl, for the specified files and attempts to load them to the kernel. For example, if the cert1024.pem and rsa1024.pem files are available in the /nsconfig/ssl directory of the appliance, both of the following commands are successful:

```
1 add ssl certKey cert1 -cert cert1024.pem -key rsa1024.pem
2 add ssl certKey cert1 -cert /nsconfig/ssl/cert1024.pem -key /nsconfig/ssl/rsa1024.pem
```

I have configured a high availability setup. I want to implement the SSL feature on the setup. How should I handle the certificate and key files in a high availability setup?

In a high availability setup, you must store the certificate and key files on both the primary and the secondary Citrix ADC appliance. The directory path for the certificate and key files must be the same on both appliances before you add an SSL certificate-key pair on the primary appliance.

**Thales nShield® HSM**

**When integrating with Thales nShield® HSM, do we have to keep in mind any specific configuration when adding the Citrix ADC appliance to HA?**

You must configure the same Thales device(s) on both the nodes in HA. Thales configuration commands don’t synchronize in HA. For information about the prerequisites for Thales nShield® HSM, see Prerequisites.

**Do we have to individually integrate both the appliances with Thales nShield® HSM and RFS? Do we need to do this before or after the HA setup?**

You can complete the integration before or after the HA setup. However, if the integration is done after the HA setup, the keys imported on the primary node prior to configuring the secondary node are not synced to the secondary node. Therefore, Citrix recommends Thales integration before the HA setup.
Do we have to import the key into both the primary and secondary Citrix ADC appliances, or are the keys synchronized from the primary node to the secondary node?

If Thales is integrated on both devices before forming the HA, the keys are automatically synchronized from RFS in the process of integration.

Given that the HSM is not on the Citrix ADC appliance, but on Thales, what happens to the keys and certificates when a node fails and is replaced?

If a node fails, it is possible to synchronize the keys and certificates to the new node, by first integrating Thales on the new node and then running the following commands:

1. `sync ha files ssl`
2. `force ha sync`

The certificates are synchronized and added if the keys are synchronized in the process of integrating Thales.

Ciphers

What is a NULL-Cipher?

Ciphers with no encryption are known as NULL-Ciphers. For example, NULL-MD5 is a NULL-Cipher.

Are the NULL-Ciphers enabled by default for an SSL VIP or an SSL service?

No. NULL-Ciphers are not enabled by default for an SSL VIP or an SSL service.

What is the procedure to remove NULL-Ciphers?

To remove the NULL-Ciphers from an SSL VIP, run the following command:

1. `bind ssl cipher <SSL_VIP> REM NULL`

To remove the NULL-Ciphers from an SSL Service, run the following command:

1. `bind ssl cipher <SSL_Service> REM NULL -service`
What are the various cipher aliases supported on the Citrix ADC appliance?

To list the cipher aliases supported on the appliance, at the command prompt, type:

```
sh cipher
```

What is the command to display all the predefined ciphers of the Citrix ADC appliance?

To display all the predefined ciphers of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher
```

What is the command to display the details of an individual cipher of the Citrix ADC appliance?

To display the details of an individual cipher of the Citrix ADC appliance, at the CLI, type:

```
show ssl cipher <Cipher_Name/Cipher_Alias_Name/Cipher_Group_Name>
```

Example:

```
show cipher SSL3-RC4-SHA
1) Cipher Name: SSL3-RC4-SHA
2) Description: SSLv3 Kx=RSA Au=RSA Enc=RC4(128)
3) Mac=SHA1
4) Done
```

What is the significance of adding the predefined ciphers of the Citrix ADC appliance?

Adding the predefined ciphers of the Citrix ADC appliance causes the NULL-Ciphers to get added to an SSL VIP or an SSL service.

Certificates

Is the distinguished name in a client certificate available for the length of the user session?

Yes. You can access the distinguished name of the client certificate in subsequent requests during the length of the user session, that is even after the SSL handshake is complete and the certificate is not sent again by the browser. To do this, use a variable and an assignment as detailed in the following sample configuration:

Example:
add ns variable v2 -type "text(100)"
add ns assignment a1 -variable "$v2" -set "CLIENT.SSL.CLIENT_CERT.SUBJECT.TYPECAST_NVLIST_T(=':','/').VALUE("CN")"
add rewrite action act1 insert_http_header subject "$v2" // example: to insert the distinguished name in the header
add rewrite policy pol1 true a1
add rewrite policy pol2 true act1
bind rewrite global pol1 1 next -type RES_DEFAULT
bind rewrite global pol2 2 next -type RES_DEFAULT
set rewrite param -undefAction RESET

Why do I need to bind the server certificate?

Binding the server certificates is the basic requirement for enabling the SSL configuration to process SSL transactions.

To bind the server certificate to an SSL VIP, at the CLI, type:

bind ssl vserver <vServerName> -certkeyName <cert_name>

To bind the server certificate to an SSL service, at the CLI, type:

bind ssl service <serviceName> -certkeyName <cert_name>

How many certificates can I bind to an SSL VIP or an SSL service?

On a Citrix ADC virtual appliance, you can bind a maximum of three certificates to an SSL VIP or an SSL service, one each of type RSA, ECDSA, and DSA. On a Citrix ADC MPX (N2) or MPX-FIPS appliance, if SNI is enabled, you can bind multiple server certificates of type RSA. If SNI is disabled, you can bind a maximum of one certificate of type RSA. On a Citrix ADC MPX (N3) and Citrix ADC MPX/SDX FIPS appliance, you can bind a maximum of two certificates to an SSL VIP or an SSL service, one each of type RSA and type ECDSA.

Note: DSA certificates are not supported on MPX or MPX-FIPS platforms.
Does SNI support Subject Alternative Name (SAN) certificates?

No. On a Citrix ADC appliance, SNI is not supported with a SAN extension certificate.

What happens if I unbind or overwrite a server certificate?

When you unbind or overwrite a server certificate, all the connections and SSL sessions created by using the existing certificate are terminated. When you overwrite an existing certificate, the following message appears:

```
ERROR:
Warning: Current certificate replaces the previous binding.
```

How do I install an intermediate certificate on Citrix ADC and link to a server certificate?

See the article at http://support.citrix.com/article/ctx114146 for information about installing an intermediate certificate.

Why am I getting a “resource already exists” error when I try to install a certificate on the Citrix ADC?

See the article at http://support.citrix.com/article/CTX117284 for instructions for resolving the “resource already exists” error.

I want to create a server certificate on a Citrix ADC appliance to test and evaluate the product. What is the procedure to create a server certificate?

Perform the following procedure to create a test certificate.

**Note:** A certificate created with this procedure cannot be used to authenticate all the users and browsers. After using the certificate for testing, you should obtain a server certificate signed by an authorized Root CA.

To create a self-signed server certificate:

1. To create a Root CA certificate, at the CLI, type:
2. Perform the following procedure to create a server certificate and sign it with the root CA certificate that you just created

a) To create the request and the key, at the CLI, type:

```
create ssl rsakey /nsconfig/ssl/test-server.key 1024
create ssl certreq /nsconfig/ssl/test-server.csr -keyfile /nsconfig/ssl/test-server.key
```

b) Enter the required information when prompted.

c) To create a serial-number file, at the CLI, type:

```
shell
# echo '01' > /nsconfig/ssl/serial.txt
# exit
```

d) To create a server certificate signed by the root CA certificate created in step 1, at the CLI, type:

```
create ssl cert /nsconfig/ssl/test-server.cer /nsconfig/ssl/test-server.csr SRVR_CERT -CAcert /nsconfig/ssl/test-ca.cer -CAkey /nsconfig/ssl/test-ca.key -CAserial /nsconfig/ssl/serial.txt
```

e) To create a Citrix ADC certkey, which is the in-memory object that holds the server certificate information for SSL handshakes and bulk encryption, at the CLI, type:

```
add ssl certkey test-certkey -cert /nsconfig/ssl/test-server.cer -key /nsconfig/ssl/test-server.key
```

f) To bind the certkey object to the SSL virtual server, at the CLI, type:
I have received a Citrix ADC appliance on which NetScaler software release 9.0 is installed. I have noticed an additional license file on the appliance. Is there any change in the licensing policy starting with NetScaler software release 9.0?

Yes. Starting with Citrix NetScaler software release 9.0, the appliance might not have a single license file. The number of license files depends on the Citrix ADC software release edition. For example, if you have installed the Advanced edition, you might need additional license files for the full functionality of the various features. However, if you have installed the Premium edition, the appliance has only one license file.

**How do I export the certificate from Internet Information Service (IIS)?**

There are many ways to do this, but by using the following method the appropriate certificate and private key for the Web site are exported. This procedure must be performed on the actual IIS server.

1. Open the Internet Information Services (IIS) Manager administration tool.
2. Expand the Web Sites node and locate the SSL-enabled Web site that you want to serve through the Citrix ADC appliance.
3. Right-click this Web site and click Properties.
4. Click the Directory Security tab and, in the Secure Communications section of the window, select the View Certificate box.
5. Click the Details tab, and then click Copy to File.
7. Select Yes, export the private key and click Next.
   **Note:** The private key MUST be exported for SSL Offload to work on the Citrix ADC.
8. Make sure that the Personal Information Exchange -PKCS #12 radio button is selected, and select only the Include all certificates in the certification path if possible check box. Click Next.
9. Enter a password and click Next.
10. Enter a file name and location, and then click Next. Give the file an extension of .PFX.
11. Click Finish.
How do I convert the PKCS#12 certificate and install it on the Citrix ADC?

1. Move the exported .PFX certificate file to a location from where it may be copied to the Citrix ADC (that is, to a machine that permits SSH access to the management interface of a Citrix ADC appliance). Copy the certificate to the appliance by using a secure copy utility such as SCP.

2. Access the BSD shell and convert the certificate (for example, cert.PFX) to .PEM format:

   ```
   root@ns# openssl pkcs12 -in cert.PFX -out cert.PEM
   ```

3. To make sure that the converted certificate is in correct x509 format, verify that the following command produces no error:

   ```
   root@ns# openssl x509 -in cert.PEM -text
   ```

4. Verify that the certificate file contains a private key. Begin by issuing the following command:

   ```
   root@ns# cat cert.PEM
   ```

   Verify that the output file includes an RSA PRIVATE KEY section.

   ```
   -----BEGIN RSA PRIVATE KEY-----
   Mkm^s9KM59023z/s...
   -----END RSA PRIVATE KEY-----
   ```

   The following is another example of an RSA PRIVATE KEY section:

   ```
   Bag Attributes
   1.3.6.1.4.1.311.17.2: <No Values>
   localKeyID: 01 00 00 00
   Microsoft CSP Name: Microsoft RSA SChannel Cryptographic Provider
   friendlyName:
   4b9cef4cc8c9b849ff5c662fd3e0ef7e_76267e3e-6183-4d45-886e-6e067297b38f
   Key Attributes
   X509v3 Key Usage: 10
   -----BEGIN RSA PRIVATE KEY-----
   Proc-Type: 4,ENCRYPTED
   DEK-Info: DES-EDE3-CBC, 43E7ACA5F4423968
   pZJ2SfsSVqMbRRf6ug37Clua5gY0Wld4frPIxFXyJquUHr3ildilW5ta3hbIaQ+Rg
   ... (more random characters)
   ```
The following is a SERVER CERTIFICATE section:

```
Bag Attributes
localKeyID: 01 00 00 00
friendlyName: AG Certificate
subject=/C=AU/ST=NSW/L=Wanniassa/O=Dave Mother
Asiapacific/OU=Support/CN=davemother.food.lan
issuer=/DC=lan/DC=food/CN=hotdog
-----BEGIN CERTIFICATE-----
MIIFiTCCBHGgAwIBAgIKCGryDgAAAAAAHzANBgkqhkiG9w0BAQUFADA8MRMwEQYK... (more random characters) 5
pLDWyHhLkA1pSxvFjNJHRSIydWhc5ltGyKqIUcBezVaYye194pNSUYx07NpPV/
MY2ovQyQM8Ge3+LGum0VHbv/y/gB9HhFesog=
-----END CERTIFICATE-----
```

The following is an INTERMEDIATE CA CERTIFICATE section:

```
Bag Attributes: <Empty Attributes>
snbc=lan/dn=food/cn=hotdog
issuer=/DC=lan/DC=food/CN=hotdog
-----BEGIN CERTIFICATE-----
MIIESDCCAzCgAwIBAgIQah20fCRYTY9LRXYMIRaKGjANBgkqhkiG9w0BAQUFADA8...
... (more random characters)
Nt0nksawDnbKo86rQcNnY5xUs7c7pj2xjj/IOsgNHiup5W6dDI9pQoqFFaDk =
-----END CERTIFICATE-----
```

Further Intermediate CA certificates may follow, depending on the certification path of the exported certificate.

5. Open the .PEM file in a text editor
6. Locate the first line of the .PEM file and the first instance of the following line, and copy those two lines and all the lines between them:

```
1  -----END CERTIFICATE-----
2
3  Note: Make sure that last copied line is the first
4  -----END CERTIFICATE-----  line in the .PEM file.
```

7. Paste the copied lines into a new file. Call the new file something intuitive, such as cert-key.pem. This is the certificate-key pair for the server hosting the HTTPS service. This file should contain both the section labeled RSA PRIVATE KEY and the section labeled SERVER CERTIFICATE in the example above.

   **Note:** The certificate-key pair file contains the private key and must therefore be kept secure.

8. Locate any subsequent sections beginning with ——BEGIN CERTIFICATE—— and ending with ——END CERTIFICATE——, and copy each such section to a separate new file.

   These sections correspond to certificates of trusted CAs that have been included in the certification path. These sections should be copied and pasted into new individual files for these certificates. For example, the INTERMEDIATE CA CERTIFICATE section of the example above should be copied and pasted into a new file.

   For multiple intermediate CA certificates in the original file, create new files for each intermediate CA certificate in the order in which they appear in the file. Keep track (using appropriate filenames) of the order in which the certificates appear, as they need to be linked together in the correct order in a later step.

9. Copy the certificate-key file (cert-key.pem) and any additional CA certificate files into the /nsconfig/ssl directory on the Citrix ADC appliance.

10. Exit the BSD shell and access the Citrix ADC prompt.

11. Follow the steps in “Install the certificate-key files on the appliance” to install the key/certificate once uploaded on the device.

**How do I convert the PKCS#7 certificate and install it on the Citrix ADC appliance?**

You can use OpenSSL to convert a PKCS #7 Certificate to a format recognizable by the Citrix ADC appliance. The procedure is identical to the procedure for PKCS #12 certificates, except that you invoke OpenSSL with different parameters. The steps for converting PKCS #7 certificates are as follows:

1. Copy the certificate to the appliance by using a secure copy utility, such as SCP.

2. Convert the certificate (for example, cert.P7B) to PEM format:
3. Follow steps 3 through 7 as described in the answer for PKCS #12 certificates.
   Note: Before loading the converted PKCS #7 certificate to the appliance, be sure to verify that it contains a private key, exactly as described in step 3 for the PKCS #12 procedure. PKCS #7 certificates, particularly those exported from IIS, do not typically contain a private key.

When I bind a cipher to a virtual server or service by using the bind cipher command, I see the error message “Command deprecated.”?

The command for binding a cipher to a virtual server or service has changed.
Use the bind ssl vserver <vsername> -ciphername <ciphername> command to bind an SSL cipher to an SSL virtual server.
Use the bind ssl service <serviceName> -ciphername <ciphername> command to bind an SSL cipher to an SSL service.
   Note: New ciphers and cipher groups are added to the existing list and not replaced.

Why can’t I create a new cipher group and bind ciphers to it by using the add cipher command?

The add cipher command functionality has changed in release 10. The command only creates a cipher group. To add ciphers to the group, use the bind cipher command.

OpenSSL

How do I use OpenSSL to convert certificates between PEM and DER?

To use OpenSSL, you must have a working installation of the OpenSSL software and be able to execute OpenSSL from the command line.

x509 certificates and RSA keys can be stored in a number of different formats.
Two common formats are DER (a binary format used primarily by Java and Macintosh platforms) and PEM (a base64 representation of DER with header and footer information, which is used primarily by UNIX and Linux platforms). There is also an obsolete NET (Netscape server) format that was used by earlier versions of IIS (up to and including 4.0) and various other less common formats that are not covered in this article.

A key and the corresponding certificate, as well as the root and any intermediate certificates, can also be stored in a single PKCS#12 (.P12, .PFX) file.
**Procedure**

Use the OpenSSL command to convert between formats as follows:

1. To convert a certificate from PEM to DER:
   ```bash
   x509 -in input.crt -inform PEM -out output.crt -outform DER
   ```

2. To convert a certificate from DER to PEM:
   ```bash
   x509 -in input.crt -inform DER -out output.crt -outform PEM
   ```

3. To convert a key from PEM to DER:
   ```bash
   rsa -in input.key -inform PEM -out output.key -outform DER
   ```

4. To convert a key from DER to PEM:
   ```bash
   rsa -in input.key -inform DER -out output.key -outform PEM
   ```

   **Note:** If the key you are importing is encrypted with a supported symmetric cipher, you are prompted to enter the pass-phrase.

   **Note:** To convert a key to or from the obsolete NET (Netscape server) format, substitute NET for PEM or DER as appropriate. The stored key is encrypted in a weak unsalted RC4 symmetric cipher, so a pass-phrase will be requested. A blank pass-phrase is acceptable.

**System Limits**

**What are the important numbers to remember?**

1. Create Certificate Request:
   - Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase (For Encrypted Key): Maximum 31 characters
   - Common Name: Maximum 63 characters
   - City: Maximum 127 characters
   - Organization Name: Maximum 63 characters
   - State/Province Name: Maximum 63 characters
   - Email Address: Maximum 39 Characters
   - Organization Unit: Maximum 63 characters
   - Challenge Password: Maximum 20 characters
   - Company Name: Maximum 127 characters
2. Create Certificate:
   - Certificate File Name: Maximum 63 characters
   - Certificate Request File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - Validity Period: Maximum 3650 days
   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - PEM Passphrase: Maximum 31 characters
   - CA Serial Number File: Maximum 63 characters

3. Create and Install a Server Test Certificate:
   - Certificate File Name: Maximum 31 characters
   - Fully Qualified Domain Name: Maximum 63 characters

4. Create Diffie-Hellman (DH) key:
   - DH Filename (with path): Maximum 63 characters
   - DH Parameter Size: Maximum 2048 bits

5. Import PKCS12 key:
   - Output File Name: Maximum 63 characters
   - PKCS12 File Name: Maximum 63 characters
   - Import Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters
   - Verify PEM Passphrase: Maximum 31 characters

6. Export PKCS12
   - PKCS12 File Name: Maximum 63 characters
   - Certificate File Name: Maximum 63 characters
   - Key File Name: Maximum 63 characters
   - Export Password: Maximum 31 characters
   - PEM Passphrase: Maximum 31 characters

7. CRL Management:
   - CA Certificate File Name: Maximum 63 characters
   - CA Key File Name: Maximum 63 characters
   - CA Key File Password: Maximum 31 characters
   - Index File Name: Maximum 63 characters
   - Certificate File Name: Maximum 63 characters

8. Create RSA Key:
9. Create DSA Key:

- Key Filename: Maximum 63 characters
- Key Size: Maximum 4096 bits
- PEM Passphrase: Maximum 31 characters
- Verify Passphrase: Maximum 31 characters

10. Change advanced SSL settings:

- Maximum CRL memory size: Maximum 1024 Mbytes
- Encryption trigger timeout (10 ms ticks): Maximum 200
- Encryption trigger packet count: Maximum 50
- OCSP cache size: Maximum 512 Mbytes

11. Install Certificate:

- Certificate-Key pair Name: Maximum 31 characters
- Certificate File Name: Maximum 63 characters
- Private Key File Name: Maximum 63 characters
- Password: Maximum 31 characters
- Notification Period: Maximum 100

12. Create Cipher Group:

- Cipher Group Name: Maximum 39 characters

13. Create CRL:

- CRL Name: Maximum 31 characters
- CRL File: Maximum 63 characters
- URL: Maximum 127 characters
- Base DN: Maximum 127 characters
- Bind DN: Maximum 127 characters
- Password: Maximum 31 characters
- Day(s): Maximum 31

14. Create SSL Policy:

- Name: Maximum 127 characters

15. Create SSL Action:

- Name: Maximum 127 characters
16. Create OCSP Responder:
   - Name: Maximum 32 characters
   - URL: Maximum 128 characters
   - Batching Depth: Maximum 8
   - Batching Delay: Maximum 10000
   - Produced At Time Skew: Maximum 86400
   - Request Time-out: Maximum 120000

17. Create Virtual Server:
   - Name: Maximum 127 characters
   - Redirect URL: Maximum 127 characters
   - Client Time-out: Maximum 31536000 secs

18. Create Service:
   - Name: Maximum 127 characters
   - Idle Time-out (secs):
     - Client: Maximum 31536000
     - Server: Maximum 31536000

19. Create Service Group:
   - Service Group Name: Maximum 127 characters
   - Server ID: Maximum 4294967295
   - Idle Time-out (secs):
     - Client: Maximum value 31536000
     - Server: Maximum 31536000

20. Create Monitor:
   - Name: Maximum 31 characters

21. Create Server:
   - Server Name: Maximum 127 characters
   - Domain Name: Maximum 255 characters
   - Resolve Retry: Maximum 20939 secs

**Global site certificates**

April 23, 2019

A global site certificate is a special-purpose server certificate whose key length is greater than 128 bits. A global site certificate consists of a server certificate and an accompanying intermediate-CA
You must import the global site certificate and its key from the server to the Citrix ADC appliance.

**How global site certificates work**

Export versions of browsers use 40-bit encryption to initiate connections to SSL Web-servers. The server responds to connection requests by sending its certificate. The client and server then decide on an encryption strength based on the server certificate type:

- If the server certificate is a normal certificate and not a global site certificate, the export client and server complete the SSL handshake and uses 40-bit encryption for data transfer.
- If the server certificate is a global site certificate (and if the export client feature is supported by the browser), the export client automatically upgrades to 128-bit encryption for data transfer.

If the server certificate is a global site certificate, the server sends its certificate, along with the accompanying intermediate-CA certificate. The browser first validates the intermediate-CA certificate by using one of the Root-CA certificates that are normally included in web browsers. Upon successful validation of the intermediate-CA certificate, the browser uses the intermediate-CA certificate to validate the server certificate. Once the server is successfully validated, the browser renegotiates (upgrades) the SSL connection to 128-bit encryption.

With Microsoft’s Server Gated Cryptography (SGC), if the Microsoft IIS server is configured with an SGC certificate, export clients that receive the certificate renegotiate to use 128-bit encryption.

**Import a global site certificate**

To import a global site certificate, first export the certificate and server key from the Web server. Global site certificates are generally exported in some binary format, therefore, before importing the global site certificate, convert the certificate and key to the PEM format.

**To import a global site certificate**

1. Using a text editor, copy the server certificate and the accompanying intermediate-CA certificate into two separate files.
   
   The individual PEM encoded certificate will begin with the header --- BEGIN CERTIFICATE--- and end with the trailer ---END CERTIFICATE---.

2. Use an SFTP client to transfer the server certificate, intermediate-CA certificate, and server-key to the Citrix ADC appliance.

3. Use the following OpenSSL command to identify the server certificate and intermediate-CA certificate from the two separate files.
**Note:** You can launch the OpenSSL interface from the configuration utility. In the navigation pane, click SSL. In the details pane, under Tools, click Open SSL interface.

```plaintext
1 openssl x509 -in >path of the CA cert file< text X509v3 Basic Constraints: CA:TRUE
   X509v3 Key Usage:
   Certificate Sign, CRL Sign
   Netscape Cert Type:
   SSL CA, S/MIME CA
2
3 openssl x509 -in >path of the server certificate file< -text
4
5 X509v3 Basic Constraints:
6   CA:FALSE
7   Netscape Cert Type:
8   SSL Server
```

4. At the FreeBSD shell prompt, enter the following command:

```plaintext
1 openssl x509 -in cert.pem -text | more
```

Where `cert.pem` is one of the two certificate files.

Read the **Subject** field in the command output. For example,

```plaintext
1 Subject: C=US, ST=Oregon, L=Portland, O=mycompany, Inc., OU=IT, CN =www.mycompany.com
```

If the CN field in the Subject matches the domain-name of your Web site, then this is the server certificate and the other certificate is the accompanying intermediate-CA certificate.

5. Use the server certificate and its private key) to create a certificate key pair on the Citrix ADC appliance. For details on creating a certificate-key pair on the Citrix ADC, see [Add a certificate key pair](#).

6. Add the intermediate-CA certificate on the Citrix ADC appliance. Use the server certificate you created in step 4 to sign this intermediate certificate. For details on creating an Intermediate-CA certificate on the Citrix ADC, see [Generate a test certificate](#).
Content inspection

May 16, 2019

With the expansion of the device types that can display various multimedia content from mobile handsets to tablets and to desktops, intermediate infrastructure providers need to transform original content from a web server to a format suitable for the device that asks for the content. This requires content to be inspected by external devices that transcode and send it back to the client. Commonly used protocol to achieve this is ICAP. ICAP enables Citrix ADC appliance to be put in various deployments. ICAP uses content inspection technique that inspects data for malware and security issues.

ICAP for remote content inspection

September 18, 2019

The Internet Content Adaptation Protocol (ICAP) is a simple lightweight protocol for executing value-added transformation service on HTTP messages. In a typical scenario, an ICAP client forwards HTTP requests and responses to one or more ICAP servers for processing. The ICAP servers perform content transformation on the requests and sends back responses with appropriate action to take on the request or response.

ICAP on a Citrix ADC appliance

In a Citrix ADC setup, the appliance acts as an ICAP client interoperating with third-party ICAP servers such as antimalware and Data Leak Prevention (DLP). When the appliance receives an incoming web traffic, the appliance intercepts the traffic and uses a Content Inspection policy to evaluate if the HTTP request needs an ICAP processing. If yes, the appliance decrypts and sends the message as a plain text to the ICAP servers. The ICAP servers execute the content transformation service on the request message and sends back a response to the appliance. The adapted messages can either be an HTTP request or an HTTP response. If the appliance interoperates with multiple ICAP servers, the appliance performs load balancing of ICAP servers. This happens in scenarios where one ICAP server is not sufficient to handle all the traffic load. Once the ICAP servers return a modified message, the appliance forwards the modified message to the back-end origin server.

The Citrix ADC appliance also provides a secured ICAP service if the incoming traffic is an HTTPS type. The appliance uses a SSL based TCP service to establish a secured connection between the appliance and ICAP servers.
How ICAP request modification (REQMOD) works

In the request modification (REQMOD) mode, the Citrix ADC appliance forwards the HTTP request received from client to the ICAP server. The ICAP server then performs one of the following:

1. Sends back a modified version of the request and the appliance in turn sends the modified request to the back-end origin server or it pipelines the modified request to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message back to the user.

How ICAP response modification (RESPMOD) works

In the response modification (RESPMOD) mode, the Citrix ADC appliance sends an HTTP response to the ICAP server (the response sent by the appliance is typically the response sent by the origin server). The ICAP server then performs one of the following:

1. Sends back a modified version of the response and the appliance in turn sends the modified response to the user or pipeline the modified response to another ICAP server.
2. Responds with a message indicating no adaptation is required.
3. Returns an error and the appliance in turn sends the error message to the user.

ICAP license

The ICAP feature works on a Citrix ADC standalone or high availability setup with Citrix ADC Premium or Advanced license edition.

Configure ICAP for content transformation service

To use ICAP for content transformation service, you must begin by enabling the Content inspection and load balancing features. Once you enable the features, you can complete the following tasks

To enable content inspection

If you want the Citrix ADC appliance to act as an ICAP client and send requests or responses to third-party ICAP server, you must first enable the Content Inspection and load balancing features.

At the command prompt, type:

```
1 enable ns feature contentInspection LoadBalancing
```
Add ICAP profile

ICAP configurations for a Citrix ADC appliance are specified in an entity called ICAP profile. The profile has a collection of ICAP settings. The settings includes parameters to dynamically generate an ICAP request, receive ICAP response, and log content inspection data.

To dynamically generate ICAP request to the ICAP server, a new parameter, “insertHTTPRequest” is added to the ICAP profile. If this parameter is configured, the appliance takes the configured value as a policy expression and evaluates the expression and includes the result as an encapsulated http request or response and then sent it to the ICAP server. Also, a new parameter “insertICAPHeaders” is configurable to dynamically evaluate and include the ICAP headers.

When the appliance sends an ICAP request and does not receive a response the ICAP server, the connection becomes unresponsive. This occurs until the ICAP server sends a response or session gets freed. The behavior can be handled by configuring ICAP response time out option. You can set a request time out parameter for ICAP to taken an action if there is delayed ICAP response. If the Citrix ADC appliance does not receive a response within the configured request time out, the request timeout action is performed.

ReqTimeoutAction: Possible values are BYPASS, RESET, DROP.
BYPASS: This Ignores the remote ICAP server’s response and sends the request/response to Client/Server.
RESET (default): Reset the client connection by closing it.
DROP: Drop the request without sending a response to the user

To evaluate an ICAP response, a new policy expression ICAP.RES is used in content inspection callout return expression. This expression evaluates the ICAP response similar to HTTP.RES expression in a HTTP_CALLOUT.

For example, when a Citrix ADC appliance receives an HTTP request for a service hosted behind the Citrix ADC virtual IP address, the appliance might have to check the client’s authentication with an external server and take an action.

At the command prompt, type:

```
add icapProfile <ICAP Profile Name> -mode <ICAP Mode> -insertHTTPRequest <Expression> -logAction icap_log_expr -Mode REQMOD -reqtimeout <positive_integer> -reqTimeoutAction <reqTimeoutAction>
```

**Example:**

```
add icapProfile reqmode-profile -mode REQMOD -insertHTTPRequest q{ HTTP.REQ.METHOD + "" HTTP.REQ.URL + "HTTP/1.1" + "Host: " + HTTP.REQ.HOSTNAME + "\r\n\r\n"}
add icapProfile respmode-profile -mode RESPMOD -insertHTTPResponse q{ HTTP
```
**Log ICAP content inspection action**

To dynamically generate content inspection log stream records or SYSLOG logs, you can use the ICAP.RESP based policy expression on the ICAP response. This parameter is configurable in the ICAP profile to configure the policy expression to generate the dynamic log records.

At the command prompt, type:
```
add audit messageaction icap_log_expr INFORMATIONAL icap.res.full_header
set icapProfile reqmode-profile -logAction messageaction
```

**Add ICAP service as a TCP or SSL_TCP service**

After you enable the Content Inspection feature, you must add an ICAP service for the ICAP servers that will be part of the load balancing setup. The service that you add provides the ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

**Note:** As an administrator, you can add an ICAP service and directly configure the ICAP server IP address in the Content Inspection action.

At the command prompt, type the following:
```
add service <name> <IP> <serviceType> <port>
```

**Example:**
```
1 add service icapsv1 10.102.29.200 TCP 80 - gslb NONE - maxclient 0 - maxReq 0 - cip DISABLED - usip NO - useproxport YES - sp ON - cltTimeout 9000 - svrTimeout 9000 - CKA NO - TCPB NO - CMP NO
2 add service icapsv2 10.102.29.200 SSL_TCP 11344 - gslb NONE - maxclient 0 - maxReq 0 - cip DISABLED - usip NO - useproxport YES - sp ON - cltTimeout 9000 - svrTimeout 9000 - CKA NO - TCPB NO - CMP NO
```

**Add a TCP or SSL_TCP based load balancing virtual server**

After creating an ICAP service, you must create a virtual server to accept ICAP traffic and load balance the ICAP servers.
You can also use a SSL based TCP service over a secured channel. To do this, you must use a SSL_TCP service and bind to the Content Inspection action.

At the command prompt, type the following:

```bash
add lb vserver <name> <serviceType> <port>
```

**Example:**

```bash
add lb vserver vicap TCP 0.0.0.0 -persistenceType NONE -cltTimeout 9000
```

**Bind ICAP service to the load balancing virtual server**

After you create an ICAP service and virtual server, you must bind the ICAP service to the virtual server.

At the command prompt, type the following:

```bash
bind lb vserver <name> <serviceName>
```

**Example:**

```bash
bind lb vserver vicap icapsv1
```

**Add content inspection action**

After you enable the Content Inspection feature, you must add an ICAP action for handling the ICAP request information. The ICAP profile and services, or load balancing virtual server that are created are bound to the ICAP action. If the ICAP server is down, you can configure the ifserverdown parameter for the appliance to trigger any one of the following action.

- **CONTINUE**: If the User wants to bypass the content inspection if the remote server is down, this action can be chosen and it is default action.
- **RESET (default)**: This action respond to client by closing the connection with RST.
- **DROP**: This action silently drop the packets without sending a response to the user.

At the command prompt, type the following:
Add contentInspection action

```
1 add contentInspection action <name> -type ICAP -serverName <string> -icapProfileName <string>
2
3 add ContentInspection action <name> -type ICAP -serverip <ip> -serverport <port> -icapProfileName <string>
```

**Note:**

If you can configuring ICAP service instead of a load balancing virtual server, you can mention the service name in the `<serverip>` option. When adding the Content Inspection action, the TCP service is automatically created for the given IP address with port 1344 and it is used for ICAP communication.

**Example:**

```
1 add ContentInspection action ci_act_lb -type ICAP -serverName vicap -icapProfileName icap_reqmod
2
3 add ContentInspection action ci_act_svc -type ICAP -serverName icapsv1 -icapProfileName icap_reqmod
4
5 add ContentInspection action ci_act_svc -type ICAP -serverip <ip> -serverport <port> -icapProfileName icap_reqmod
```

Add content inspection policies

After you create a Content Inspection action, you must create content inspection policies to evaluate requests for ICAP processing and audit logging. The policy is based on a rule which consists of one or more expressions. The rule is associated to the content inspection action that is associated if a request matches the rule.

At the command prompt, type the following:

```
1 add contentInspection policy <name> -rule <expression> -action <string>
```

**Example:**

```
1 add ContentInspection policy ci_pol_basic -rule true -action ci_act_svc
2
3 add ContentInspection policy ci_pol_HTTP -rule HTTP.REQ.URL.CONTAINS(“html”) -action ci_act_svc
```
Bind content inspection policies to the content switching or load balancing virtual server

To put an ICAP policy into effect, you must bind it globally or bind it to a Content Switching or load balancing virtual server, which front end the application. When you bind the policy, you must assign a priority to it. The priority determines the order in which the policies you define are evaluated.

For information about configuring a load balancing setup for forwarding the traffic to back-end origin server after content transformation, see Load Balancing.

Configure secured ICAP service

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.
3. Bind SSL-based TCP service or load balancing virtual server to Content Inspection action.

Add SSL-based TCP service to load balancing virtual server

To establish a secured connection between the Citrix ADC appliance and the ICAP web servers, the appliance uses an SSL-based TCP service or load balancing virtual server bound to an ICAP action.

To establish a secured ICAP connection, complete the following tasks:

1. Add SSL-based TCP service.
2. Bind SSL-based TCP service to load balancing virtual server of type TCP or SSL_TCP.

Bind SSL-based TCP service or load balancing virtual server to Content Inspection action

Add SSL-based TCP service to load balancing virtual server

After you enable the Content Inspection feature, you must add a secured ICAP service that will be part of the load balancing setup. The service that you add provides a secured ICAP connection between the Citrix ADC appliance and load balancing virtual servers.

At the command prompt, type the following:

```bash
add service <name> <IP> <serviceType> <port>
```

Example:
Bind SSL-based TCP service to SSL_TCP or TCP load balancing virtual server

After you create a secured ICAP service, you must bind the service to the load balancing virtual server (if you are using a load balancing virtual server to load balance the ICAP servers).

At the command prompt, type the following:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver vicap icapsv2
```

Bind SSL-based TCP service or load balancing virtual server to the Content Inspection action

You must add an ICAP action for handling the ICAP request information and also bind the SSL-based TCP service to the action.

At the command prompt, type the following:

```
add contentInspection action <name> -type ICAP -serverName <string> -icapProfileName <string>
```

Example:

```
add ContentInspection action ci_act_svc -type ICAP -serverName icapsv2 -icapProfileName icap_reqmod
```

Configure ICAP protocol by using the GUI

1. Navigate to **Load Balancing > Services** and click **Add**.
2. In the **Services** page, enter the service details.
3. Navigate to **Load Balancing > Servers**. Add a virtual server of type TCP. Or, you can select a virtual server and click **Edit**.
4. After entering the server details, click **OK** and again **OK**.
5. In the Advanced Settings section, click **Policies**.
6. Go the Policies section and click the Pencil icon to configure Content Inspection policy.
7. On the Choose Policy page, select **Content Inspection**. Click **Continue**.
8. In the Policy Binding section, click “+” to add a Content Inspection policy.
9. In the Create ICAP Policy page, enter a name for the policy.
10. In the **Action** field, click the “+” sign to add an ICAP action.
11. In the Create ICAP Action page, enter a name for the action.
12. Enter a name for the action.
13. In the Server Name field, enter the name of the TCP service already created.
14. In ICAP Profile field, click the “+” sign to add an ICAP profile.
15. In the Create ICAP Profile page, enter a profile name, URI, and MODE.
16. Click **Create**.
17. In the Create ICAP Action page, click **Create**.
18. In the Create ICAP Policy page, enter “true” in the Expression Editor and then click **Create**.
19. Click **Bind**.
20. When prompted to enable the Content Inspection feature, click **Yes**.
21. Click **Done**.

For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to back-end origin server after content transformation, see **Load Balancing**.

**Configure secured ICAP protocol by using the GUI**

1. Navigate to **Load Balancing > Services** and click **Add**.
2. In the Services page, enter the service details.
3. Navigate to **Load Balancing > Servers**. Add a virtual server of type TCP_SSL. Or, you can select a virtual server of type TCP_SSL and click **Edit**.
4. After entering the server details, click **OK** and again **OK**.
5. In the Advanced Settings section, click **Policies**.
6. Go the Policies section and click the Pencil icon to configure Content Inspection policy.
7. On the Choose Policy page, select **Content Inspection**. Click **Continue**.
8. In the Policy Binding section, click “+” to add a Content Inspection policy.
9. In the Create ICAP Policy page, enter a name for the policy.
10. In the **Action** field, click the “+” sign to add an ICAP action.
11. In the Create ICAP Action page, enter a name for the action.
12. Enter a name for the action.
13. In the Server Name field, enter the name of the TCP_SSL service already created.
14. In ICAP Profile field, click the “+” sign to add an ICAP profile.
15. In the Create ICAP Profile page, enter a profile name, URI, and MODE.
16. Click Create.
17. In the Create ICAP Action page, click Create.
18. In the Create ICAP Policy page, enter “true” in the Expression Editor and then click Create.
19. Click Bind.
20. When prompted to enable the Content Inspection feature, click Yes.
21. Click Done.

Auditlog support for remote content inspection

If an incoming request or outgoing response is content inspected, the Citrix ADC appliance logs the ICAP details. The appliance stores the details as a log message in the ns.log file.

Each log message typically contains the following details:

<table>
<thead>
<tr>
<th>Source IP</th>
<th>Destination IP</th>
<th>Domain</th>
<th>ICAP server IP</th>
<th>ICAP Mode</th>
<th>Service URI</th>
<th>ICAP response</th>
<th>Policy action</th>
</tr>
</thead>
</table>

Example for content inspected request log message:

```
```

Example for content inspected response log message:

```
```

Integration with IPS or NGFW as inline devices

October 11, 2019

Security devices such as Intrusion Prevention System (IPS) and Next Generation Firewall (NGFW) protect servers from network attacks. These devices can inspect live traffic and are typically deployed in layer 2 inline mode. The SSL forward proxy appliance provides security of users and the enterprise network when accessing resources on the internet.
A SSL forward proxy appliance can be integrated with one or more inline devices to prevent threats and provide advanced security protection. The inline devices can be any security device, such as IPS and NGFW.

Some use cases where you can benefit by using the SSL forward proxy appliance and inline device integration are:

- **Inspecting encrypted traffic**: Most IPS and NGFW appliances bypass encrypted traffic, which can leave servers vulnerable to attacks. A SSL forward proxy appliance can decrypt traffic and send it to the inline devices for inspection. This integration enhances the customer’s network security.

- **Offloading inline devices from TLS/SSL processing**: TLS/SSL processing is expensive, which can result in high CPU utilization in IPS or NGFW appliances if they also decrypt the traffic. A SSL forward proxy appliance helps in offloading TLS/SSL processing from inline devices. As a result, inline devices can inspect a higher volume of traffic.

- **Loading balancing inline devices**: If you have configured multiple inline devices to manage heavy traffic, a SSL forward proxy appliance can load balance and distribute traffic evenly to these devices.

- **Smart selection of traffic**: Instead of sending all the traffic to the inline device for inspection, the appliance does a smart selection of traffic. For example, it skips sending text files for inspection to the inline devices.

### SSL forward proxy integration with inline devices

The following diagram shows how a SSL forward proxy is integrated with inline security devices.

When you integrate inline devices with SSL forward proxy appliance, the components interact as follows:

1. A client sends a request to a SSL forward proxy appliance.

2. The appliance sends the data to the inline device for content inspection based on the policy evaluation. For HTTPS traffic, the appliance decrypts the data and sends it in plain text to the inline device for content inspection.

   **Note:**
   If there are two or more inline devices, the appliance load balances the devices and sends the traffic.

3. The inline device inspects the data for threats and decides whether to drop, reset, or send the data back to the appliance.

4. If there are security threats, the device modifies the data and sends it to the appliance.
5. For HTTPS traffic, the appliance re-encrypts the data and forwards the request to the backend server.

6. The backend server sends the response to the appliance.

7. The appliance again decrypts the data and sends it to the inline device for inspection.

8. The inline device inspects the data. If there are security threats, the device modifies the data and sends it to the appliance.

9. The appliance re-encrypts the data and sends the response to the client.

**Configuring inline device integration**

You can configure a SSL forward proxy appliance with an inline device in three different ways as follows:

**Scenario 1: Using a single inline device**

To integrate a security device (IPS or NGFW) in inline mode, you must enable content inspection and MAC-based forwarding (MBF) in global mode on the SSL forward proxy appliance. Then, add a content inspection profile, a TCP service, a content inspection action for inline devices to reset, block, or drop the traffic based on inspection. Also add a content inspection policy that the appliance uses to decide the subset of traffic to send to the inline devices. Finally, configure the proxy virtual server with layer 2 connection enabled on the server and bind the content inspection policy to this proxy virtual server.

Perform the following steps:

1. Enable MAC-based forwarding (MPF) mode.
2. Enable the content inspection feature.
3. Add a content inspection profile for the service. The content inspection profile contains the inline device settings that integrate the SSL forward proxy appliance with an inline device.
4. *(Optional)* Add a TCP monitor.

   **Note:**
   
   Transparent devices do not have an IP address. Therefore, to perform health checks, you must explicitly bind a monitor.

5. Add a service. A service represents an inline device.
6. *(Optional)* Bind the service to the TCP monitor.
7. Add a content inspection action for the service.
8. Add a content inspection policy and specify the action.
9. Add an HTTP or HTTPS proxy (content switching) virtual server.
10. Bind the content inspection policy to the virtual server.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after most commands.

1. Enable MBF.
   ```
   1 enable ns mode mbf
   ```

2. Enable the feature.
   ```
   1 enable ns feature contentInspection
   ```

3. Add a content inspection profile.
   ```
   1 add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
   ```
   **Example:**
   ```
   1 add contentInspection profile ipsprof -type InlineInspection -ingressinterface "1/2" -egressInterface "1/3"
   ```

4. Add a service. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. By default, health monitoring is ON, bind the service to a health monitor, and also set the TRANSPARENT option in the monitor ON.
   ```
   1 add service <service_name> <IP> TCP * -contentinspectionProfileName <Name> -healthMonitor YES -usip YES -useproxyport NO
   ```
   **Example:**
   ```
   1 add service ips_service 198.51.100.2 TCP * -healthMonitor YES -usip YES -useproxyport NO -contentInspectionProfileName ipsprof
   ```

1. Add a health monitor. By default the health monitor is turned on and you also have the option to disable it, if required. At the command prompt, type:
   ```
   add lb monitor <name> TCP -destIP <ip address> -destPort 80 -transparent <YES, NO>
   ```
Example:

add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent YES

1. Bind the service to the health monitor

After configuring the health monitor, you must bind the service to the health monitor. At the command prompt, type:

bind service <name> -monitorName <name>

Example:

bind service ips_svc -monitorName ips_tcp

1. Add a content inspection action.

```
1 add contentInspection action <name> -type INLINEINSPECTION -serverName <string>
```

Example:

```
1 add contentInspection action ips_action -type INLINEINSPECTION -serverName ips_service
```

2. Add a content inspection policy.

```
1 add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
1 add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE(\"CONNECT\")" -action ips_action
```

3. Add a proxy virtual server.

```
1 add cs vserver <name> PROXY <IPAddress> <port> -cltTimeout <secs> -listenPolicy <expression> -authn401 (ON | OFF) -authnVsName <string> -l2Conn ON
```

Example:

```
1 add cs vserver transparentcs PROXY * * -cltTimeout 180 -listenPolicy exp1 -authn401 on -authnVsName swg-auth-vs-trans-http -l2Conn ON
```
4. Bind the policy to the virtual server.

```bash
bind cs vserver <name> -policyName <string> -priority <positive_integer> -gotoPriorityExpression <expression> -type REQUEST
```

**Example:**

```bash
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression END -type REQUEST
```

**Configuration using the GUI**

1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.
2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.
3. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.
4. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in monitor to ON.
5. Navigate to **Secure Web Gateway > Proxy Virtual Servers > Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.
6. In **Choose Policy** select **Content Inspection**. Click **Continue**.
7. Click **Add**. Specify a name. In **Action**, click **Add**.
8. Specify a name. In **Type**, select **INLINEINSPECTION**. In **Server Name**, select the TCP service created earlier.
9. Click **Create**. Specify the rule and click **Create**.
10. Click **Bind**.
11. Click **Done**.

**Scenario 2: Load balance multiple inline devices with dedicated interfaces**

If you are using two or more inline devices, you can load balance the devices using different content inspection services with dedicated interfaces. In this case, the SSL forward proxy appliance load balances the subset of traffic sent to each device through a dedicated interface. The subset is decided
based on the policies configured. For example, TXT or image files might not be sent for inspection to
the inline devices.

The basic configuration remains the same as in scenario 1. However, you must create a content inspection
profile for each inline device and specify the ingress and egress interface in each profile. Add a
service for each inline device. Add a load balancing virtual server and specify it in the content inspection action. Perform the following extra steps:

1. Add content inspection profiles for each service.
2. Add a service for each device.
3. Add a load balancing virtual server.
4. Specify the load balancing virtual server in the content inspection action.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

   ```
   1 enable ns mode mbf
   ```

2. Enable the feature.

   ```
   1 enable ns feature contentInspection
   ```

3. Add profile 1 for service 1.

   ```
   1 add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
   ```

   **Example:**

   ```
   1 add contentInspection profile ipsprof1 -type InlineInspection -ingressInterface "1/2" -egressInterface "1/3"
   ```

4. Add profile 2 for service 2.

   ```
   1 add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
   ```

   **Example:**
5. Add service 1. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. Turn off the health monitor. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.

```
add contentInspection profile ipsprof2 -type InlineInspection -ingressInterface "1/4" -egressInterface "1/5"
```

Example:

```
add service <service_name> <IP> TCP <Port> -contentinspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentInspectionProfileName ipsprof1
```

6. Add service 2. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. Turn off the health monitor. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.

Example:

```
add service <service_name> <IP> TCP <Port> -contentinspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```
add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentInspectionProfileName ipsprof2
```

7. Add a load balancing virtual server.

```
add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>
```

Example:

```
add lb vserver lb_inline_vserver TCP 192.0.2.100 *
```

8. Bind the services to the load balancing virtual server.

```
bind lb vserver <LB_VSERVER_NAME> <service_name>
```
2 bind lb vserver <LB_VSERVER_NAME> <service_name>

Example:

1 bind lb vserver lb_inline_vserver ips_service1
2 bind lb vserver lb_inline_vserver ips_service2

9. Specify the load balancing virtual server in the content inspection action.

1 add contentInspection action <name> -type INLINEINSPECTION -serverName <string>

Example:

1 add contentInspection action ips_action -type INLINEINSPECTION -serverName lb_inline_vserver

10. Add a content inspection policy. Specify the content inspection action in the policy.

1 add contentInspection policy <name> -rule <expression> -action <string>

Example:

1 add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE("CONNECT")" -action ips_action

11. Add a proxy virtual server.

1 add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON

Example:

1 add cs vserver transparentcs PROXY * * -l2Conn ON

12. Bind the content inspection policy to the virtual server.

1 bind cs vserver <name> -policyName <string> -priority <positive_integer> -gotoPriorityExpression <expression> -type REQUEST

Example:

1 bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression END -type REQUEST
Configuration using the GUI

1. Navigate to System > Settings. In Modes and Features, click Configure Modes.

3. Navigate to Secure Web Gateway > Content Inspection > Content Inspection Profiles. Click Add.

   Specify the ingress and egress interfaces.

   Create two profiles. Specify a different ingress and egress interface in the second profile.

4. Navigate to Load Balancing > Services > Add and add a service. In Advanced Settings, click Profiles. In the CI Profile Name list, select the content inspection profile created earlier. In Service Settings, set Use Source IP Address to YES and Use Proxy Port to No. In Basic Settings, set Health Monitoring to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPOSE option in monitor to ON.

   Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the inline devices.

5. Navigate to Load Balancing > Virtual Servers > Add. Create a TCP load balancing virtual server. Click OK.

6. Click inside the Load Balancing Virtual Server Service Binding section. In Service Binding, click the arrow in Select Service. Select the two services created earlier, and click Select. Click Bind.

8. In Choose Policy select Content Inspection. Click Continue.

10. Specify a name. In Type, select INLINEINSPECTION. In Server Name, select the load balancing virtual server created earlier.

11. Click Create. Specify the rule and click Create.

12. Click Bind.

13. Click Done.

Scenario 3: Load balance multiple inline devices with shared interfaces

If you are using two or more inline devices, you can load balance the devices using different content inspection services with shared interfaces. In this case, the SSL forward proxy appliance load balances
the subset of traffic sent to each device through a shared interface. The subset is decided based on
the policies configured. For example, TXT or image files might not be sent for inspection to the inline
devices.

The basic configuration remains the same as in scenario 2. For this scenario, bind the interfaces to dif-
ferent VLANs to segregate the traffic for each inline device. Specify the VLANs in the content inspection
profiles. Perform the following extra steps:

1. Bind the shared interfaces to different VLANs.
2. Specify the ingress and egress VLANs in the content inspection profiles.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

   ```
   1 enable ns mode mbf
   ```

2. Enable the feature.

   ```
   1 enable ns feature contentInspection
   ```

3. Bind the shared interfaces to different VLANs.

   ```
   1 bind vlan <id> -ifnum <interface> -tagged
   ```

   **Example:**

   ```
   1 bind vlan 100 -ifnum 1/2 tagged
   2 bind vlan 200 -ifnum 1/3 tagged
   3 bind vlan 300 -ifnum 1/2 tagged
   4 bind vlan 400 -ifnum 1/3 tagged
   ```

4. Add profile 1 for service 1. Specify the ingress and egress VLANs in the profile.

   ```
   1 add contentInspection profile <name> -type InlineInspection -
egressInterface <interface_name> -ingressInterface <
interface_name>[-egressVlan <positive_integer>] [-ingressVlan <
positive_integer>]
   ```

   **Example:**

   ```
   1 add contentInspection profile ipsprof1 -type InlineInspection -
egressInterface “1/3” -ingressInterface “1/2” -egressVlan
   100 -ingressVlan 300
   ```
5. Add profile 2 for service 2. Specify the ingress and egress VLANs in the profile.

```
1 add contentInspection profile <name> -type InlineInspection -
   egressInterface <interface_name> -ingressInterface <
   interface_name>[-egressVlan <positive_integer>] [-ingressVlan <
   positive_integer>]
```

**Example:**

```
1 add contentInspection profile ipsprof2 -type InlineInspection -
   egressInterface "1/3" -ingressInterface "1/2" -egressVlan 200
   -ingressVlan 400
```

6. Add service 1.

```
1 add service <service_name> <IP> TCP <Port> -
   contentinspectionProfileName <Name> -healthMonitor NO -usip
   YES -useproxyport NO
```

**Example:**

```
1 add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -
   usip YES -useproxyport NO -contentInspectionProfileName
   ipsprof1
```

7. Add service 2.

```
1 add service <service_name> <IP> TCP <Port> -
   contentinspectionProfileName <Name> -healthMonitor NO -usip
   YES -useproxyport NO
```

**Example:**

```
1 add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -
   usip YES -useproxyport NO -contentInspectionProfileName
   ipsprof2
```

8. Add a load balancing virtual server.

```
1 add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>
```

**Example:**

```
1 add lb vserver lb_inline_vserver TCP 192.0.2.100 *
```

9. Bind the services to the load balancing virtual server.
1. Specify the load balancing virtual server in the content inspection action.

Example:

1 bind lb vserver <LB_VSERVER_NAME> <service_name>
2 bind lb vserver <LB_VSERVER_NAME> <service_name>

Example:

1 bind lb vserver lb_inline_vserver ips_service1
2 bind lb vserver lb_inline_vserver ips_service2

10. Specify the load balancing virtual server in the content inspection action.

Example:

1 add contentInspection action <name> -type INLINEINSPECTION -serverName <string>

Example:

1 add contentInspection action ips_action -type INLINEINSPECTION -serverName lb_inline_vserver

11. Add a content inspection policy. Specify the content inspection action in the policy.

Example:

1 add contentInspection policy <name> -rule <expression> -action <string>

Example:

1 add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE("CONNECT")" -action ips_action

12. Add a proxy virtual server.

Example:

1 add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON

Example:

1 add cs vserver transparentcs PROXY * * -l2Conn ON

13. Bind the content inspection policy to the virtual server.

Example:

1 bind cs vserver <name> -policyName <string> -priority <positive_integer> -gotoPriorityExpression <expression> -type REQUEST

Example:

1 bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression END -type REQUEST

Configuration using the GUI

1. Navigate to System > Settings. In Modes and Features, click Configure Modes.
3. Navigate to System > Network > VLANs > Add. Add four VLANs and tag them to the interfaces.
4. Navigate to Secure Web Gateway > Content Inspection > Content Inspection Profiles. Click Add.
   Specify the ingress and egress VLANs.
   Create another profiles. Specify a different ingress and egress VLAN in the second profile.
5. Navigate to Load Balancing > Services > Add and add a service. In Advanced Settings, click Profiles. In the CI Profile Name list, select the content inspection profile created earlier. In Service Settings, set Use Source IP Address to YES and Use Proxy Port to No. In Basic Settings, set Health Monitoring to NO.
   Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the inline devices. Specify profile 1 in service 1, and profile 2 in service 2.
6. Navigate to Load Balancing > Virtual Servers > Add. Create a TCP load balancing virtual server. Click OK.
7. Click inside the Load Balancing Virtual Server Service Binding section. In Service Binding, click the arrow in Select Service. Select the two services created earlier, and click Select. Click Bind.
9. In Choose Policy select Content Inspection. Click Continue.
11. Specify a name. In Type, select INLINEINSPECTION. In Server Name, select the load balancing virtual server created earlier.
12. Click Create. Specify the rule and click Create.
13. Click Bind.
14. Click Done.

Integration with IPS or NGFW as inline devices

October 11, 2019
Security devices such as Intrusion Prevention System (IPS) and Next Generation Firewall (NGFW) protect servers from network attacks. These devices can inspect live traffic and are typically deployed in layer 2 inline mode. The SSL forward proxy appliance provides security of users and the enterprise network when accessing resources on the internet.

A SSL forward proxy appliance can be integrated with one or more inline devices to prevent threats and provide advanced security protection. The inline devices can be any security device, such as IPS and NGFW.

Some use cases where you can benefit by using the SSL forward proxy appliance and inline device integration are:

- **Inspecting encrypted traffic**: Most IPS and NGFW appliances bypass encrypted traffic, which can leave servers vulnerable to attacks. A SSL forward proxy appliance can decrypt traffic and send it to the inline devices for inspection. This integration enhances the customer’s network security.

- **Offloading inline devices from TLS/SSL processing**: TLS/SSL processing is expensive, which can result in high CPU utilization in IPS or NGFW appliances if they also decrypt the traffic. A SSL forward proxy appliance helps in offloading TLS/SSL processing from inline devices. As a result, inline devices can inspect a higher volume of traffic.

- **Loading balancing inline devices**: If you have configured multiple inline devices to manage heavy traffic, a SSL forward proxy appliance can load balance and distribute traffic evenly to these devices.

- **Smart selection of traffic**: Instead of sending all the traffic to the inline device for inspection, the appliance does a smart selection of traffic. For example, it skips sending text files for inspection to the inline devices.

**SSL forward proxy integration with inline devices**

The following diagram shows how a SSL forward proxy is integrated with inline security devices.

When you integrate inline devices with SSL forward proxy appliance, the components interact as follows:

1. A client sends a request to a SSL forward proxy appliance.

2. The appliance sends the data to the inline device for content inspection based on the policy evaluation. For HTTPS traffic, the appliance decrypts the data and sends it in plain text to the inline device for content inspection.

   **Note:**

   If there are two or more inline devices, the appliance load balances the devices and sends
3. The inline device inspects the data for threats and decides whether to drop, reset, or send the data back to the appliance.

4. If there are security threats, the device modifies the data and sends it to the appliance.

5. For HTTPS traffic, the appliance re-encrypts the data and forwards the request to the backend server.

6. The backend server sends the response to the appliance.

7. The appliance again decrypts the data and sends it to the inline device for inspection.

8. The inline device inspects the data. If there are security threats, the device modifies the data and sends it to the appliance.

9. The appliance re-encrypts the data and sends the response to the client.

Configuring inline device integration

You can configure a SSL forward proxy appliance with an inline device in three different ways as follows:

Scenario 1: Using a single inline device

To integrate a security device (IPS or NGFW) in inline mode, you must enable content inspection and MAC-based forwarding (MBF) in global mode on the SSL forward proxy appliance. Then, add a content inspection profile, a TCP service, a content inspection action for inline devices to reset, block, or drop the traffic based on inspection. Also add a content inspection policy that the appliance uses to decide the subset of traffic to send to the inline devices. Finally, configure the proxy virtual server with layer 2 connection enabled on the server and bind the content inspection policy to this proxy virtual server.

Perform the following steps:

1. Enable MAC-based forwarding (MPF) mode.

2. Enable the content inspection feature.

3. Add a content inspection profile for the service. The content inspection profile contains the inline device settings that integrate the SSL forward proxy appliance with an inline device.

4. (Optional) Add a TCP monitor.

Note:
Transparent devices do not have an IP address. Therefore, to perform health checks, you must explicitly bind a monitor.

5. Add a service. A service represents an inline device.

6. (Optional) Bind the service to the TCP monitor.

7. Add a content inspection action for the service.

8. Add a content inspection policy and specify the action.

9. Add an HTTP or HTTPS proxy (content switching) virtual server.

10. Bind the content inspection policy to the virtual server.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after most commands.

1. Enable MBF.

   ```
   1 enable ns mode mbf
   ```

2. Enable the feature.

   ```
   1 enable ns feature contentInspection
   ```

3. Add a content inspection profile.

   ```
   1 add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
   ```

   **Example:**

   ```
   1 add contentInspection profile ipsprof -type InlineInspection -ingressinterface "1/2" -egressInterface "1/3"
   ```

4. Add a service. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. By default, health monitoring is ON, bind the service to a health monitor, and also set the TRANSPARENT option in the monitor ON.

   ```
   1 add service <service_name> <IP> TCP * -contentinspectionProfileName <Name> -healthMonitor YES -usip YES -useproxyport NO
   ```
Example:

```
  add service ips_service 198.51.100.2 TCP -healthMonitor YES -usip YES -useproxyport NO -contentInspectionProfileName ipsprof
```

1. Add a health monitor. By default the health monitor is turned on and you also have the option to disable it, if required. At the command prompt, type:

```
  add lb monitor <name> TCP -destIP <ip address> -destPort 80 -transparent <YES, NO>
```

Example:

```
  add lb monitor ips_tcp TCP -destIP 192.168.10.2 -destPort 80 -transparent YES
```

1. Bind the service to the health monitor

After configuring the health monitor, you must bind the service to the health monitor. At the command prompt, type:

```
  bind service <name> -monitorName <name>
```

Example:

```
  bind service ips_svc -monitorName ips_tcp
```

1. Add a content inspection action.

```
  add contentInspection action <name> -type INLINEINSPECTION -serverName <string>
```

Example:

```
  add contentInspection action ips_action -type INLINEINSPECTION -serverName ips_service
```

2. Add a content inspection policy.

```
  add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
  add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE(\"CONNECT\")" -action ips_action
```

3. Add a proxy virtual server.
1 add cs vserver <name> PROXY <IPAddress> <port> -cltTimeout <secs> -Listenpolicy <expression> -authn401 ( ON | OFF ) -authnVsName <string> -l2Conn ON

Example:

1 add cs vserver transparentcs PROXY * * -cltTimeout 180 - Listenpolicy exp1 -authn401 on -authnVsName swg-auth-vs-trans-http -l2Conn ON

4. Bind the policy to the virtual server.

1 bind cs vserver <name> -policyName <string> -priority < positive_integer> -gotoPriorityExpression <expression> -type REQUEST

Example:

1 bind cs vserver explicitcs -policyName ips_pol -priority 1 - gotoPriorityExpression END -type REQUEST

Configuration using the GUI

1. Navigate to System > Settings. In Modes and Features, click Configure Modes.
3. Navigate to Secure Web Gateway > Content Inspection > Content Inspection Profiles. Click Add.
4. Navigate to Load Balancing > Services > Add and add a service. In Advanced Settings, click Profiles. In the CI Profile Name list, select the content inspection profile created earlier. In Service Settings, set Use Source IP Address to YES and Use Proxy Port to No. In Basic Settings, set Health Monitoring to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in monitor to ON.
6. In Choose Policy select Content Inspection. Click Continue.
7. Click Add. Specify a name. In Action, click Add.
8. Specify a name. In Type, select INLINEINSPECTION. In Server Name, select the TCP service created earlier.
9. Click **Create**. Specify the rule and click **Create**.

10. Click **Bind**.

11. Click **Done**.

**Scenario 2: Load balance multiple inline devices with dedicated interfaces**

If you are using two or more inline devices, you can load balance the devices using different content inspection services with dedicated interfaces. In this case, the SSL forward proxy appliance load balances the subset of traffic sent to each device through a dedicated interface. The subset is decided based on the policies configured. For example, TXT or image files might not be sent for inspection to the inline devices.

The basic configuration remains the same as in scenario 1. However, you must create a content inspection profile for each inline device and specify the ingress and egress interface in each profile. Add a service for each inline device. Add a load balancing virtual server and specify it in the content inspection action. Perform the following extra steps:

1. Add content inspection profiles for each service.
2. Add a service for each device.
3. Add a load balancing virtual server.
4. Specify the load balancing virtual server in the content inspection action.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

   ```plaintext
   enable ns mode mbf
   ```

2. Enable the feature.

   ```plaintext
   enable ns feature contentInspection
   ```

3. Add profile 1 for service 1.

   ```plaintext
   add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name> [-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
   ```

   **Example:**
4. Add profile 2 for service 2.

```bash
add contentInspection profile ipsprof2 -type InlineInspection -
    ingressInterface "1/4" -egressInterface "1/5"
```

Example:

```bash
add contentInspection profile ipsprof2 -type InlineInspection -
    egressInterface <interface_name> -ingressInterface <interface_name>[-egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

5. Add service 1. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. Turn off the health monitor. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.

```bash
add service <service_name> <IP> TCP <Port> -
    contentInspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```bash
add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentInspectionProfileName ipsprof1
```

6. Add service 2. Specify a dummy IP address that is not owned by any of the devices, including the inline devices. Set `use source IP address (USIP)` to YES. Set `useproxyport` to NO. Turn off the health monitor. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the TRANSPARENT option in the monitor to ON.

```bash
add service <service_name> <IP> TCP <Port> -
    contentInspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

Example:

```bash
add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentInspectionProfileName ipsprof2
```
7. Add a load balancing virtual server.

```
1 add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>
```

Example:

```
1 add lb vserver lb_inline_vserver TCP 192.0.2.100 *
```

8. Bind the services to the load balancing virtual server.

```
1 bind lb vserver <LB_VSERVER_NAME> <service_name>
2 bind lb vserver <LB_VSERVER_NAME> <service_name>
```

Example:

```
1 bind lb vserver lb_inline_vserver ips_service1
2 bind lb vserver lb_inline_vserver ips_service2
```

9. Specify the load balancing virtual server in the content inspection action.

```
1 add contentInspection action <name> -type INLINEINSPECTION -serverName <string>
```

Example:

```
1 add contentInspection action ips_action -type INLINEINSPECTION -serverName lb_inline_vserver
```

10. Add a content inspection policy. Specify the content inspection action in the policy.

```
1 add contentInspection policy <name> -rule <expression> -action <string>
```

Example:

```
1 add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE("CONNECT")")" -action ips_action
```

11. Add a proxy virtual server.

```
1 add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON
```

Example:

```
1 add cs vserver transparentcs PROXY * * -l2Conn ON
```
12. Bind the content inspection policy to the virtual server.

```
bind cs vserver <name> -policyName <string> -priority <positive_integer> -gotoPriorityExpression <expression> -type REQUEST
```

**Example:**

```
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression END -type REQUEST
```

**Configuration using the GUI**

1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.
2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.
3. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.
   Specify the ingress and egress interfaces.
   Create two profiles. Specify a different ingress and egress interface in the second profile.
4. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO. Turn on health monitoring only if you bind this service to a TCP monitor. If you bind a monitor to a service, then set the **TRANSPARENT** option in monitor to ON.
   Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the inline devices.
5. Navigate to **Load Balancing > Virtual Servers > Add**. Create a TCP load balancing virtual server. Click **OK**.
6. Click inside the **Load Balancing Virtual Server Service Binding** section. In **Service Binding**, click the arrow in **Select Service**. Select the two services created earlier, and click **Select**. Click **Bind**.
7. Navigate to **Secure Web Gateway > Proxy Virtual Servers > Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.
8. In **Choose Policy** select **Content Inspection**. Click **Continue**.
9. Click **Add**. Specify a name. In **Action**, click **Add**.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
10. Specify a name. In **Type**, select **INLINEINSPECTION**. In **Server Name**, select the load balancing virtual server created earlier.

11. Click **Create**. Specify the rule and click **Create**.

12. Click **Bind**.

13. Click **Done**.

**Scenario 3: Load balance multiple inline devices with shared interfaces**

If you are using two or more inline devices, you can load balance the devices using different content inspection services with shared interfaces. In this case, the SSL forward proxy appliance load balances the subset of traffic sent to each device through a shared interface. The subset is decided based on the policies configured. For example, TXT or image files might not be sent for inspection to the inline devices.

The basic configuration remains the same as in scenario 2. For this scenario, bind the interfaces to different VLANs to segregate the traffic for each inline device. Specify the VLANs in the content inspection profiles. Perform the following extra steps:

1. Bind the shared interfaces to different VLANs.

2. Specify the ingress and egress VLANs in the content inspection profiles.

**Configuration using the CLI**

Type the following commands at the command prompt. Examples are given after each command.

1. Enable MBF.

```bash
1 enable ns mode mbf
```

2. Enable the feature.

```bash
1 enable ns feature contentInspection
```

3. Bind the shared interfaces to different VLANs.

```bash
1 bind vlan <id> -ifnum <interface> -tagged
```

**Example:**

```bash
1 bind vlan 100 -ifnum 1/2 tagged
2 bind vlan 200 -ifnum 1/3 tagged
3 bind vlan 300 -ifnum 1/2 tagged
4 bind vlan 400 -ifnum 1/3 tagged
```
4. Add profile 1 for service 1. Specify the ingress and egress VLANs in the profile.

```
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name>[ -egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

**Example:**

```
add contentInspection profile ipsprof1 -type InlineInspection -egressInterface "1/3" -ingressInterface "1/2" -egressVlan 100 -ingressVlan 300
```

5. Add profile 2 for service 2. Specify the ingress and egress VLANs in the profile.

```
add contentInspection profile <name> -type InlineInspection -egressInterface <interface_name> -ingressInterface <interface_name>[ -egressVlan <positive_integer>] [-ingressVlan <positive_integer>]
```

**Example:**

```
add contentInspection profile ipsprof2 -type InlineInspection -egressInterface "1/3" -ingressInterface "1/2" -egressVlan 200 -ingressVlan 400
```

6. Add service 1.

```
add service <service_name> <IP> TCP <Port> -contentinspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

**Example:**

```
add service ips_service1 192.168.10.2 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentinspectionProfileName ipsprof1
```

7. Add service 2.

```
add service <service_name> <IP> TCP <Port> -contentinspectionProfileName <Name> -healthMonitor NO -usip YES -useproxyport NO
```

**Example:**
1. add service ips_service2 192.168.10.3 TCP * -healthMonitor NO -usip YES -useproxyport NO -contentInspectionProfileName ipsprof2

8. Add a load balancing virtual server.

   1. add lb vserver <LB_VSERVER_NAME> TCP <IP> <port>

   Example:

   ```
   add lb vserver lb_inline_vserver TCP 192.0.2.100 *
   ```

9. Bind the services to the load balancing virtual server.

   ```
   bind lb vserver <LB_VSERVER_NAME> <service_name>
   bind lb vserver <LB_VSERVER_NAME> <service_name>
   ```

   Example:

   ```
   bind lb vserver lb_inline_vserver ips_service1
   bind lb vserver lb_inline_vserver ips_service2
   ```

10. Specify the load balancing virtual server in the content inspection action.

   ```
   add contentInspection action <name> -type INLINEINSPECTION -serverName <string>
   ```

   Example:

   ```
   add contentInspection action ips_action -type INLINEINSPECTION -serverName lb_inline_vserver
   ```

11. Add a content inspection policy. Specify the content inspection action in the policy.

   ```
   add contentInspection policy <name> -rule <expression> -action <string>
   ```

   Example:

   ```
   add contentInspection policy ips_pol -rule "HTTP.REQ.METHOD.NE("CONNECT")")" -action ips_action
   ```

12. Add a proxy virtual server.

   ```
   add cs vserver <name> PROXY <IPAddress> <port> -l2Conn ON
   ```
Example:

```
add cs vserver transparentcs PROXY * * -l2Conn ON
```

13. Bind the content inspection policy to the virtual server.

```
bind cs vserver <name> -policyName <string> -priority <positive_integer> -gotoPriorityExpression <expression> -type REQUEST
```

Example:

```
bind cs vserver explicitcs -policyName ips_pol -priority 1 -gotoPriorityExpression END -type REQUEST
```

**Configuration using the GUI**

1. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Modes**.
2. Navigate to **System > Settings**. In **Modes and Features**, click **Configure Advanced Features**.
3. Navigate to **System > Network > VLANs > Add**. Add four VLANs and tag them to the interfaces.
4. Navigate to **Secure Web Gateway > Content Inspection > Content Inspection Profiles**. Click **Add**.

Specify the ingress and egress VLANs.

Create another profiles. Specify a different ingress and egress VLAN in the second profile.

5. Navigate to **Load Balancing > Services > Add** and add a service. In **Advanced Settings**, click **Profiles**. In the **CI Profile Name** list, select the content inspection profile created earlier. In **Service Settings**, set **Use Source IP Address** to YES and **Use Proxy Port** to No. In **Basic Settings**, set **Health Monitoring** to NO.

Create two services. Specify dummy IP addresses that are not owned by any of the devices, including the-inline devices. Specify profile 1 in service 1, and profile 2 in service 2.

6. Navigate to **Load Balancing > Virtual Servers > Add**. Create a TCP load balancing virtual server. Click **OK**.

7. Click inside the **Load Balancing Virtual Server Service Binding** section. In **Service Binding**, click the arrow in **Select Service**. Select the two services created earlier, and click **Select**. Click **Bind**.

8. Navigate to **Secure Web Gateway > Proxy Virtual Servers > Add**. Specify a name, IP address, and port. In **Advanced Settings**, select **Policies**. Click the “+” sign.
9. In Choose Policy select Content Inspection. Click Continue.

11. Specify a name. In Type, select INLINEINSPECTION. In Server Name, select the load balancing virtual server created earlier.

12. Click Create. Specify the rule and click Create.

13. Click Bind.

14. Click Done.

Integrating Citrix ADC with passive security devices (Intrusion Detection System)

September 18, 2019

A Citrix ADC appliance is now integrated with passive security devices such as Intrusion Detection System (IDS). These passive devices store logs and trigger alerts when it detects a bad or non-compliant traffic. It also generate reports for compliance purpose. If Citrix ADC appliance is integrated with two or more IDS devices and when there is a high volume of traffic, the appliance can load balance the devices by cloning traffic at the virtual server level.

For advanced security protection, a Citrix ADC appliance is integrated with passive security devices such as Intrusion Detection System (IDS) deployed in detection-only mode. These devices store log and trigger alerts when it sees a bad or non-compliant traffic. It also generates reports for compliance purpose. Following are some of the benefits of integrating Citrix ADC with an IDS device.

- **Inspecting encrypted traffic.** Most security devices bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to IDS devices for enhancing customer’s network security.

- **Offloading inline devices from TLS/SSL processing.** TLS/SSL processing is expensive and it results in high system CPU in intrusion detection devices if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading traffic to IDS devices from TLS/SSL processing. This way of offloading data results in an IDS device supporting a high volume of traffic inspection.

- **Loading balancing IDS devices.** The Citrix ADC appliance load balances multiple IDS devices when there is a high volume of traffic by cloning traffic at the virtual server level.

- **Replicating traffic to passive devices.** The traffic flowing into the appliance can be replicated to other passive devices for generating compliance reports. For example, few government agencies mandate every transaction to be logged in some passive devices.
- **Fanning traffic to multiple passive devices.** Some customers prefer to fan out or replicate incoming traffic into multiple passive devices.
- **Smart selection of traffic.** Every packet flowing into the appliance might need to be content inspected, for example, download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example, .exe files) for inspection and send the traffic to IDS devices for processing data.

## How Citrix ADC is integrated with IDS device with L2 connectivity

The following diagram shows how intrusion detection system (IDS) is integrated with a Citrix ADC appliance.

The component interaction is given as follows:

1. A client sends an HTTP/HTTPS request to Citrix ADC appliance.
2. The appliance intercepts the traffic and replicates it to an IDS device based on content inspection policy evaluation.
3. If the traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text.
4. Based on policy evaluation, the appliance applies a “MIRROR” type content inspection action.
5. The action has IDS service or load balancing service (for multiple IDS device integration) configured in it.
6. The IDS device is configured as content inspection service type “Any” on the appliance. The content inspection service is then associated to the content inspection profile of type “MIRROR” which specifies the egress interface through which the data has to be forwarded to the IDS device. Note: Optionally, you can also configure a VLAN tag in the content inspection profile.
7. The appliance then, replicates the data through the egress interface to one or more IDS devices.
8. Similarly, when the back-end server sends a response to Citrix ADC, the appliance replicates the data and forwards it to the IDS device.
9. If your appliance is integrated to one or more IDS devices and if you prefer to load balance the devices, then you can use the load balancing virtual server.

## Software licensing

To deploy the inline device integration, your Citrix ADC appliance must be provisioned with one of the licenses given below:

1. ADC Premium
2. ADC Enterprise
3. Telco Advanced
4. Telco Premium
Configuring intrusion detection system integration

You can integrate IDS device with Citrix ADC in two different ways.

Scenario 1: Integration with a single IDS device

Following are the steps you must configure using the command line interface.

1. Enable content inspection
2. Add content inspection profile of type MIRROR for service representing IDS device.
3. Add IDS service of type “ANY”
4. Add content inspection action of type “MIRROR”
5. Add content inspection policy for IDS inspection
6. Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

Enable Content Inspection

If you want Citrix ADC appliance to send the content for inspection to the IDS devices, you must enable the Content Inspection and load balancing features irrespective of performing decryption.

At the command prompt, type:

```
enable ns feature contentInspection LoadBalancing
```

Add Content Inspection profile of type “MIRROR”

The Content Inspection profile of type “MIRROR” explains how you can connect to the IDS device.

At the command prompt, type:

```
add contentInspection profile <name> -type MIRROR -egressInterface <interface_name> [-egressVlan <positive_integer>]
```

Example:

```
add contentInspection profile IDS_profile1 -type MIRROR -egressInterface 1/1 -egressVLAN 10
```

Add IDS service

You must configure a service of type “ANY” for each IDS device that is integrated with the appliance.

The service has the IDS device configuration details. The service represents the IDS device.

At the command prompt, type:
add service <Service_name> <IP> ANY <Port> - contentinspectionProfileName <Name> - healthMonitor OFF - usip ON - useproxyport OFF

Example:
add service IDS_service 1.1.1.1 ANY 8080 - contentInspectionProfileName IDS_profile1 - healthMonitor OFF

Add content inspection action of type MIRROR for IDS service

After you enable the Content Inspection feature and then add the IDS profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the appliance can drop, reset, block or send data to IDS device.

At the command prompt, type:

add ContentInspection action < action_name > - type MIRROR - serverName Service_name/Vserver_name

Example:
add ContentInspection action IDS_action - type MIRROR - serverName IDS_service

Add content inspection policy for IDS inspection

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:

add contentInspection policy < policy_name > - rule <Rule> - action <action_name>

Example:
add contentInspection policy IDS_pol1 - rule true - action IDS_action

Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

To receive the web traffic, you must add a load balancing virtual server.

At the command prompt, type:

add lb vserver <name> <vserver name>

Example:
add lb vserver HTTP_vserver HTTP 1.1.1.3 8080
Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL

You must bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

```
bind lb vserver <vserver name> -policyName < policy_name > -priority < priority > -type <REQUEST>
```

**Example:**

```
bind lb vserver HTTP_vserver -policyName IDS_pol1 -priority 100 -type REQUEST
```

**Scenario 2: Load balancing multiple IDS devices**

If you are using two or more IDS devices, you must load balance the devices using different content inspection services. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device.

For basic configuration steps, refer to scenario 1.

Following are the steps you must configure using the command line interface.

1. Add content inspection profile 1 of type MIRROR for IDS service 1
2. Add content inspection profile 2 of type MIRROR for IDS service 2
3. Add IDS service 1 of type ANY for IDS device 1
4. Add IDS service 2 of type ANY for IDS device 2
5. Add load balancing virtual server of type ANY
6. Bind IDS service 1 to load balancing virtual server
7. Bind IDS service 2 to load balancing virtual server
8. Add content inspection action for the load balancing of IDS devices.
9. Add content inspection policy for inspection
10. Add content switching or load balancing virtual server of type HTTP/SSL
11. Bind content inspection policy to load balancing virtual server of type HTTP/SSL

**Add content inspection profile1 of type MIRROR for IDS service 1**

IDS configuration can be specified in an entity called Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile1 is created for IDS service 1.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY -egressInterface <interface_name> [ -egressVlan <positive_integer> ]
```
Example:

add contentInspection profile IDS_profile1 -type MIRROR -egressInterface 1/1 -egressVLAN 1

Add content inspection profile 2 for type MIRROR for IDS service 2

The Content Inspection profile 2 is added for service 2 and the inline device communicates with the appliance through egress 1/1 interface.

At the command prompt, type:

add contentInspection profile <name> -type MIRROR -egressInterface -egressVlan <positive_integer>

Example:

add contentInspection profile IDS_profile1 -type MIRROR -egressInterface 1/1 -egressVLAN 1

Add IDS service 1 of type ANY for IDS device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 1 for inline device 1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY <Port> -contentInspectionProfileName <IDS_Profile_1> -usip ON -useproxyport OFF
```

Example:

```
add service IDS_service1 1.1.1.1 ANY 80 -contentInspectionProfileName IDS_profile1 -usip ON -useproxyport OFF
```

Note

The IP address mentioned in the example is a dummy one.

Add IDS service 2 of type ANY for IDS device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 2 for inline device 2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY -contentInspectionProfileName <Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```
Example:

```
add service IDS_service 1 1.1.2 ANY 80 -contentInspectionProfileName IDS_profile2
```

**Note**

The IP address mentioned in the example is a dummy one.

**Add load balancing virtual server**

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:

```
add lb vserver <vserver_name> ANY <Pvt_IP3> <port>
```

**Example:**

```
add lb vserver lb-IDS_vserver ANY 1.1.1.2
```

**Bind IDS service 1 to load balancing virtual server**

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

**Example:**

```
bind lb vserver lb-IDS_vserver IDS_service1
```

**Bind IDS service 2 to load balancing virtual server**

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

**Example:**

```
bind lb vserver lb-IDS_vserver IDS_service2
```
Add content inspection action for the IDS service

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the appliance drops, resets, blocks or sends traffic to the IDS device.

At the command prompt, type:

```
add contentInspection action <name> -type <type> [-serverName <string> [ -ifserverdown <ifserverdown> ]
```

Example:

```
add ContentInspection action IDS_action -type MIRROR -serverName lb-IDS_vserver
```

Add content inspection policy for inspection

After you create a Content Inspection action, you must add Content Inspection policy to evaluate requests for service.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name>
```

Example:

```
add contentInspection policy IDS_pol1 -rule true -action IDS_action
```

Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer2 connection on the virtual server.

For more information about load balancing, refer to How load balancing works topic.

At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

Example:

```
add lb vserver http_vserver HTTP 1.1.1.1 8080
```

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.
At the command prompt, type the following:

```
bind lb vserver <vserver name> -policyName < policy_name > -priority <> -type <REQUEST>
```

**Example:**

```
bind lb vserver http_vserver -policyName IDS_pol1 -priority 100 -type REQUEST
```

**Configure inline service integration using the Citrix ADC GUI**

1. Navigate to Security > Content Inspection > ContentInspection Profiles.
2. In the ContentInspection Profile page, click Add.
3. In the Create ContentInspectionProfile page, set the following parameters.
   a) Profile Name. Name of the content inspection profile for IDS.
   b) Type. Select the profile types as MIRROR.
   c) Egress Interface. The interface through which the traffic is sent from Citrix ADC to the IDS device.
   d) Egress VLAN (optional). The interface VLAN ID through which the traffic is sent to the IDS device.
4. Click Create.
5. Navigate to Traffic Management > Load Balancing > Services and click Add.
6. In the Load Balancing Service page, enter the content inspection service details.
7. In the Advanced Settings section, click Profiles.
8. Go to the Profiles section and click the Pencil icon to add the content inspection profile.
9. Click OK.
10. Navigate to Load Balancing > Servers. Add a virtual server of type HTTP or SSL.
11. After entering the server details, click OK and again OK.
12. In the Advanced Settings section, click Policies.
13. Go the Policies section and click the Pencil icon to configure content inspection policy.
15. In the Policy Binding section, click “+” to add a Content Inspection policy.
16. In the Create CIPolicy page, enter a name for the Inline content inspection policy.
17. In the Action field, click the “+” sign to create an IDS content inspection action of type MIRROR.
18. In the Create CI Action page, set the following parameters.
   a. Name. Name of the content inspection Inline policy.
   b. Type. Select the type as MIRROR.
   c. Server Name. Select the server/service name as Inline devices.
   d. If Server Down. Select an operation if server goes down.
   e. Request Time-out. Select a time-out value. Default values can be used.
   f. Request Time-out Action. Select a time-out action. Default values can be used.

19. Click Create.

20. In the Create CI Policy page, enter other details.

21. Click OK and Close.

For information about the Citrix ADC GUI configuration for load balancing and replicating the traffic to IDS devices, see Load Balancing.

For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to back-end origin server after content transformation, see Load Balancing topic.

**Integrating Citrix ADC layer 3 with passive security devices (Intrusion Detection System)**

August 27, 2019

A Citrix ADC appliance is now integrated with passive security devices such as Intrusion Detection System (IDS). In this setup, the appliance sends a copy of the original traffic securely to remote IDS devices. These passive devices store logs and trigger alerts when it detects a bad or non-compliant traffic. It also generate reports for compliance purpose. If Citrix ADC appliance is integrated with two or more IDS devices and when there is a high volume of traffic, the appliance can load balance the devices by cloning traffic at the virtual server level.

For advanced security protection, a Citrix ADC appliance is integrated with passive security devices such as Intrusion Detection System (IDS) deployed in detection-only mode. These devices store log and trigger alerts when it sees a bad or non-compliant traffic. It also generates reports for compliance purpose. Following are some of the benefits of integrating Citrix ADC with an IDS device.

- **Inspecting encrypted traffic.** Most security devices bypass encrypted traffic, thereby leaving servers vulnerable to attacks. A Citrix ADC appliance can decrypt traffic and send it to IDS devices for enhancing customer’s network security.
- **Offloading inline devices from TLS/SSL processing.** TLS/SSL processing is expensive and it results in high system CPU in intrusion detection devices if they decrypt the traffic. As encrypted traffic is growing at a fast pace, these systems fail to decrypt and inspect encrypted traffic. Citrix ADC helps in offloading traffic to IDS devices from TLS/SSL processing. This way of offloading data results in an IDS device supporting a high volume of traffic inspection.

- **Loading balancing IDS devices.** The Citrix ADC appliance load balances multiple IDS devices when there is a high volume of traffic by cloning traffic at the virtual server level.

- **Replicating traffic to passive devices.** The traffic flowing into the appliance can be replicated to other passive devices for generating compliance reports. For example, few government agencies mandate every transaction to be logged in some passive devices.

- **Fanning traffic to multiple passive devices.** Some customers prefer to fan out or replicate incoming traffic into multiple passive devices.

- **Smart selection of traffic.** Every packet flowing into the appliance might not be need to be content inspected, for example download of text files. User can configure the Citrix ADC appliance to select specific traffic (for example .exe files) for inspection and send the traffic to IDS devices for processing data.

### How Citrix ADC is integrated with IDS device with L3 connectivity

The following diagram shows how intrusion detection system (IDS) is integrated with a Citrix ADC appliance.

The component interaction is given as follows:

1. A client sends an HTTP/HTTPS request to Citrix ADC appliance.
2. The appliance intercepts the traffic and sends the data to remote IDS devices across different data centers or even in a cloud. This integration is done through IP tunneled layer 3. For more information about IP tunneling in a Citrix ADC appliance, see IP tunnels topic.
3. If the traffic is an encrypted one, the appliance decrypts the data and sends it as a plain text.
4. Based on policy evaluation, the appliance applies a “MIRROR” type content inspection action.
5. The action has IDS service or load balancing service (for multiple IDS device integration) configured in it.
6. The IDS device is configured as content inspection service type “Any” on the appliance. The content inspection service is then associated to the content inspection profile of type “MIRROR” and tunnel parameter which specifies the IP tunneled layer 3 interface through which the data is forwarded to the IDS device. Note: Optionally, you can also configure a VLAN tag in the content inspection profile.
7. Similarly, when the back-end server sends a response to Citrix ADC, the appliance replicates the data and forwards it to the IDS device.
8. If your appliance is integrated to one or more IDS devices and if you prefer to load balance the devices, then you can use the load balancing virtual server.

**Software licensing**

To deploy the intrusion detection system (IDS) integration, your Citrix ADC appliance must be provisioned with one of the licenses given below:

1. ADC Premium
2. ADC Advanced

**Configuring intrusion detection system integration**

You can integrate IDS device with Citrix ADC in two different ways.

**Scenario 1: Integration with a single IDS device**

Following are the steps you must configure using the command line interface.

1. Enable content inspection
2. Add content inspection profile of type MIRROR for service representing IDS device.
3. Add IDS service of type “ANY”
4. Add content inspection action of type “MIRROR”
5. Add content inspection policy for IDS inspection
6. Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL

**Enable Content Inspection**

If you want Citrix ADC appliance to send the content for inspection to the IDS devices, you must enable the Content Inspection and load balancing features irrespective of performing decryption.

At the command prompt, type:

`enable ns feature contentInspection LoadBalancing`

**Add Content inspection profile of type “MIRROR”**

The Content Inspection profile of type “MIRROR” explains how you can connect to the IDS device. At the command prompt, type:
**Note**

IP tunnel parameter must be used only for layer 3 IDS topology. Otherwise, you must use the egress interface with egress VLAN option.

```
add contentInspection profile <name> -type MIRROR -ipTunnel <iptunnel_name>
```

**Example:**

```
add contentInspection profile IDS_profile1 -type MIRROR -ipTunnel ipsectunnel1
```

**Add IDS service**

You must configure a service of type “ANY” for each IDS device that is integrated with the appliance. The service has the IDS device configuration details. The service represents the IDS device.

At the command prompt, type:

```
add service <Service_name> <IP> ANY <Port> -contentinspectionProfileName <Name> -healthMonitor OFF -usip ON -useproxyport OFF
```

**Example:**

```
add service IDS_service 1.1.1.1 ANY 8080 -contentInspectionProfileName IDS_profile1 -healthMonitor OFF
```

**Add content inspection action of type MIRROR for IDS service**

After you enable the Content Inspection feature and then add the IDS profile and service, you must add the Content Inspection action for handling the request. Based on the content inspection action, the appliance can drop, reset, block or send data to IDS device.

At the command prompt, type:

```
add ContentInspection action < action_name > -type MIRROR -serverName Service_name/Vserver_name>
```

**Example:**

```
add ContentInspection action IDS_action -type MIRROR -serverName IDS_service
```

**Add content inspection policy for IDS inspection**

After you create a Content Inspection action, you must add Content Inspection policies to evaluate requests for inspection. The policy is based on a rule which consists of one or more expressions. The policy evaluates and selects the traffic for inspection based on the rule.

At the command prompt, type the following:
add contentInspection policy < policy_name > -rule <Rule> -action <action_name>

**Example:**

add contentInspection policy IDS_pol1 -rule true -action IDS_action

**Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL**

To receive the web traffic, you must add a load balancing virtual server.

At the command prompt, type:

add lb vserver <name> <vserver name>

**Example:**

add lb vserver HTTP_vserver HTTP 1.1.1.3 8080

**Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL**

You must bind the load balancing virtual server or content switching virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

bind lb vserver <vserver name> -policyName <policy_name> -priority <priority > -type <REQUEST>

**Example:**

bind lb vserver HTTP_vserver -policyName IDS_pol1 -priority 100 -type REQUEST

**Scenario 2: Load balancing multiple IDS devices**

If you are using two or more IDS devices, you must load balance the IDS devices using different content inspection services. In this case, the Citrix ADC appliance load balances the devices on top of sending a subset of traffic to each device.

For basic configuration steps, refer to scenario 1.

Following are the steps you must configure using the command line interface.

1. Add content inspection profile 1 of type MIRROR for IDS service 1
2. Add content inspection profile 2 of type MIRROR for IDS service 2
3. Add IDS service 1 of type ANY for IDS device 1
4. Add IDS service 2 of type ANY for IDS device 2
5. Add load balancing virtual server of type ANY
6. Bind IDS service 1 to load balancing virtual server
7. Bind IDS service 2 to load balancing virtual server
8. Add content inspection action for the load balancing of IDS devices.
9. Add content inspection policy for inspection
10. Add content switching or load balancing virtual server of type HTTP/SSL
11. Bind content inspection policy to load balancing virtual server of type HTTP/SSL

Add content inspection profile 1 of type MIRROR for IDS service 1

IDS configuration can be specified in an entity called Content Inspection profile. The profile has a collection of device settings. The Content Inspection profile 1 is created for IDS service 1.

**Note:**
IP tunnel parameter must be used only for layer 3 IDS topology. Otherwise, you must use the egress interface with egress VLAN option.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY - ipTunnel <iptunnel_name>
```

**Example:**

```
add contentInspection profile IDS_profile1 -type MIRROR - ipTunnel ipsect_tunnel1
```

Add content inspection profile 2 for type MIRROR for IDS service 2

The Content Inspection profile 2 is added for service 2 and the inline device communicates with the appliance through egress 1/1 interface.

At the command prompt, type:

```
add contentInspection profile <name> -type ANY - ipTunnel <iptunnel_name>
```

**Example:**

```
add contentInspection profile IDS_profile2 -type ANY - ipTunnel ipsect_tunnel2
```

Add IDS service 1 of type ANY for IDS device 1

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 1 for inline device 1 to be part of the load balancing setup. The service that you add, provides all the inline configuration details.
At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY <Port> -contentInspectionProfileName <IDS_Profile_1> -usip ON -useproxyport OFF
```

**Example:**

```
add service IDS_service1 1.1.1.1 ANY 80 -contentInspectionProfileName IDS_profile1 -usip ON -useproxyport OFF
```

**Note:**
The IP address mentioned in the example is a dummy one.

### Add IDS service 2 of type ANY for IDS device 2

After you enable the Content Inspection feature and add the inline profile, you must add an inline service 2 for inline device 2. The service that you add, provides all the inline configuration details.

At the command prompt, type:

```
add service <Service_name_1> <Pvt_IP1> ANY <Port> -contentInspectionProfileName <Inline_Profile_2> -healthmonitor OFF -usip ON -useproxyport OFF
```

**Example:**

```
add service IDS_service1 1.1.2 ANY 80 -contentInspectionProfileName IDS_profile2
```

**Note:**
The IP address mentioned in the example is a dummy one.

### Add load balancing virtual server

After you have added the inline profile and the services, you must add a load balancing virtual server for load balancing the services.

At the command prompt, type:

```
add lb vserver <vserver_name> ANY <Pvt_IP3> <port>
```

**Example:**

```
add lb vserver lb-IDS_vserver ANY 1.1.1.2
```

### Bind IDS service 1 to load balancing virtual server

After you add the load balancing virtual server, now bind the load balancing virtual server to the first service.
At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

**Example:**

```
bind lb vserver lb-IDS_vserver IDS_service1
```

**Bind IDS service 2 to load balancing virtual server**

After you add the load balancing virtual server, now bind the server to the second service.

At the command prompt, type:

```
bind lb vserver <Vserver_name> <Service_name_1>
```

**Example:**

```
bind lb vserver lb-IDS_vserver IDS_service2
```

**Add content inspection action for the IDS service**

After you enable the Content Inspection feature, you must add the Content Inspection action for handling the inline request information. Based on the action selected, the appliance drops, resets, blocks or sends traffic to the IDS device.

At the command prompt, type:

```
add contentInspection action <name> -type <type> (-serverName <string> [-ifserverdown <ifserverdown>])
```

**Example:**

```
add contentInspection action IDS_action -type MIRROR -serverName lb-IDS_vserver
```

**Add content inspection policy for inspection**

After you create a Content Inspection action, you must add Content Inspection policy to evaluate requests for service.

At the command prompt, type the following:

```
add contentInspection policy <policy_name> -rule <Rule> -action <action_name>
```

**Example:**

```
add contentInspection policy IDS_poll -rule true -action IDS_action
```
Add content switching or load balancing virtual server of type HTTP/SSL

Add a content switching or load balancing virtual server to accept web traffic. Also you must enable the layer 2 connection on the virtual server.

For more information about load balancing, refer to How load balancing works topic.

At the command prompt, type:

```
add lb vserver <name> <vserver name>
```

**Example:**

```
add lb vserver http_vserver HTTP 1.1.1.1 8080
```

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL

You must bind the content switching or load balancing virtual server of type HTTP/SSL to the Content Inspection policy.

At the command prompt, type the following:

```
bind lb vserver <vserver name> -policyName <policy_name> -priority <> -type <REQUEST>
```

**Example:**

```
bind lb vserver http_vserver -policyName IDS_pol1 -priority 100 -type REQUEST
```

Configure inline service integration using the Citrix ADC GUI

1. Navigate to Security > Content Inspection > ContentInspection Profiles.
2. In the ContentInspection Profile page, click Add.
3. In the Create ContentInspectionProfile page, set the following parameters.
   a) Profile Name. Name of the content inspection profile for IDS.
   b) Type. Select the profile types as MIRROR.
   c) Connectivity. Layer 2 or Layer 3 interface.
   d) IP Tunnel. Select the network communication channel between two networks.
4. Click Create.
5. Navigate to Traffic Management > Load Balancing > Services and click Add.
6. In the Load Balancing Service page, enter the content inspection service details.
7. In the Advanced Settings section, click Profiles.
8. Go to the Profiles section and click the Pencil icon to add the content inspection profile.

9. Click OK.

10. Navigate to Load Balancing > Servers. Add a virtual server of type HTTP or SSL.

11. After entering the server details, click OK and again OK.

12. In the Advanced Settings section, click Policies.

13. Go the Policies section and click the Pencil icon to configure content inspection policy.

15. In the Policy Binding section, click “+” to add a Content Inspection policy.

16. In the Create CI Policy page, enter a name for the Inline content inspection policy.

17. In the Action field, click the “+” sign to create an IDS content inspection action of type MIRROR.

18. In the Create CI Action page, set the following parameters.
   a) Name. Name of the content inspection Inline policy.
   b) Type. Select the type as MIRROR.
   c) Server Name. Select the server/service name as Inline devices.
   d) If Server Down. Select an operation if server goes down.
   e) Request Time-out. Select a time-out value. Default values can be used.
   f) Request Time-out Action. Select a time-out action. Default values can be used.

19. Click Create.

20. In the Create CI Policy page, enter other details.

21. Click OK and Close.

For information about the Citrix ADC GUI configuration for load balancing and replicating the traffic to IDS devices, see Load Balancing.

For information about the Citrix ADC GUI configuration for load balancing and forwarding the traffic to back-end origin server after content transformation, see Load Balancing.

**SSL forward proxy**

May 14, 2019

**Note:** SSL forward proxy feature is available with the ADC premium license.

Web traffic has increased exponentially in recent years, and corporations are increasingly relying on the internet for their day to day operations. That, combined with the emergence of more diverse end-
points, mobility, and BYOD, along with a growing attacker base, is making users easy targets of modern malware. They are increasingly vulnerable to identity theft and having their data compromised. Traditionally, enterprises have inspected HTTP traffic for malware and viruses. They bypassed HTTP-S/TLS traffic, because it was not as prominent. It was used sparingly for content that was sensitive and trusted. But that has changed rapidly as most public internet websites now prefer to use HTTPS to protect user privacy. As a result, the inability to inspect encrypted packets allows malware or intrusions into the enterprise network. The SSL forward proxy solution offers tools that enterprises can use to protect against internet threats.

A proxy is a server that controls all the traffic between users and the Internet or SaaS applications. Since all the traffic passes through this proxy, it performs security-related functions, such as user authentication and URL categorization.

The following figure is an overview of SSL forward proxy implementation. Traffic flows through the enterprise network from the head office, branch offices, data center, and remote employees. A Citrix ADC appliance at the edge of the network acts as a proxy. The appliance can operate in transparent proxy mode or explicit proxy mode and offers controls to intercept internet traffic, including HTTPS. Policies configured on the appliance determine whether it intercepts, bypasses, or blocks a particular request. Access to restricted sites can be blocked by using URL filtering. A user is authenticated before logging on to the enterprise network. All requests and responses are tagged to identify the user, and internet-site access is categorized. User activity is logged and used to generate reports. If a breach occurs, administrators can isolate the infected system, determine whether the devices of any other users who visited that website are compromised, and take appropriate action. When you integrate Citrix Application Delivery Management (ADM) with SSL forward proxy, the logged user activity and the subsequent records in the appliance are exported to Citrix ADM by using logstream. Citrix ADM collates and presents information about the activities of users, from websites visited to the time spent online. It also provides information about bandwidth use and detected threats, such as malware and phishing sites. You can use these key metrics to monitor your network, and use SSL forward proxy feature to take corrective actions.

SSL forward proxy enables IT directors to do the following:

- Gain visibility into the otherwise bypassed secure traffic.
- Block access to malicious or unknown sites and avoid infecting users within the enterprise.
- Control access to some websites, such as personal mail, social networking, and job search websites, from the enterprise network.
- Apply intelligent content control policies to ensure maximum user productivity.
Getting started with SSL forward proxy

June 14, 2019

Important:

- OCSP check requires an internet connection to check the validity of certificates. If your appliance is not accessible from the internet by using the NSIP address, add access control lists (ACLs) to perform NAT from the NSIP address to the subnet IP (SNIP) address. The SNIP must be accessible from the Internet. For example,

```plaintext
1  add ns acl a1 ALLOW -srcIP = <NSIP> -destIP "!=" 10.0.0.0-10.255.255.255
2
3  add rnat RNAT-1 a1 -natIP <SNIP>
4
5  bind rnat RNAT-1 -natIP <SNIP>
6
7  apply acls
```

- Specify a DNS name server to resolve domain names.

- Make sure that the date on the appliance is synchronized with the NTP servers. If the date is not synchronized, the appliance cannot effectively verify whether an origin server certificate is an expired one.

To use the SSL forward proxy feature, you must perform the following tasks:

- Add a proxy server in explicit or transparent mode.
- Enable SSL interception.
  - Configure an SSL profile.
  - Add and bind SSL policies to the proxy server.
  - Add and bind a CA certificate-key pair for SSL interception.

Note:

An ADC appliance configured in transparent proxy mode can intercept only HTTP and HTTPS protocols. To bypass any other protocol, such as telnet, you must add the following listen policy on the proxy virtual server.

The virtual server now accepts only HTTP and HTTPS incoming traffic.

```plaintext
1  set cs vserver transparent-pxy1 PROXY * * -cltTimeout 180 -Listenpolicy
2  "CLIENT.TCP.DSTPORT.EQ(80) || CLIENT.TCP.DSTPORT.EQ(443)"
```

You might need to configure the following features, depending on your deployment:
• Authentication Service (recommended) – to authenticate users. Without the Authentication Service, user activity is based on client IP address.
• URL Filtering – to filter URLs by categories, reputation score, and URL lists.
• Analytics – to view user activity, user risk indicators, bandwidth consumption, and transactions break down in Citrix Application Delivery Management (ADM).

Note: SSL Forward Proxy implements most typical HTTP and HTTPS standards followed by similar products. This implementation is done with no specific browser in mind and is compatible with most common browsers. SSL Forward Proxy has been tested with common browsers and recent versions of Google Chrome, Internet Explorer, and Mozilla Firefox.

SSL forward proxy wizard

The SSL forward proxy wizard provides administrators with a tool for managing the entire SSL forward proxy deployment by using a web browser. It helps guide the customers to bring up an SSL forward proxy service quickly and helps simplify the configuration by following a sequence of well-defined steps.

2. Follow the steps in the wizard to configure your deployment.

Add a listen policy to the transparent proxy server

1. Navigate to Security > SSL Forward Proxy > Proxy Virtual Servers. Select the transparent proxy server and click Edit.
2. Edit Basic Settings, and click More.
3. In Listen priority, enter 1.
4. In Listen Policy Expression, enter the following expression:

```
1 (CLIENT.TCP.DSTPORT.EQ(80)) || CLIENT.TCP.DSTPORT.EQ(443))
```

This expression assumes standard ports for HTTP and HTTPS traffic. If you have configured different ports, for example 8080 for HTTP or 8443 for HTTPS, modify the expression to reflect those ports.

Limitations

SSL forward proxy is not supported in a cluster setup, in admin partitions, and on a Citrix ADC FIPS appliance.
Proxy modes

May 13, 2019

The Citrix ADC appliance acts as a client’s proxy to connect to the internet and SaaS applications. As a proxy, it accepts all the traffic and determines the traffic’s protocol. Unless the traffic is HTTP or SSL, it is forwarded to the destination as is. When the appliance receives a request from a client, it intercepts the request and performs some actions, such as user authentication, site categorization, and redirection. It uses policies to determine which traffic to allow and which traffic to block.

The appliance maintains two different sessions, one between the client and the proxy and the other between the proxy and the origin server. The proxy relies on customer defined policies to allow or block HTTP and HTTPS traffic. Therefore, it is important that you define policies to bypass sensitive data, such as financial information. The appliance offers a rich set of Layer 4 to Layer 7 traffic attributes and user-identity attributes to create traffic management policies.

For SSL traffic, the proxy verifies the origin server’s certificate and establishes a legitimate connection with the server. It then emulates the server certificate, signs it using a CA certificate installed on Citrix ADC, and presents the created server certificate to the client. You must add the CA certificate as a trusted certificate to the client’s browser in order for the SSL session to be successfully established.

The appliance supports transparent and explicit proxy modes. In explicit proxy mode, the client must specify an IP address in their browser, unless the organization pushes the setting onto the client’s device. This address is the IP address of a proxy server that is configured on the ADC appliance. All client requests are sent to this IP address. For explicit proxy, you must configure a content switching virtual server of type PROXY and specify an IP address and a valid port number.

Transparent proxy, as the name implies, is transparent to the client. That is, the clients might not be aware that a proxy server is mediating their requests. The ADC appliance is configured in an inline deployment, and transparently accepts all HTTP and HTTPS traffic. For transparent proxy, you must configure a content switching virtual server of type PROXY, with asterisks (**) as the IP address and port. When using the Secure Web Gateway wizard in the GUI, you do not have to specify an IP address and port.

Note

To intercept protocols other than HTTP and HTTPS in transparent proxy mode, you must add a listen policy and bind it to the proxy server.

Configure SSL forward proxy by using the CLI

At the command prompt, type:
1. `add cs vserver <name> PROXY <ipaddress> <port>`

Arguments:

Name:

Name for the proxy server. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CS virtual server is created.

The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my server” or ‘my server’).

This is a mandatory argument. Maximum Length: 127

IP Address:

IP address of the proxy server.

Port:

Port number for proxy server. Minimum value: 1

Example for explicit proxy:

```
add cs vserver swgVS PROXY 192.0.2.100 80
```

Example for transparent proxy:

```
add cs vserver swgVS PROXY *
```

Add a listen policy to the transparent proxy server by using the GUI

1. Navigate to Security > SSL Forward Proxy > Proxy Virtual Servers. Select the transparent proxy server and click Edit.

2. Edit Basic Settings, and click More.

3. In Listen priority, enter 1.

4. In Listen Policy Expression, enter the following expression:

```
(CLIENT.TCP.DSTPORT.EQ(80) || CLIENT.TCP.DSTPORT.EQ(443))
```
SSL interception

August 26, 2019

A Citrix ADC appliance configured for SSL interception acts as a proxy. It can intercept and decrypt SSL/TLS traffic, inspect the unencrypted request, and enable an admin to enforce compliance rules and security checks. SSL interception uses a policy that specifies which traffic to intercept, block, or allow. For example, traffic to and from financial websites, such as banks, must not be intercepted, but other traffic can be intercepted, and blacklisted sites can be identified and blocked. Citrix recommends that you configure one generic policy to intercept traffic and more specific policies to bypass some traffic.

The client and the proxy establish an HTTPS/TLS handshake. The proxy establishes another HTTP-S/TLS handshake with the server and receives the server certificate. The proxy verifies the server certificate on behalf of the client, and also checks the validity of the server certificate by using Online Certificate Status Protocol (OCSP). It regenerates the server certificate, signs it by using the key of the CA certificate installed on the appliance, and presents it to the client. Therefore, one certificate is used between the client and the Citrix ADC appliance, and another certificate between the appliance and the back-end server.

Important

The CA certificate that is used to sign the server certificate must be preinstalled on all the client devices, so that the regenerated server certificate is trusted by the client.

For intercepted HTTPS traffic, the proxy server decrypts the outbound traffic, accesses the clear text HTTP request, and can use any Layer 7 application to process the traffic, such as by looking into the plain text URL and allowing or blocking access based on the corporate policy and URL reputation. If the policy decision is to allow access to the origin server, the proxy server forwards the re-encrypted request to the destination service (on the origin server). The proxy decrypts the response from the origin server, accesses the clear text HTTP response, and optionally applies any policies to the response. The proxy then reencrypts the response and forwards it to the client. If the policy decision is to block the request to the origin server, the proxy can send an error response, such as HTTP 403, to the client.

To perform SSL interception, in addition to the proxy server configured earlier, you must configure the following on the ADC appliance:
SSL profile
• SSL policy
• CA certificate store
• SSL-error autolearning and caching

SSL interception certificate store

An SSL certificate, which is an integral part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. An SSL certificate is issued by a certificate authority (CA). A CA can be private or public. Certificates issued by public CAs, such as Verisign, are trusted by applications that conduct SSL transactions. These applications maintain a list of CAs that they trust.

As a forward proxy, the ADC appliance performs encryption and decryption of traffic between a client and a server. It acts as a server to the client (user) and as a client to the server. Before an appliance can process HTTPS traffic, it must validate the identity of a server to prevent any fraudulent transactions. Therefore, as a client to the origin server, the appliance must verify the origin server certificate before accepting it. To verify a server’s certificate, all the certificates (for example, root and intermediate) that are used to sign and issue the server certificate must be present on the appliance.

A default set of CA certificates is preinstalled on an appliance. The appliance can use these certificates to verify almost all of the common origin-server certificates. This default set cannot be modified. However, if your deployment requires more CA certificates, you can create a bundle of such certificates and import the bundle to the appliance. A bundle can also contain a single certificate.

When you import a certificate bundle to the appliance, the appliance downloads the bundle from the remote location and, after verifying that the bundle contains only certificates, installs it on the appliance. You must apply a certificate bundle before you can use it to validate a server certificate. You can also export a certificate bundle for editing or to store it in an offline location as a backup.

Import and apply a CA certificate bundle on the appliance by using the CLI

At the command prompt, type:

```
1 import ssl certBundle <name> <src>
2 apply ssl certBundle <name>
```

ARGUMENTS:

Name:

Name to assign to the imported certificate bundle. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.),...
space, colon (:), at (@), equals (=), and hyphen (-) characters. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my file” or ‘my file’).

Maximum Length: 31

src:

URL specifying the protocol, host, and path, including file name, to the certificate bundle to be imported or exported. For example, http://www.example.com/cert_bundle_file.

**NOTE**: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

Maximum Length: 2047

**Example**:

```bash
1 import ssl certbundle swg-certbundle http://www.example.com/cert_bundle
2 apply ssl certBundle swg-certbundle
```

```bash
1 show ssl certbundle
2
3 Name : swg-certbundle(Inuse)
4
5 URL : http://www.example.com/cert_bundle
6
7 Done
```

**Import and apply a CA certificate bundle on the appliance by using the GUI**

2. Do one of the following:
   - Select a certificate bundle from the list.
   - To add a certificate bundle, click “+” and specify a name and source URL. Click **OK**.
3. Click **OK**.

**Remove a CA certificate bundle from the appliance by using the CLI**

At the command prompt, type:

```bash
1 remove certBundle <cert bundle name>
```
Example:

```
1 remove certBundle mytest-cacert
```

Export a CA certificate bundle from the appliance by using the CLI

At the command prompt, type:

```
1 export certBundle <cert bundle name> <Path to export>
```

ARGUMENTS:

Name:

Name to assign to the imported certificate bundle. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my file” or ‘my file’).

Maximum Length: 31

src:

URL specifying the protocol, host, and path, including file name, to the certificate bundle to be imported or exported. For example, http://www.example.com/cert_bundle_file.

NOTE: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

Maximum Length: 2047

Example:

```
1 export certBundle mytest-cacert http://192.0.2.20/
```

Import, apply, and verify a CA certificate bundle from the Mozilla CA certificate store

At the command prompt, type:

```
1 > import certbundle mozilla_public_ca https://curl.haxx.se/ca/cacert.pem
2 Done
```
To apply the bundle, type:

```
1 > apply certbundle mozilla_public_ca
2 Done
```

To verify the certificate bundle in use, type:

```
1 > sh certbundle | grep mozilla
2 Name : mozilla_public_ca (Inuse)
```

**Limitations**

- Certificate bundles are not supported in a cluster setup, or on a partitioned appliance.
- TLSv1.3 protocol is not supported with SSL Forward Proxy.

**SSL policy infrastructure for SSL interception**

A policy acts like a filter on incoming traffic. Policies on the ADC appliance help define how to manage proxied connections and requests. The processing is based on the actions that are configured for that policy. That is, data in connection requests is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression). After defining an action to assign to the policy and create the policy, you must bind it to a proxy server, so that it applies to traffic flowing through that proxy server.

An SSL policy for SSL interception evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). A decision to intercept, bypass, or reset a connection is made based on the defined SSL policy. You can configure one of three actions for a policy—INTERCEPT, BYPASS, or RESET. You must specify an action when you create a policy. To put a policy into effect, you must bind it to a proxy server on the appliance. To specify that a policy is intended for SSL interception, you must specify the type (bind point) as INTERCEPT_REQ when you bind the policy to a proxy server. When unbinding a policy, you must specify the type as INTERCEPT_REQ.

**Note:**

The proxy server cannot make a decision to intercept unless you specify a policy.

Traffic interception can be based on any SSL handshake attribute. The most commonly used is the SSL domain. The SSL domain is usually indicated by the attributes of the SSL handshake. It can be the Server Name Indicator value extracted from the SSL Client Hello message, if present, or the Server Alternate Name (SAN) value extracted from the origin server certificate. The SSLi policy presents a special attribute named DETECTED_DOMAIN, which makes it easier for the customers to author interception policies based on the SSL domain from the origin server certificate. The customer can match
the domain name against a string, URL list (URL set or patset), or a URL category derived from the domain.

Create an SSL policy by using the CLI

At the command prompt, type:

1 add ssl policy <name> -rule <expression> -action <string>

Examples:

The following examples are for policies with expressions that use the detected_domain attribute to check for a domain name.

Do not intercept traffic to a financial institution, such as XYZBANK

1 add ssl policy pol1 -rule client.ssl.detected_domain.contains("XYZBANK") -action BYPASS

Do not allow a user to connect to YouTube from the corporate network

1 add ssl policy pol2 -rule client.ssl.client.ssl.detected_domain.url_categorize(0,0).category.eq ("YouTube") -action RESET

Intercept all user traffic

1 add ssl policy pol3 - rule true - action INTERCEPT

If the customer doesn’t want to use the detected_domain, they can use any of the SSL handshake attributes to extract and infer the domain.

For example, a domain name is not found in the SNI extension of the client hello message. The domain name must be taken from the origin server certificate. The following examples are for policies with expressions that check for a domain name in the subject name of the origin server certificate.

Intercept all user traffic to any Yahoo domain

1 add ssl policy pol4 - rule client.ssl.origin_server_cert.subject.contains("yahoo") - action INTERCEPT

Intercept all user traffic for the category “Shopping/Retail”

1 add ssl policy pol_url_category -rule client.ssl.origin_server_cert.subject.URL_CATEGORIZE(0,0).CATEGORY.eq("Shopping/Retail") -action INTERCEPT
Intercept all user traffic to an uncategorized URL

```
add ssl policy pol_url_category -rule client.ssl.origin_server_cert.
    subject.url_categorize(0,0).category.eq("Uncategorized")
    -action INTERCEPT
```

The following examples are for policies that match the domain against an entry in a URL set.

Intercept all user traffic if the domain name in SNI matches an entry in the URL set “top100”

```
add ssl policy pol_url_set -rule client.ssl.client_hello.SNI.
    URLSET_MATCHES_ANY("top100")
    -action INTERCEPT
```

Intercept all user traffic of the domain name if the origin server certificate matches an entry in the URL set “top100”

```
add ssl policy pol_url_set -rule client.ssl.origin_server_cert.subject
    URLSET_MATCHES_ANY("top100")
    -action INTERCEPT
```

Create an SSL policy to a proxy server by using the GUI

1. Navigate to Traffic Management > **SSL > Policies.**
2. On the SSL Policies tab, click Add and specify the following parameters:
   - Policy name
   - Policy action – Select from intercept, bypass, or reset.
   - Expression
3. Click Create.

Bind an SSL policy to a proxy server by using the CLI

At the command prompt, type:

```
bind ssl vserver <vServerName> -policyName <string> -priority <positive_integer>
    -type INTERCEPT_REQ
```

Example:

```
bind ssl vserver <name> -policyName pol1 -priority 10 -type INTERCEPT_REQ
```
Bind an SSL policy to a proxy server by using the GUI

2. Select a virtual server and click Edit.
3. In Advanced Settings, click SSL Policies.
4. Click inside the SSL Policy box.
5. In Select Policy, select a policy to bind.
6. In Type, select INTERCEPT_REQ.
7. Click Bind and then click OK.

Unbind an SSL policy to a proxy server by using the command line

At the command prompt, type:

```bash
unbind ssl vserver <vServerName> -policyName <string> -type INTERCEPT_REQ
```

SSL expressions used in SSL policies

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CLIENT.SSL.CLIENT_HELLO.SNI.*</code></td>
<td>Returns the SNI extension in a string format. Evaluate the string to see if it contains the specified text. Example: <code>client.ssl.client_hello.sni.contains(&quot;xyz.com&quot;)</code></td>
</tr>
<tr>
<td><code>CLIENT.SSL.ORIGIN_SERVER_CERT.*</code></td>
<td>Returns a certificate, received from a back-end server, in a string format. Evaluate the string to see if it contains the specified text. Example: <code>client.ssl.origin_server_cert.subject.contains(&quot;xyz.com&quot;)</code></td>
</tr>
<tr>
<td><code>CLIENT.SSL.DETECTED_DOMAIN.*</code></td>
<td>Returns a domain, either from the SNI extension or from the origin server certificate, in a string format. Evaluate the string to see if it contains the specified text. Example: <code>client.ssl.detected_domain.contains(&quot;xyz.com&quot;)</code></td>
</tr>
</tbody>
</table>
SSL error autolearning

The appliance adds a domain to the SSL bypass list if learning mode is on. The learning mode is based on the SSL alert message received from either a client or an origin server. That is, learning depends on the client or server sending an alert message. There is no learning if an alert message is not sent. The appliance learns if any of the following conditions are met:

1. A request for a client certificate is received from the server.
2. Any one of following alerts is received as part of the handshake:
   - BAD_CERTIFICATE
   - UNSUPPORTED_CERTIFICATE
   - CERTIFICATE_REVOKED
   - CERTIFICATE_EXPIRED
   - CERTIFICATE_UNKNOWN
   - UNKNOWN_CA (If a client uses pinning, it sends this alert message if it receives a server certificate.)
   - HANDSHAKE_FAILURE

To enable learning, you must enable the error cache and specify the memory reserved for this.

Enable learning by using the GUI

1. Navigate to Traffic Management > SSL.
2. In Settings, click **Change advanced SSL settings**.
3. In SSL Interception, select SSL Interception Error Cache.
4. In SSL Interception Max Error Cache Memory, specify the memory (in bytes) to reserve.
5. Click OK.

Enable learning by using the CLI

At the command prompt type:

```
set ssl parameter -ssliErrorCache ( ENABLED | DISABLED ) -ssliMaxErrorCacheMem <positive_integer>
```

Arguments:

ssliErrorCache:
Enable or disable dynamic learning, and cache the learned information to make subsequent decisions to intercept or bypass requests. When enabled, the appliance performs a cache lookup to decide whether to bypass the request.

Possible values: ENABLED, DISABLED
Default value: DISABLED

**ssliMaxErrorCacheMem:**

Specify the maximum memory, in bytes, that can be used to cache the learned data. This memory is used as an LRU cache so that the old entries are replaced with new entries after the set memory limit is exhausted. A value of 0 decides the limit automatically.

Default value: 0
Minimum value: 0
Maximum value: 4294967294

**SSL profile**

An SSL profile is a collection of SSL settings, such as ciphers and protocols. A profile is helpful if you have common settings for different servers. Instead of specifying the same settings for each server, you can create a profile, specify the settings in the profile, and then bind the profile to different servers. If a custom front-end SSL profile is not created, the default front-end profile is bound to client-side entities. This profile enables you to configure settings for managing the client-side connections.

For SSL interception, you must create an SSL profile and enable SSL interception (SSLi) in the profile. A default cipher group is bound to this profile, but you can configure more ciphers to suit your deployment. You must bind an SSLi CA certificate to this profile and then bind the profile to a proxy server. For SSL interception, the essential parameters in a profile are the ones used to check the OCSP status of the origin server certificate, trigger client renegotiation if the origin server requests renegotiation, and verify the origin server certificate before reusing the front-end SSL session. You must use the default back-end profile when communicating with the origin servers. Set any server-side parameters, such as cipher suites, in the default back-end profile. A custom back-end profile is not supported.

For examples of the most commonly used SSL settings, see “Sample Profile” at the end of this section.

Cipher/protocol support differs on the internal and external network. In the following tables, the connection between the users and an ADC appliance is the internal network. The external network is between the appliance and the internet.

Table 1: Cipher/protocol support matrix for the internal network
### Table 2: Cipher/protocol support matrix for the external network

<table>
<thead>
<tr>
<th>(Cipher/protocol)/Platform</th>
<th>MPX (N3)*</th>
<th>VPX</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS 1.1/1.2</td>
<td>12.1, 13.0</td>
<td>12.1, 13.0</td>
</tr>
<tr>
<td>ECDHE/DHE(Example TLS1-ECDHE-RSA-AES128-SHA)</td>
<td>12.1, 13.0</td>
<td>12.1, 13.0</td>
</tr>
<tr>
<td>AES-GCM(Example TLS1.2-AES128-GCM-SHA256)</td>
<td>12.1, 13.0</td>
<td>12.1, 13.0</td>
</tr>
<tr>
<td>SHA-2 Ciphers(Example TLS1.2-AES-128-SHA256)</td>
<td>12.1, 13.0</td>
<td>12.1, 13.0</td>
</tr>
<tr>
<td>ECDSA(Example TLS1-ECDHE-ECDSA-AES256-SHA)</td>
<td>12.1, 13.0</td>
<td>12.1, 13.0</td>
</tr>
</tbody>
</table>

* Use the **sh hardware** (show hardware) command to identify whether your appliance has N3 chips.

**Example:**

```plaintext
1  sh hardware
2
3  Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100
4
5  Manufactured on: 8/19/2013
6
7  CPU: 2900MHZ
8
9  Host Id: 1006665862
```
Add an SSL profile and enable SSL interception by using the CLI

At the command prompt, type:

```
add ssl profile <name> -sslinterception ENABLED -ssliReneg ( ENABLED | DISABLED )-ssliOCSPCheck ( ENABLED | DISABLED )-ssliMaxSessPerServer < positive_integer>
```

**Arguments:**

- **sslInterception:**
  - Enable or disable interception of SSL sessions.
  - Possible values: ENABLED, DISABLED
  - Default value: DISABLED

- **ssliReneg:**
  - Enable or disable triggering client renegotiation when a renegotiation request is received from the origin server.
  - Possible values: ENABLED, DISABLED
  - Default value: ENABLED

- **ssliOCSPCheck:**
  - Enable or disable OCSP check for an origin-server certificate.
  - Possible values: ENABLED, DISABLED
  - Default value: ENABLED

- **ssliMaxSessPerServer:**
  - Maximum number of SSL sessions to be cached per dynamic origin server. A unique SSL session is created for each SNI extension received from the client in a client hello message. The matching session is used for server-session reuse.
  - Default value: 10
  - Minimum value: 1
Maximum value: 1000

Example:

```
add ssl profile swg_ssl_profile -sslinterception ENABLED
Done
sh ssl profile swg_ssl_profile
1) Name: swg_ssl_profile (Front-End)
   SSLv3: DISABLED         TLSv1.0: ENABLED   TLSv1.1: ENABLED   TLSv1.2: ENABLED

Bind an SSL interception CA certificate to an SSL profile by using the GUI

1. Navigate to System > Profiles > SSL Profile.
2. Click Add.
3. Specify a name for the profile.
4. Enable SSL Sessions Interception.
5. Click OK.
6. In Advanced Settings, click Certificate Key.
7. Specify an SSLi CA certificate key to bind to the profile.
8. Click Select and then click Bind.
9. Optionally, configure ciphers to suit your deployment.
   - Click the edit icon, and then click Add.
   - Select one or more cipher groups, and click the right arrow.
   - Click OK.
10. Click Done.

Bind an SSL profile to a proxy server by using the GUI

1. Navigate to Security > SSL Forward Proxy > Proxy Virtual Servers, and add a server or select a server to modify.
2. In SSL Profile, click the edit icon.
3. In the SSL Profile list, select the SSL profile that you created earlier.
4. Click OK.
5. Click Done.

Sample Profile:
<table>
<thead>
<tr>
<th>Name: swg_ssl_profile (Front-End)</th>

**User identity management**

May 28, 2019

An increasing number of security breaches and the growing popularity of mobile devices has empha-
sized the need to ensure that use of the external internet is compliant with the corporate policies and only authorized users access external resources provisioned by the corporate personnel. Identity Man-
agement makes this possible by verifying the identity of a person or a device. It does not determine what tasks the individual can take or what files the individual can see.

An SSL forward proxy deployment identifies the user before allowing access to the internet. All requests and responses from the user are inspected. User activity is logged, and records are exported to the Citrix Application Delivery Management (ADM) for reporting. In Citrix ADM, you can view the statistics about the user activities, transactions, and bandwidth consumption.

By default, only the user’s IP address is saved, but you can configure the feature to record more details about the user, and use this identity information to create richer internet usage policies for specific users.

The Citrix ADC appliance supports the following authentication modes for an explicit-proxy configuration.

- **Lightweight Directory Access Protocol (LDAP).** Authenticates the user through an external LDAP authentication server. For more information, see LDAP Authentication Policies.
- **RADIUS.** Authenticates the user through an external RADIUS server. For more information, see RADIUS Authentication Policies.
- **TACACS+.** Authenticates the user through an external Terminal Access Controller Access-Control System (TACACS) authentication server. For more information, see Authentication Policies.
- **Negotiate.** Authenticates the user through a Kerberos authentication server. If there is an error in Kerberos authentication, appliance uses NTLM authentication. For more information, see Negotiate Authentication Policies.

For transparent proxy, only IP-based LDAP authentication is currently supported. When a client request is received, the proxy authenticates the user by checking an entry for the client IP address in the active directory, and creates a session based on the user IP address. However, if you configure the ssoNameAttribute in an LDAP action, a session is created by using the username instead of the IP address. Classic policies are not supported for authentication in a transparent proxy setup.

**Note**

For explicit proxy, you must set the LDAP login name to **sAMAccountName**. For transparent proxy, you must set the LDAP login name to **networkAddress** and attribute1 to **sAMAccountName**.

**Example for explicit proxy:**

```
1 add authentication ldapAction swg-auth-action-explicit -serverIP 10.105.157.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "CN=Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword freebsd123$ -ldapLoginName sAMAccountName
```

**Example for transparent proxy:**
Set up user authentication by using the CLI

At the command prompt type:

```
1 add authentication ldapAction swg-auth-action-explicit -serverIP 10.105.157.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "CN=Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword freebsd123$ -ldapLoginName networkAddress -authentication disable -Attribute1 sAMAccountName
```

Arguments:

**Vserver name:**

Name of the authentication virtual server to which to bind the policy.

Maximum Length: 127

**serviceType:**

Protocol type of the authentication virtual server. Always SSL.

Possible values: SSL

Default value: SSL

**Action name:**

Name for the new LDAP action. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.), pound (#), space ( ),
at (@), equals (=), colon (:), and underscore characters. Cannot be changed after the LDAP action is added. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my authentication action” or ‘my authentication action’).

Maximum Length: 127

**serverIP:**

IP address assigned to the LDAP server.

**ldapBase:**

Base (node) from which to start LDAP searches. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com. Maximum Length: 127

**ldapBindDn:**

Full distinguished name (DN) that is used to bind to the LDAP server.

Default: cn=Manager,dc=netscaler,dc=com

Maximum Length: 127

**ldapBindDnPassword:**

Password used to bind to the LDAP server.

Maximum Length: 127

**ldapLoginName:**

LDAP login name attribute. The Citrix ADC appliance uses the LDAP login name to query external LDAP servers or Active Directories. Maximum Length: 127

**Policy name:**

Name for the advance AUTHENTICATION policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Cannot be changed after AUTHENTICATION policy is created. The following requirement applies only to the CLI:

If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my authentication policy” or ‘my authentication policy’).

Maximum Length: 127

**rule:**

Name of the rule, or a default syntax expression, that the policy uses to determine whether to attempt to authenticate the user with the AUTHENTICATION server.

Maximum Length: 1499
**action:**

Name of the authentication action to be performed if the policy matches.

Maximum Length: 127

**priority:**

Positive integer specifying the priority of the policy. A lower number specifies a higher priority. Policies are evaluated in the order of their priorities, and the first policy that matches the request is applied. Must be unique within the list of policies bound to the authentication virtual server.

Minimum value: 0

Maximum Value: 4294967295

**Example:**

```
1  add authentication vserver swg-auth-vs SSL
2  Done
3  bind ssl vserver explicit-auth-vs -certkeyName ns-swg-ca-certkey
4  Done
5  add authentication ldapAction swg-auth-action-explicit -serverIP 192.0.2.116 -ldapBase "CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDn "CN=Administrator,CN=Users,DC=CTXNSSFB,DC=COM" -ldapBindDnPassword zzzzzz -ldapLoginName sAMAccountName
6  Done
7  add authenticationpolicy swg-auth-policy -rule true -action swg-auth-action-explicit
8  Done
9  bind authentication vserver swg-auth-vs -policy swg-auth-policy -priority 1
10  Done
11  set cs vserver testswg -authn401 ON -authnVsName swg-auth-vs
12  Done
```
Enable user name logging by using the CLI

At the command prompt, type:

```
set appflow param -AAAUserName ENABLED
```

**Arguments:**

AAAUserName

Enable AppFlow AAA user name logging.

Possible values: ENABLED, DISABLED

Default value: DISABLED

**Example:**

```
set appflow param -AAAUserName ENABLED
```

URL filtering

July 5, 2019

URL Filtering provides policy based control of websites by using the information contained in URLs. This feature helps network administrators monitor and control user access to malicious websites on the network.

**Get started**

If you are a new user and want to configure URL filtering, you must complete the initial SSL forward proxy setup. To get started with URL Filtering, you must first log on to the SSL forward proxy wizard. The wizard takes you through a series of configuration steps before you apply the URL Filtering policies.

**Note**

Before you begin, be sure you have a valid URL Threat Intelligence feature license installed on your appliance. If you are using a trial version, be sure to purchase a valid license to continue using this feature on the ADC appliance.
Log on to SSL forward proxy wizard

The SSL forward proxy wizard guides you through a series of simplified configuration tasks and the right pane displays the corresponding flow sequence. You can use this wizard to apply URL Filtering policies to a URL list or a predefined list of categories.

Step 1: Configure proxy settings

You must first configure a proxy server through which the client accesses the gateway. This server is of type SSL, and it operates in explicit or transparent mode. For more information about proxy server configuration, see Proxy Modes.

Step 2: Configure SSL interception

After configuring the proxy server, you must configure the SSL interception proxy to intercept encrypted traffic at the Citrix ADC appliance. In the case of URL filtering, the SSL proxy intercepts the traffic and blocks blacklisted URL while all other traffic can be bypassed. For more information about configuring SSL interception, see SSL Interception.

Step 3: Configure identity management

A user is authenticated before being allowed to log on to the enterprise network. Authentication provides the flexibility to define specific policies for a user or a group of users, based on their roles. For more information about user authentication, see User Identify Management.

Step 4: Configure URL filtering

The administrator can apply a URL filtering policy either by using the URL Categorization feature or by using the URL List feature.

URL Categorization. Controls access to websites and web pages by filtering traffic on the basis of a predefined list of categories.

URL List. Controls access to blacklisted websites and web pages by denying access to URLs that are in a URL set imported into the appliance.

Step 5: Configure security configuration

This step enables you to configure a reputation score and allow users to control access to the websites by denying access if the score is too low. Your reputation score can range from one to four, and you
can configure the threshold at which the score becomes unacceptable. For scores that exceed the threshold, you can select a policy action to allow, block, or redirect traffic. For more information, see URL Reputation Score.

**Step 6: Configure SSL forward proxy analytics**

This step enables you to activate SSL forward proxy analytics for categorizing web traffic, logging URL category in the user transaction logs and viewing traffic analytics. For more information about SSL forward proxy analytics, see Analytics.

**Step 7: Click Done to complete the initial configuration and continue managing URL filtering configuration**

**URL list**

May 28, 2019

The URL List feature enables enterprise customers to control access to specific websites and website categories. The feature filters websites by applying a responder policy bound to a URL matching algorithm. The algorithm matches the incoming URL against a URL set consisting of up to one million (1,000,000) entries. If the incoming URL request matches an entry in the set, the appliance uses the responder policy to evaluate the request (HTTP/HTTPS) and control access to it.

**URL set types**

Each entry in a URL set can include a URL and, optionally, its metadata (URL category, category groups, or any other related data). For URLs with metadata, the appliance uses a policy expression that evaluates the metadata. For more information, see URL Set.

SSL forward proxy supports custom URL sets and IWF-style URL sets. You can also use pattern sets to filter URLs.

**Custom URL set.** You can create a customized URL set with up to 1,000,000 URL entries and import it as a text file into your appliance.

**IWF-style URL set.** You can import a URL set managed by IWF or internet enforcement agencies. To import the set to your appliance, you can specify the website URL.

**Pattern set.** An ADC appliance can use pattern sets to filter URLs before granting access to websites. A pattern set is a string-matching algorithm that looks for an exact string match between an incoming URL and up to 5000 entries. For more information, see Pattern Set.
Each URL in an imported URL set can have a custom category in the form of URL metadata. Your organization can host the set and configure the ADC appliance to periodically update the set without requiring manual intervention.

After the set is updated, the Citrix ADC appliance automatically detects the metadata, and the category is available as a policy expression for evaluating the URL and applying an action such as allow, block, redirect, or notify the user.

**Advanced policy expressions used with URL sets**

The following table describes the basic expressions you can use to evaluate incoming traffic.

1. `.URLSET_MATCHES_ANY` - Evaluates to TRUE if the URL exactly matches any entry in the URL set.
2. `.GET_URLSET_METADATA()` - The `GET_URLSET_METADATA()` expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there is no match.
3. `.GET_URLSET_METADATA().EQ(<METADATA)`
4. `.GET_URLSET_METADATA().TYPECAST_LIST_T(', ').GET(0).EQ()` - Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata but match only the first field.
5. `HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL)` - Joins the host and URL parameters, which can then be used as a for matching.

**Responder action types**

*Note: In the table, HTTP.REQ.URL is generalized as `<URL expression>`.*

The following table describes the actions that can be applied to incoming internet traffic.

<table>
<thead>
<tr>
<th>Responder Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow</td>
<td>Allow the request to access the target URL.</td>
</tr>
<tr>
<td>Redirect</td>
<td>Redirect the request to the URL specified as the target.</td>
</tr>
<tr>
<td>Block</td>
<td>Deny the request.</td>
</tr>
</tbody>
</table>
**Prerequisites**

You must configure a DNS server if you import a URL Set from a hostname URL. This is not required if you use an IP address.

At the command prompt, type:

```
add dns nameServer ((<IP> [-local]])| <dnsVserverName>)[-state (ENABLED | DISABLED )] [-type <type>] [-dnsProfileName <string>]
```

**Example:**

```
1 add dns nameServer 10.140.50.5
```

**Configure a URL list**

To configure a URL list, you can use the Citrix SSL forward proxy wizard or the Citrix ADC command-line interface (CLI). On the Citrix ADC appliance, you must first configure the responder policy and then bind the policy to a URL set.

Citrix recommends that you use the Citrix SSL forward proxy wizard as the preferred option to configure a URL list. Use the wizard to bind a responder policy to a URL set. Alternatively, you can bind the policy to a pattern set.

**Configure a URL list by using the SSL forward proxy wizard**

To configure URL List for HTTPS traffic by using the GUI:

1. Navigate to Security > SSL Forward Proxy page.
2. In the details pane, do one of the following:
   a) Click SSL Forward Proxy Wizard.
   b) Select an existing configuration and click Edit.
3. In the URL Filtering section, click Edit.
4. Select the URL List check box to enable the feature.
5. Select a URL List policy and Click Bind.
6. Click Continue and then Done.

For more information, see How to Create a URL List Policy.

**Configure a URL list by using the CLI**

To configure a URL list, do the following.
1. Configure a proxy virtual server for HTTP and HTTPS traffic.
2. Configure SSL interception for intercepting HTTPS traffic.
3. Configure a URL list containing a URL set for HTTP traffic.
4. Configure URL list containing URL set for HTTPS traffic.
5. Configure a private URL set.

**Note**
If you have already configured an ADC appliance, you can skip steps 1 and 2, and configure with step 3.

**Configuring a proxy virtual server for Internet traffic**

The Citrix ADC appliance supports transparent and explicit proxy virtual servers. To configure a proxy virtual server for internet traffic in explicit mode, do the following:

1. Add a proxy SSL virtual server.
2. Bind a responder policy to the proxy virtual server.

To add a proxy virtual server by using the CLI:

```
1 add cs vserver <name> <serviceType> <IPAddress> <port>
```

**Example:**
```
1 add cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180
```

To bind a responder policy to a proxy virtual server by using the CLI:
```
1 bind ssl vserver <vServerName> -policyName <string> [-priority <positive_integer>]
```

**Note**
If you have already configured the SSL interceptor as part of Citrix ADC configuration, you can skip the following procedure.

**Configure SSL interception for HTTPS traffic**

To configure SSL interception for HTTPS traffic, do the following:

1. Bind a CA certificate-key pair to the proxy virtual server.
2. Enable the default SSL profile.
3. Create a front-end SSL profile, and bind it to the proxy virtual server and enable SSL interception in the front-end SSL profile.

To bind a CA certificate-key pair to the proxy virtual server by using the CLI:

At the command prompt, type:
```
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
```

To configure a front-end SSL profile by using the CLI:

At the command prompt, type:
```
set ssl parameter -defaultProfile ENABLED
2
3 add ssl profile <name> -sslInterception ENABLED -ssliMaxSessPerServer < positive_integer>
```

To bind a front-end SSL profile to a proxy virtual server by using the CLI

At the command prompt, type:
```
set ssl vserver <vServer name> -sslProfile <name>
```

**Configure a URL list by importing a URL set for HTTP traffic**

For information about how to configure a URL Set for HTTP traffic, see [URL Set](#).

**Perform explicit subdomain match**

You can now perform an explicit subdomain match for an imported URL set. To do this, a new parameter, “subdomainExactMatch” is added to the `import policy URLset` command.

When you enable the parameter, the URL Filtering algorithm performs an explicit subdomain match. For example, if the incoming URL is `news.example.com` and if the entry in the URL set is `example.com`, the algorithm does not match the URLs.

At the command prompt, type:
```
```

**Example**

```
import policy urlset test -url http://10.78.79.80/top-1k.csv -privateSet -subdomainExactMatch -interval 900
```
Configure a URL set for HTTPS traffic

To configure a URL Set for HTTPS traffic by using the CLI

At the command prompt type:

```bash
add ssl policy <name> -rule <expression> -action <string> [-undefAction <string>] [-comment <string>]
```

Example:

```bash
add ssl policy pol1 -rule "client.ssl.client_hello.SNI.URLSET_MATCHES_ANY(“top1m”)" -action INTERCEPT
```

To configure a URL set for HTTPS traffic by using the SSL forward proxy wizard

Citrix recommends that you use the SSL forward proxy wizard as the preferred option to configure a URL list. Use the wizard to import a custom URL set and bind to a responder policy.

1. Navigate to Security > SSL Forward proxy > URL Filtering > URL Lists.
2. In the details pane, click Add.
3. On the URL List Policy page, specify the policy name.
4. Select an option to import a URL set.
5. On the URL List Policy tab page, select the Import URL Set check box and specify the following URL Set parameters.
   a) URL Set Name—Name of the custom URL set.
   b) URL—Web address of the location at which to access the URL Set.
   c) Overwrite—Overwrite a previously imported URL set.
   d) Delimiter—Character sequence that delimits a CSV file record.
   e) Row Separator—Row separator used in the CSV file.
   f) Interval—Interval in seconds, rounded off to the nearest number of seconds equal to 15 minutes, at which the URL set is updated.
   g) Private Set—Option to prevent exporting the URL set.
   h) Canary URL—Internal URL for testing whether the content of the URL set is to be kept confidential. The maximum length of the URL is 2047 characters.
6. Select a responder action from the drop-down list.
7. Click Create and Close.

Configure a private URL set

If you configure a private URL set and keep its contents confidential, the network administrator might not know the blacklisted URLs in the set. For such cases, you can configure a Canary URL and add it
to the URL set. Using the Canary URL, the administrator can request the private URL Set to be used for every lookup request. You can refer to the wizard section for descriptions of each parameter.

To import a URL set by using the CLI:

At the command prompt, type:

```
```

**Example:**

```
import policy urlset test1 -url http://10.78.79.80/alytra/top-1k.csv -private -canaryUrl http://www.in.gr
```

**Display imported URL set**

You can now display imported URL sets in addition to added URL sets. To do this, a new parameter “imported” is added to the “show urlset” command. If you enable this option, the appliance displays all imported URL sets and distinguishes the imported URL sets from the added URL sets.

At the command prompt, type:

```
show policy urlset [<name>] [-imported]
```

**Example**

```
show policy urlset -imported
```

**Configure audit log messaging**

Audit logging enables you to review a condition or a situation in any phase of URL List process. When a Citrix ADC appliance receives an incoming URL, if the responder policy has an URL Set advanced policy expression, the audit log feature collects URL Set information in the URL and stores the details as a log message for any target allowed by audit logging.

The log message contains the following information:

1. Timestamp.
2. Log message type.
3. The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency).
4. Log message information, such as URLset name, policy action, URL.

To configure audit logging for URL List feature, you must complete the following tasks:
1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.

**URL Pattern Semantics**

May 14, 2019

The following table shows the URL patterns used for specifying the list of pages you want to filter. For example, the pattern, www.example.com/bar matches only one page at www.example.com/bar. To match all the pages whose URL starts with ‘www.example.com/bar’, you add an asterisk (*) at the end of the URL.

**Semantics for URL pattern to match metadata mapping**

The pattern matching semantics is available in a table format. For more information, see Pattern Semantics pdf page.

**Mapping URL Categories**

May 14, 2019

A list of third party categories and category groups. For more information, see URL Category Mapping page.

**Use case: URL filtering by using custom URL set**

May 14, 2019

If you are an enterprise customer looking for a way to control access to specific websites and website categories, you can do by using a custom URL set bound to a responder policy. Your organization’s network infrastructure can use a URL filter to block access to malicious or dangerous websites such as websites featuring adult, violence, gaming, drugs, politics, or job portals. In addition to filtering the URLs, you can create a customized list of URLs and import it to the ADC appliance. For example, your
organization's policies might call for blocking access to certain websites such as social networking, shopping portals, and job portals.

Each URL in the list can have a custom category in the form of metadata. The organization can host the list of URLs as a URL set on the Citrix ADC appliance and configure the appliance to periodically update the set without requiring manual intervention.

After the set is updated, the Citrix ADC appliance automatically detects the metadata, and the responder policy uses the URL metadata (category details) to evaluate the incoming URL and apply an action such as allow, block, redirect or notify the user.

To implement this configure in your network, you can perform the following tasks:

1. Import a custom URL set
2. Add a custom URL set
3. Configure a custom URL list in the SSL Forward Proxy wizard.

**Import a custom URL set by using the CLI**

At the command prompt, type:

```plaintext
2
3 import policy urlset test1 - url http://10.78.79.80/alytra/top-1k.csv
```

**Add a custom URL set by using the CLI**

At the command prompt, type:

```plaintext
add urlset <urlset_name>
```

Example:

```plaintext
add urlset test1
```

**Configure a URL list by using the SSL Forward Proxy wizard**

Citrix recommends that you use the SSL Forward Proxy wizard as the preferred option to configure a URL list. Use the wizard to import a custom URL set and bind it to a responder policy.

2. In the details pane, click Add.
On the URL List Policy page, specify the policy name.

Select an option to either import a URL set.

In the URL List Policy tab page, select the Import URL Set check box and specify the following URL Set parameters.

- **URL Set Name**—Name of the custom URL set.
- **URL**—Web address of the location at which to access the URL Set.
- **Overwrite**—Overwrite a previously imported URL set.
- **Delimiter**—Character sequence that delimits a CSV file record.
- **Row Separator**—Row separator used in the CSV file.
- **Interval**—Interval in seconds, rounded off to the nearest 15 minutes, at which the URL set is updated.
- **Private Set**—Option to prevent exporting the URL set.
- **Canary URL**—Internal URL for testing if the content of the URL set is to be kept confidential.

The maximum length of the URL is 2047 characters.

Select a responder action from the drop-down list.

Click Create and Close.

**Metadata semantics for custom URL sets**

To import a custom URL set, add the URLs to a text file and bind it to a responder policy to block Social networking URLs.

Following are examples of URLs that you might add to the text file:

- cnn.com,News
- bbc.com,News
- google.com,Search Engine
- yahoo.com,Search Engine
- facebook.com,Social Media
- twitter.com,Social Media

**Configure a responder policy to block social media URLs by using the CLI**

```
1   add responder action act_url_unauthorized respondwith '"HTTP/1.1 451
   Unavailable For Legal Reasons\r\n\r\nURL is NOT authorized\n"
2
3   add responder policy pol_url_meta_match 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("u1").EQ("Social Media")'
   act_url_meta_match
```
URL Categorization

June 19, 2019

URL Categorization restricts user access to specific websites and website categories. As a subscribed service offered by Citrix ADC, the feature enables enterprise customers to filter web traffic by using a commercial categorization database. The database has a vast number (billions) of URLs classified into different categories, such as social networking, gambling, adult content, new media, and shopping. In addition to categorization, each URL has a reputation score kept up to date based on the site’s historical risk profile. To filter your traffic, you can configure advanced policies based on categories, category groups (such as Terrorism, Illegal drugs), or site-reputation scores.

For example, you might block access to dangerous sites, such as sites known to be infected with malware, and selectively restrict access to content such as adult content or entertainment streaming media for enterprise users. You can also capture the user’s transactional details and outbound traffic details for monitoring web traffic analytics on the Citrix ADM server.

How URL categorization works

The following figure shows how Citrix ADC URL categorization service is integrated with a commercial URL Categorization database and cloud services for frequent updates.

The components interact as follows:

1. A client sends internet bound URL request.
2. The SSL forward proxy applies a policy enforcement to the request based on the category details (such as, category, category group, and site-reputation score) retrieved from the URL categorization database. If the database returns the category details, the process jumps to step 5.
3. If the database misses the categorization details, the request is sent to a cloud-based lookup service maintained by a URL categorization vendor. However, the appliance does not wait for a response, instead, the URL is marked as uncategorized and a policy enforcement is performed (jump to step 5). The appliance continues to monitor the cloud query feedback and updates the cache so that future requests can benefit from the cloud lookup.
4. The ADC appliance receives the URL category details (category, category group, and reputation score) from the cloud-based service and stores it in the categorization database.
5. The policy allows the URL and the request is sent to the origin server. Otherwise, the appliance drops, redirects, or responds with a custom HTML page.
6. The origin server responds with the requested data to the ADC appliance.
7. The appliance sends the response to the client.

**Use Case: Internet usage under corporate compliance for enterprises**

You can use the URL Filtering feature to detect and implement compliance policies to block sites that violate corporate compliance. These could be sites such as adult, streaming media, social networking which could be deemed nonproductive or consume excess internet bandwidth in an enterprise network. Blocking access to these web sites can improve employee productivity, reduce operating costs for bandwidth usage, and reduce the overhead of network consumption.

**Prerequisites**

The URL Categorization feature works on a Citrix ADC platform only if it has an optional subscription service with URL filtering capabilities and threat intelligence for SSL forward proxy. The subscription allows customers to download the latest threat categorizations for websites and then enforce those categories on the Secure Web Gateway. Before enabling and configuring the feature, you must install the following licenses:

- CNS_WEBF_SSERVER_Retail.lic
- CNS_XXXX_SERVER_PLT_Retail.lic

Where, XXXXX is the platform type, for example: V25000

**Responder policy expressions**

The following table lists the different policy expressions that you can use to verify if an incoming URL must be allowed, redirected, or blocked.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;. URL_CATEGORIZE (&lt;min_reputation&gt;, &lt;max_reputation&gt;)</code></td>
<td>Returns a URL_CATEGORY object. If <code>&lt;min_reputation&gt;</code> is greater than 0, the returned object does not contain a category with a reputation lower than <code>&lt;min_reputation&gt;</code>. If <code>&lt;max_reputation&gt;</code> is greater than 0, the returned object does not contain a category with a reputation higher than <code>&lt;max_reputation&gt;</code>. If the category fails to resolve in a timely manner, the undef value is returned.</td>
</tr>
<tr>
<td><code>&lt;url_category&gt;. CATEGORY()</code></td>
<td>Returns the category string for this object. If the URL does not have a category, or if the URL is malformed, the returned value is “Unknown.”</td>
</tr>
<tr>
<td><code>&lt;url_category&gt;. CATEGORY_GROUP()</code></td>
<td>Returns a string identifying the object’s category group. This is a higher level grouping of categories, which is useful in operations that require less detailed information about the URL category. If the URL does not have a category, or if the URL is malformed, the returned value is “Unknown.”</td>
</tr>
</tbody>
</table>
4. `<url_category>`. **REPUTATION()** - Returns the reputation score as a number from 0 to 5, where 5 indicates the riskiest reputation. If there is the category is “Unknown”, the reputation value is 1.

**Policy types:**

1. Policy to select requests for URLs that are in the Search Engine category - add responder policy p1 `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY()("Search Engine")`
2. Policy to select requests for URLs that are in the Adult category group - add responder policy p1 `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY_GROUP().EQ("Adult")`
3. Policy to select requests for Search Engine URLs with a reputation score lower than 4 - add responder policy p2 `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(4,0).HAS_CATEGORY("Search Engine")`
4. Policy to select requests for Search Engine and Shopping URLs - add responder policy p3 `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY().EQ("good_categories")`
5. Policy to select requests for Search Engine URLs with a reputation score equal to or greater than 4 - add responder policy p5 `'CLIENT.SSL.DETECTED_DOMAIN.URL_CATEGORIZE(4,0).CATEGORY().EQ("Search Engines")`
6. Policy to select requests for URLs that are in the Search Engine category and compare them with a URL Set - `'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY().EQ("Search Engine")&& HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("u1")`

**Responder policy types**

There are two types of policies used in URL Categorization feature and each of these policy types is explained below:

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL Category</td>
<td>Categorize web traffic and based on evaluation result blocks, allows or redirects traffic.</td>
</tr>
<tr>
<td>URL Reputation Score</td>
<td>Determines the reputation score of the website and allows you to control access based on the reputation score threshold level set by the administrator.</td>
</tr>
</tbody>
</table>
Configure URL categorization

To configure URL categorization on a Citrix ADC appliance, do the following:

1. Enable URL filtering.
2. Configure a proxy server for Web traffic.
3. Configure SSL interception for Web traffic in explicit mode.
4. Configure shared memory to limit cache memory.
5. Configure URL categorization parameters.
6. Configure URL categorization by using the Citrix SSL forward proxy wizard.
7. Configure URL categorization parameters by using the SSL forward proxy wizard.
8. Configure seedd database path and cloud server name

Step 1: Enabling URL Filtering

To enable URL categorization, enable the URL filtering feature and enable modes for URL categorization.

To enable URL Categorization by using the CLI

At the command prompt, type:

```
enable ns feature URLFiltering
disable ns feature URLFiltering
```

Step 2: Configure a proxy server for web traffic in explicit mode

The Citrix ADC appliance supports transparent and explicit proxy virtual servers. To configure a proxy virtual server for SSL traffic in explicit mode, do the following:

1. Add a proxy server.
2. Bind an SSL policy to the proxy server.

To add a proxy server by using the CLI

At the command prompt, type:

```
add cs vserver <name> [-td <positive_integer>] <serviceType> [-cltTimeout <secs>]
```

Example:

```
ad cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180
```
Citrix ADC 13.0

**Bind an SSL policy to a proxy virtual server by using the CLI**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bind ssl vserver &lt;vServerName&gt; -policyName &lt;string&gt; [-priority &lt;positive_integer&gt;]</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 3: Configure SSL interception for HTTPS traffic**

To configure SSL interception for HTTPS traffic, do the following:

1. Bind a CA certificate-key pair to the proxy virtual server.
2. Configure the default SSL profile with SSL parameters.
3. Bind a front-end SSL profile to the proxy virtual server and enable SSL interception in the front-end SSL profile.

**To bind a CA certificate-key pair to the proxy virtual server by using the CLI**

At the command prompt, type:

```bash
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
```

**To configure the default SSL profile by using the CLI**

At the command prompt, type:

```bash
set ssl profile <name> -denySSLReneg <denySSLReneg> -sslInterception (ENABLED | DISABLED) -ssliMaxSessPerServer positive_integer
```

**Bind a front-end SSL profile to a proxy virtual server by using the CLI**

At the command prompt, type:

```bash
set ssl vserver <vServer name> -sslProfile ssl_profile_interception
```

**Step 4: Configure shared memory to limit cache memory**

To configure shared memory to limit cache memory by using the CLI

At the command prompt, type:

```bash
set cache parameter [-memLimit <megaBytes>]
```

Where, the memory limit configured for caching is set as 10 MB.
**Step 5: Configure URL categorization parameters**

To configure the URL categorization parameters by using the CLI

At the command prompt, type:

```bash
set urlfiltering parameter [-HoursBetweenDBUpdates <positive_integer>] [-TimeOfDayToUpdateDB <HH:MM>]
```

Example:

```bash
set urlfiltering parameter -urlfilt_hours_betweenDB_updates 20
```

**Step 6: Configure URL Categorization by using the Citrix SSL forward proxy wizard**

To configure URL Categorization by using the GUI

1. Log on to the Citrix ADC appliance and navigate to Security > SSL Forward Proxy page.
2. In the details pane, do one of the following:
   a) Click SSL Forward Proxy Wizard to create a new configuration.
   b) Select an existing configuration and click Edit.
3. In the URL Filtering section, click Edit.
4. Select the URL Categorization checkbox to enable the feature.
5. Select a URL Categorization policy and Click Bind.
6. Click Continue and then Done.

For more information about URL Categorization policy, see How to Create a URL Categorization Policy.

**Step 7: Configuring URL Categorization parameters by using SSL forward proxy Wizard**

To configure URL Categorization parameters by using the GUI

1. Log on to Citrix ADC appliance and navigate to Security > URL Filtering.
2. In the URL Filtering page, click Change URL filtering settings link.
3. In the Configuring URL Filtering Params page, specify the following parameters.
   a) Hours Between DB Updates. URL Filtering hours between database updates. Minimum value: 0 and Maximum value: 720.
   b) Time of Day to Update DB. URL Filtering time of day to update database.
   c) Cloud Host. The URL path of the cloud server.
   d) Seed DB Path. The URL path of the seed database lookup server.
4. Click OK and Close.

**Sample Configuration:**
enable ns feature LB CS SSL IC RESPONDER AppFlow URLFiltering
enable ns mode FR L3 Edge USNIP PMTUD
set ssl profile ns_default_ssl_profile_frontend -denySSLReneg NONSECURE -sslInterception ENABLED -ssliMaxSessPerServer 100
add ssl certKey swg_ca_cert -cert ns_swg_ca.crt -key ns_swg_ca.key
set cache parameter -memLimit 100
add cs vserver starcs PROXY 10.102.107.121 80 -cltTimeout 180
add responder action act1 respondwith "\"HTTP/1.1 200 OK\r\n\r\n\" + http.req.url.url_categorize(0,0).reputation + "\"\n\n\"
add responder policy p1 "HTTP.REQUEST.URL_CATEGORIZE(0,0).CATEGORY.eq("Shopping/Retail") || HTTP.REQUEST.URL_CATEGORIZE(0,0).CATEGORY.eq("Search Engines & Portals") ||")" act1
bind cs vserver starcs_PROXY -policyName p1 -priority 10 -gotoPriorityExpression END -type REQUEST
add dns nameServer 10.140.50.5
set ssl parameter -denySSLReneg NONSECURE -defaultProfile ENABLED -sigDigestType RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384 RSA-SHA512 -ssliErrorCache ENABLED -ssliMaxErrorCacheMem 100000000
add ssl policy pol1 -rule "client.ssl.origin_server_cert.subject.URL_CATEGORIZE(0,0).CATEGORY.eq("Search Engines & Portals")" -action INTERCEPT
add ssl policy pol3 -rule "client.ssl.origin_server_cert.subject.ne("citrix")" -action INTERCEPT
add ssl policy swg_pol -rule "client.ssl.client_hello.SNI.URL_CATEGORIZE(0,0).CATEGORY.ne("Uncategorized")" -action INTERCEPT
Configure seed database path and cloud server name

You can now configure the seed database path and cloud lookup server name for manual setting of the cloud lookup server name and the seed database path. To do this, two new parameters, “CloudHost” and “SeedDBPath”, are added to the URL filtering parameter command.

At the command prompt, type:

```
set urlfiltering parameter -HoursBetweenDBUpdates <positive_integer> [-TimeOfDayToUpdateDB <HH:MM>] [-LocalDatabaseThreads <positive_integer>] [-CloudHost <string>] [-SeedDBPath <string>]
```

**Example**

```
set urlfiltering parameter -HoursBetweenDBUpdates 3 -TimeOfDayToUpdateDB 03:00 -CloudHost localhost -SeedDBPath /mypath
```

Configure audit log messaging

Audit logging enables you to review a condition or a situation in any phase of URL Categorization process. When a Citrix ADC appliance receives an incoming URL, if the responder policy has an URL Filtering expression, the audit log feature collects URL Set information in the URL and stores it as log messages for any target allowed by audit logging.

- Source IP address (the IP address of the client that made the request).
- Destination IP address (the IP address of the requested server).
- Requested URL containing the schema, the host and the domain name (http://www.example.com).
- URL category that the URL filtering framework returns.
- URL category group that the URL filtering framework returned.
- URL reputation number that the URL filtering framework returned.
- Audit log action taken by the policy.

To configure audit logging for URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.
Storing failure errors using SYSLOG messaging

At any stage of the URL Filtering process, if there is a system-level failure, the Citrix ADC appliance uses the audit log mechanism to store logs in the ns.log file. The errors are stored as text messages in SYSLOG format so that, an administrator can view it later in a chronological order of event occurrence. These logs are also sent to an external SYSLOG server for archival. For more information, see article CTX229399.

For example, if a failure occurs when you initialize the URL Filtering SDK, the error message is stored in the following messaging format.

Oct 3 15:43:40 <local0.err> ns URLFiltering[1349]: Error initializing NetStar SDK (SDK error=-1). (status=1).

The Citrix ADC appliance stores the error messages under four different failure categories:

- **Download failure.** If an error occurs when you try to download the categorization database.
- **Integration failure.** If an error occurs when you integrate an update into the existing categorization database.
- **Initialization failure.** If an error occurs when you initialize the URL Categorization feature, set categorization parameters, or end a categorization service.
- **Retrieval failure.** If an error occurs when the appliance retrieves the categorization details of the request.

Configure SNMP traps for NetSTAR events

The URL Filtering feature generates SNMP traps, if the following conditions occur:

- NetSTAR database update fails or succeeds.
- NetSTAR SDK initialization fails or succeeds.

The appliance has a set of conditional entities called SNMP alarms. When a condition in the SNMP alarm is met, the appliance generates traps and sends it to a specified trap destination. For example, if the NetSTAR SDK initialization fails, a SNMP OID 1.3.6.1.4.1.5951.1.1.0.183 is generated and sent to the trap destination.

For the appliance to generate traps, you must first enable and configure SNMP alarms. Then, you specify trap destination to which the appliance will send the generated trap messages.

Enable an SNMP alarm

The Citrix ADC appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.
When you enable an SNMP alarm, the URL filtering feature generates trap messages when a success or failure event occurs. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface:

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
enable
snmp
alarm <trapName>
show snmp alarm <trapName>
```

To enable an SNMP alarm by using the Citrix ADC GUI

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.

To configure SNMP alarm by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>] [-time <secs>] [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

**Example:**

```
set snmp alarm URL-FIL-DB-UPDATE-STATUS -state ENABLED
set snmp alarm URL-FIL-INIT-SDK -state ENABLED
```

To configure SNMP alarms by using the Citrix ADC GUI

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.

For more information about SNMP traps, see SNMP topic

### URL reputation score

May 28, 2019

The URL Categorization feature provides policy-based control to restrict blacklisted URLs. You can control access to websites based on URL category, reputation score, or URL category and reputation score. If a network administrator monitors a user accessing highly risky websites, he or she can use a responder policy bound to the URL reputation score to block such risky websites.

Upon receiving an incoming URL request, the appliance retrieves the category and reputation score from the URL categorization database. Based on the reputation score returned by the database, the
appliance assigns a reputation rating for websites. The value can range from 1 to 4, where 4 is the riskiest type of websites, as shown in the following table.

<table>
<thead>
<tr>
<th>URL Reputation Rating</th>
<th>Reputation Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Clean site</td>
</tr>
<tr>
<td>2</td>
<td>Unknown site</td>
</tr>
<tr>
<td>3</td>
<td>Potentially dangerous or affiliated to a dangerous site</td>
</tr>
<tr>
<td>4</td>
<td>Malicious site</td>
</tr>
</tbody>
</table>

**Use Case: Filtering by URL reputation score**

Consider an enterprise organization with a network administrator monitoring user transactions and network bandwidth consumption. If malware can enter the network, the administrator must enhance the data security and control access to malicious and dangerous websites accessing the network. To protect the network against such threats, the administrator can configure the URL filtering feature to allow or deny access by URL reputation score.

For more information about monitoring outbound traffic and user activities on the network, see Analytics.

If an employee of the organization tries to access a social networking website, the ADC appliance receives a URL request and queries the URL Categorization database to retrieve the URL category as social networking and a reputation score 3, which indicates a potentially dangerous website. The appliance then checks the security policy configured by the administrator, such as block access to sites with reputation rating of 3 or more. It then applies the policy action to control access to the website.

To implement this feature, you must configure the URL reputation score and security threshold levels by using the SSL Forward Proxy wizard.

**Configure reputation score by using the GUI**

Citrix recommends that you use the SSL forward proxy wizard to configure the reputation score and security levels. Based on the configured threshold, you can select a policy action to allow, block or redirect traffic.

1. Navigate to Security > SSL Forward Proxy.
2. In the details pane, click SSL Forward Proxy Wizard.
3. In the details page, specify the proxy server settings.
4. Click **Continue** to specify other settings such as SSL interception and identify management.
5. Click **Continue** to access the **Security Configuration** section.
6. In the **Security Configuration** section, select the **Reputation Score** checkbox to control access based on URL reputation score.
7. Select the security level and specify the reputation score threshold value:
   a) **Greater than or equals to**—Allow or block a website if the threshold value is greater than or equal to N, where N ranges from one to four.
   b) **Less than or equals to**—Allow or block a website if the threshold value is less than or equal to N, where N ranges from one to four.
   c) **In between**—Allow or block a website if the threshold value is between N1 and N2 and the range is from one to four.
8. Select a responder action from the drop-down list.
9. Click **Continue** and Close.

The following image shows the Security Configuration section on the SSL Forward Proxy wizard. Enable the URL Reputation Score option to configure the policy settings.

**Analytics**

May 15, 2019

In the Citrix ADC appliance, all the user records and subsequent records are logged. When you integrate Citrix Application Delivery Management (ADM) with the Citrix ADC appliance, the logged user activity and the subsequent records in the appliance are exported to Citrix ADM using logstream.

Citrix ADM collates and presents information on the activities of users, such as, websites visited and the bandwidth spent. It also reports bandwidth use and detected threats, such as malware and phishing sites. You can use these key metrics to monitor your network and take corrective actions with the Citrix SWG appliance. For more information, see [Citrix SSL Forward Proxy Analytics](#).

To integrate Citrix ADC appliance with Citrix ADM:

1. In the Citrix ADC appliance, while configuring SSL forward proxy, enable Analytics and provide the details of the Citrix ADM instance that you want to use for analytics.
2. In Citrix ADM, add the Citrix ADC appliance as an instance to Citrix ADM. For more information see [Add Instances to Citrix ADM](#).
Use case: Making enterprise network secure by using ICAP for remote malware inspection

May 15, 2019

The Citrix ADC appliance acts as a proxy and intercepts all the client traffic. The appliance uses policies to evaluate the traffic and forwards client requests to the origin server on which the resource resides. The appliance decrypts the response from the origin server and forwards the plain text content to the ICAP server for an antimalware check. The ICAP server responds with a message indicating “No adaptation required,” or error, or modified request. Depending on the response from the ICAP server, the content requested is either forwarded to the client, or an appropriate message is sent.

For this use case, you must perform some general configuration, proxy and SSL interception related configuration, and ICAP configuration on the Citrix ADC appliance.

General configuration

Configure the following entities:

- NSIP address
- Subnet IP (SNIP) address
- DNS name server
- CA certificate-key pair to sign the server certificate for SSL interception

Proxy server and SSL interception configuration

Configure the following entities:

- Proxy server in explicit mode to intercept all outbound HTTP and HTTPS traffic.
- SSL profile to define SSL settings, such as ciphers and parameters, for connections.
- SSL policy to define rules for intercepting traffic. Set to true to intercept all client requests.

For more details, see the following topics:

- Proxy modes
- SSL interception

In the following sample configuration, the antimalware detection service resides at www.example.com.

Sample general configuration:
Sample proxy server and SSL interception configuration:

```
1  add cs vserver explicitswg PROXY 192.0.2.100 80 - Authn401 ENABLED - authnVsName explicit-auth-vs
2  set ssl parameter -defaultProfile ENABLED
3  add ssl profile swg_profile -sslInterception ENABLED
4  bind ssl profile swg_profile -sslICACertkey ns-swg-ca-certkey
5  set ssl vserver explicitswg -sslProfile swg_profile
6  add ssl policy sslI-pol_ssli -rule true -action INTERCEPT
7  bind ssl vserver explicitswg -policyName sslI-pol_ssli -priority 100 - type INTERCEPT_REQ
```

Sample ICAP Configuration:

```
1  add service icap_svc 203.0.113.225 TCP 1344
2  enable ns feature contentinspection
3  add icapprofile icapprofile1 -uri /example.com -Mode RESMOD
4  add contentInspection action CiRemoteAction -type ICAP -serverName icap_svc -icapProfileName icapprofile1
5  add contentInspection policy CiPolicy -rule "HTTP.REQ.METHOD.NE("CONNECT")" -action CiRemoteAction
6  bind cs vserver explicitswg -policyName CiPolicy -priority 200 -type response
```

Configure the proxy settings

2. Click **Get Started** and then click **Continue**.

3. In the **Proxy Settings** dialog box, enter a name for the explicit proxy server.

4. For **Capture Mode**, select **Explicit**.

5. Enter an IP address and port number.

6. Click **Continue**.

**Configure the SSL interception settings**

1. Select **Enable SSL Interception**.

2. In **SSL Profile**, select an existing profile or click “+” to add a new front-end SSL profile. Enable **SSL Sessions Interception** in this profile. If you select an existing profile, skip the next step.

3. Click **OK** and then click **Done**.

4. In **Select SSL interception CA Certificate-Key Pair**, select an existing certificate or click “+” to install a CA certificate-key pair for SSL interception. If you select an existing certificate, skip the next step.

5. Click **Install** and then click **Close**.

6. Add a policy to intercept all the traffic. Click **Bind**. Click **Add** to add a new policy or select an existing policy. If you select an existing policy, click **Insert**, and skip the next three steps.

7. Enter a name for the policy and select **Advanced**. In the Expression editor, enter true.

8. For **Action**, select **INTERCEPT**.

9. Click **Create**.

10. Click **Continue** four times, and then click **Done**.

**Configure the ICAP settings**

1. Navigate to **Load Balancing > Services** and click **Add**.

2. Type a name and IP address. In **Protocol**, select **TCP**. In **Port**, type **1344**. Click **OK**.

3. Navigate to **SSL Forward Proxy > Proxy Virtual Servers**. Add a proxy virtual server or select a virtual server and click **Edit**. After entering details, click **OK**.

   Click **OK** again.

4. In **Advanced Settings**, click **Policies**.

5. In **Choose Policy**, select **Content Inspection**. Click **Continue**.
6. In Select Policy, click the “+” sign to add a policy.

7. Enter a name for the policy. In Action, click the “+” sign to add an action.

8. Type a name for the action. In Server Name, type the name of the TCP service created earlier. In ICAP Profile, click the “+” sign to add an ICAP profile.

9. Type a profile name, URI. In Mode, select REQMOD.

10. Click Create.

11. In the Create ICAP Action page, click Create.

12. In the Create ICAP Policy page, enter true in the Expression Editor. Then, click Create.

13. Click Bind.

14. If prompted to enable the content inspection feature, select Yes.

15. Click Done.

Sample ICAP transactions between the Citrix ADC appliance and the ICAP server in RESPMOD

Request from the Citrix ADC appliance to the ICAP server:

```
RESPMOD icap://10.106.137.15:1344/resp ICAP/1.0
Host: 10.106.137.15
Connection: Keep-Alive
Encapsulated: res-hdr=0, res-body=282
HTTP/1.1 200 OK
Date: Fri, 01 Dec 2017 11:55:18 GMT
Server: Apache/2.2.21 (Fedora)
Last-Modified: Fri, 01 Dec 2017 11:16:16 GMT
ETag: "20169-45-55f457f42ae4"
Accept-Ranges: bytes
Content-Length: 69
```
Response from the ICAP server to the Citrix ADC appliance:

ICAP/1.0 200 OK
Connection: keep-alive
Date: Fri, 01 Dec, 2017 11:40:42 GMT
Encapsulated: res-hdr=0, res-body=224
Server: IWSVA 6.5-SP1_Build_Linux_1080 $Date: 04/09/2015 01:19:26 AM$
ISTag: "9.8-13.815.00-3.100.1027-1.0"
X-Virus-ID: Eicar_test_file
X-Infection-Found: Type=0; Resolution=2; Threat=Eicar_test_file;
HTTP/1.1 403 Forbidden
Date: Fri, 01 Dec, 2017 11:40:42 GMT
Cache-Control: no-cache
Content-Type: text/html; charset=UTF-8
Server: IWSVA 6.5-SP1_Build_Linux_1080 $Date: 04/09/2015 01:19:26 AM$
Content-Length: 5688

How-to articles

May 14, 2019

Following are some configuration instructions or functional use cases available as “How to” articles to help you manage your SSL forward proxy deployment.

URL filtering

- How to create a URL categorization policy
- How to create a URL list policy
- How to whitelist an exceptional URL
- How to block adult category web sites

Security

April 23, 2019

The following topics cover configuration and installation information for Citrix ADC security features. Most of these features are policy based.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication, Authorization, Auditing (AAA)</td>
<td>Keeps unauthorized users out of the network, denies users access to tasks for which they are not authorized, and tracks the resources used during user sessions.</td>
</tr>
<tr>
<td>Application Firewall</td>
<td>Prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information.</td>
</tr>
<tr>
<td>Content Filtering</td>
<td>Blocks inappropriate HTML requests, preventing the requests from reaching the Web servers.</td>
</tr>
<tr>
<td>HTTP Denial-of-Service Protection</td>
<td>Prevents hackers from attacking your Web site with large numbers of HTTP requests.</td>
</tr>
</tbody>
</table>
Priority Queuing

Detects high-priority connections and allows those connections to proceed ahead of other connections, guaranteeing unimpeded access to those users.

SureConnect

Services all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

Surge Protection

Detects any rapid rise in connection attempts and adjusts the rate at which connections are allowed to proceed to the server, preventing server overload.

Content filtering

April 23, 2019

Content filtering can do some of the same tasks as the Citrix Web App Firewall, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex Web site that makes extensive use of scripts and accesses back-end databases, the Application Firewall may be the better tool for protecting that Web site. For more information about the Citrix Web App Firewall, see Application Firewall.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you could use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:

- Prevent users from accessing certain parts of your Web sites unless they are connecting from authorized locations.
- Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
- Redirect specified requests to a different server or service.
To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

**Enabling content filtering**

April 23, 2019

By default, content filtering is enabled on Citrix ADC appliances running the Citrix ADC operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you may need to enable the content filtering feature itself manually.

**Enable content filtering by using the CLI**

At the command prompt, type the following commands to enable content filtering and verify the configuration:

```
1 - enable ns feature ContentFiltering
2 - show ns feature
```

**Example:**

```
1 > enable ns feature ContentFiltering
Done
2 > show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Logging</td>
<td>WL</td>
<td>ON</td>
</tr>
<tr>
<td>Surge Protection</td>
<td>SP</td>
<td>OFF</td>
</tr>
<tr>
<td>Http DoS Protection</td>
<td>HDOSP</td>
<td>OFF</td>
</tr>
<tr>
<td>Content Filtering</td>
<td>CF</td>
<td>ON</td>
</tr>
</tbody>
</table>
```
Enable content by filtering by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Configure basic features.
3. In the Configure Basic Features pane, select the Content Filter check box, and then click OK.

Configure a content filtering action

April 23, 2019

After you enable the content filtering feature, you create one or more actions to tell your Citrix ADC appliance how to handle the connections it receives.

Content filtering supports the following actions for HTTP requests:

- **Add**: Adds the specified HTTP header before sending the request to the web server.
- **Reset**: Terminates the connection, sending the appropriate termination notice to the user’s browser.
- **Forward**: Redirects the request to the designated service.
- **Drop**: Silently deletes the request, without sending a response to the user’s browser.
- **Corrupt**: Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

Content filtering supports the following actions for HTTP responses:

- **Add**: Adds the specified HTTP header before sending the response to the user’s browser.
- **ErrorCode**: Returns the designated HTTP error code to the user’s browser.
- **Corrupt**: Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the response to the user’s browser.

Configure a content filtering action by using the CLI

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:
Configure a content filtering action by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, do one of the following:
   • To create a new action, click Add.
   • To modify an existing action, select the action, and then click Open.
3. In the Add Filter Action or Configure Filter Action dialog box, specify values for the parameters:
   • Action Name*—name
   • Qualifier*—qualifier (Determines which of the following parameters you can configure)
   • Service Name—servicename
   • HeaderName:Value—value
   • Response Code—respcode
   • Response Page—page
4. Fill in any other required information. For example, if you are configuring an action to send an HTTP error code, you must choose the appropriate error code from a drop-down list. If necessary, you can then modify the text of the error message, which is displayed beneath the drop-down list.
5. Click Create or OK, and then click Close. The Actions list displays the action you configured, and a message in the status bar indicates that your action has been created.

Configure a content filtering policy

April 23, 2019

To implement content filtering, you must configure at least one policy to tell your Citrix ADC appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.
Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

- **URL**: The URL in the HTTP request.
- **URL query**: Only the query portion of the URL, which is the portion after the query (?) symbol.
- **URL token**: Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.
- **HTTP method**: The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.
- **HTTP version**: The HTTP version in the request, which is usually HTTP 1.1.
- **Standard HTTP header**: Any of the standard HTTP headers defined in the HTTP 1.1 specification.
- **Standard HTTP header value**: The value portion of the HTTP header, which is the portion after the colon and space (:).
- **Custom HTTP header**: A non-standard HTTP header issued by your Web site or that appears in a user request.
- **Custom header value**: The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:).
- **Client Source IP**: The IP from which the client request was sent.

Content filtering policies use the simpler of two Citrix ADC expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see “Policies and Expressions.”

**Note**: Users who are not experienced in configuring policies at the Citrix ADC command line will usually find using the configuration utility considerably easier.

**Configure a content filtering policy by using the CLI**

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

```
1 - add filter policy <name> -rule <expression> (-reqAction <action> | -resAction <string>)
2 - show filter policy <name>
```

**Example:**

```
1 > add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com" -reqAction DROP
```
Configure a content filtering policy by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. Navigate to Protection Features > Filter.
3. In the details pane, to create a new policy, click Add.
4. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.
5. Select either Request Action or Response Action to activate the drop-down list to the right of that item.
6. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.
   **Note:** You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.
7. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.
   a) Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.
   b) Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.
   c) Click Add Expression to add that named expression to the Expression list.
      **Note:** You should perform either this step or step 7, but not both.
8. If you want to create a new expression to define your policy, use the Expression Editor.
   a) Click the Add button. The Add Expression dialog box appears.
   b) In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the Citrix ADC appliance to look at incoming
connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.

c) If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.
   Note: In the Citrix ADC classic expressions language, “HTTP” includes HTTPS requests, as well.

d) Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:
   - **METHOD**: The HTTP method used in the request.
   - **URL**: The contents of the URL header.
   - **URLTOKENS**: The URL tokens in the HTTP header.
   - **VERSION**: The HTTP version of the connection.
   - **HEADER**: The header portion of the HTTP request.
   - **URLEN**: The length of the contents of the URL header.
   - **URLQUERY**: The query portion of the contents of the URL header.
   - **URLQUERYLEN**: The length of the query portion of the URL header.
   The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name* appears below the Flow Type list box.

e) Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:
   - **==**: Matches the following text string exactly.
   - **!=**: Does not exactly match the following text string.
   - **>**: Is greater than the following integer.
   - **CONTAINS**: Contains the following text string.
   - **CONTENTS**: The contents of the designated header, URL, or URL query.
   - **EXISTS**: The specified header or query exists.
   - **NOTCONTAINS**: Does not contain the following text string.
   - **NOTEXISTS**: The specified header or query does not exist.

f) If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.

g) If you chose HEADER as the Protocol, type the header you want in the Header Name* text box.

h) Click OK to add your expression to the Expressions list.

i) Repeat steps B through H to create any additional expressions you want for your profile.

j) Click Close to close the Expressions Editor.

9. If you created a new expression, in the Expression frame select an option from the Match Any
Expression drop-down list. Your choices are:

- **Match Any Expression.** If a request matches any expression in the Expressions list, the request matches this policy.
- **Match All Expressions** If a request matches all expressions in the Expressions list, the request matches this policy. If it does not match all of them, it does not match this policy.
- **Tabular Expression Switches** the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [ [ ] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.
- **The AND [&&] operator** tells the appliance to require that a request match both the current expression and the following expression.
- **The OR [ ] operator** tells the appliance to require that a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.
- **The END [ ] operator** tells the appliance that this is the last expression in this expression group or policy.

Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression basis. You are not limited to just one or the other.

- **Advanced Free-Form Switches** off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the Citrix ADC appliance and PCRE-format regular expressions.

Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.

10. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the Citrix ADC appliance, they are all the same.
11. Click Create to create your new policy. Your new policy appears in the Policies pane list.
12. Click Close. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the Policies tab and click Remove.

**Binding a content filtering policy**

April 23, 2019

You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific vserver are evaluated only when that vserver receives traffic that matches the policy.

**Bind a policy to a virtual server by using the CLI**

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

```
1 - bind lb vserver <name>@ -policyName <string> -priority <positive_integer>
2 - show lb vserver <name>
```

**Example:**

```
1 > bind lb vserver vs-loadbal -policyName policyTwo -priority 100
2    Done
3 > show lb vserver vs-loadbal
4 1)   vs-loadbal (10.102.29.20:80) - HTTP       Type: ADDRESS
5       State: OUT OF SERVICE
6       Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
7       Time since last state change: 2 days, 00:58:03.260
8       Effective State: DOWN
9       Client Idle Timeout: 180 sec
10      Down state flush: ENABLED
11      Disable Primary Vserver On Down : DISABLED
12      Port Rewrite : DISABLED
13      No. of Bound Services : 0 (Total)      0 (Active)
14      Configured Method: LEASTCONNECTION
15      Mode: IP
16      Persistence: NONE
```
Globally bind a policy by using the CLI

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

```
1 - bind filter global (<policyName> [-priority <positive_integer>]) [-state ( ENABLED | DISABLED )]
2 - show filter global
```

Example:

```
1 bind filter global cf-pol -priority 1  
2 Done show filter global
3 1) Policy Name: cf-pol Priority: 1
4 Done
```

Bind a policy to a virtual server by using the GUI

2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click OK. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

Globally bind a policy by using the GUI

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, in the Policies tab, select the policy that you want to bind, and then click Global Bindings.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select a policy, and then click Add. The policy is added to the Configured list.
   Note: To select multiple policies from the list, press and hold the Ctrl key, then click each policy you want.
4. Click OK, and then click Close. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

### Configuring content filtering for a commonly used deployment scenario

April 23, 2019

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy filter-CF-nimda is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

#### Enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

#### Configure the content filtering policy filter-CF-nimda

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name filter-CF-nimda.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type cmd.exe, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type root.exe. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy filter-CF-nimda appears in the Filter list.
14. Click Close.

**Globally bind the content filtering policy**

2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy filter-CF-nimda, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

**Bind the content filtering policy to a virtual server**

2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy filter-CF-nimda, and then click OK. Your content filtering policy is now active, and should be filtering requests. If it is functioning correctly, the Hits counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.
Verifying the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:

```
show filter policy filter-CF-nimda
```

**Example:**

```
1   sh filter policy filter-CF-nimda
2       Name: filter-CF-nimda  Rule: REQ.HTTP.URL CONTAINS cmd.exe ||
            REQ.HTTP.URL CONTAINS root.exe
3       Request action: RESET
4       Response action:
5       Hits: 0
6   Done
```

**Note:** The

Hits counter displays an integer that denotes the number of times the filter-CF-nimda policy is evaluated. In the preceding steps, the Hits counter is set to zero because no requests for a URL containing either cmd.exe or root.exe have been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

Verifying the content filtering configuration by using the GUI

1. Navigate to Security > Protection Features > Filter.

2. In the details pane, select the filter policy filter-CF-nimda. The bottom of the pane should display the following:

```
**Request Action:**
RESET

**Rule:**
REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe

**Hits:**
0
```
Troubleshooting

April 23, 2019

If the content filtering feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for troubleshooting

You can use the following tools and resources to troubleshoot most Content Filtering issues on a Citrix ADC appliance:

- The Wireshark application customized for the Citrix ADC trace files
- Trace files recorded when accessing the resource
- The configuration files
- The ns.log file
- The iehttpheaders, or a Fiddler trace or a similar utility

Troubleshooting content filtering issues

To troubleshoot a content filtering issue, proceed as follows:

- Verify that the feature is enabled.
- Verify that the content filtering policy is configured correctly. Pay special attention to the expression that evaluates the incoming requests.
  
  Note: Most content filtering issues are caused by incorrect configuration, and the error is most often in the policy configuration.
- Check the policy’s Hits counter to verify that it is incrementing. If it is not, the policy is not getting evaluated.
- If the policy is getting evaluated and the required filtering is still not performed, you need to look into the policy expressions and action.
- If the policy’s expression seems valid, test it by assigning a simple NSTRUE value to see if the evaluation of the expression is creating any issue.
- Reevaluate whether the filtering should be based on the request or the response.
- Verify that the action is configured correctly. For example, if a custom action is used to corrupt a header in the request, verify that the header name in the action is correct. If you are not sure about the header name, start a browser with iehttpheaders or a similar utility, and then verify the headers in the request. When this feature is used, you can use nstrace to find out if appropriate action is performed when the packets leave Citrix ADC appliance.
An iehttpheaders or Fiddler trace can help you find header options and names, client-side request headers, and response headers recorded on the client.

To check the modifications made to the request header, record an nstrace on the Citrix ADC appliance or a Wireshark trace on the server.

If none of the above measures resolves the issue, verify that the connection has not become untrackable, which can happen in certain circumstances. If a connection becomes untrackable, the appliance does not perform any application-level processing of the requests. In that event, contact Citrix Technical Support.

Surge protection

April 23, 2019

When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The Citrix ADC appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as will be the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the Citrix ADC appliance will allow before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a Web site.

Figure 1. A Functional Illustration of Citrix ADC Surge Protection

Note: If the Citrix ADC appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the...
crash, usually several minutes later, it sends resets for all pending requests, which is abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection

**Disable and reenable surge protection**

April 23, 2019

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.

**Disable or reenable surge protection by using the CLI**

At the command prompt, type one of the following sets of commands to disable or reenable surge protection and verify the configuration:

```
1 - disable ns feature SurgeProtection
2 - show ns feature
3 - enable ns feature SurgeProtection
4 - show ns feature
```

**Example:**

```
1 disable ns feature SurgeProtection
2 Done show ns feature
3
4 Feature Acronym Status
5 ------ ------ -----
6 1) Web Logging WL ON
7 2) Surge Protection SP OFF
```
Enable or disable surge protection by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change Advanced Features.
3. In the Configure Advanced Features dialog box, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click OK.
5. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

Enable or reenable surge protection for a particular service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.

**Note:** Surge protection works only when both the feature and the service setting are enabled.

### Set thresholds for surge protection

April 23, 2019

To set the rate at which the Citrix ADC appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.

**Figure 1. Surge Protection Curves**

Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

**Figure 2. Aggressive Rate with the Default or a Set Base Threshold**

### Set the threshold for surge protection by using the GUI

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step. **Note:** If you do not set an explicit value here, the default value will be used.

4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the Citrix ADC appliance allows connections to the server to be opened. The throttle can be set to the following values:
   - **Aggressive:** Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent connections to the server.
   - **Normal:** Choose this option when there is no external load balancer behind the Citrix ADC appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.
   - **Relaxed:** Choose this option when the Citrix ADC appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.

5. Click OK. A message appears in the status bar, stating that the global settings are configured.

Flush the surge queue

April 23, 2019

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection
to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note:

- You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.
- Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

Flush a surge queue by using the CLI

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.

- You cannot directly specify a service group member `<servername>` and `<port>` without specifying the name of the service group `<name>` and you cannot specify `<port>` without a `<servername>`. Specify the `<servername>` and `<port>` if you want to flush the surge queue for a specific service group member.

- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.

- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-servername <servername> <port>] 
```

**Examples**

1. `flush ns surgeQ -name SVC1ANZGB -servername 10.10.10.1 80`
2. The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10
3. `flush ns surgeQ`
4. The above command flushes all the surge queues on the appliance.

**Flush a surge queue by using the GUI**

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

**DNS security options**

April 23, 2019

You can now configure the DNS security options from the Add DNS Security Profile page in the Citrix ADC GUI. To configure the DNS security options from the Citrix ADC CLI or the NITRO API, use the AppExpert components. For instructions, see the NITRO API documentation and the Citrix ADC Command Reference Guide.

One option, cache poisoning protection, is enabled by default and cannot be disabled. You can apply the other options to all DNS endpoints or to specific DNS virtual servers in your deployment, as shown in the following table:
Cache poisoning protection

A cache poisoning attack redirects users from legitimate sites to malicious websites. For example, the attacker replaces a genuine IP address in the DNS cache with a fake IP address that they control. When the server responds to requests from these addresses, the cache is poisoned and the subsequent requests for the addresses of the domain are redirected to the attacker’s site.

The Cache Poisoning Protection option prevents insertion of corrupt data into the database that caches DNS server requests and responses. This is an inbuilt feature of the Citrix ADC appliances and is always enabled.

DNS DDoS protection

You can configure the DNS DDoS Protection option for each type of request that you suspect might be used in a DDoS attack. For each type, the Citrix ADC appliance drops any requests received after a threshold value for the number of requests received in a specified period of time (time slice) is exceeded. You can also configure this option to log a warning to the SYSLOG server. For example:

- **DROP**: Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen DROP. When the incoming requests exceed 15 in 1 second, then the packets start getting dropped.
- **WARN**: Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen WARN. When the incoming requests exceeds around 15 queries in 1 second, a warning message is logged indicating a threat and then the packets start getting dropped.
is recommended to set threshold values for WARN smaller than that of DROP for a record type. This will help administrators identify an attack by logging a warning message before the actual attack happens and Citrix ADC starts dropping incoming requests.

**Set a threshold for incoming traffic by using the Citrix ADC GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profile** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
4. Expand **DNS DDoS Protection**.
   a) Select the record type and enter the threshold limit and the time slice value.
   b) Select **DROP** or **WARN**.
   c) Repeat steps a and b for each of the other record types that you want to protect against.
5. Click **Submit**.

**Manage exceptions – whitelist/blacklist servers**

Manage excepts enables you to add exceptions either to blacklist or whitelist domain name and IP addresses. For example:

- When a particular IP address is identified posting an attack, such IP address can be blacklisted.
- When administrators find that there is unexpectedly high request for a particular domain name, then that domain name can be blacklisted.
- NXDomains and some of the existent domains which can consume the server resources can be blacklisted.
- When administrators whitelist domain names or IP addresses, queries or requests only from these domains or IP addresses are answered and all others are dropped.

**Create a whitelist or blacklist by using the GUI**

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   a) Expand **Manage exceptions – Whitelist/Blacklist Servers**.
   b) Select **Block** to block queries from blacklisted domains/addresses, or select **Allow** only to allow queries from whitelisted domains/addresses.
   c) In the **Domain name / IP Address** box, enter the domain names, IP addresses, or IP address ranges. Use commas to separate the entries.

   **Note:** If you select **Advanced Option**, you can use the “start with,” “contains,” and “ends
with " options to set the criteria.
For example, you can set criteria to block a DNS query that starts with "image" or ends with ".co.ru" or contains "mobilesites."

4. Click Submit.

**Prevent random subdomain attacks**

In random subdomain attacks, queries are sent to random, nonexistent subdomains of legitimate domains. This increases the load on the DNS resolvers and servers. As a result, they can become overloaded and slow down.

The Prevent Random Subdomain Attacks option directs the DNS responder to drop DNS queries that exceed a specified length.

Assume that example.com is a domain name owned by you and hence the resolution request comes to your DNS server. The attacker can append a random subdomain to example.com and send a request. Based on the specified query length and the FQDN, the random queries will be dropped.

For example, if the query is www.image987trending.example.com, it will be dropped if the query length is set to 20.

**Specify a DNS query length by using the GUI**

2. On the DNS Security Profiles page, click Add.
3. On the Add DNS Security Profile page, do the following:
   a) Expand Prevent Random Subdomain Attacks.
   b) Enter the numerical value for the query length.
4. Click Submit.

**Bypassing the cache**

During an attack, the data that is already cached must be protected. To protect the cache, new requests for certain domains or record types or response codes can be sent to the origin servers instead of cached.

The Bypassing the cache option directs the Citrix ADC appliance to bypass the cache for specified domains, record types, or response codes when an attack is detected.

**Bypass the cache for specified domains or record types or response types by using the GUI**

2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Bypassing the cache** and enter the domain names and / or choose the record types or the response types for which the cache has to be bypassed.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
   - Click **Response Types** and choose the response type.

4. Click **Submit**.

### Enforce DNS transactions over TCP

Some DNS attacks can be prevented if the transactions are forced to use TCP instead of UDP. For example, during a bot attack, the client sends a flood of queries but cannot handle responses. If the use of TCP is enforced for these transactions, then the bots cannot understand the responses and therefore cannot send requests over TCP.

### Force domains or record types to operate at the TCP level by using the GUI

1. Navigate to **Configuration > Security > DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Enforce DNS Transactions over TCP** and enter the domain names and / or choose the record types for which the DNS transactions must be forced over TCP.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
4. Click **Submit**.

### Provide root details in the DNS response

In some attacks, the attacker sends a flood of queries for unrelated domains that are not configured or cached on the Citrix ADC appliance. If the dnsRootReferral parameter is ENABLED, it exposes all the root servers.

The **Provide Root Details in the DNS Response** option directs the Citrix ADC appliance to restrict access to root referrals for a query that is not configured or cached. The appliance sends a blank response.

The **Provide Root Details in the DNS Response** option can also mitigate or block amplification attacks. When the dnsRootReferral parameter is DISABLED, there will be no root referral in the Citrix ADC responses and hence they do not get amplified.
Enable or disable access to the root server by using the GUI

2. On the DNS Security Profiles page, click Add.
3. On the Add DNS Security Profile page, do the following:
   a) Expand Provide Root Details in the DNS Response.
   b) Click ON or OFF to allow or restrict access to the root server.
4. Click Submit.

System

April 23, 2019

This section provides system-level information of the Citrix ADC. This includes a detailed explanation of system-level features, the scenarios in which the features can be used, the configuration steps, and examples to help you better understand the features.

- Basic Operations
- Authentication and Authorization
- TCP Configurations
- HTTP Configurations
- SNMP
- Audit Logging
- Web Server Logging
- Call Home
- Reporting Tool
- CloudBridge Connector
- High Availability
- TCP Optimization

Basic operations

April 23, 2019

Any changes you make to the configuration of a Citrix ADC appliance are not saved automatically. You have to save the settings manually. When an appliance is restarted, it loads the latest saved configuration.
View and save configurations

Configurations are stored in the /nsconfig/ns.conf directory. For configurations to be available across sessions, you must save the configuration after every configuration change.

To view the running configuration by using the command line interface
At the command prompt, type:
```
show ns runningConfig
```
To view the running configuration by using the GUI
- Navigate to System > Diagnostics and, in the View Configuration group, click Running Configuration.

To find the difference between two configuration files by using the command line interface
At the command prompt, type:
```
diff ns config <configfile> <configfile2>
```
To find the difference between two configuration files by using the GUI
- Navigate to System > Diagnostics and, in the View Configuration group, click Configuration difference.

To save configurations by using the command line interface
At the command prompt, type:
```
save ns config
```
To save configurations by using the GUI
On the Configuration tab, in the top-right corner, click the Save icon.

To view the saved configurations by using the command line interface
At the command prompt, type:
```
show ns ns.conf
```
To view the saved configurations by using the GUI
Navigate to System > Diagnostics ** and, in the **View Configuration group, click Saved Configuration.

Clear configuration

You have the following three options for clearing the Citrix ADC configuration.

**Basic level.** Clearing your configuration at the basic level clears all settings except the following:
Citrix ADC 13.0

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (nsroot)

**Extended level.** Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions

Feature and mode settings revert to their default values.

**Full level.** Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them could cause the appliance to lose network connectivity.

To clear the configuration by using the command line interface

At the command prompt, type:

```
clear ns config -force
```

**Example:** To forcefully clear the basic configurations on an appliance.

```
1 clear ns config -force basic
```

To clear the configuration by using the GUI

- Navigate to **System > Diagnostics** and, in the Maintenance group, click **Clear Configuration** and select the configuration level to be cleared from the appliance.

**Clock synchronization**

May 15, 2019

You can configure your Citrix ADC appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the ntp.conf file from either the GUI or the command line interface, or by manually modifying the ntp.conf file and then starting the NTP daemon (NTPD). The clock synchronization configuration
Citrix ADC 13.0

does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration
does not get propagated to the secondary Citrix ADC in a high availability setup.

Citrix ADC GUI allows you to configure the time zone and the NTP server IP address required for clock
synchronization on the first-time-user (FTU) screen.

**Note:**
If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the
to use a public NTP server, be sure to read the Rules of Engagement page (link included on all
Public Time Servers pages).

In Citrix ADC release 11, the NTP version has been updated from 4.2.6p3 to 4.2.8p2.

**Set clock synchronization**

To configure clock synchronization, you must add NTP servers and then enable NTP synchronization.

**To add an NTP server by using the command line interface**

At the command prompt, type the following commands to add an NTP server and verify the configu-
ration:

- `add ntp server (serverIP | serverName)[-minpoll positive_integer][-maxpoll positive_integer]`
- `show ntp server`

**Example:**

`add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11`

**To configure an NTP server by using the GUI**

Navigate to System > NTP Servers, and create the NTP server.

**Start NTP daemon**

When you enable NTP synchronization, the Citrix ADC starts the NTP daemon and uses the NTP server
entries in the ntp.conf file to synchronize its local time setting. If you do not want to synchronize the
appliance time with the other servers in the network, you can disable NTP synchronization, which
stops the NTP daemon (NTPD).
To enable NTP synchronization by using the command line interface

At the command prompt, type one of the following commands:

```
enable ntp sync
```

To enable NTP synchronization by using the GUI

Navigate to System > NTP Servers, click Action and select NTP Synchronization.

Configure clock synchronization

You can configure clock synchronization manually by logging on to the Citrix ADC appliance and editing the ntp.conf file.

To enable clock synchronization on your Citrix ADC appliance by modifying the ntp.conf file

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the /etc/ntp.conf file to /nsconfig/ntp.conf, unless the /nsconfig directory already contains an ntp.conf file.
4. For each NTP server you want to add, you must add the following two lines to the /nsconfig/ntp.conf file:

```
server <IP address for NTP server> iburst
restrict <IP address for NTP server> mask <netmask> nomodify notrap nopeer noquery
```

**Note:**
For security reasons, there should be a corresponding restrict entry for each server entry.

**Example:**

In the following example, an administrator has inserted # characters to “comment out” an existing NTP entry, and then added a new entry:

```
##server 1.2.3.4 iburst
##restrict 1.2.3.4 mask 55.255.255.255 nomodify notrap nopeer noquery
server 10.102.29.160 iburst
restrict 10.102.29.160 mask 255.255.255.255 nomodify notrap nopeer noquery
```

1. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.
2. Add the following entry to `/nsconfig/rc.netscaler`: `/bin/sh /etc/ntpd_ctl full_start`

This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the `/var/log` directory. This process runs every time the Citrix ADC is restarted.

1. Restart the Citrix ADC appliance to enable clock synchronization. Or, to start the time synchronization process without restarting the appliance, enter the following commands at the shell prompt:

   - `rm /etc/ntp.conf`
   - `ln -s /nsconfig/ntp.conf /etc/ntp.conf`
   - `/bin/sh /etc/ntpd_ctl full_start`

### Session timeout

April 23, 2019

A session timeout interval is provided to restrict the time duration for which a session (GUI, CLI, or API) remains active when not in use. For the Citrix ADC, the system session timeout can be configured at the following levels:

- **User level timeout.** Applicable to the specific user.

<table>
<thead>
<tr>
<th>Interface type</th>
<th>Time out configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>GUI</td>
<td>Navigate to System &gt; User Administration &gt; Users, select a user, and edit the user’s timeout setting.</td>
</tr>
<tr>
<td>CLI</td>
<td>At the command prompt, enter the following command: <code>set system user &lt;name&gt; - timeout &lt;secs&gt;</code></td>
</tr>
</tbody>
</table>

- **User group level timeout.** Applicable to all users in the group.

<table>
<thead>
<tr>
<th>Interface type</th>
<th>Time out configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>GUI</td>
<td>Navigate to System &gt; User Administration &gt; Groups, select a group, and edit the group’s timeout setting.</td>
</tr>
</tbody>
</table>
Interface type | Time out configuration
---|---
CLI | At the command prompt, enter the following command:
\[
\text{set system group } \langle \text{groupName} \rangle \ - \text{-timeout } \langle \text{secs} \rangle|
\]

- **Global system timeout.** Applicable to all users and users from groups who do not have a timeout configured.

<table>
<thead>
<tr>
<th>Interface type</th>
<th>Time out configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>GUI</td>
<td>Navigate to System &gt; Settings, click Change global system settings, and update the timeout value as required.</td>
</tr>
</tbody>
</table>
| CLI | At the command prompt, enter the following command:
\[
\text{set system parameter -timeout } \langle \text{secs} \rangle
\]

The timeout value specified for a user has the highest priority. If timeout is not configured for the user, the timeout configured for a member group is considered. If timeout is not specified for a group (or the user does not belong to a group), the globally configured timeout value is considered. If timeout is not configured at any level, the default value of 900 seconds is set as the system session timeout.

Additionally, you can specify timeout durations for each of the interfaces you are accessing. However, the timeout value specified for a specific interface is restricted to the timeout value configured for the user that is accessing the interface. For example, let us consider an user "publicadmin" who has a timeout value of 20 minutes. Now, when accessing an interface, the user must specify a timeout value that is within 20 minutes.

**Note:**
You can choose to keep a check on the minimum and maximum timeout values by specifying the timeout as restricted (in CLI by specifying the *restrictedTimeout* parameter). This parameter is provided to account for previous Citrix ADC versions where the timeout value was not restricted.

- When enabled, the minimum configurable timeout value is 5 minutes (300 secs) and the maximum value is 1 day (86400 secs). If the timeout value is already configured to a value larger than 1 day, when this parameter is enabled, you are prompted to change it. If you do not change the value, the timeout value will automatically be reconfigured to the default timeout duration of 15 minutes (900 secs) on next reboot. The same will happen is the configured timeout value is less than 5 minutes.
- When disabled, the configured timeout durations are considered.
To configure the timeout duration at each interface:

<table>
<thead>
<tr>
<th>Interface type</th>
<th>Time out configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLI</td>
<td>Specify the timeout value on the command prompt by using the following command: <code>set cli mode -timeout &lt;secs&gt;</code></td>
</tr>
<tr>
<td>API</td>
<td>Specify the timeout value in the login payload.</td>
</tr>
</tbody>
</table>

System date and time

April 23, 2019

To change the system date and time, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the GUI.

To view the system date and time by using the command line interface

At the command prompt, type:

```
show ns config
```

To view the system date and time by using the GUI

Navigate to System and select the System Information tab to view the system date.

Backup and restore a Citrix ADC appliance

September 3, 2019

When your appliance gets corrupted or needs an upgrade, you can back up your system configuration. This is done either through the Citrix CLI or GUI interface. The appliance also enables you to import the backup file from an external source. However, you can do this only through the GUI interface and there is no support through the CLI interface.
Points to remember

You must remember the following points when you backup and restore your appliance.

- There must be a support for network configuration on a new platform.
- The new platform build must be same as the backup file or a later version.

Back up a Citrix ADC appliance

Depending on data and backup requirement, you can create a “basic” backup or a “full” backup.

- **Basic backup.** You can perform this type of backup if you want to back up files that constantly change. The files that you can back up are in the following table.

For information about the basic backup details, see the Table topic.

- **Full backup.** In addition to the files that are backed up by a basic backup, a full backup has less frequently updated files. The files that are backed up when you use the “Full” backup option are:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Sub-Directory or Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>nsconfig</td>
<td>ssl, license, fips*</td>
</tr>
<tr>
<td>/var/</td>
<td>netscaler/ssl/, wi/-</td>
</tr>
<tr>
<td></td>
<td>java_home/jre/lib/security/cacerts/, wi/-</td>
</tr>
<tr>
<td></td>
<td>java_home/lib/security/cacerts/*</td>
</tr>
</tbody>
</table>

The backed-up data is stored as a compressed TAR file in the /var/ns_sys_backup/ directory. To avoid issues due to non-availability of disk space, you can store up to 50 backup files in this directory. You can use the `rm system backup` command to delete existing backup files and create more backups.

**Note**

When the backup operation is in progress, do not execute commands that affect the configuration.

If a file that is required to be backed up is not available, the operation skips that file.

To back up a Citrix ADC appliance

Follow the procedure given below to back up a Citrix ADC appliance by using the Citrix ADC command line interface.
Citrix ADC 13.0

At the command prompt, do the following:

1. Save the Citrix ADC configurations.

```plaintext
save ns config
```

1. Create the backup file.

```plaintext
create system backup [fileName] -level basic | full -comment <string>
```

**Note:**
If the file name is not specified, the appliance creates a TAR file with the following naming convention: `backup_<level>_<nsip_address>_<date-timestamp>.tgz`.

**Example:** To back up the full appliance using the default naming convention for the backup file.

```plaintext
> create system backup -level full
```

1. Verify that the backup file was created.

```plaintext
show system backup
```

You can view properties of a specific backup file by using the `fileName` parameter.

---

**Restore a Citrix ADC appliance**

**Important**
You cannot successfully restore your appliance, if your rename or modify your backup file.

When you restore your appliance, the restore operation untars the backup file from the `/var/ns_sys_backup/` directory. Once the files are untarred, the files are copied to the respective directories.

**To restore the Citrix ADC from a local backup file by using the command line interface**

**Note:** Citrix recommends you to back up the current configuration before restoring a previous configuration. However, if you do not want the restore command to automatically create a backup of the current configuration, use the `-skipBackup` parameter.

At the command prompt, do the following:

1. Obtain a list of the backup files available on the appliance.

```plaintext
show system backup
```

2. Restore the appliance by specifying one of the backup files.

```plaintext
restore system backup <filename> [-skipBackup]
```
**Example:** To restore by using a full backup of an appliance

```
> restore system backup backup_full_<nsip_address>_<date-timestamp>.tgz
```

3. Reboot the appliance.

```
reboot
```

**To backup and restore a Citrix ADC appliance by using the GUI**

1. Navigate to **System > Backup and Restore**.
2. Click **Backup/Import** to start the process.
3. In the **Backup/Import** page, select **Create** and set the following parameters.
   a) File Name. Name of the appliance backup file.
   b) Level. Select a backup level as basic or full.
   c) Comment. Provide a brief description for the backup.
4. Click **Backup**.
5. If you want to import a backup, you must select **Import**.
6. Once backup is complete, you can select the file and click **Download**.
7. To restore, select the backup file and click **Restore**.
8. In the **Restore** page, verify backup file details and click **Restore**.

For more information on how to backup and restore Citrix ADC instances, see **Backup and Restore using Cirix ADM** topic.

For more information on how to backup and restore an SDX appliance, see **Backup and restore SDX appliance**

For information about operations performed on system backup, see **System Backup** topic.

**Restart or shut down**

April 23, 2019

The Citrix ADC appliance can be remotely restarted or shut down from the available user interfaces. When a standalone Citrix ADC appliance is restarted or shut down, the unsaved configurations (configurations performed since the last save ns config command was issued) are lost.
In a high availability setup, when the primary appliance is rebooted/shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance.

You can also restart the appliance by only rebooting the Citrix ADC software and not rebooting the underlying operating system. This is called a warm reboot. For example, when you add a new license or change the IP address, you can warm reboot the Citrix ADC appliance for these changes to take place.

**Note**
Warm reboot can be performed only on nCore appliances.

To restart by using the command line interface

At the command prompt, type:

```
reboot [-warm]
```

To restart the Citrix ADC by using the GUI

1. In the GUI, click Reboot on the home page of the Configuration tab.
2. When prompted to reboot, select Save configuration to make sure that you do not lose any configurations.

**Note**
You can perform a warm reboot by selecting Warm reboot.

To shut down the Citrix ADC by using the command line interface

At the command prompt, type:

- `shutdown -p now`: Shuts down the software and switches off the Citrix ADC. To restart Citrix ADC MPX, press the AC power switch. To Restart Citrix ADC VPX, restart the VPX instance.
- `shutdown -h now`: Shuts down the software and leaves the Citrix ADC switched on. Press any key to restart the Citrix ADC. This command does not switch off the Citrix ADC. Therefore, do not switch off the AC power or remove the AC power cables.

**Note**
The appliance cannot be shut down from the GUI.

---

**Generate technical support bundle**

April 23, 2019
For help with analyzing and resolving any issues with a Citrix ADC appliance, you can generate a technical support bundle on the appliance and send the bundle to Citrix Technical Support. The Citrix ADC technical support bundle is a gzipped tar archive of system configuration data and statistics. It collects the following data from the Citrix ADC appliance on which you generate the bundle:

- **Configuration files.** All files in the /flash/nsconfig directory.
- **Newnslog files.** The currently running newnslog and some previous files. To minimize the archive file size, newnslog collection is restricted to 500 MB, 6 files, or 7 days, whichever occurs first. If older data is needed, it might require manual collection.
- **Log files.** Files in /var/log/messages, /var/log/ns.log, and other files under /var/log and /var/nslog.
- **Application core files.** Files created in the /var/core directory within the last week, if any.
- **Output of some CLI show commands.**
- **Output of some CLI stat commands.**
- **Output of BSD shell commands.**

You can use a single command to generate the technical support bundle and securely upload it to the Citrix Technical Support server. To upload, you must specify your My Citrix credentials. When you generate the bundle, you can specify the case or service request number that was allotted to you by Citrix Technical Support. If you have already generated a technical support bundle, you can upload the existing archive file to the Citrix Technical Support server by specifying the file name with the full path.

The technical support bundle is saved on the Citrix ADC appliance in an archive at the following location:

/var/tmp/support/support.tgz

The above path is a symlink to the most recent collector for easy access. The full filename varies, depending on the deployment topology, but generally follows a format similar to:

`collector_<P/S>_<NS_IP>_<DateTime>.tgz.`

If your Citrix ADC appliance does not have direct Internet connectivity, you can use a proxy server to directly upload the technical support bundle to the Citrix Technical Support server. The basic format of the proxy string is:

`proxy_IP:<proxy_port>`

If the proxy server requires authentication, the format is:

`username:password@proxy_IP:<proxy_port>`

**Note**

For Citrix ADC appliances in a high availability pair, you must generate the technical support bundle on each of the two nodes.
For Citrix ADC appliances in a Cluster setup, you can generate the technical support bundle on each node individually, or you can generate smaller abbreviated archives for all nodes by using the cluster IP address.

For Citrix ADC Admin Partitions, you must generate the technical support bundle from the default admin partition. To get the technical support bundle for a specific partition, you must specify the name of the partition for which you want to generate the technical support bundle. If you do not specify the name of the partition, data is collected from all admin partitions.

To generate the Citrix ADC technical support bundle by using the command line interface

At the command prompt, type:

```
show techsupport [-scope <scope> <partitionName>] [-upload [-proxy <string>]] [-casenumber <string>] [-file <string>] [-description <string>] [-userName <string> -password]]
```

<table>
<thead>
<tr>
<th>Sr. No</th>
<th>Task</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Generate and upload the technical support bundle to the Citrix Technical Support server.</td>
<td>show techsupport –upload –userName account1 –password xxxxxxx</td>
</tr>
<tr>
<td>2</td>
<td>Generate and upload the technical support bundle to the Citrix Technical Support server through a proxy server</td>
<td>show techsupport –upload –proxy 1.1.1:80 –userName account1 –password xxxxxxx</td>
</tr>
<tr>
<td>3</td>
<td>Upload an existing technical support bundle to the Citrix Technical Support server.</td>
<td>show techsupport –upload –file,/var/tmp/support/collector_P_10.102.29.160_9Sep2015_15_22.tar.gz –userName account1 –password xxxxxxx</td>
</tr>
<tr>
<td>4</td>
<td>Generate small, abbreviated archives for all nodes in a Cluster setup. Execute this command by using the cluster IP address</td>
<td>show techsupport –scope CLUSTER</td>
</tr>
<tr>
<td>5</td>
<td>Generate a technical support bundle specific to an admin partition. Execute this command on the default admin partition.</td>
<td>show techsupport –scope PARTITION partition1</td>
</tr>
</tbody>
</table>
Extra management CPU

April 23, 2019

If you need better performance for configuration and monitoring of a Citrix ADC MPX appliance, you can allocate an extra management CPU from the appliance's packet engine pool. This feature is supported on certain Citrix ADC MPX models and all VPX models except the VPX instances that run on Citrix ADC SDX appliances. It affects the output of the stat system cpu and stat system commands.

Supported Citrix ADC MPX models:

- 25xxx
- 22xxx
- 14xxx
- 115xx
- 15xxx
- 26xxx

**Note**

For Citrix ADC MPX 26xxx models with more than 20 cores, the mandatory extra management CPU feature is enabled by default. For Citrix ADC VPX models, a license that supports atleast 12 vCPUs is required to enable this feature.

Allocate or deallocate an extra management CPU by using the Citrix ADC CLI

At the command prompt, type one of the following commands:

- `enable extramgmtcpu`
- `disable extramgmtcpu`

**Note**

After you enable and disable this feature, the Citrix ADC appliance displays a warning to restart the appliance, for the changes to take effect.

To show the configured and effective state of an extra management CPU.

At the command prompt, type:

```
1 'show extramgmtcpu'
```

**Example**

```
1 > show extramgmtcpu
2
```
Parameter descriptions of commands listed in the command line interface

- **enable extramgmtcpu**
  Enables and dedicates extra CPU for management from PE pool.
  See also:
  - disable system extramgmtcpu
  - show system extramgmtcpu

- **disable extramgmtcpu**
  Disables extra CPU for management and returns it to the PE pool.
  See also:
  - enable system extramgmtcpu
  - show system extramgmtcpu

- **show extramgmtcpu**
  Displays configured and effective states of the extra management CPU.
  Configured and effective state are different if enable extramgmtcpu command has been entered but system is has not been restarted.
  See also:
  - enable system extramgmtcpu
  - disable system extramgmtcpu

**Allocate an extra management CPU by using the GUI**

To allocate an extra management CPU by using the GUI, navigate to System > Settings and click Configure Extra Management CPU. From the Configured State drop-down menu, select Enabled and then select OK.

To check CPU usage, go to System > Settings > Dashboard.
Configure an extra management CPU by using the NITRO API

Use the following NITRO methods and formats to enable, disable, and show an extra management CPU.

To enable an extra management CPU:

HTTP Method: POST

URL: `http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=enable`

Payload: 
```
{ "systemextramgmtcpu":{} }
```

```
curl -v -X POST -H "Content-Type: application/json" -u nsroot:
  nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?
  action=enable -d '{
    "systemextramgmtcpu":{
      }
    }
  ',
```

To disable an extra management CPU

HTTP Method: POST

URL: `http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=disable`

Payload: 
```
{ "systemextramgmtcpu":{} }
```

```
curl -v -X POST -H "Content-Type: application/json" -u nsroot:
  nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?
  action=disable -d '{
    "systemextramgmtcpu":{
      }
    }
  ',
```

To show an extra management CPU

HTTP Method: GET

URL: `http://<NSIP>/nitro/v1/config/systemextramgmtcpu`

Example
Statistics and monitoring

The following examples show the differences in the output of the stat system cpu and stat system commands before and after adding an extra management CPU.

1. stat system cpu

This command displays statistics of CPUs.

Here is a sample output before adding an extra management CPU on one of the supported models.

Example output

```
> stat system cpu
CPU statistics

ID  Usage

 8   1
 7   1
11   2
 1   1
 6   1
 9   1
 3   1
 5   1
 4   1
10   1
 2   1
```

Here is the output after adding an extra management CPU on the same MPX appliance.
> stat system cpu

CPU statistics

<table>
<thead>
<tr>
<th>ID</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

2. stat system

This command displays CPU use. In the following example, the output before adding an extra management CPU on one of the supported models is:

Mgmt Additional-CPU usage (%) 0.00

Example output

> stat system

Citrix ADC Executive View

System Information:

Up since Wed Oct 11 11:17:54 2017

/flash Used (%) 0
Packet CPU usage (%) 1.30
Management CPU usage (%)  4.00
Mgmt CPU0 usage (%)  4.00
Mgmt Additional-CPU usage (%)  0.00
Memory usage (MB)  2167
InUse Memory (%)  5.76
/var Used (%)  0

In the following example, the output after adding an extra management CPU on the same MPX appliance is:

Mgmt Additional-CPU usage (%)  0.80
Configure HTTP and HTTPS management ports

April 23, 2019

In a single-IP mode deployment of a Citrix ADC appliance, a single IP address is used as NSIP, SNIP, and VIP addresses. This single IP address uses different port numbers to function as NSIP, SNIP, and VIP addresses.

Port numbers 80 and 443 are well-known ports for HTTP and HTTPS services. Earlier, port 80 and 443 of Citrix ADC IP address (NSIP) were dedicated ports for internal HTTP and HTTPS management services. Because these ports were reserved for internal services, you cannot use these well-known ports for providing HTTP and HTTPS data services from a VIP address, which has the same address as the NSIP address in a single-IP mode deployment.

To address this requirement, you can now configure ports for internal HTTP and HTTPS management services (of the NSIP address) other than port 80 and 443.

The following lists the default port numbers for internal HTTP and HTTPS management services in Citrix ADC MPX, VPX, and CPX appliances:

- Citrix ADC MPX and VPX appliances: 80 (HTTP) and 443 (HTTPS)
- Citrix ADC CPX appliances: 9080 (HTTP) and 9443 (HTTPS)

How to collect technical support bundle from a Citrix ADC appliance

April 23, 2019

A Citrix ADC appliance has a built-in mechanism to collect log files. The log files are in turn sent to Citrix Insight Services for analysis.

| Note: All procedures are applicable for software release 9.2 or later. |

Download technical support bundle from Citrix ADC MPX and VPX appliances

To run a collector file by using the Citrix ADC GUI, you must complete the following procedure:

| Note: The procedure is applicable for software release 9.2 or later. |

1. Navigate to **System > Diagnostic**.
2. In the Technical Support Tools section, click **Generate Support File** link.
3. In the **Tech Support** page, set the following parameters:
a) **Scope.** To collect data from one or more nodes.
b) **Partition.** Name of the partition.
c) **Citrix Technical Support pload Options.** Set all options such as proxy server, service case number, collector archive file name, and a brief description of the archive file for uploading the technical support bundle.
d) **My Citrix Account.** Enter your Citrix credentials.

4. Click **Run.**

5. The Technical Support bundle is generated.

6. Click **Yes** to download the Technical Support bundle to your local desktop.

**Obtain technical support bundle by using the command interface**

1. Download the file from the appliance using a Secure FTP (SFTP) or Secure Copy (SCP) utility, such as WinSCP, and upload it to Citrix Insight Services for analysis.

   **Note:** In NetScaler software release earlier than 9.0, the collector script must be downloaded separately and executed.

   > show techsupport -scope CLUSTER

2. This will collect techsupport information from all nodes in the cluster and compress the files into a single archive.

3. After the appliance generates the collector archive the location of the file is displayed as shown in the following screen shot.

The file is stored in /var/tmp/support and you can verify it by logging into a Citrix ADC appliance and running the following command from a shell prompt.

root@NS## cd /var/tmp/support/
root@NS## ls -l

**Obtain technical support bundle by using the GUI**

In order to generate the collector file from Graphical User Interface (GUI) please select “Partition” option from the Scope.

1. In the **Tech Support** page, enter the details and click **Run.** Wait for the script to generate the collector archive.

2. After the appliance generates the collector archive, download and save the file on your local computer before uploading it to **Citrix Insight Services.**
**Upload and run collector script on Citrix ADC appliance**

To upload and run the updated collector script on a NetScaler appliance, complete the following procedure:

**Note**: The procedure is applicable for software release 9.2 or later.

1. Copy the updated collector script `showtechsupport.pl` (attached with this article) to the `/nsconfig` directory of the NetScaler appliance. Use an SFTP or SCP utility, such as WinSCP, to copy the file to the NetScaler appliance.
2. Run the following commands from the CLI of the appliance:

   ```
   > shell
   # cd /nsconfig
   # chmod +x showtechsupport.pl
   # ./showtechsupport.pl
   ```

1. Switch to the CLI of the appliance.
2. Run the following command to create log files for analysis:

   ```
   > show techsupport
   ```

   The `collector_<NSIP>_<>(P/S)_<DateTime>.tgz` file is created in the `/var/tmp/support` directory of the appliance.

   **Note**: You must then upload the `.tgz` file to Citrix Insight Services for analysis.
3. If you must uninstall this script, run the following commands from the CLI of the appliance:

   ```
   > shell
   rm /nsconfig/showtechsupport.pl
   ```

**Obtain diagnostic bundle from Citrix ADC SDX**

1. Open the NetScaler SDX Configuration Utility with the NetScaler SDX Management IP address from a web browser.
2. Expand the **Diagnostics** node.
3. Select the **Technical Support** node.
4. Click **Generate Technical Support File**.
5. Select **Appliance** (including instances) from the drop-down menu.
6. Click **Add**.
7. Select one or more instances to add in.
8. Click **OK**. Wait for the process to complete.
9. Select the bundle name that was generated and then click **Download**
10. Upload the bundle file to Citrix Insight Services.

For information on collecting/deleting NetScaler SDX support bundle using CLI/serial console refer to Citrix Documentation.

Authentication and authorization

July 23, 2019

To configure Citrix ADC authentication and authorization, you must first define the users who have access to the Citrix ADC appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default Citrix ADC administrator user name is nsroot. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the Citrix ADC appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

Note

- Local users can authenticate to the Citrix ADC even if external authentication servers are configured. You can restrict this by disabling the localAuth parameter of the set system parameter command.

- For enhanced security, Citrix recommends that you change the nsroot password. Frequently changing the password is advisable. For information about how to change the nsroot password, see Resetting the default administrator (nsroot) password.

Configuring users, user groups, and command policies

April 23, 2019
You must define your users by configuring accounts for them. To simplify the management of user accounts, you can organize them into groups. You can create command policies, or use built-in command policies, to regulate user access to commands.

You can also customize the command-line prompt for a user. Prompts can be defined in a user’s configuration, in a user-group configuration, and in the global system configuration settings. The prompt displayed for a given user is determined by the following order of precedence:

1. Display the prompt as defined in the user’s configuration.
2. Display the prompt as defined in the group configuration for the user’s group.
3. Display the prompt as defined in the system global configuration settings.

You can now specify a timeout value for inactive CLI sessions for a system user. If a user’s CLI session is idle for a time that exceeds the timeout value, the Citrix ADC appliance terminates the connection. The timeout can be defined in a user’s configuration, in a user-group configuration, and in the global system configuration settings. The timeout for inactive CLI sessions for a user is determined by the following order of precedence:

1. Timeout value as defined in the user’s configuration.
2. Timeout value as defined in the group configuration for the user’s group.
3. Timeout value as defined in the system global configuration settings.

A Citrix ADC root administrator can configure the maximum concurrent session limit for system users. By restricting the limit, you can reduce the number of open connections and improve server performance. As long as the CLI count is within the configured limit, concurrent users can log on to the GUI any number of times. However, if the number of CLI sessions reaches the configured limit, users can no longer log on to the GUI. For example, if the number of concurrent session is configured to 20, concurrent users can log on to 19 CLI sessions. But if the user is logged on to the 20th CLI session, any attempt to log on to the GUI, CLI or NITRO results in an error message (ERROR: Connection limit to CFE exceeded).

**Note**
The default the number of concurrent sessions is configured to 20 and the maximum number of concurrent sessions is configured to 40.

**Configuring user accounts**

To configure user accounts, you simply specify usernames and passwords. You can change passwords and remove user accounts at any time.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:
add system user <username> [-externalAuth ( ENABLED | DISABLED )]
  [-promptString <string>] [-timeout <secs>] [-logging ( ENABLED | DISABLED )] [-maxsession <positive_integer>]

Where Logging option is for external users to collect log data externally using weblogging or audit logging mechanism. If enabled, the auditing client authenticates itself with Citrix ADC to collect logs through this user account.

Example

> add system user johnd -promptString user-%u-at-%T

```
Enter password: 
Confirm password: 
> show system user johnd
user name: john
  Timeout:900 Timeout Inherited From: Global
  External Authentication: ENABLED
  Logging: DISABLED
  Maximum Client Sessions: 20
```

To configure a user account by using the GUI

Navigate to System > User Administration > Users, and create the user.

Configuring user groups

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account to more than one group. Binding user accounts to multiple groups might allow more flexibility when applying command policies.
To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- `add system group <groupName> [-promptString <string>] [-timeout <secs>]`
- `show system group <groupName>`

Example

> add system group Managers -promptString Group-Managers-at-%h

To bind a user to a group by using the command line interface

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

- `bind system group <groupName> -userName <userName>`
- `show system group <groupName>`

Example

> bind system group Managers -userName user1

To configure a user group by using the GUI

Navigate to **System > User Administration > Groups**, and create the user group.

**Note:**

To add members to the group, in the Members section, click **Add**. Select users from the Available list and add them to the Configured list.

Configuring command policies

Command policies regulate which commands, command groups, virtual servers, and other entities that users and user groups are permitted to use.

The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them to users and/or groups.

Here are the key points to keep in mind when defining and applying command policies:

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
• Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to execute any configuration commands until the proper command policies are bound to their accounts.
• All users inherit the policies of the groups to which they belong.
• You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.
• The following commands are available by default to any user and are unaffected by any command you specify:
  • help, show cli attribute, set cli prompt, clear cli prompt, show cli prompt, alias, unalias, history, quit, exit, whoami, config, set cli mode, unset cli mode, and show cli mode.

Built-in Command Policies

The following table describes the built-in policies.

Table 1. Built-in Command Policies

<table>
<thead>
<tr>
<th>Policy name</th>
<th>Allows</th>
</tr>
</thead>
<tbody>
<tr>
<td>read-only</td>
<td>Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the Citrix ADC command group.</td>
</tr>
<tr>
<td>operator</td>
<td>Read-only access and access to commands to enable and disable services and servers.</td>
</tr>
<tr>
<td>network</td>
<td>Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.</td>
</tr>
<tr>
<td>sysadmin</td>
<td>[Included in Citrix ADC 12.0 and later] A sysadmin is lower than a superuser in terms of access allowed on the appliance. A sysadmin user can perform all Citrix ADC operations with the following exceptions: no access to the Citrix ADC shell, cannot perform user configurations, cannot perform partition configurations, and some other configurations as stated in the sysadmin command policy.</td>
</tr>
<tr>
<td>superuser</td>
<td>Full access. Same privileges as the nsroot user.</td>
</tr>
</tbody>
</table>
Creating custom command policies

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need additional levels of control but are unfamiliar with regular expressions might want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that will be affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with show, type the following:
  - "ˆshow . *$"
- To create a command policy that includes all commands that begin with rm, type the following:
  - "ˆrm . *$"
- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions:

<table>
<thead>
<tr>
<th>Command specification</th>
<th>Matches these commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;ˆrm\s+. *$&quot;</td>
<td>All remove actions, because all remove actions begin with the rm string, followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
<tr>
<td>&quot;ˆshow\s+. *$&quot;</td>
<td>All show commands, because all show actions begin with the show string, followed by a space and additional parameters such as command groups, command object types, and arguments.</td>
</tr>
<tr>
<td>&quot;ˆshell$&quot;</td>
<td>The shell command alone, but not combined with any additional parameters such as command groups, command object types, and arguments.</td>
</tr>
</tbody>
</table>
The following table shows the command specifications for each of the built-in command policies.

Table 3. Expressions Used in the Built-in Command Policies

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Command Specification Regular Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>read-only</td>
<td>(^man.*)</td>
</tr>
<tr>
<td>operator</td>
<td>(^man.*)</td>
</tr>
<tr>
<td>network</td>
<td>(?!clear ns config.<em>)(?!scp.</em>)</td>
</tr>
<tr>
<td>sysadmin</td>
<td>[From Citrix ADC 11 onwards] (?!\shell)(?!sftp)(?!scp)(?!batch)(?!source)(?!.*superuser)(?!.*nsroot)(?!\show\s+system\s+(user</td>
</tr>
</tbody>
</table>

To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

- `add system cmdPolicy <policyName> <action> <cmdspec>`
- `show system cmdPolicy <policyName>`
Example

> add system cmdPolicy read_all ALLOW (^shows+(!system)(!ns ns.conf)(!ns runningConfig).*|(^stat.*))

To configure a command policy by using the GUI

Navigate to **System > User Administration > Command Policies**, and create the command policy.

**Binding command policies to users and groups**

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

- `bind system user <userName> -policyName <policyName> <priority>
- `show system user <userName>

Example

> bind system user user1 -policyName read_all 1

To bind command policies to a user by using the GUI

Navigate to **System > User Administration > Users**, select the user and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user group and verify the configuration:

- `bind system group <groupName> -policyName <policyName> <priority>`
Citrix ADC 13.0

- show system group <groupName>

Example

> bind system group Managers -policyName read_all 1

To bind command policies to a group by using the GUI

Navigate to System > User Administration > Groups, select the group and bind command policies. Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

Resetting the default administrator (nsroot) password

September 24, 2019

The nsroot account provides complete access to all features of the appliance. Therefore, to preserve security, the nsroot account should be used only when necessary, and only individuals whose duties require full access should know the password for the nsroot account. Frequently changing the nsroot password is advisable. If you lose the password, you can reset it to the default and then change it.

To reset your nsroot password, you can log onto your appliance and change the password. However, if you do not remember the password that you have set, then you must reboot appliance to single user mode, mount the file system in read/write mode and remove the Citrix ADC user nsroot entry from the ns.conf file. As a final step, reboot and log onto your appliance with the default password and set a new password.

To reset the nsroot password

1. Connect a computer to the console port of the Citrix ADC and log on.

   Note

   You cannot log on by using SSH to perform this procedure; you must connect directly to the appliance.

2. Reboot the Citrix ADC.

3. Press CTRL+C when the following message appears:

   Press [Ctrl-C] for command prompt, or any other key to boot immediately.

   Booting [kernel] in # seconds.
4. Run the following command to start the Citrix ADC in a single user mode:

```
boot -s
```

**Note:** If boot -s does not work, then try reboot -- -s and appliance will reboot in single user mode.

After the appliance boots, it displays the following message:

Enter full path name of shell or RETURN for /bin/sh:

5. Press ENTER key to display the # prompt, and type the following commands to mount the file systems:

   a) Run the following command to check the disk consistency:

```
fsck /dev/ad0s1a
```

   **Note:**

Your flash drive will have a specific device name depending on your Citrix ADC; hence, you have to replace ad0s1a in the preceding command with the appropriate device name.

   b) Run the following command to display the mounted partitions:

```
df
```

If the flash partition is not listed, you need to mount it manually.

   c) Run the following command to mount the flash drive:

```
mount /dev/ad0s1a /flash
```

6. Run the following command to change to the nsconfig directory:

```
cd /flash/nsconfig
```

7. Run the following commands to rewrite the ns.conf file and remove the set of system commands defaulting to the nsroot user:

   a) Run the following command to create a new configuration file that does not have commands defaulting to the nsroot user:

```
grep -v "set system user nsroot" ns.conf > new.conf
```

   b) Run the following command to make a backup of the existing configuration file:

```
mv ns.conf old.ns.conf
```

   c) Run the following command to rename the new.conf file to ns.conf:

```
mv new.conf ns.conf
```
8. Run the following command to reboot the Citrix ADC:

```
reboot
```

9. Log on using the default nsroot user credentials.

10. Run the following command to reset the nsroot user password:

```
set system user nsroot <New_Password>
```

**Note:**
To use the “?” character in a password string, precede this character with the “\” character.

For example, `yourexamplepasswd?` is set for the nsroot account after you perform the following operation:

```
> set system user nsroot yourexamplepasswd?
```

### Example of a user scenario

April 23, 2019

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the Citrix ADC appliance:

- **John Doe.** The IT manager. John needs to be able to see all parts of the Citrix ADC configuration but does not need to modify anything.

  **Maria Ramiez.** The lead IT administrator. Maria needs to be able to see and modify all parts of the Citrix ADC configuration except for Citrix ADC commands (which local policy dictates must be performed while logged on as nsroot).

- **Michael Baldrock.** The IT administrator in charge of load balancing. Michael needs to be able to see all parts of the Citrix ADC configuration, but needs to modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Citrix ADC host name</td>
<td>ns01.example.net</td>
<td>N/A</td>
</tr>
</tbody>
</table>

© 1999-2018 Citrix Systems, Inc. All rights reserved.
The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the Citrix ADC appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the Citrix ADC.

### Configuration steps

1. Use the procedure described in “Configuring User Accounts” to create user accounts **johnd**, **mariar**, and **michaelb**.

2. Use the procedure described in “Configuring User Groups” to create user groups **Managers** and **SysOps**, and then bind the users **mariar** and **michaelb** to the **SysOps** group and the user **johnd** to the **Managers** group.

3. Use the procedure described in “[Creating Custom Command Policies]” to create the following command policies:
   - **read_all** with action **Allow** and command spec
     
     ```
     (^show\s+(?!system)(?!ns ns. conf)(?!ns runningConfig).*)|^\s(s.*)
     ```
   - **modify_lb** with action as **Allow** and the command spec
     
     ```
     ^\s+set\slb\s+.*$
     ```
   - **modify_all** with action as Allow and the command spec
     
     ```
     ^\s+s+(?!system).*
     ```

---

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>User accounts</td>
<td>johnd, mariar, and michaelb</td>
<td>John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.</td>
</tr>
<tr>
<td>Groups</td>
<td>Managers and SysOps</td>
<td>All managers and all IT administrators.</td>
</tr>
<tr>
<td>Command Policies</td>
<td>read_all, modify_lb, and modify_all</td>
<td>Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.</td>
</tr>
</tbody>
</table>
4. Use the procedure described in “Binding Command Policies to Users and Groups” to bind the `read_all` command policy to the `SysOps` group, with priority value 1.

5. Use the procedure described in “Binding Command Policies to Users and Groups” to bind the `modify_lb` command policy to user `michaelb`, with priority value 5.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire Citrix ADC configuration, but he cannot make modifications.
- Maria Ramirez, the IT lead, has near-complete access to all areas of the Citrix ADC configuration, having to log on only to perform Citrix ADC-level commands.
- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the Citrix ADC configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user’s account and command policies applied to the group(s) of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the Citrix ADC appliance’s default deny policy.

**Note**

When placing a user into multiple groups, take care not to cause unintended user command restrictions or privileges. To avoid these conflicts, when organizing your users in groups, bear in mind the Citrix ADC command policy search procedure and policy ordering rules.

## Configuring external user authentication

April 23, 2019

Authentication in a Citrix ADC appliance can be local or external. For authenticating external users, the appliance uses an external authentication server such as LDAP, RADIUS and TACACS+. In order to authenticate an external user and grant user access into the appliance, you must use an authentication policy. The Citrix ADC system authentication uses Advanced authentication policy. Advanced authentication policies use Citrix ADC advanced policy expressions. Advanced authentication policies are used for system user management in a partitioned Citrix ADC appliance.
Note:
If your appliance has Classic policies and its expressions, you must stop using it and migrate Classic policy usage to Advanced policy infrastructure.

Once you create an authentication policy, you must bind it to system global entity. You can configure an external authentication server (for example, TACACS) by binding a single authentication policy to the system global entity. Or, you can configure a cascade of authentication servers by binding multiple policies to the system global entity.

Note:
When an external user logs into the appliance, the system generates an error message, “User does not exist” in ns.log file. This occurs because the system runs the systemuser_systemcmdpolicy_binding command to initialize the GUI for the user.

Configuring LDAP authentication

You can configure the Citrix ADC appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in Active Directory, on the LDAP server, and on the appliance. The characters and case must also be the same.

By default, LDAP authentication is secured by using SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecure and secure LDAP connections and is handled by a single port on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the LDAP command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all of the subdirectories are
also searched to find the user attribute. In large directories, this can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of the base distinguished name (DN).

<table>
<thead>
<tr>
<th>LDAP server</th>
<th>Base DN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Active Directory</td>
<td>DC=citrix, DC=local</td>
</tr>
<tr>
<td>Novell eDirectory</td>
<td>dc=citrix, dc=net</td>
</tr>
<tr>
<td>IBM Directory Server</td>
<td>cn=users</td>
</tr>
<tr>
<td>Lotus Domino</td>
<td>OU=City, O=Citrix, C=US</td>
</tr>
<tr>
<td>Sun ONE directory (formerly iPlanet)</td>
<td>ou=People, dc=citrix, dc=com</td>
</tr>
</tbody>
</table>

Table 2. Examples of Base Distinguished Name

The following table lists examples of the bind distinguished name (DN).

<table>
<thead>
<tr>
<th>LDAP server</th>
<th>Bind DN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Active Directory</td>
<td>CN=Administrator, CN=Users, DC=citrix, DC=local</td>
</tr>
<tr>
<td>Novell eDirectory</td>
<td>cn=admin, dc=citrix, dc=net</td>
</tr>
<tr>
<td>IBM Directory Server</td>
<td>LDAP_dn</td>
</tr>
<tr>
<td>Lotus Domino</td>
<td>CN=Notes Administrator, O=Citrix, C=US</td>
</tr>
<tr>
<td>Sun ONE directory (formerly iPlanet)</td>
<td>uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot</td>
</tr>
</tbody>
</table>

Table 3. Examples of Bind Distinguished Name

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Configure LDAP authentication by using the command line interface

To configure LDAP classic policy

At the command prompt, do the following:

Step 1: Create an LDAP action.

```
add authentication ldapAction <name> { -server <ip_addr|ipv6_addr|*> | { -serverName <string> } } ] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] { -ldapBindDnPassword } [-ldapLoginName <string>] [-groupAttrName <string>] [-subAttributeName <string>]
```

Example:

```
1 add authentication ldapAction ldap_act -serverIP <IP> -authTimeout 30 -
ldapBase "CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDn "CN=xxxxx,CN=xxxxx,DC=
xxxx,DC=xxx" -ldapBindDnPassword abcd -ldapLoginName sAMAccountName -
groupattrName member0f -subAttributeNme CN
```

Step 2: Create an LDAP policy.

```
add authentication ldapPolicy <name> <rule> [reqAction]
```

Example:

```
add authentication ldapPolicy ldap_pol_classic ns_true ldap_act.
```

Step 3: Create an LDAP policy

Creating an LDAP advanced authentication policy:

```
add authentication ldapPolicy <name> <rule> [reqAction]
```

Example:

```
add authentication policy ldap_pol_advance -rule true -action ldap_act
```

Step 4: Bind the LDAP policy to the following bind points at which the policy will be evaluated.

System Global: bind system global <policyName> [-priority <positive_integer> ]

VPN Global: bind vpn global <policyName> [-priority <positive_integer>]

Authentication Server: bind authentication vserver <name> [-policy <string> ] [-priority <positive_integer>]

VPN Server: bind vpn vserver <name> [-policy <string> ] [-priority <positive_integer> ]

To configure LDAP classic policy
At the command prompt, type:

```
add authentication Policy <name> -rule <expression> -action <string>
```

**Example:**

```
add authentication policy ldap_pol_classic -rule true -action ldap_act
```

To configure LDAP authentication by using the GUI

Navigate to **System > Authentication > LDAP**, and create the LDAP authentication policy.

**Determining attributes in the LDAP directory**

If you need help determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator Web site at [http://www.ldapbrowser.com](http://www.ldapbrowser.com). After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.
- The base DN field can be left blank.
- The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
- The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

**Configuring RADIUS authentication**

You can configure the Citrix ADC appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:

- If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
- If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
- When the NAS IP is enabled, the appliance ignores any NAS ID that was configured by using the NAS IP to communicate with the RADIUS server.
To configure RADIUS authentication by using the GUI

Navigate to System > Authentication > Radius, and create the RADIUS authentication policy.

Choosing RADIUS authentication protocols

The Citrix ADC appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:

- Password Authentication Protocol
- Challenge-Handshake Authentication Protocol (CHAP)
- Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment of the appliance is configured to use RADIUS authentication and your RADIUS server is configured to use Password Authentication Protocol, you can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are at least 22 characters long. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. If you do this, you must configure separately each policy that uses RADIUS authentication.

Shared secrets are configured on the appliance when a RADIUS policy is created.

Configuring IP address extraction

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:

- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type ipaddress, including those that are vendor encoded.

When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that...
the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the RADIUS attribute *framed IP address*. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

**To configure IP address extraction by using the GUI**

1. Navigate to **System > Authentication > Radius**, and select a policy.
2. Modify the server parameters and set relevant values in **Group Vendor Identifier** and **Group Attribute Type** fields.

**Configuring TACACS+ authentication**

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the appliance to use a TACACS+ server, provide the server IP address and the TACACS+ secret. The port needs to be specified only when the server port number in use is something other than the default port number of 49.

**To configure TACACS+ authentication by using the GUI**

Navigate to **System > Authentication > TACACS**, and create the TACACS authentication policy.

After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity.

**Binding authentication policies to the system global entity**

When the authentication policies are configured, bind the policies to the system global entity.

**To bind a classic authentication policy to system global using the command line interface**

At the command line prompt, do the following:

```
bind system global <policyName> [-priority <positive_integer>]
```

**Example:**

```
bind system global ldap_pol_classic -priority 10
```
To bind advanced authentication policy to system global using the command line interface

At the command line prompt, do the following:

```
binding system global <policyName> [-priority <positive_integer>]
```

**Example:**

```
binding system global ldap_pol_advanced -priority 10
```

To bind an authentication policy to system global using the GUI

1. Navigate to System > Authentication, and select the authentication type.
2. On the Policies tab, click Global Bindings and bind the authentication policies.

**SSH Key-based authentication for Citrix ADC administrators**

May 14, 2019

SSH key-based authentication is preferred over traditional username/password type authentication for following reasons:

- provides better cryptographic strength than user passwords.
- eliminates the need of remembering complicated passwords and prevents shoulder-surfing attacks which are possible if passwords are used.
- provides a password-less login for making automation scenarios more secured.

Citrix ADC supports SSH key-based authentication by leveraging the public and private key concept. The SSH key-based authentication in Citrix ADC can be enabled either at a user-specific level for Citrix ADC local users or enabled for Citrix ADC local users in common.

**Note:** This is currently supported only for Citrix ADC local users and not supported for external users.

**Configuring SSH key-based authentication for local system users**

In a Citrix ADC appliance, an administrator can set up SSH key-based authentication for a secured system access. When a user log into Citrix ADC using a private key, the system authenticates using the public key configured on the appliance.
To configure SSH key-based authentication for Citrix ADC local system users by using command line interface

Follow the below configuration to configure key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. By default your sshd_config file will access this path: `AuthorizedKeysFile /nsconfig/ssh/authorized_keys`
3. Append the public key to the authorized_keys file: `/nsconfig/ssh/authorized_keys`

Once you have configured, restart the sshd process in your appliance.

**Note**

If authorized_keys file is not available, you must first create one and then append the public key. Make sure the file has the following permission for the authorized_keys*.

```
root@CitrixADC# chmod 0644 authorized_keys
```

**Configuring user-specific SSH key-based authentication for local system users**

In a Citrix ADC appliance, an administrator can now set up a user specific key-based authentication for a secured system access. To do this, the administrator must first configure the Authorizedkeysfile option in sshd_config file and then add the public key in the authorized_keys file for a system user.

**Note**

If the authorized_keys file is not available for a user, the administrator must first create one and...
then add the public key to it.

To configure user-specific SSH key-based authentication by using command line interface

Follow the procedure below to configure user-specific SSH key-based authentication for Citrix ADC local system users.

1. Log on to a Citrix ADC appliance using administrator credentials.
2. At the shell prompt, access the sshd_config file and add the following configuration line: `AuthorizedKeysFile ~/.ssh/authorized_keys`
3. Change directory to system user folder and add the public keys in the `authorized_keys` file.

```
/var/pubkey/<username>/.ssh/authorized_keys
```

Once you have completed the above steps, restart the sshd process on your appliance.

**Note**

If `authorized_keys` file is not available, you must first create one and then add the public key.

```
> shell
Copyright (c) 1992-2013 The FreeBSD Project.
   The Regents of the University of California. All rights reserved.
root@ns# cd /var/pubkey/<username>/
root@ns# ls
  .ssh
root@ns# cd .ssh
root@ns# vi authorized_keys
### Add public keys in authorized_keys file
```
Display unsuccessful external user logon attempts

April 23, 2019

When an external LDAP user successfully logs on to a Citrix ADC appliance, the command interface now displays the number of unsuccessful logon attempts since the last successful logon. The feature works only if the persistentLoginAttempts option is enabled on the appliance.

A Citrix ADC administrator can use this information to verify if any unauthorized activity has occurred on a secured LDAP user account.

To use this feature, at the Citrix ADC command prompt, type:

```
set aaa parameter -maxloginAttempts <value> -failedLoginTimeout <value> -persistentLoginAttempts (ENABLED | DISABLED )]
```

```
| 'Set aaa parameter - maxloginAttempts 5 -failedLoginTimeout 4 - persistentLoginAttempts ENABLED' |
```

Two Factor Authentication for Citrix ADC Console

April 23, 2019

Two-factor authentication is a security mechanism where a Citrix ADC appliance authenticates a system user at two authenticator levels. The appliance grants access to the user only after successful validation of passwords by both levels of authentication. If a user is authenticated locally, the user profile must be created in Citrix ADC database. If the user is authenticated externally then, the user name and password must match the user identity registered in the external authentication server.

**Note:**

Two factor authentication feature works on Citrix ADC 12.1 build 51.16 onwards.

**How two-factor authentication works**

Consider a user trying to log on to a Citrix ADC appliance. The requested application server sends the user name and password to the first external authentication server (RADIUS, TACACS, LDAP or AD). Once the username and password are validated, the user is prompted for second level of authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance. The below diagram is an illustration of how two-factor authentication works for a Citrix ADC appliance.
Following are the different use cases for configuring two factor authentication for external and system users.

**Configuring two-factor authentication for Citrix ADC management access**

You can configure two-factor authentication feature on a Citrix ADC appliance in different ways. The configuration scenarios are given below:

1. Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH.
2. External authentication enabled and local authentication disabled for system users.
3. External authentication enabled with policy based local authentication for system users.
4. External authentication disabled for system users with local authentication enabled.
5. External authentication enabled and local authentication enabled for system users.
6. External authentication enabled for selected LDAP users

**Case 1: Two factor authentication (2FA) across Citrix ADC, GUI, CLI, API and SSH**

Two-factor authentication is enabled and available across all Citrix ADC management access for GUI, API, and SSH.

**Case 2: Two factor authentication is supported on external authentication servers such as LDAP, RADIUS, Active Directory and TACACS**

You can configure two-factor authentication on the following external authentication servers for first-level and second-level user authentication.

- RADIUS
- LDAP
- Active Directory
- TACACS

**Case 3: External authentication enabled and local authentication disabled for system users**

You begin the authentication process by enabling the external authentication option and disabling local authentication for system users.

Complete the following steps by using the command line interface:

1. Add authentication action for LDAP policy
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add and bind authentication policy label to RADIUS server
7. Bind system global authentication for LDAP policy
8. Disable local authentication in system parameter

**Add authentication action for LDAP server (first level authentication)**

At the command prompt, type:

```plaintext
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldapLoginname <loginname> -groupattrname <grp attribute name> -subAttributename <string>-ssoNameAttribute <string>
```

**Example:**

```plaintext
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name
```

**Add authentication policy for LDAP server (first level authentication)**

At the command prompt, type:

```plaintext
add authentication policy <ldap policy name> -rule true -action <ldap action name>
```

**Example:**

```plaintext
add authentication policy pol1 -rule true -action ldapact1
```

**Add authentication action for RADIUS server (second level authentication)**

At the command prompt, type:

```plaintext
add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>
```

**Example:**

```plaintext
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttributeType 2
```
Add authentication policy for RADIUS server (second level authentication)

At the command prompt, type:

```
add authentication policy <radius policy name> -rule true -action <rad action name>
```

**Example:**

```
add authentication policy radpol11 -rule true -action radact11
```

Add authentication login schema

You can use the “SingleAuth.xml” login schema for system users to provide the second password for the Citrix ADC appliance. At the command prompt, type:

```
add authentication loginSchema <login schema name> -authenticationSchema LoginSchema/SingleAuth.xml
```

**Example:**

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml
```

Add and bind authentication policy label to RADIUS server

At the command prompt, type:

```
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )] [-comment <string>] [-loginSchema <string>]
bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]
```

**Example:**

```
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel label1 -policyName rad_pol11 -priority 1
```

Bind authentication system global for LDAP policy

At the command prompt, type:

```
bind system global ldappolicy -priority <priority> -nextFactor <policy label name>
```
Example:

```
bind system global radpol11 -priority 1 -nextFactor label11
```

**Disable local authentication in system parameter**

At the command prompt, type:

```
set system parameter -localauth disabled
```

**Case 4: External authentication enabled for system user with local authentication policy attached**

In this scenario, the user is allowed to log on to the appliance using two-factor authentication with local authentication policy evaluation at the second level of user identification.

Complete the following steps by using the command line interface.

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add local authentication policy
4. Add authentication policy label
5. Bind LDAP policy as system global
6. Disable local authentication in system parameter

**Add authentication action for LDAP server (first level authentication)**

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname <loginname> -groupattrname <grp attribute name> -subAttributename <string>-ssoNameAttribute <string>
```

**Example:**

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name -ssoNameAttribute name
```

**Add authentication policy for LDAP server (first level authentication)**

At the command prompt, type:
add authentication policy <ldap policy name> -rule true -action <ldap action name>

Example:
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name -ssoNameAttribute name

Add local authentication policy for system users (second level authentication)

At the command prompt, type:
add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>

Example:
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttributeType 2

Add and bind authentication policy label

At the command prompt, type:
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )] [-comment <string>] [-loginSchema <string>]
bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]

Example:
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel label1 -policyName rad_pol11 -priority 1

Disable local authentication in system parameter

At the command prompt, type:
set system parameter -localauth disabled
Case 5: External authentication disabled and local authentication enabled for system user

If the user has “externalAuth” disabled, it indicates the user does not exist on the authentication server. User will not be authenticated with the external authenticated server even if user with same username exists on the external authenticated server. User will be authenticated locally.

To enable system user password and disable external authentication

At the command prompt, type the following:

```
add system user <name> <password> -externalAuth DISABLED
```

Example:

```
add system user user1 password1 -externalAuth DISABLED
```

Case 6: External authentication enabled and local authentication enabled for system users

To configure the appliance to authenticate system users using local password. If this authentication fails, the user is then authenticated using external authentication password on the external authentication servers at two levels.

To configure using command line interface, follow the steps given below:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy
9. Bind authentication system global for LDAP policy

Add authentication action for LDAP server

At the command prompt, type:

```
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginname <loginname> -groupattrname <grp attribute name> -subAttributename <>-ssoNameAttribute <>
```
Example:

```
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -
ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName
name -subAttributeName name -ssoNameAttribute name
```

**Add authentication policy for LDAP policy**

At the command prompt, type:

```
add authentication policy <policy name> --rule true -action <ldap action name>
```

Example:

```
add authentication policy pol1 -rule true -action ldapact1
```

**Add authentication action for RADIUS server**

At the command prompt, type:

```
add authentication radiusaction <rad action name> -serverip <rad server ip> -
radkey <key> -radVendorID <ID> -radattributetype <rad attribute type>
```

Example:

```
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -
radVendorID 1234 -rad attributetype 2
```

**Add advanced authentication policy for RADIUS server**

At the command prompt, type:

```
add authentication policy <policy name> -rule true -action <rad action name>
```

Example:

```
add authentication policy radpol11 -rule true -action radact11
```

**Add authentication login schema**

You can use the SingleAuth.xml login schema to display the login page and authenticate the system
user at the second level authentication.

At the command prompt, type:
add authentication loginSchema <name> -authenticationSchema <string>

Example:
add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml

Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:
add authentication policylabel <labelName> [-type ( AAATM_REQ | RBA_REQ )] [-comment <string>] [-loginSchema <string>]

Example:
add authentication policylabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]

Example:
bind authentication policylabel label1 -policyName rad_pol11 -priority 1

Bind authentication policy global

At the command prompt, type:
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor <string>] [-gotoPriorityExpression <expression>]]

Example:
bind system global radpol11 -priority 1 -nextFactor label11

Case 7: External authentication enabled for selected external users only

To configure selective external users with two-factor authentication as per the search filter configured in LDAP action while other system users are authenticated using single factor authentication.

To configure using command line interface, follow the steps given below:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP policy
3. Add authentication action for RADIUS policy
4. Add authentication policy for RADIUS policy
5. Add authentication login schema
6. Add authentication policy label
7. Bind authentication policy label for login schema
8. Bind authentication system global for RADIUS policy

Add authentication action for LDAP server

At the command prompt, type:
```
cmd
add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password>-ldaploginnname <loginnname> -groupattrname <grp attribute name> -subAttributename <>-ssoNameAttribute <>
```

Example:
```
cmd
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttribute name -ssoNameAttribute name
```

Add authentication policy for LDAP policy

At the command prompt, type:
```
cmd
add authentication policy <policy name> --rule true -action <ldap action name>
```

Example:
```
cmd
add authentication policy pol1 --rule true -action ldapact1
```

Add authentication action for RADIUS server

At the command prompt, type:
```
cmd
add authentication radiusaction <rad action name> -serverip <rad server ip> -radkey <key> -radVendorID <ID >-radattributetype <rad attribute type>
```

Example:
```
cmd
add authentication radiusaction radact1 -serverip 1.1.1.1 -radkey 123 -radVendorID 1234 -radAttribute Type 2
```
Add advanced authentication policy for RADIUS server

At the command prompt, type:

```
add authentication policy <policy name> -rule true -action <rad action name>
```

**Example:**

```
add authentication policy radpol11 -rule true -action radact11
```

Add authentication login schema

You can use the SingleAuth.xml login schema to provide the login page for the appliance to authenticate a system user at second level of authentication.

At the command prompt, type:

```
add authentication loginSchema <name> -authenticationSchema <string>
```

**Example:**

```
add authentication loginSchema radschema -authenticationSchema LoginSchema/SingleAuth.xml
```

Add and bind authentication policy label to RADIUS authentication policy for user login

At the command prompt, type:

```
add authentication policyLabel <labelName> [-type (AAATM_REQ | RBA_REQ)] [-comment <string>] [-loginSchema <string>]
```

**Example:**

```
add authentication policyLabel label1 -type RBA_REQ -loginSchema radschema
bind authentication policyLabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-nextFactor <string>]
```

**Example:**

```
bind authentication policyLabel label1 -policyName rad_pol11 -priority
```

Bind authentication policy global

At the command prompt, type:
bind system global [<policyName> [-priority <positive_integer>] [-nextFactor <string>] [-gotoPriorityExpression <expression>]]

Example:
bind system global radpol11 -priority 1 -nextFactor label11

To configure without two-factor authentication for group users using search filter:

1. Add authentication action for LDAP server
2. Add authentication policy for LDAP server
3. Bind authentication system global for LDAP server

Add authentication action for LDAP server

At the command prompt, type:

add authentication ldapaction <ldap action name> -serverip <IP> -ldapbase <> -ldapbinddn <binddn name> -ldapbinddnpassword <password> -ldaploginname <loginname> -groupattrname <grp attribute name> -subAttributeName <> -searchFilter<>

Example:
add authentication ldapaction ldapact1 -serverip 1.1.1.1 -ldapbase base -ldapbindDn name -ldapbindDNpassword password -ldapLoginName name -groupAttrName name -subAttributeName name - searchFilter "memberOf=CN=grp4,CN=Users,DC=aaatm-test,DC=com"

Add authentication policy for LDAP server

At the command prompt, type:

add authentication policy <policy name> --rule true -action <ldap action name>

Example:
add authentication policy pol1 --rule true -action ldapact1

Bind authentication system global for LDAP policy

At the command prompt, type:

bind system global ldappolicy -priority <priority> -nextFactor <policy label> name
**Example:**

```
bind system global radpol11 -priority 1 -nextFactor label11
```

**Display customized prompt message for two factor authentication**

When you configure two factor password field with SingleAuth.xml file at `/flash/nsconfig/loginschema/LoginSchema`

Following is the snippet of SingleAuth.xml file where ‘SecondPassword:’ is the 2nd password field name which will be prompted to user to enter 2nd password.

```xml
<authenticateResponse xmlns="http://citrix.com/authentication/response/1">
    <status>success</status>
    <result>more-info</result>
    <stateContext />
    <authenticationRequirements />
    <requirement>
        <credential><id>login</id><saveID>explicitForms-Username</saveID><label><text>
            singleauth_user_name</text><type>nsg-login-label</type></label><input><assistiveText>
            username_or_user@fully.qualified.domain</assistiveText><text><secret>false</secret><readonly>false</readonly><initialValue/><constraint>+</constraint></text></input></credential>
    </requirement>
    <requirement>
        <credential><id>password</id><saveID>explicitForms-Password</saveID><label><text>
            SecondPassword</text><type>nsg-login-label</type></label><input><secret>true</secret><readonly>false</readonly><initialValue/><constraint>+</constraint></text></input></credential>
    </requirement>
    <requirement>
        <credential><type>none</type><label><text>
            singleauth_first_factor</text><type>nsg_confirmation</type></label><input/>
    </requirement>
    <requirement>
        <credential><id>saveCredentials</id><type>savecredentials</type><label><text>
            singleauth_remember_my_password</text><type>nsg-login-label</type></label><input><checkBox><initialValue>false</initialValue></checkBox></input>
    </requirement>
    <requirement>
        <credential><id>loginBtn</id><type>none</type><label><text>
            singleauth_log_on</text></label><input><button>singleauth_log_on</button></input>
    </requirement>
</authenticateResponse>
```
Configuring two-factor authentication by using the Citrix ADC GUI

1. Log onto Citrix ADC appliance.
2. Go to **System > Authentication > Advanced Policies > Policy**.
3. Click Add to create the first level authentication policy.
4. In **Create Authentication Policy** page, set the following parameters.
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS etc.
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create a new action of the proper type.
   d) Expression. Provide an advanced policy expression.
5. Click **Create** and then **Close**.
   a) Expression. Provide an advanced policy expression.
6. Click **Create**.
7. Click **Add** to create the second level authentication policy.
8. In the **Create Authentication Policy** page, set the follow parameters
   a) Name. Name of the policy
   b) Action Type. Select action type as LDAP, Active Directory, RADIUS, TACACS etc.
   c) Action. The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the + icon to create an action of the proper type.
   d) Expression. Provide an advanced policy expression.
9. Click **Create** and then **Close**.
   a) Expression. Provide an advanced policy expression.
10. Click **Create**.
11. In the **Authentication Policies** page, click **Global Binding**.
12. In the **Create Global Authentication Policy Binding** page, select the first level authentication policy and click **Add Binding**.
13. In the **Policy Binding** page, select the authentication policy and set the following policy binding parameter.
a) Next Factor. Select the second level authentication policy label.

14. Click **Bind** and **Close**.

15. Click **Done**.

16. Log on to the Citrix ADC appliance for the second level authentication. The user can now provide the second password. Only if both passwords are correct, the user is allowed to access the Citrix ADC appliance.

For more information about Configuring login schema, see Native OTP Support feature.

**Restrict user permission to Citrix ADC management interfaces**

**September 18, 2019**

The allowed management interface parameter enables a system administrator to restrict user access to specific Citrix ADC management interfaces such as CLI or API. The parameter defines the list of permitted management interfaces for a user. For example, if the management interface for a user or a group is set to API, all users in the group can access Citrix ADC through API and not through CLI. However, GUI is part of the API interface and users with API permission can also access the GUI interface.

**Note**

By default, users and groups have access to all interfaces (CLI, API and GUI).

You can configure the parameter either at the user level or at the user group level. When you configure at the group level, the configuration is applied across all user accounts in the group. If a user is bound to multiple groups, the appliance allows access to an aggregated set of management interfaces. You can provide specific settings for a user of a group by setting this parameter at user level, in this case – user level setting is given preference over group for that particular user.

In certain scenarios, when the customer is using an external authentication server for managing user accounts, the server details are configured on the appliance. In this case, the administrator can create a user group in the Citrix ADC appliance and add all users (grouped in the external server) to the group. For example, all users managed in the external server are added to the API_users group and the admin can configure the group locally on the appliance.

**Note**

The Citrix ADC appliance allows only network administrators to configure the parameter and does not allow any system user to change the parameter setting.
Configure allowed management interface parameter

To allow user access to a specific management interface, you can set the allowed management interface parameter. At the command prompt, type:

```
set system group <groupName> [-allowedManagementInterface ( CLI | API )]
```

Example:

```
set system group network_usergroup -allowedManagementInterface CLI
```

TCP Configurations

May 8, 2019

TCP configurations for a Citrix ADC appliance can be specified in an entity called a TCP profile, which is a collection of TCP settings. The TCP profile can then be associated with services or virtual servers that want to use these TCP configurations.

A default TCP profile can be configured to set the TCP configurations that will be applied by default, globally to all services and virtual servers.

Note

When a TCP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence. The Citrix ADC appliance also provides other approaches for configuring TCP. Read on for more information.

Supported TCP configuration

The Citrix ADC appliance supports the following TCP capabilities:

Defending TCP against spoofing attacks

The Citrix ADC implementation of window attenuation is RFC 4953 compliant.

Explicit Congestion Notification (ECN)

The appliance sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption. The Citrix ADC implementation of ECN is RFC 3168 compliant.
Round trip time measurement (RTTM) using the timestamp option

For the TimeStamp option to work, at least one side of the connection (client or server) must support it. The Citrix ADC implementation of TimeStamp option is RFC 1323 compliant.

Detection of spurious retransmissions

This can be done using TCP duplicate selective acknowledgement (D-SACK) and forward RTO-Recovery (F-RTO). In case of spurious retransmissions, the congestion control configurations are reverted to their original state. The Citrix ADC implementation of D-SACK is RFC 2883 compliant, and F-RTO is RFC 5682 compliant.

Congestion control

This functionality use New-Reno, BIC, CUBIC, Nile and TCP Westwood algorithms.

Window scaling

This increases the TCP receive window size beyond its maximum value of 65,535 bytes.

Points to consider before you configure window scaling

- You do not set a high value for the scale factor, because this could have adverse effects on the appliance and the network.
- You do not configure window scaling unless you clearly know why you want to change the window size.
- Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, window scaling is not used for the connection.
- Each connection for same session is an independent window scaling session. For example, when a client’s request and the server’s response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.

TCP maximum congestion window

The window size is a user configurable one. The default value is 8190 bytes.

Selective acknowledgment (SACK)

This uses the data receiver (either a Citrix ADC appliance or a client) notifies the sender about all the segments that have been received successfully.
Forward acknowledgment (FACK)

This functionality avoids TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either a Citrix ADC or a client) control the amount of data injected into the network during retransmission timeouts.

TCP connection multiplexing

This functionality enables reuse of existing TCP connections. The Citrix ADC appliance stores established TCP connections to the reuse pool. Whenever a client request is received, appliance checks for an available connection in the reuse pool and serves the new client if the connection is available. If it is unavailable, the appliance creates a new connection for the client request and stores the connection to the reuse pool. Citrix ADC supports connection multiplexing for HTTP, SSL, and DataStream connection types.

Dynamic receive buffering

This allows the receive buffer to be adjusted dynamically based on memory and network conditions.

MPTCP Connection

MPTCP connections between client and Citrix ADC. MPTCP connections are not supported between Citrix ADC and the backend server. The Citrix ADC implementation of MPTCP is RFC 6824 compliant.

You can view MPTCP statistics such as active MPTCP connections and active subflow connections by using the command line interface.

At the command prompt, type one of the following commands to display a summary or detailed summary of MPTCP statistics, or to clear the statistics display:

1. Stat MPTCP
2. Stat mptcp –detail
3. Clearstats basic

Note

To establish an MPTCP connection, both the client and the Citrix ADC appliance must support the same MPTCP version. If you use the Citrix ADC appliance as an MPTCP gateway for your servers, the servers do not have to support MPTCP. When the client starts a new MPTCP connection, the appliance identifies the client’s MPTCP version from the MP_CAPABALE option in the SYN packet. If the client’s version is higher than the one supported on the appliance, the
the appliance indicates its highest version in the MP_CAPABALE option of the SYN-ACK packet. The client then falls back to a lower version and sends the version number in the MP_CAPABALE option of the ACK packet. If that version is supportable, the appliance continues the MPTCP connection. Otherwise, the appliance falls back to a regular TCP. The Citrix ADC appliance does not initiate subflows (MP_JOIN’s). The appliance expects the client to initiate subflows.

Extracting the TCP/IP path overlay option and inserting client-IP HTTP header

Extracting TCP/IP path overlay and inserting client-IP HTTP header. Data transport through overlay networks often uses connection termination or Network Address Translation (NAT), in which the IP address of the source client is lost. To avoid this, the Citrix ADC appliance extracts the TCP/IP path overlay option and inserts the source client’s IP address into the HTTP header. With the IP address in the header, the web server can identify the source client that made the connection. The extracted data is valid for lifetime of the TCP connection and therefore, this prevents the next hop host from having to interpret the option again. This option is applicable only for web services that have the client-IP insertion option enabled. For more information, see Client Insertion on backend topic.

TCP segmentation offload

Synchronizing cookie for TCP handshake with clients

Learning MSS to enable MSS learning for all the virtual servers configured on the appliance

Supportable TCP Parameters

The following table provides a list of TCP parameters and its default value configured on a Citrix ADC appliance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window Management</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TCP Delayed-ACK Timer</td>
<td>100 millisec</td>
<td>Timeout for TCP delayed ACK, in milliseconds.</td>
</tr>
<tr>
<td>TCP minimum Resttransmission Timeout(RTO in millisec)</td>
<td>1000 millisec</td>
<td>Minimum retransmission timeout, in milliseconds, specified in 10-millisecond increments (value must yield a whole number if divided by 10)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------</td>

### Setting Global TCP Parameters

The Citrix ADC appliance allows you to specify values for TCP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default TCP profile
- Global TCP command
- TCP buffering feature

**Note:**

The recvBuffSize parameter of the set ns tcpParam command is deprecated from release 9.2 onwards. In later releases, set the buffer size by using the bufferSize parameter of the set ns tcpProfile command. If you upgrade to a release where the recvBuffSize parameter is deprecated, the bufferSize parameter is set to its default value.

### Default TCP profile

A TCP profile, named as nstcp_default_profile, is used to specify TCP configurations that will used if no TCP configurations are provided at the service or virtual server level.

**Notes:**

- Not all TCP parameters can be configured through the default TCP profile. Some settings have to be performed by using the global TCP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default TCP profile

- Using the command line interface, at the command prompt enter:
  ```
  set ns tcpProfile nstcp_default_profile …
  ```
- On the GUI, navigate to **System > Profiles**, click **TCP Profiles** and update nstcp_default_profile.

### Global TCP command

Another approach you can use to configure global TCP parameters is the global TCP command. In addition to some unique parameters, this command duplicates some parameters that can be set by
using a TCP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default TCP profile.

For example, if the SACK parameter is updated using this approach, the value is reflected in the SACK parameter of the default TCP profile (nstcp_default_profile).

**Note:**
Citrix recommends that you use this approach only for TCP parameters that are not available in the default TCP profile.

To configure the global TCP command

- Using the command line interface, at the command prompt enter:
  ```
  set ns tcpParam ...
  ```
- On the GUI, navigate to System > Settings, click Change TCP parameters and update the required TCP parameters.

**TCP buffering feature**

Citrix ADC provides a feature called TCP buffering that you can use to specify the TCP buffer size. The feature can be enabled globally or at service level.

**Note**
The buffer size can also be configured in the default TCP profile. If the buffer size has different values in the TCP buffering feature and the default TCP profile, the greater value is applied.

To configure the TCP buffering feature globally

- At the command prompt enter:
  ```
  enable ns mode TCPB
  set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>
  ```
- On the GUI, navigate to System > Settings, click Configure Modes and select TCP Buffering.
  And, navigate to System > Settings, click Change TCP parameters and specify the values for Buffer size and Memory usage limit.

**Setting Service or Virtual Server Specific TCP Parameters**

Using TCP profiles, you can specify TCP parameters for services and virtual servers. You must define a TCP profile (or use a built-in TCP profile) and associate the profile with the appropriate service and virtual server.
You can also modify the TCP parameters of default profiles as per your requirements.

You can specify the TCP buffer size at service level using the parameters specified by the TCP buffering feature.

To specify service or virtual server level TCP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the TCP profile.
   
   ```
   set ns tcpProfile <profile-name>...
   ```

2. Bind the TCP profile to the service or virtual server.
   
   ```
   set service <name> ....
   ```

   **Example**:

   ```
   > set service service1 -tcpProfileName profile1
   ```

   To bind the TCP profile to the virtual server:

   ```
   > set lb vserver <name> ....
   ```

   **Example**:

   ```
   > set lb vserver lbvserver1 -tcpProfileName profile1
   ```

   To specify service or virtual server level TCP configurations by using the GUI

   At the GUI, perform the following:

   1. Configure the TCP profile.
      
      Navigate to **System > Profiles > TCP Profiles**, and create the TCP profile.

   2. Bind the TCP profile to the service or virtual server.
      
      Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the TCP profile, which should be bound to the service or virtual server.

   **Built-in TCP Profiles**

   For convenience of configuration, the Citrix ADC provides some built-in TCP profiles. Review the built-in profiles listed below and select a profile and use it as is or modify it to meet your requirements.
You can bind these profiles to your required services or virtual servers.

<table>
<thead>
<tr>
<th>Built-in profile</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nstcp_default_profile</td>
<td>Represents the default global TCP settings on the appliance.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lan</td>
<td>Useful for back-end server connections, where these servers reside on the same LAN as the appliance.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lan_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lan profile; however, the settings are tuned to small size packet flows.</td>
</tr>
<tr>
<td>nstcp_default_tcp_interactive_stream</td>
<td>Similar to the nstcp_default_tcp_lan profile; however, it has a reduced delayed ACK timer and ACK on PUSH packet settings.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lfp</td>
<td>Useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lfp_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lfp profile; however, the settings are tuned for small size packet flows.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lnp</td>
<td>Useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss once in a while.</td>
</tr>
<tr>
<td>nstcp_default_tcp_lnp_thin_stream</td>
<td>Similar to the nstcp_default_tcp_lnp profile; however, the settings are tuned for small size packet flows.</td>
</tr>
<tr>
<td>nstcp_internal_apps</td>
<td>Useful for internal applications on the appliance (for example, GSLB sitesyncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.</td>
</tr>
<tr>
<td>nstcp_default_Mobile_profile</td>
<td>Useful for mobile devices.</td>
</tr>
<tr>
<td>nstcp_default_XA_XD_profile</td>
<td>Useful for a XenApp or XenDesktop deployment.</td>
</tr>
</tbody>
</table>
Sample TCP Configurations

Sample command line interface examples for configuring the following:

Defending TCP against spoofing attacks

Enable the Citrix ADC to defend TCP against spoof attacks. By default the “rstWindowAttenuation” parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable, it will reply with corrective acknowledgement (ACK) for an invalid sequence number. Possible values are Enabled, Disabled.

Where RST window attenuate parameter protects the appliance against spoofing. When enabled, will reply with corrective ACK when a sequence number is invalid.

```
1 > set ns tcpProfile profile1 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```

Explicit Congestion Notification (ECN)

Enable ECN on the required TCP profile

```
1 > set ns tcpProfile profile1 -ECN ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```

Selective ACKnowledgment (SACK)

Enable SACK on the required TCP profile.

```
1 > set ns tcpProfile profile1 -SACK ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done
```
**Forward ACKnowledgment (FACK)**

Enable FACK on the required TCP profile.

```
1 > set ns tcpProfile profile1 -FACK ENABLED
2   Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4   Done
```

**Window Scaling (WS)**

Enable window scaling and set the window scaling factor on the required TCP profile.

```
1 > set ns tcpProfile profile1 -WS ENABLED -WSVal 9
2   Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4   Done
```

**Maximum Segment Size (MSS)**

Update the MSS related configurations.

```
1 > set ns tcpProfile profile1 -mss 1460 -maxPktPerMss 512
2   Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4   Done
```

**Citrix ADC to learn the MSS of a virtual server**

Enable the Citrix ADC to learn the VSS and update other related configurations.

```
1 > set ns tcpParam -learnVsrvMSS ENABLED -mssLearnInterval 180 -mssLearnDelay 3600
2   Done
```

**TCP keep-alive**

Enable TCP keep-alive and update other related configurations.
Buffer size - using TCP profile

Specify the buffer size.

Buffer size - using TCP buffering feature

Enable the TCP buffering feature (globally or for a service) and then specify the buffer size and the memory limit.

MPTCP

Enable MPTCP and then set the optional MPTCP configurations.
**Congestion control**

Set the required TCP congestion control algorithm.

1 > set ns tcpProfile profile1 -flavor Westwood
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done

**Dynamic receive buffering**

Enable dynamic receive buffering on the required TCP profile.

1 > set ns tcpProfile profile1 -dynamicReceiveBuffering ENABLED
2 Done
3 > set lb vserver lbvserver1 -tcpProfileName profile1
4 Done

**Support for TCP Fast Open (TFO) in Multipath TCP (MPTCP)**

A Citrix ADC appliance now supports TCP Fast Open (TFO) mechanism for establishing Multipath TCP (MPTCP) connections and speed up data transfers. The mechanism allows subflow data to be carried during the initial MPTCP connection handshake in SYN and SYN-ACK packets and also enables data to be consumed by the receiving node during the MPTCP connection establishment.

For more information, see [TCP Fast Open](#) topic.

**Support for Variable TFO Cookie Size for MPTCP**

A Citrix ADC appliance now enables you to configure a variable length TCP Fast Open (TFO) cookie of a minimum size of 4 bytes and a maximum size of 16 bytes in a TCP profile. By doing this, the appliance can respond with the configured TFO cookie size in the SYN-ACK packet to the client.

To configure TCP Fast Open (TFO) cookie in a TCP profile by using the command line interface:

At the command prompt, type:

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize <positive_integer>
```

Example

```
set tcpProfile nstcp_default_profile -tcpFastOpenCookieSize 8
```

To configure TCP Fast Open (TFO) cookie in a TCP profile by using GUI
1. Navigate to Configuration > System > Profiles.
2. In the details pane, go to TCP Profiles tab and select a TCP profile.
3. In the Configure TCP Profile page, set the TCP Fast Open cookie size.
4. Click OK and Done.

SYN-Cookie timeout interval

In a Citrix ADC appliance, by default, the SYN cookie parameter on the TCP profile is enabled to resist SYN attacks. If you prefer to detect an attack for a virtual server and check the SYN-ACK retransmission rate, the SYN cookie value is toggled from Enabled to Disabled state. However, the toggling effect of the cookie from Enabled to Disabled state and vice versa causes a configuration inconsistency between nodes in a cluster deployment. To overcome this, you can use the second SYN cookie parameter maintained on each virtual server of the appliance. When a SYN attack is detected, the SYN cookie on the TCP profile is disabled and the second SYN cookie value on the server is toggled from Disabled to Enabled state. The cookie remains in Enabled state for a autosyncookietimeout interval that you can specify. During the timeout interval, the virtual server fights the SYN attack in SYN Cookie mode. After the interval times out, the SYN Cookie value is toggled back to Disabled state if the virtual server's SYN-ACK retransmission rate is below the threshold. Otherwise, if the rate is still above the threshold, it implies it is a SYN attack and the cookie is again toggled to Enabled state for the specified timeout period.

To configure the maximum SYN ACK retransmission threshold by using the command line interface

At the command prompt, type:

1. `set ns tcpparam [-maxSynAckRetx <positive_integer>]`
2. `Set ns tcpparam [-maxSynAckRetx 150]`

To configure auto SYN cookie timeout interval by using the command line interface

At the command prompt, type:

`set ns tcpparam [-autosyncookietimeout <positive_integer>]`

1. `Set ns tcpparam [-autosyncookietimeout 90]`

HTTP configurations

May 16, 2019
HTTP configurations for a Citrix ADC appliance can be specified in an entity called an HTTP profile, which is a collection of HTTP settings. The HTTP profile can then be associated with services or virtual servers that want to use these HTTP configurations.

A default HTTP profile can be configured to set the HTTP configurations that will be applied by default, globally to all services and virtual servers.

**Note**: When a HTTP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.

The Citrix ADC appliance also provides other approaches for configuring HTTP. Read on for more information.

The Citrix ADC supports WebSocket protocol which allows browsers and other clients to create a bi-directional, full duplex TCP connection to the servers. The Citrix ADC implementation of WebSocket is RFC 6455 compliant.

**Note**: A Citrix ADC appliance now supports the User Source IP (USIP) address configuration for both HTTP/1.1 and HTTP/2 protocols.

### Setting global HTTP parameters

The Citrix ADC appliance allows you to specify values for HTTP parameters that are applicable to all Citrix ADC services and virtual servers. This can be done using:

- Default HTTP profile
- Global HTTP command

### Default HTTP profile

A HTTP profile, named as nshttp_default_profile, is used to specify HTTP configurations that will be used if no HTTP configurations are provided at the service or virtual server level.

**Notes**:

- Not all HTTP parameters can be configured through the default HTTP profile. Some settings have to be performed by using the global HTTP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default HTTP profile

- Using the command line interface, at the command prompt enter:
Global HTTP command

Another approach you can use to configure global HTTP parameters is the global HTTP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a HTTP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default HTTP profile.

For example, if the maxReusePool parameter is updated using this approach, the value is reflected in the maxReusePool parameter of the default HTTP profile (nshttp_default_profile).

Note:
Citrix recommends that you use this approach only for HTTP parameters that are not available in the default HTTP profile.

To configure the global HTTP command

- Using the command line interface, at the command prompt enter:
  ```
  set ns httpParam ...
  ```
- On the GUI, navigate to System > Settings, click Change HTTP parameters and update the required HTTP parameters.

Configure HTTP profile to drop TRACE or TRACK invalid requests

You can enable the markTraceReqInval parameter to mark TRACK and TRACK requests as invalid. When you enable this option along with dropInvalidReqs option on the virtual IP address, you can reset a client sending TRACE or TRACK requests to a Citrix ADC appliance.

To configure the HTTP profile using the CLI

At the command prompt, type:

```
set ns httpProfile <profile name> [-markTraceReqInval ENABLED | DISABLED ]
```

Example:

```
set ns httpProfile profile1 -markTraceReqInval ENABLED
```

Configure the HTTP profile using the Citrix ADC GUI

To mark TRACE or TRACK invalid requests, complete the following procedure.
1. Sign into Citrix ADC appliance and navigate to **Configuration > System > Profiles**.

2. In the **HTTP Profiles** tab page, click **Add**.

3. In the **Create HTTP Profile** page, select **Mark TRACE Requests as Invalid** option.

4. Click **Create**.

**Setting service or virtual server specific HTTP parameters**

Using HTTP profiles, you can specify HTTP parameters for services and virtual servers. You must define a HTTP profile (or use a built-in HTTP profile) and associate the profile with the appropriate service and virtual server.

**Note:**
You can also modify the HTTP parameters of default profiles as per your requirements.

**To specify service or virtual server level HTTP configurations by using the command line interface**

At the command prompt, perform the following:

1. Configure the HTTP profile.
   
   ```
   set ns httpProfile <profile-name>...
   ```

2. Bind the HTTP profile to the service or virtual server.
   
   To bind the HTTP profile to the service:
   
   ```
   set service <name> ..... 
   ```
   
   **Example:**
   
   ```
   1 > set service service1 -httpProfileName profile1
   ```

   To bind the HTTP profile to the virtual server:
   
   ```
   'set lb vserver <name> .....'
   ```
   
   **Example:**
   
   ```
   1 > set lb vserver lbvserver1 -httpProfileName profile1
   ```
To specify service or virtual server level HTTP configurations by using the GUI

At the GUI, perform the following:

1. Configure the HTTP profile.
   
   Navigate to System > Profiles > HTTP Profiles, and create the HTTP profile.

2. Bind the HTTP profile to the service or virtual server.
   
   Navigate to Traffic Management > Load Balancing > Services/Virtual Servers, and create the HTTP profile, which should be bound to the service/virtual server.

Built-in HTTP profiles

For convenience of configuration, the Citrix ADC provides some built-in HTTP profiles. Review the profiles listed below and use it as is or modify it to meet your requirements. You can bind these profiles to the required services or virtual servers.

<table>
<thead>
<tr>
<th>Built-in profile</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nshttp_default_profile</td>
<td>Represents the default global HTTP settings on the appliance.</td>
</tr>
<tr>
<td>nshttp_default_strict_validation</td>
<td>Settings for deployments that require strict validation of HTTP requests and responses.</td>
</tr>
</tbody>
</table>

Sample HTTP configurations

Sample command line interface examples to configure the following:

- HTTP band statistics
- WebSocket connections

HTTP band statistics

Specify the band size for HTTP requests and responses.

```
1 > set protocol httpBand reqBandSize 300 respBandSize 2048
2 Done
3 > show protocol httpband ~type REQUEST
```
WebSocket connections

Enable webSocket on the required HTTP profile.

```
1 > set ns httpProfile http_profile1 -webSocket ENABLED
2 Done
3 > set lb vserver lbvserver1 -httpProfileName profile1
4 Done
```

Configuring HTTP/2 on the Citrix ADC appliance

August 30, 2019

**Note:** The HTTP/2 functionality is supported on the Citrix ADC MPX, VPX, and SDX models. For Citrix ADC VPX, the HTTP/2 functionality is supported from 11.0 release onwards.

The problem with web application performance is directly related to the trend toward increasing the page size and the number of objects on the web pages. HTTP/1.1 was developed to support smaller web pages, slower Internet connections, and more limited server hardware than are common today. It is not well suited for newer technologies such as JavaScript and cascading style sheets (CSS), nor for new media types such as Flash videos and graphics-rich images, because it can request only one resource per connection to the server. This limitation significantly increases the number of round trips, causing longer page-rendering time and reduced network performance.

The HTTP/2 protocol addresses these limitations by allowing communication to occur with less data transmitted over the network, and providing the ability to send multiple requests and responses across a single connection. At its core, HTTP/2 addresses the key limitations of HTTP/1.1 by using the underlying network connections more efficiently. It changes the way requests and responses travel over the network.

HTTP/2 is a binary protocol. It is more efficient to parse, more compact on the wire, and most importantly, it is less error-prone, compared to textual protocols like HTTP/1.1. The HTTP/2 protocol uses a binary framing layer that defines the frame type and how HTTP messages are encapsulated and transferred between the client and server. The HTTP/2 functionality supports the use of the CONNECT method to establish a tunnel connection through a single HTTP/2 stream to a remote host.

The HTTP/2 protocol includes a lot of performance-enhancing changes that significantly improve performance, particularly for clients connecting over a mobile network.

The following table lists the major improvements in HTTP/2 over HTTP/1.1:
## HTTP/2 Features Description

<table>
<thead>
<tr>
<th>HTTP/2 Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header Compression</td>
<td>HTTP headers have a lot of repetitive information and therefore consume unnecessary bandwidth during data transmission. HTTP/2 reduces bandwidth requirements by compressing the header and minimizing the requirement to transport HTTP headers with every request and response.</td>
</tr>
<tr>
<td>Connection Multiplexing</td>
<td>Latency can have a huge impact on page load times and the end user experience. Connection multiplexing overcomes this problem by sending multiple requests and responses across a single connection.</td>
</tr>
<tr>
<td>Server Push</td>
<td>Server push enables the server to proactively push content to the client browser, avoiding round trip delay. This feature caches the responses it thinks the client will need, reduces the number round trips, and improves the page rendering time. Important: The Citrix ADC appliance does not support the server push functionality.</td>
</tr>
<tr>
<td>No Head-of-line Blocking</td>
<td>Under HTTP/1.1, browsers can download one resource at a time per connection. When a browser has to download a large resource, it blocks all other resources from downloading until the first download is complete. HTTP/2 overcomes this problem with a multiplexing approach. It allows the client browser to download other web components in parallel over the same connection and display them as they become available.</td>
</tr>
</tbody>
</table>
Request Prioritization

Not all resources have equal priority when the browser renders a web page. To accelerate the load time, all modern browsers prioritize requests by type of asset, their location on the page, and even by learned priority from previous visits. With HTTP/1.1, the browser has limited ability to leverage the priority data, because this protocol does not support multiplexing, and there is no way to communicate request prioritization by the server. The result is unnecessary network latency. HTTP/2 overcomes this problem by allowing the browser to dispatch all requests. The browser can communicate its stream prioritization preference via stream dependencies and weights, enabling the servers to optimize response delivery. Important: The Citrix ADC appliance does not support the request prioritization functionality.

How HTTP/2 works on a Citrix ADC appliance

A Citrix ADC appliance supports HTTP/2 on the client side as well on the server side. On the client side, the Citrix ADC appliance acts as a server that hosts an HTTP/HTTPS virtual server for HTTP/2. On the backend side, the Citrix ADC acts as a client to the servers that are bound to the virtual server.

Therefore, the Citrix ADC appliance maintains separate connections on the client side as well on the server side. The Citrix ADC appliance has separate HTTP/2 configurations for the client side and the server side.

HTTP/2 for HTTPS (SSL) load balancing configuration

For an HTTPS load balancing configuration, the Citrix ADC appliance uses the TLS ALPN extension (RFC 7301) to determine whether the client/server supports HTTP/2. If it does, the appliance chooses HTTP/2 as the application-layer protocol to transmit data (as described in RFC 7540 - Section 3.3) on the client/server side.
The appliance uses the following order of preference when choosing the application-layer protocol through the TLS ALPN extension:

- HTTP/2 (if enabled in the HTTP profile)
- SPDY (if enabled in the HTTP profile)
- HTTP/1.1

**HTTP/2 for HTTP load balancing configuration**

For an HTTP load balancing configuration, the Citrix ADC appliance uses one of the following methods to start communicating with the client/server using HTTP/2.

*Note*

In the following method descriptions, client and server are generals terms for an HTTP/2 connection. For example, for a load balancing setup of a Citrix ADC appliance using HTTP/2, the Citrix ADC appliance acts as a server on the client side and acts as a client to the server side.

- **HTTP/2 Upgrade.** A client sends an HTTP/1.1 request to a server. The request includes an upgrade header, which asks the server for upgrading the connection to HTTP/2. If the server supports HTTP/2, the server accepts the upgrade request and notifies it in its response. The client and the server start communicating using HTTP/2 after the client receives the upgrade confirmation response.

- **Direct HTTP/2.** A client directly starts communicating to a server in HTTP/2 instead of using the HTTP/2 upgrade method. If the server does not support HTTP/2 or is not configured to directly accept HTTP/2 requests, it drops the HTTP/2 packets from the client. This method is helpful if the admin of the client device already knows that the server supports HTTP/2.

- **Direct HTTP/2 using Alternative Service (ALT-SVC).** A server advertises that it supports HTTP/2 to a client by including an Alternative Service (ALT-SVC) field in its HTTP/1.1 response. If the client is configured to understand the ALT-SVC field, the client and the server starts directly communicating using HTTP/2 after the client receives the response.

The Citrix ADC appliance provides configurable options in an HTTP profile for the HTTP/2 methods. These HTTP/2 options can be applied to the client side as well to the server side of an HTTPS or HTTP load balancing setup. For more information for HTTP/2 methods and options, refer to the [HTTP/2 options pdf](#).

**Before you Begin**

Before you begin configuring HTTP/2 on a Citrix ADC appliance, note the following points:

- The Citrix ADC appliance supports HTTP/2 on the client side as well on the server side.
The Citrix ADC appliance does not support the HTTP/2 server push functionality.

The Citrix ADC appliance does not support the HTTP/2 request prioritization functionality.

The Citrix ADC appliance does not support HTTP/2 SSL renegotiation for HTTPS load balancing setups.

The Citrix ADC appliance does not support HTTP/2 NTLM authentication.

HTTP/2 does not work if User Source IP (USIP) mode is enabled and the Proxy mode is disabled on the Citrix ADC appliance.

Configuring HTTP/2

Configuring HTTP/2 for a load balancing setup (HTTPS or HTTP) consists of the following tasks:

- **Enable HTTP/2 and set optional HTTP/2 parameters in an HTTP Profile.** Enable HTTP/2 in an HTTP profile. When you only enable HTTP/2 in an HTTP profile, the Citrix ADC appliance uses only the upgrade method (for HTTP) or TLS ALPN method (for HTTPS) for communicating in HTTP/2.

  For the Citrix ADC appliance to use the direct HTTP/2 method, **Direct HTTP/2** option must be enabled in the HTTP profile. For the Citrix ADC appliance to use the direct HTTP/2 using the alternative service method, **Alternative Service (altsvc)** option must be enabled in the HTTP profile.

- **Bind the HTTP profile to a virtual server or a service.** Bind the HTTP profile to a virtual server to configure HTTP/2 for the client side of the load balancing setup. Bind the HTTP profile to a service to configure HTTP2 for the server side of the load balancing setup.

  **Note**

  Citrix recommends binding separate HTTP profiles for the client side and the server side.

- **Enable the global parameter for HTTP/2 server side support.** Enable the **HTTP/2 Service Side (HTTP2Serverside)** global HTTP parameter for enabling the HTTP/2 support on the server side of all the load balancing setups that has HTTP/2 configured.

  HTTP/2 does not work on the server side of any load balancing setups if **HTTP/2 Service Side** is disabled even if the **HTTP/2** is enabled on the HTTP profile bound to the related load balancing services.

**Citrix ADC Command Line procedures:**

To enable HTTP/2 and set HTTP/2 parameters by using the Citrix ADC command line

- To enable HTTP/2 and set HTTP/2 parameters while adding an HTTP profile, at the command prompt, type:

  ```
  - add ns httpProfile <name> - http2 ( ENABLED | DISABLED ) [-http2Direct ( ENABLED | DISABLED )] [-altsvc ( ENABLED | DISABLED )]
  ```
To enable HTTP/2 and set HTTP/2 parameters while modifying an HTTP profile, at the command prompt, type:

```
set ns httpProfile <name> http2 ( ENABLED | DISABLED ) \[-http2Direct ( ENABLED | DISABLED)\] \[-altsvc ( ENABLED | DISABLED )\]
```

To bind the HTTP profile to a virtual server by using the Citrix ADC command line

At the command prompt, type:

```
set lb vserver <name> -httpProfileName <string>
```

To bind the HTTP profile to a load balancing service by using the Citrix ADC command line

At the command prompt, type:

```
set service <name> -httpProfileName <string>
```

To enable HTTP/2 support globally on the server side by using the Citrix ADC command line

At the command prompt, type:

```
set ns httpParam -HTTP2Serverside ( ENABLED | DISABLED )
```

GUI Procedures

To enable HTTP/2 and set HTTP/2 parameters by using the GUI

1. Navigate to System > Profiles, and click HTTP Profiles tab.
2. Enable HTTP/2 while adding an HTTP profile or modifying an existing HTTP profile.

To bind the HTTP profile to a virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open the virtual server.
2. In Advanced Settings, click + HTTP Profile to bind the created HTTP profile to the virtual server.

To bind the HTTP profile to a load balancing service by using the GUI

1. Navigate to Traffic Management > Load Balancing > service, and open the service.
2. In Advanced Settings, click + HTTP Profile to bind the created HTTP profile to the service.

To enable HTTP/2 support globally on the server side by using the GUI

Navigate to System > Settings, click Change HTTP parameters and enable HTTP/2 Server Side.
Sample configurations

In the following sample configuration, HTTP/2 and direct HTTP/2 is enabled on HTTP profile HTTP-PROFILE-HTTP2-CLIENT-SIDE. The profile is bound to virtual server LB-VS-1.

```plaintext
> set ns httpProfile HTTP-PROFILE-HTTP2-CLIENT-SIDE -http2 enabled
  -http2Direct enabled
Done
> set lb vserver LB-VS-1 -httpProfileName HTTP-PROFILE-HTTP2-CLIENT-SIDE
Done
```

In the following sample configuration, HTTP/2 and alternative service (AL-T-SVC) is enabled on HTTP profile HTTP-PROFILE-HTTP2-SERVER-SIDE. The profile is bound to service LB-SERVICE-1.

```plaintext
> set ns httpparam -HTTP2Serverside ENABLED
Done
> set ns httpProfile HTTP-PROFILE-HTTP2-SERVER-SIDE -http2 ENABLED
  -altsvc ENABLED
Done
> set service LB-SERVICE-1 -httpProfileName HTTP-PROFILE-HTTP2-SERVER-SIDE
Done
```

Proxy protocol

October 7, 2019

Citrix ADC uses Proxy protocol for safely transporting client connection information from client to server across Citrix ADC appliances in the proxy layer. The appliance adds a proxy protocol header to insert the client side details and forward it to appliances and then to the back-end server. Following are some of the usage scenarios for proxy protocol in a Citrix ADC appliance.

- Learning original client IP address
- Selecting a language for a website
• Blacklisting selected IP addresses
• Logging and collecting statistics.

How proxy protocol works in a Citrix ADC appliance

The following diagram shows how Proxy protocol configured in a Citrix ADC appliance:

The component interact is as follows:

• A client sends an HTTP request to Citrix ADC.
• At Citrix ADC 1 instance, if proxy protocol is disabled on load balancing virtual server (VIP) and enabled on the service (SNIP) it is an Insert operation.
• In Insert operation, Citrix ADC 1 adds a proxy header with client connection details and forwards it to Citrix ADC 2 appliance.
• At Citrix ADC 2, it is a Forward operation. The proxy protocol is enabled on load balancing virtual server and enabled on the service. The appliance receives the proxy header and forwards the header details to the Citrix ADC 3 appliance.
• At Citrix ADC 3, it can either be a Forward or Stripped operation. For Forward, the proxy protocol is enabled on the load balancing virtual server and on the service. The appliance receives the proxy header and forwards the header details to the origin server.
• If the operation is Stripped, the Proxy protocol is enabled on load balancing virtual server and disabled on the service. The appliance receives the Proxy header details and stores it for audit logging or statistics.
• If the proxy header details are in invalid format, the appliance resets the connection.
• On the receiving side, based on proxy protocol data, the appliance decides the proxy protocol version. There are two versions, Proxy Protocol Version-1 and Proxy Protocol Version-2.
• On the sending side, the appliance decides the proxy protocol version based on CLI configuration.

Proxy protocol version formats

The Proxy protocol version is available as two formats. The appliance decides to use a format based on the incoming data length.

1. Proxy protocol version-1 format

   `PROXY TCP4/TCP6/UNKNOWN <SRC IP> <DST IP> <SRC PORT> <DST PORT>`

   • PROXY -> Unique string format for Proxy header version -1.
   • Support protocols TCP over IPv4 and TCP over IPv6. For remaining protocols, this is UNKNOWN.
   • SRC IP – Source IP (Original Client IP) address of a packet.
   • DST IP – Destination IP address of a packet.
• SRC port – Source port of a packet.
• DST port – Destination port of a packet.

2. Proxy protocol version-2 format

0D 0A 0D 0A 00 0D 0A 51 55 49 54 0A <13th byte> <14th byte> <15-16th byte> <17th byte onwards>

• D 0A 0D 0A 00 0D 0A 51 55 49 54 0A -> Unique binary string for Proxy header version -2.
• Support protocols TCP over IPv4 and TCP over IPv6. For remaining protocols, this is UN-KNOWN.
• 13th byte – protocol version and command.
• 14th byte – address and protocol family.
• 15-16th byte – Address length in network order.
• 17th byte onwards – Addresses info present in network order- src IP, dst IP, src port, dst port.

Configure Proxy protocol in Citrix ADC appliance

Following the procedure given below to configure Proxy protocol in your Citrix ADC appliance.

1. Enable Proxy protocol as global.
2. Configure Proxy protocol for Insert operation
3. Configure Proxy protocol for Forward operation
4. Configure Proxy protocol for Strip operation
5. Configure Proxy protocol for no operation

Enable Proxy protocol as global

At the command prompt, type the following:

set ns param -proxyProtocol ENABLED

Configure Proxy protocol for Insert operation

At the command prompt, type the following:
To configure proxy protocol for Insert operation, you must enable or disable the protocol on the load balancing virtual server and enable it on the service.

Add net profile with Proxy protocol disabled for load balancing virtual server

At the command prompt, type the following:
Add net profile with Proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

Example:
```
add netprofile proxyprofile-1 -proxyProtocol DISABLED -proxyprotocoltxversion V1
```

Note
If you disable proxy protocol on your appliance, you need not set the protocol version parameter.

Add load balancing virtual server for Citrix ADC appliance 1 in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

Example:
```
add lb vserver lbvserver-1 http 1.1.1.1 80
```

Add HTTP service for Citrix ADC appliance 1 in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

Example:
```
Add service http-service-1 2.2.2.1 http 80
```
Set net profile with load balancing virtual server in Citrix ADC appliance 1

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

**Example:**

```
set lb vserver lbvserver-1 -netprofile proxyProfile-1
```

Bind net profile with HTTP service in Citrix ADC appliance 1

At the command prompt, type the following:

```
bind service <service name> -netprofile <name>
```

**Example:**

```
bind service http-service-1 -netprofile proxyProfile-1
```

Configure Proxy protocol for Forward operation

To configure proxy protocol for Forward operation for the next Citrix ADC instance in the proxy layer. You must enable or disable the protocol and bind to the virtual server or service.

Add net profile with Proxy protocol enabled for load balancing virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**

```
add netprofile proxyprofile-3 -proxyProtocol ENABLED -proxyprotocoltxversion V1
```

Add net profile with Proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**

```
add netprofile proxyprofile-4 -proxyProtocol ENABLED -proxyprotocoltxversion V1
```
Add load balancing virtual server for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

**Example:**

```
add lb vserver lbvserver-2 http 2.2.2.2 80
```

Add HTTP service for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@) <serviceType> <port>
```

**Example:**

```
Add service http-service-2 3.3.3.1 http 80
```

Set net profile with load balancing virtual server in Citrix ADC appliance 2

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

**Example:**

```
set lb vserver lbvserver-2 -netprofile proxyProfile-3
```

Set net profile with HTTP service in Citrix ADC appliance 2

At the command prompt, type the following:

```
set service <service name> -netprofile <name>
```

**Example:**

```
set service http-service-2 -netprofile proxyProfile-4
```

Configure Proxy protocol for Strip operation

To configure proxy protocol for Strip operation, you must disable the proxy protocol on the load balancing virtual server and enable the proxy protocol on the service.
Add net profile with Proxy protocol disabled for load balancing virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**

```
add netprofile proxyprofile-5 –proxyProtocol DISABLED –proxyprotocoltxversion V1
```

Add net profile with Proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**

```
add netprofile proxyprofile-5 -proxyProtocol DISABLED -proxyprotocoltxversion V1
```

**Note**

If you disable proxy protocol on your appliance, you need not set the protocol version parameter.

Add load balancing virtual server for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@<serviceType> [(<IPAddress>@<port>)]
```

**Example:**

```
add lb vserver lbvserver-3 http 2.2.2.2 80
```

Add HTTP service for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@<serviceType> [(<IPAddress>@<port>)]
```

**Example:**

```
add lb vserver lbvserver-3 http 2.2.2.2 80
```
Set net profile with load balancing virtual server in Citrix ADC appliance 2

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

**Example:**
```
add service http-service-3 3.3.3.1 http 80
```

Set net profile with HTTP service in Citrix ADC appliance 2

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

**Example:**
```
set lb vserver lbvserver-3 -netprofile proxyProfile-5
```

Configure Proxy protocol for no operation

To configure proxy protocol for no operation, you must disable the proxy protocol on virtual server and also on the service.

Add net profile with Proxy protocol enabled for load balancing virtual server

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**
```
add netprofile proxyprofile-3 -proxyProtocol ENABLED -proxyprotocoltxversion V1
```

Add net profile with Proxy protocol enabled for service

At the command prompt, type the following:

```
add netprofile <name> -proxyProtocol ENABLED/DISABLED -proxyprotocoltxversion <V1/V2>
```

**Example:**
```
add netprofile proxyprofile-4 -proxyProtocol ENABLED -proxyprotocoltxversion V1
```
Add load balancing virtual server for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add lb vserver <name>@ <serviceType> [(<IPAddress>@ <port>)]
```

**Example:**

```
add lb vserver lbvserver-2 http 2.2.2.2 80
```

Add HTTP service for Citrix ADC appliance 2 in the proxy layer

At the command prompt, type the following:

```
add service <name>@ (<IP>@ | <serverName>@)<serviceType> <port>
```

**Example:**

```
add service http-service-2 3.3.3.1 http 80
```

Set net profile with load balancing virtual server in Citrix ADC appliance 2

At the command prompt, type the following:

```
set lb vserver <vserver name> -netprofile <name>
```

**Example:**

```
set lb vserver lbvserver-2 -netprofile proxyProfile-3
```

Set net profile with HTTP service in Citrix ADC appliance 2

At the command prompt, type the following:

```
set service <service name> -netprofile <name>
```

**Example:**

```
set service http-service-2 -netprofile proxyProfile-4
```

Configure Proxy protocol by using Citrix ADC GUI

1. Navigate to **System > Settings > Change Global System Settings**.
2. In the **Configure Global System Settings Parameters** page, select **Proxy Protocol** checkbox.
3. Click **OK** and **Close**.
4. Navigate to **System > Network > Net Profiles**.

5. In the details pane, click **Add** to create a net profile for the load balancing virtual server.

6. In the **Net Profile** page, set the following parameters:
   
   a) Name. Name of the net profile.
   
   b) Traffic Domain. Add or select the default traffic domain or a different one to configure the entity.
   
   c) IP address. IP address of the virtual server network.
   
   d) Enable Source IP Persistency. Same address specified in the net profile to communicate to servers for all sessions initiated from a particular client to the virtual server.
   
   e) Override LSN. USNIP or USIP settings override LSN settings for configured service or virtual server traffic.
   
   f) Proxy Protocol. Enable or disable proxy protocol for the load balancing virtual server.
   
   g) Proxy Protocol TX Version. Set proxy protocol version as V1 or V2 based on incoming data format.
   
   h) MBF. Disable MAC based forwarding mode.
   
   i) Source Port Range. Enter the source port range. Based on the range, the appliance chooses a port from the range to establish connection with the back-end servers.

7. Click **OK**.

8. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

9. In the details pane, click **Add**.

10. In the **Load Balancing Virtual Server** page, set the basic parameters.

11. In the **Advanced Settings** section, select **Profiles**.

12. In the **Profiles** section, click the pencil icon.

13. Select a net profile and click **OK**.

14. Click **Done**.

15. Navigate to **Traffic Management > Load Balancing > Services**.

16. In the details pane, click **Add**.

17. In the **Load Balancing Service** page, set the basic parameters.

18. In the **Advanced Settings** section, select **Profiles**.

19. In the **Profiles** section, click the pencil icon.

20. Select a net profile and click **OK**.

21. Click **Done**.
If you have more than one Citrix ADC appliance as part of the proxy layer, you must set the proxy protocol configuration on each appliance for the Forward operation.

SNMP

April 23, 2019

You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix ADC appliance to generate asynchronous events, which are called traps. The traps are generated whenever there are abnormal conditions on the Citrix ADC. The traps are then sent to a remote device called a trap listener, which signals the abnormal condition on the Citrix ADC appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an SNMP manager. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

For information about SNMP parameters, traps, and its descriptions, see Citrix ADC SNMP OID reference.

The SNMP agent on the Citrix ADC can generate traps compliant with SNMPv1, SNMPv2, and SNMPv3. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

The following figure illustrates a network with a Citrix ADC that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the Citrix ADC. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.

Figure 1. Citrix ADC Supporting SNMP

Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a Citrix ADC appliance, you must download the MIB object definition files. The MIB files include the following:

‘MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP’

Citrix ADC-specific configuration and statistics.

You can obtain the MIB object definition files from the /netscaler/snmp directory or from the Downloads tab of the GUI.

If the SNMP management application is other than WhatsUpGold, download the following files to the SNMP management application:
NS-MIB-smiv1.mib. Used by SNMPv1 managers and trap listeners.

If the SNMP management application is WhatsUpGold, download the following files to the SNMP management application:

- `mib.txt`
- `traps.txt`

**Configuring the Citrix ADC to generate SNMP traps**

April 23, 2019

You can configure the Citrix ADC appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a *trap listener*. This helps administrators monitor the appliance and respond promptly to any issues.

The Citrix ADC appliance provides a set of condition entities called *SNMP alarms*. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the Citrix ADC appliance to generate traps, you need to enable and configure alarms. Then, you specify trap listeners to which the appliance will send the generated trap messages.

**Enabling an SNMP alarm**

The Citrix ADC appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

**To enable an SNMP alarm by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `enable snmp alarm <trapName>`
- `show snmp alarm <trapName>`
To enable an SNMP alarm by using the GUI

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.

Configuring alarms

The Citrix ADC appliance provides a set of condition entities called SNMP alarms. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure will be assigned with the warning severity level.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the command line interface

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

```
set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state ( ENABLED | DISABLED )] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

```
show snmp alarm <trapName>
```

Where,

ThresholdValue: Value for the high threshold. The Citrix ADC appliance generates an SNMP trap message when the value of the attribute associated with the alarm is greater than or equal to the specified high threshold value.
NormalValue: Value for the normal threshold. A trap message is generated if the value of the respective attribute falls to or below this value after exceeding the high threshold.

**To configure SNMP alarms by using the GUI**

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.

**Configuring SNMPv1 or SNMPv2 traps**

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the Citrix ADC IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener on the basis of a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

**To add an SNMP trap by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 )-destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>`
- `show snmp trap`

**Example:**
To configure SNMP traps by using the GUI

Navigate to System > SNMP > Traps, and create the SNMP trap.

Configuring SNMPv3 traps

SNMPv3 provides security capabilities such as authentication and encryption by using the credentials of SNMP users. An SNMP manager can receive SNMPv3 trap messages only if its configuration includes the password assigned to the SNMP user.

The trap destination can now receive SNMPv1, SNMPv2, and SNMPv3 trap messages.

To configure an SNMPv3 trap by using the command line interface

At the command prompt, do the following:

1. Add an SNMPv3 trap.

```
add snmp trap <trapClass> <trapDestination> -version ( V1 | V2 | V3) 
-destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>
```

**Note:**
Once set, the SNMP trap version cannot not be modified.

**Example**

```
1 > add snmp trap specific 10.102.29.3 -version V3 -destPort 80 -
communityName com1 -severity Major
```

2. Add an SNMP user.

```
add snmp user <name> -group <string> [ -authType ( MD5 | SHA ){ -
authPasswd } ] [ -privType ( DES | AES ){ -privPasswd } ]
```

**Example**

```
1 > add snmp user edocs_user -group edocs_group
```

3. Bind the SNMPv3 trap to the SNMP user.
bind snmp trap <trapClass> <trapDestination> [-version <version>] (-userName <string> [-securityLevel <securityLevel>])

Example

```
> bind snmp trap specific 10.102.29.3 -version V3 -userName edocs_user -securityLevel authPriv
```

To configure an SNMPv3 trap by using the GUI

1. Add an SNMPv3 trap.
   
   Navigate to System > SNMP > Traps, and create the SNMP trap by selecting V3 as the SNMP version.

2. Add an SNMP user.
   
   Navigate to System > SNMP > **Users** and create the SNMP user.

3. Bind the SNMPv3 trap to the SNMP user.
   
   - Navigate to System > SNMP > Traps, and select the SNMP version 3 trap.
   - Select the user to which the trap should be bound and define the appropriate Security Level.

SNMP trap logging

A Citrix ADC appliance can log SNMP trap messages (for SNMP alarms in which logging capability is enabled) when you enable the SNMP trap logging option and at least one trap listener is configured on the appliance. Now, you can specify the audit log level of trap messages sent to an external log server. The default log level is Informational. Possible values are Emergency, Alert, Critical, Error, Warning, Debug, and Notice.

For example, you can set the audit log level to Critical for an SNMP trap message generated by a logon failure. That information is then available on the NSLOG or SYSLOG server for troubleshooting.

To enable SNMP trap logging and configure trap log level by using the command line interface

At the command prompt, type the following commands to configure SNMP trap logging and verify the configuration:
To enable SNMP trap logging and configure SNMP trap log level by using the GUI

Navigate to System > SNMP, click Change SNMP Options and set the following parameters:

1. SNMP Trap Logging—Select this check box to enable SNMP trap logging when at least one trap listener is configured on the appliance.
2. SNMP Trap Logging Level—Select an audit log level for the SNMP trap. By default, the audit level for SNMP trap is set to “Informational.”

Configuring Citrix ADC for SNMP v1 and v2 queries

April 23, 2019

You can query the Citrix ADC SNMP agent for system-specific information from a remote device called SNMP managers. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called community strings and associate each of these to query types. You can associate one or more community strings to each query type. Community string are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as abc and bcd, to the query type GET NEXT, the SNMP agent on the Citrix ADC appliance considers only those GET NEXT SNMP query packets that contain abc or bcd as the community string.

Specifying an SNMP manager

You must configure the Citrix ADC appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required Citrix ADC-specific information. You can add up to a maximum of 100 SNMP managers or networks.
For an IPv4 SNMP manager you can specify a host name instead of the manager’s IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.

**Note:**
The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.

If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

### To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp manager <IPAddress> ... [-netmask <netmask>]`
- `show snmp manager`

**Example**

```plaintext
> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30
```

### To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager’s host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager’s IP address. For more information, see “Adding a Name Server.”

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp manager <IPAddress> [-domainResolveRetry ****<integer>]`
- `show snmp manager`

**Example**
add nameserver 10.103.128.15
add snmp manager engwiki.eng.example.net -domainResolveRetry 10

To add an SNMP manager by using the GUI

1. Navigate to System > SNMP > Managers, and create the SNMP manager.

   Important:
   If you specify the SNMP manager's host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address.

   Note:
   The appliance does not support host names for SNMP managers that have IPv6 addresses.

Specifying an SNMP community

You can create strings called community strings and associate them with the following SNMP query types on the appliance:

   - GET
   - GET NEXT
   - ALL
   - GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as abc and bcd, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain abc or bcd as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

   • add snmp community <communityName> <permissions>
   • show snmp community
Example

> add snmp community com all

To configure an SNMP community string by using the GUI

Navigate to System > SNMP > Community, and create the SNMP community.

Configuring Citrix ADC for SNMPv3 queries

April 23, 2019

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

- **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
  - **Data integrity:** To protect messages from being modified during transmission through the network.
  - **Data origin verification:** To authenticate the user who sent the message request.
  - **Message timeliness:** To protect against message delays or replays.
  - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.

- **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

Citrix ADC supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
- SNMP Groups
- SNMP Users
These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

**Note:**
The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each Citrix ADC appliance.

To implement message authentication and access control, you need to do the following:

### Setting the engine ID

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The Citrix ADC appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to override the engineID. However, if you want to change the engine ID, you can reset it.

**To set the engine ID by using the command line interface**

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `set snmp engineId <engineID>`
- `show snmp engineId`

**Example**

```
> set snmp engineId 8000173f0300c095f80c68
```

**To set the engine ID by using GUI**

Navigate to **System > SNMP > Users**, click **Configure Engine ID** and type an engine ID.

**Configure a view**

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.
To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp view <name> <subtree> -type ( included | excluded )`
- `show snmp view <name>`
- `rm snmp view <name> <subtree>`

Where,

**Name.** Name for the SNMPv3 view. It can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 view.

**Subtree.** A particular branch (subtree) of the MIB tree that you want to associate with this SNMPv3 view. You must specify the subtree as an SNMP OID. This is an argument of maximum Length: 99.

**type.** Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view. This is a mandatory argument. Possible values: included, excluded.

**Examples**

`add snmp view SNMPv3test 1.1.1.1 -type included`
`sh snmp view SNMPv3test`
`rm snmp view SNMPv3test 1.1.1.1`

To configure an SNMP view by using the GUI

Navigate to **System > SNMP > Views**, and create the SNMP view.

**Configure a group**

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.
To add an SNMP group by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- `add snmp group <name> <securityLevel> -readViewName <string>`
- `show snmp group <name> <securityLevel>`

Where,

**Name.** Name for the SNMPv3 group. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 group.

**securityLevel.** Security level required for communication between the Citrix ADC appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

- **noAuthNoPriv.** Require neither authentication nor encryption.
- **authNoPriv.** Require authentication but no encryption.
- **authPriv.** Require authentication and encryption. Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for each group member. This is a mandatory argument. Possible values: noAuthNoPriv, authNoPriv, authPriv.

**readViewName.** Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the Citrix ADC appliance has multiple SNMPv3 view entries with the same name, all such entries are associated with the SNMPv3 group. This is a mandatory argument. Maximum Length: 31

To configure an SNMP group by using the GUI

Navigate to **System > SNMP > Groups**, and create the SNMP group.

**Configuring a user**

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.

You need to configure users at the agent and assign each user to a group.
To configure a user by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp user <name> -group <string> [-authType ( MD5 | SHA ){ -authPasswd } [-privType ( DES | AES ){ -privPasswd } ]]

- show snmp user <name>

Where,

authType is the authentication option available while configuring an user. There are two authentication types such as MD5 and SHA.

privType is the encryption option available while configuring an user. There are two types of encryption such as DES of key size 128 bit, and AES of key size 128 bit.

Example

```
1 > add snmp user edocs_user -group edocs_group
```

To configure an SNMP user by using the GUI

Navigate to System > SNMP > Users, and create the SNMP user.

Configuring SNMP Alarms for rate limiting

April 23, 2019

Citrix ADC appliances such as the Citrix ADC MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the Citrix ADC logs the events associated with the traps in the /var/log/ns.log file as EVENT ALERTSTARTED and EVENT ALERTENDED.
Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see “Configuring the Citrix ADC to generate SNMP v1 and v2 Traps.”

This document includes the following details:

- Configuring an SNMP Alarm for Throughput or PPS
- Configuring SNMP Alarm for Dropped Packets

**Configuring an SNMP alarm for throughput or PPS**

To monitor both throughout and PPS, you must configure separate alarms and set threshold pps value in Mbps.

**To configure an SNMP alarm for the throughput rate by using the command line interface**

At the command prompt, type the following commands to configure the SNMP alarm, set threshold value in Mbps and verify the configuration:

- `set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state ( **ENABLED** | **DISABLED** ) [-severity <severity>]] [-logging ( **ENABLED** | **DISABLED** )]
- `show snmp alarm PF-RL-RATE-THRESHOLD`

**Example**

```
1 > set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue 50
```

**To configure an SNMP alarm for PPS by using the command line interface**

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- `set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state ( **ENABLED** | **DISABLED** ) [-severity <severity>]] [-logging ( **ENABLED** | **DISABLED** )]
- `show snmp alarm PF-RL-PPS-THRESHOLD`
Example

```
> set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for throughput or PPS by using the GUI

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-THRESHOLD (for throughput rate) or PF-RL-PPS-THRESHOLD (for packets per second).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP alarm for dropped packets

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:

```
set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging ( ENABLED | DISABLED )]
```

To configure an SNMP alarm for dropped packets by using the GUI

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-PKTS-DROPPED (for packets dropped because of excessive throughput) or PF-RL-PPS-PKTS-DROPPED (for packets dropped because of excessive PPS).
2. Set the alarm parameters and enable the selected SNMP alarm.
Configuring SNMP in FIPS mode

April 23, 2019

FIPS mode requires Simple Network Management Protocol version 3 (SNMPv3) with the authentication and privacy (authPriv) option. SNMP version 1 and version 2 use a community string mechanism to provide secured access to management data. The community string is sent as clear text between an SNMP manager and an SNMP agent. This type of communication is unsecure, allowing intruders to access SNMP information on the network.

The SNMPv3 protocol uses the User-based Security Model (USM) and View-based Access Control Model (VACM) to authenticate and control management access to SNMP messaging data. SNMPv3 has three security levels: no authentication no privacy (noAuthNoPriv), authentication and no privacy (authNoPriv), and authentication and privacy (authPriv).

Enabling FIPS mode and restarting the Citrix ADC appliance removes the following SNMP configurations from the appliance:

1. Community configuration for SNMPv1 and SNMPv2 protocols.
2. SNMPv3 groups configured with the noAuthNoPriv or authNoPriv security-level option.
3. Traps configured for SNMPv1 or SNMPv2, or SNMPv3 with the noAuthNoPriv security-level option.

After restarting the appliance, configure SNMPv3 with the authPriv option. For more information about configuring authPriv option in SNMP v3, see SNMPV3 topic

**Note:**
Enabling FIPS mode and restarting your appliance blocks execution of the following SNMP trap and group commands:

1. `add snmp community <communityName> <permissions>`
2. `add snmp trap <trapClass> <trapDestination> ... [-version: v1/v2] [-td <positive_integer>] [-destPort <port>] [-communityName <string>] [-srcIP <ip_addr|ipv6_addr>] [-severity <severity>] [-allPartitions ( ENABLED | DISABLED )]`
3. `add snmp group <name> <securityLevel : noAuthNoPriv/ authNoPriv > -readViewName <string>`
4. `bind snmp trap specific <TrapIp>-userName <v3 user name> -securityLevel <noAuthNoPriv/ authNoPriv>}`
Audit logging

April 23, 2019

Auditing is a methodical examination or review of a condition or situation. The Audit Logging feature enables you to log the Citrix ADC states and status information collected by various modules in the kernel and in the user-level daemons. For audit logging, you can use the SYSLOG protocol, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components: the SYSLOG auditing module, which runs on the Citrix ADC appliance, and the SYSLOG server, which can run on the underlying FreeBSD operating system (OS) of the Citrix ADC appliance or on a remote system. SYSLOG uses user data protocol (UDP) for data transfer.

Similarly, the native NSLOG protocol has two components: the NSLOG auditing module, which runs on the Citrix ADC appliance, and the NSLOG server, which can run on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system. NSLOG uses transmission control protocol (TCP) for data transfer.

When you run a SYSLOG or NSLOG server, it connects to the Citrix ADC appliance. The Citrix ADC appliance then starts sending all the log information to the SYSLOG or NSLOG server, and the server can filter the log entries before storing them in a log file. An NSLOG or SYSLOG server can receive log information from more than one Citrix ADC appliance, and a Citrix ADC appliance can send log information to more than one SYSLOG server or NSLOG server.

If multiple SYSLOG servers are configured, the Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastPackets, and AuditlogHash.

Note

The Citrix ADC appliance can send audit log messages up to 16 KB to an external SYSLOG server.

The log information that a SYSLOG or NSLOG server collects from a Citrix ADC appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a Citrix ADC appliance that generated the log message.
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
To configure audit logging, you first configure the audit modules on the Citrix ADC appliance. That involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the Citrix ADC appliance or on a remote system.

**Note:**
Because SYSLOG is an industry standard for logging program messages, and various vendors provide support, this documentation does not include SYSLOG server configuration information.

The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making additional modifications to the configuration file (auditlog.conf).

### Configuring Citrix ADC appliance for audit logging

April 23, 2019

Auditing module allows logging of all states and status information from different modules so that an administrator can see event history in the chronological order. Main components of Audit framework are 'audit action', 'audit policy'. ‘Audit action’ describes Audit Server configuration information whereas ‘audit policy’ links a bind entity to an ‘audit action’. The audit policies use ‘Classic Policy Engine’ (CPE) framework to link ‘audit action’ to ‘bind entities’ or Progress Integration (PI) framework to link ‘audit action’ to ‘system global bind entities’.

The policy frameworks differ from each other in the way the audit-log policies are bound to the global entities. Previously, the audit module supported only Classic expression but now it supports both Classic and Advanced policy expressions. Currently, the Advanced expression can bind audit-log policies only to System global entities.

**Note**
When binding a policy to global entities, you must bind a policy it to a system global entity of the same expression type. For example, you cannot bind a classic policy to an advanced global entity or bind an advanced policy to a classic global entity.

### Configuring audit-log policies in a Classic policy expression

Configuring audit-logging in Classic policy consists of the following steps:

1. **Configuring an audit-log action.** You can configure an audit action for different servers and for different log levels. ‘Audit action’ describes Audit Server configuration information whereas
‘audit policy’ links a bind entity to an ‘audit action’. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After the after which the logs are sent to the SYSLOG server.

2. **Configuring audit-log policy.** Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.

3. **Binding audit-log policies to global entities.** You must globally bind the audit log policies to global entities such SYSTEM, VPN, AAA etc., to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Each of these steps are explained in the following sections.

**Configuring audit-log action**

To configure SYSLOG action in Advanced Policy infrastructure by using the command line interface.

```
1 - add audit syslogAction <name> <serverIP> [-serverPort <port>] -
    logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-
    transport ( TCP | UDP )]
2 - show audit syslogAction [<name>]
```

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - add audit nslogAction <name> <serverIP> [-serverPort <port>] -
    logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )]
2 - show audit nslogAction [<name>]
```
Configuring audit-log policies

To configure audit-log Policies in Classic Policy infrastructure by using the command line interface

At the command prompt, type:

```
1 - add audit syslogpolicy <name> <rule> <action>
2 - add audit nslogpolicy <name> <rule> <action> rm audit nslogpolicy <name>
    show audit nslogpolicy [ <name> ] set audit nslogpolicy <name> [-rule <expression>] [-action <name>]
```

Binding audit syslog policies to audit syslog global

To bind audit-log policy in Classic policy framework by using the command line interface

At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType>
unbind audit syslogGlobal <policyName> [-globalBindType <globalBindType>]
```

Configuring audit-log policies using advanced policy expression

Configuring audit-logging in Advanced policy consists of the following steps:

1. **Configuring an audit-log action.** You can configure an audit action for different servers and for different log levels. ‘Audit action’ describes Audit Server configuration information whereas ‘audit policy’ links a bind entity to an ‘audit action’. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the Citrix ADC appliance to store the logs. After the after which the logs are sent to the SYSLOG server.

2. **Configuring audit-log policy.** Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.

3. **Binding audit-log policies to global entities.** You must globally bind the audit log policies to SYSTEM global entity to enable logging of all Citrix ADC system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

**Configuring audit-log action**

To configure syslog action in Advanced Policy infrastructure by using the command line interface
At the command prompt, type the following commands to set the parameters and verify the configuration:

1. `add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-transport ( TCP | UDP )]`
2. `show audit syslogAction [<name>]`

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface:

At the command prompt, type the following commands to set the parameters and verify the configuration:

1. `add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat ( MMDDYYYY | DDMMYYYY )]`
2. `show audit nslogAction [<name>]`

Configuring audit-log policies

To add a syslog audit action by using the command line interface:

At the command prompt, type:

1. `add audit syslogAction <name> (<serverIP> [(-serverPort <port>)] -logLevel <logLevel> [(-serverDomainName <serverDomainName> [-domainResolveRetry <integer>] | (-lbVserverName <string>)) [-transport ( TCP | UDP )] [-logFacility <logFacility>] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-acl ( ENABLED | DISABLED )] [-tcpProfileName <string>] [-appflowExport ( ENABLED | DISABLED )] [-lsn ( ENABLED | DISABLED )])[-maxLogDataSizeToHold]`
2. `show audit syslogAction [<name>]`
3. `add audit syslogpolicy syslog -pol1 -action1`
4. `add audit nslogPolicy nslog-poll ns_true audit-action1`
5. `bind system global nslog-poll -priority 20`

Example
To add a nslog audit action by using the command line interface

At the command prompt, type:

```
add audit nslogAction <name> (<serverIP> | (<serverDomainName>[-domainResolveRetry <integer>] | [serverPort <port>]) [-logLevel <logLevel> ... [-dateFormat <dateFormat>][-logFacility <logFacility>][-tacp ( NONE | ALL )][-acl ( ENABLED | DISABLED )][-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog (YES | NO )][-appflowExport ( ENABLED | DISABLED )][-lsn ( ENABLED | DISABLED )][-alg ( ENABLED | DISABLED )][-subscriberLog ( ENABLED | DISABLED )])
```

Binding audit-log policies to global entities

To bind syslog audit-log policy in Advanced policy framework by using the command line interface

At the command prompt, type:

```
bind audit syslogGlobal <policyName> [-globalBindType <globalBindType>
unbind audit syslogGlobal <policyName>[-globalBindType <globalBindType>]
```

Configuring audit-log policy by using the GUI

1. Navigate to Configuration > System > Auditing > Syslog.
2. Select Servers tab.
3. Click Add.
4. In the Create Auditing Server page, populate the relevant fields, and click Create.
5. To add the policy, select the Policies tab, and click Add.
6. In the Create Auditing Syslog Policy page, populate the relevant fields, and click Create.
7. To bind the policy globally, select Advanced Policy Global Bindings from the drop-down list. Select the best_syslog_policy_ever policy. Click Select.
8. From the drop-down list, select the bind point as SYSTEM_GLOBAL and click Bind, and then click Done.

Configuring policy-based logging

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based
logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages, and associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats

**Pre Requisites**

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format.
- The related audit policy is bound to system global.

**Configuring an audit message action**

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

**To create an audit message action by using the command line interface**

At the command prompt, type:

```
1 add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES|NO)] [-bypassSafetyCheck (YES|NO)]
```

```
1 add audit messageaction log-act1 CRITICAL ”Client:”+CLIENT.IP.SRC+” accessed ”+HTTP.REQ.URL’ -bypassSafetyCheck YES
```

**To configure an audit message action by using the GUI**

Navigate to **System > Auditing > Message Actions**, and create the audit message action.

**Binding audit message action to a policy**

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see "Rewrite" or “Responder”.

Installing and configuring the NSLOG server

April 23, 2019

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server, including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the Citrix ADC appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

Attention:
The version of the NSLOG server package must be the same as that of the Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSLOG server must also be of the same version.

The following table lists the operating systems on which the NSLOG server is supported:

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Software requirements</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>RedHat Linux 4 or later, SUSE Linux Enterprise 9.3 or later</td>
<td></td>
</tr>
<tr>
<td>FreeBSD</td>
<td>FreeBSD 6.3 or later</td>
<td>For Citrix ADC 10.5, use only FreeBSD 8.4.</td>
</tr>
<tr>
<td>Mac OS</td>
<td>Mac OS 8.6 or later</td>
<td>Not supported on Citrix ADC 10.1 and later releases.</td>
</tr>
</tbody>
</table>

The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)
Installing NSLOG server on the Linux operating system

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

To install the NSLOG server package on a Linux operating system

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:
   ```
   cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp
   ```
2. Type the following command to install the NSauditserver.rpm file.
   ```
   rpm -i NSauditserver.rpm
   ```
   This command extracts the files and installs them in the following directories:
   - `/usr/local/netscaler/etc`
   - `/usr/local/netscaler/bin`
   - `/usr/local/netscaler/samples`

To uninstall the NSLOG server package on a Linux operating system

1. At a command prompt, type the following command to uninstall the audit server logging feature:
   ```
   rpm -e NSauditserver
   ```
2. For more information about the NSauditserver RPM file, use the following command:
   ```
   rpm -qpi *.rpm
   ```
3. To view the installed audit server files use the following command:
   ```
   rpm -qpl *.rpm
   ```
   *.*.rpm: Specifies the file name.

Installing NSLOG server on the FreeBSD operating system

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format:
AuditServer_<release number>-<build number>.zip

For example: AuditServer_10.5-58.11.zip

This package contains files for all supported platforms: Linux, Windows, and FreeBSD. On a FreeBSD operating system, install the NSLOG package that has the following name format:

audserver_bsd-<release number>-<build number>.tgz

For example: audserver_bsd-10.5-58.11.tgz

To download NSLOG package from www.citrix.com:

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. From the Select a product list, select Citrix ADC.
6. On the Citrix ADC page, select the release for which you want to download the NSLOG package (for example, Release 10.5), and then select Firmware.
7. Under Firmware, select the Citrix ADC firmware for the build number for which you want to download the NSLOG package.
8. On the page that appears, scroll down, select Audit Servers, and click Download File next to the package that you want to download.

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) from the package.
2. Copy the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) to a directory on a system running FreeBSD OS.
3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:

   pkg_add audserver_bsd-<release number>-<build number>.tgz

   Example:

   1 pkg_add audserver_bsd-9.3-51.5.tgz

   The following directories are extracted:

   • <root directory extracted from the FreeBSD NSLOG server package tgz file> Citrix ADCbin (for example, /var/auditserver/netscaler/bin)
• <root directory extracted from the FreeBSD NSLOG server package tgz file>/netscaler/etc (for example, /var/auditserver/netscaler/etc)
• <root directory extracted from the FreeBSD NSLOG server package tgz file>/netscaler/samples (for example, /var/auditserver/samples)

4. At a command prompt, type the following command to verify that the package is installed:

    pkg_info | grep NSaudserver

**To uninstall the NSLOG server package on a FreeBSD operating system**

At a command prompt, type:

    pkg_delete NSaudserver

**Installing NSLOG Server Files on the Windows Operating System**

Before you can install the NSLOG server, you have to copy the NSLOG package from the Citrix ADC product CD or download it from www.citrix.com. The NSLOG package has the following name format AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip). This package contains NSLOG installation packages for all supported platforms.

**To download NSLOG package from www.Citrix.com**

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format AuditServer_<release number>-<build number>.zip, to your local system (for example, AuditServer_9.3-51.5.zip).

**To install NSLOG server on a Windows operating system**

1. On the system, where you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract audserver_win-_<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) from the package.
2. Copy the extracted file `audserver_<release number>-<build number>.zip` (for example, `audserver_win-9.3-51.5.zip`) to a Windows system on which you want to install the NSLOG server.

3. Unzip the `audserver_<release number>-<build number>.zip` file (for example, `audserver_win-9.3-51.5.zip`).

4. The following directories are extracted:
   a) `<root directory extracted from the Windows NSLOG server package zip file>\bin` (for example, `C:\audserver_win-9.3-51.5\bin`)
   b) `<root directory extracted from the Windows NSLOG server package zip file>\etc` (for example, `C:\audserver_win-9.3-51.5\etc`)
   c) `<root directory extracted from the Windows NSLOG server package zip file>\samples` (for example, `C:\audserver_win-9.3-51.5\samples`)

5. At a command prompt, run the following command from the `<root directory extracted from the Windows NSLOG server package zip file>\bin path`:
   
   ```
   audserver -install -f <directorypath>\auditlog.conf
   ```
   
   `<directorypath>`: Specifies the path to the configuration file (`auditlog.conf`). By default, `log.conf` is under `<root directory extracted from Windows NSLOG server package zip file>\samples` directory. But you can copy `auditlog.conf` to your desired directory.

**To uninstall the NSLOG server on a Windows operating system**

At a command prompt, run the following from the `<root directory extracted from Windows NSLOG server package zip file>\bin path`:

```
audserver -remove
```

**NSLOG Server Command Options**

For information about NSLOG server commands, see *Audit Server Options.*

Run the `audserver` command from the directory in which the audit server executable is present:

- ‘On Windows: `\ns\bin`’
- On Solaris and Linux:`/usr/local/netscaler/bin`

The audit server configuration files are present in the following directories:

- On Windows: `\ns\etc`
- On Linux:`/usr/local/netscaler/etc`

The audit server executable is started as `./auditserver` in Linux and FreeBSD.
Adding the Citrix ADC Appliance IP Addresses on the NSLOG Server

In the configuration file (auditlog.conf), add the IP addresses of the Citrix ADC appliances whose events must be logged.

To add the IP addresses of the Citrix ADC appliance

At a command prompt, type the following command:

```
audserver -addns -f <directorypath>\auditlog.conf
```

`<directorypath>`: Specifies the path to the configuration file (auditlog.conf).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the Citrix ADC appliance, for example, 10.102.29.1.

Userid: Specifies the user name, for example, nsroot.

Password: Specifies the password, for example, nsroot.

If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of the Citrix ADC appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the auditlog.conf file. For a high availability (HA) setup, you must add both primary and secondary Citrix ADC IP addresses to auditlog.conf by using the audserver command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (audit log.conf) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

```
audserver -verify -f <directorypath>\auditlog.conf
```

`<directorypath>`: Specifies the path to the configuration file (audit log.conf).

Running the NSLOG server

April 23, 2019
To start audit server logging

Type the following command at a command prompt:

```
audserver -start -f <directorypath>\auditlog.conf
```

`<directorypath>`: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

```
audserver -stop
```

To stop audit server logging that starts as a service in Windows

Type the following command:

```
audserver -stopservice
```

Customizing logging on the NSLOG server

April 23, 2019

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a Citrix ADC appliance or a set of Citrix ADC appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

- Creating Filters
- Specifying Log Properties

Creating filters

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.
Note:
For consolidated logging, if a log transaction occurs for which there is no filter definition, the
default filter is used (if it is enabled.) The only way you can configure consolidated logging of all
the Citrix ADC appliances is by defining the default filter.

To create a filter

At the command prompt, type the following command in the configuration file (auditlog.conf):

```
filter <filterName> [IP <ip>] [NETMASK <mask>] ON | OFF
```

filterName: Specify the name of the filter (maximum of 64 alphanumeric characters).
ip: Specify the IP addresses.
mask: Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument
is specified, the filter is ON.

Examples:

```
filter F1 IP 192.168.100.151 ON
```

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

```
filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON
```

filterName is a required parameter if you are defining a filter with other optional parameters, such as
IP address, or the combination of IP address and Netmask.

Specifying log properties

Log properties associated with the filter are applied to all the log entries present in the filter. The log
property definition starts with the key word BEGIN and ends with END as illustrated in the following
example:

```
BEGIN <filtername>
  logFilenameFormat ...
  logDirectory ...
  logInterval ...
  logFileSizeLimit ....
END
```
Entries in the definition can include the following:

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: A constant string that specifies the absolute path and the file name.
  - Dynamic: An expression that includes the following format specifiers:
    * Date (%{format}t)
    * creates file name with NSIP

  **Example:**

  ```
  1 LogFilenameFormat Ex%\{m\%d\%y \}t.log
  
  This creates the first file name as Exmmddyy.log. New files are named: Exmmddyy.log.0, Exmmddyy.log.1, and so on. In the following example, the new files are created when the file size reaches 100MB.
  
  **Example:**

  ```
  1 LogInterval size
  2 LogFileSize 100
  3 LogFilenameFormat Ex%\{m\%d\%y \}t
  
  Caution

  The date format %t specified in the LogFilenameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat parameter.

- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:
  - Static: Is a constant string that specifies the absolute path and file name.
  - Dynamic: Is an expression containing the following format specifiers:
    * Date (%{format}t)
    * creates directory with NSIP

  The directory separator depends on the operating system. In Windows, use the directory separator.

  **Example:**

  ```
  1 LogDirectory dir1\dir2\dir3
  ```
In the other operating systems (Linux, FreeBSD, etc.), use the directory separator.

- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour. Default value.
  - Daily: A file is created every day at midnight.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly: A file is created on the first day of the month at midnight.
  - None: A file is created only once, when audit server logging starts.
  - Size: A file is created only when the log file size limit is reached.

**Example:**

```
1 LogInterval Hourly
```

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

**Note**

You can override the loginterval property by assigning size as its value.

The default LogFileSizeLimit is 10 MB.

**Example:**

```
1 LogFileSizeLimit 35
```

**SYSLOG Over TCP**

April 23, 2019

Syslog is a standard for sending event notification messages. These messages can be stored locally or on an external log server. Syslog enables network administrators to consolidate log messages and derive insights from the collected data.

Syslog was originally designed to work over UDP, which can transmit a huge amount of data within the same network with minimal packet loss. However, telco operators prefer to transmit syslog data over TCP, because they need reliable, ordered data transmission between networks (for example, telco tracks user activities), and TCP provides retransmission in the event of network failure.
How Syslog over TCP works

To understand how syslog over TCP works, consider two hypothetical cases:

Sam, a network administrator, wants to log significant events on an external syslog server.

XYZ Telecom, an Internet service provider, has to transmit and store a significant amount of data on syslog servers to comply with government regulations.

In both cases, the log messages must be transmitted over a reliable channel and stored safely on an external syslog server. Unlike UDP, TCP establishes a connection, transmits messages securely, and retransmits (from sender to receiver) any data that is corrupted or lost because of network failure.

The Citrix ADC appliance sends log messages over UDP to the local syslog daemon, and sends log messages over TCP or UDP to external syslog servers.

SNIP support for Syslog

When the audit-log module generates syslog messages, it uses a Citrix ADC subnet IP (SNIP) address as the source address for sending the messages to an external syslog server. To configure a SNIP as the source address, you must make it part of the netProfile option and bind the netProfile to the syslog action.

Note
If a netProfile is not bound to a syslog action, the Citrix ADC IP (NSIP) is used as the source address for transmitting data to the external log server.

Use of a SNIP address is not supported in internal logging.

FQDN Support for audit Log

Previously, the audit-log module was configured with the destination IP address of the external syslog server to which the log messages are sent. Now, the audit-log server uses a Fully Qualified Domain Name (FQDN) instead of the destination IP address. The FQDN configuration resolves the configured domain name of the syslog server to the corresponding destination IP address for sending the log messages from the audit-log module. To resolve the domain name and avoid domain based service issues, the name server must be properly configured.

Note
When configuring a FQDN, server domain name configuration of the same Citrix ADC appliance in syslog action or nslog action is not supported.
Configuring Syslog over TCP by using Command Line Interface

To configure a Citrix ADC appliance to send syslog messages over TCP by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> <serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>] | -lbVserverName<string>) [-serverPort <port>] -logLevel <logLevel>[-dateFormat <dateFormat>] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )][-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog ( YES | NO )][-appflowExport ( ENABLED | DISABLED )][-lsn ( ENABLED | DISABLED )][-alg ( ENABLED | DISABLED )][-subscriberLog ( ENABLED | DISABLED )][-transport ( TCP | UDP )][-tcpProfileName <string>][-maxLogDataSizeToHold <positive_integer>][-dns ( ENABLED | DISABLED )][-netProfile <string>]
```

```
add audit syslogAction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateFormat MMDDYYYY -transport TCP
```

Adding SNIP IP address to netprofile option by using the command line interface

To add a SNIP IP address to netprofile by using the command line interface

At the command prompt, type:

```
add netProfile <name> [-td <positive_integer>] [-srcIP <string>] [-srcIpPersistency ( ENABLED | DISABLED )][-overrideLsn ( ENABLED | DISABLED )]add syslogaction <name> <serverIP> -loglevel all -netprofile net1
```

```
add netprofile net1 -srcip 10.102.147.204
```

where, srcIP is the SNIP.

Adding netprofile in a syslog action by using the command line interface

To add a netProfile option in a syslog action by using the command line interface

At the command prompt, type:
add syslogaction <name> (<serverIP> | -lbVserverName <string>) -logLevel <logLevel> -netProfile <string> ...

add syslogaction sys_act1 10.102.147.36 -loglevel all -netprofile net1

Where -net Profile specifies the name of the configured net profile. The SNIP address is configured as part of the netProfile and this netProfile option is bound to the syslog action.

Note
You must always bind the netProfile option to the SYSLOGUDP or SYSLOGTCP services bound to the SYSLOGUDP or SYSLOGTCP load balancing virtual server when LB vserver name is configured in syslogaction.

Configuring FQDN support by using the command line interface

To add a server domain name to a Syslog action by using the command line interface

At the command prompt, type:

add audit syslogAction <name> ((<serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>]) | -lbVserverName <string>)) -logLevel <logLevel> ...

set audit syslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverDomainName <string>] [-lbVserverName <string>] [-domainResolveRetry <integer>] [-domainResolveNow]

To add a server domain name to a Nslog action by using the command line interface.

At the command prompt, type:

add audit nslogAction <name> ((<serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>]) | -lbVserverName <string>)) -logLevel <logLevel> ...

set audit nslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverDomainName <string>] [-lbVserverName <string>] [-domainResolveRetry <integer>] [-domainResolveNow]

Where

serverDomainName. Domain name of the log server. This is mutually exclusive with serverIP/ lbVserverName.

DomainResolveRetry integer. Time (in seconds) that the Citrix ADC appliance waits, after a DNS resolution fails, before sending the next DNS query to resolve the domain name.
DomainResolveNow. Included if the DNS query has to be sent immediately to resolve the server's domain name.

**Configuring Syslog over TCP by using the GUI**

To configure the Citrix ADC appliance to send Syslog messages over TCP by using the GUI

1. Navigate to **System > Auditing > Syslog** and select the **Servers** tab.
2. Click **Add** and select Transport Type as **TCP**.

**Configuring netprofile for SNIP support by using the GUI**

To configure netprofile for SNIP support by using the GUI

1. Navigate to **System > Auditing > Syslog** and select the **Servers** tab.
2. Click **Add** and select a netprofile from the list.

**Configuring FQDN by using the GUI**

To configure FQDN by using the GUI

1. Navigate to **System > Auditing > Syslog** and select the **Servers** tab.
2. Click **Add** and select a Server Type and Server Domain Name from the list.

**Load balancing SYSLOG servers**

April 23, 2019

The Citrix ADC appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the Citrix ADC appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   ```bash
   add service <name> (<IP> | <servername>) <serviceType> (SYSLOGTCP | SYSLOGUDP) <port>
   ```
2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGUDP, and load balancing method as AUDITLOGHASH.

   add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod <AUDITLOGHASH>]

3. Bind the service to the load balancing virtual server.

   bind lb vserver <name> <serviceName>

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   add syslogaction <name> <serverIP> [-lbVsServerName <string>] [-logLevel <logLevel>]

5. Add a SYSLOG policy by specifying the rule and action.

   add syslogpolicy <name> <rule> <action>

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   bind system global <policyName>

*Load balancing of SYSLOG servers using the GUI

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   Navigate to Traffic Management > Services, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to Traffic Management > Virtual Servers, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

3. Bind the service to the load balancing virtual server to the service.

   Navigate to Traffic Management > Virtual Servers, select a virtual server and then select AUDITLOGHASH in the Load Balancing Method.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to System > Auditing, click Servers and add a server by selecting LB Vserver option in Servers.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to System > Syslog, click Policies and add a SYSLOG policy.
6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to System > Syslog, select a SYSLOG policy and click Action, and then click Global Bindings and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. AUDITLOGHASH method load balances the traffic based on input hash value from the audit agents. The agents are the modules which generate auditlog in a Citrix ADC appliance. For example, if an agent LSN wants to load balance auditlogs based on client IP address, LSN module generates the hash value based on clientIP and passes the hash value to auditlog module. The auditlog module sends the auditlog messages which have same hash value to the external syslog server.

The Citrix ADC appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
1 add service service1 192.0.2.10 SYSLOGUDP 514
2 add service service2 192.0.2.11 SYSLOGUDP 514
3 add service service3 192.0.2.11 SYSLOGUDP 514
4 add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH
5 bind lb vserver lbvserver1 service1
6 bind lb vserver lbvserver1 service2
7 bind lb vserver lbvserver1 service3
8 add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
9 add syslogpolicy syspol1 ns_true sysaction1
10 bind system global syspol1
```

Limitations:

- The Citrix ADC appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

Default settings for the log properties

April 23, 2019

The following is an example of the default filter with default settings for the log properties:

```
1 begin default
2 logInterval Hourly
3 logFileSizeLimit 10
4 logFilenameFormat auditlog%'{
```
Following are two examples of defining the default filters:

**Example 1:**

```
Filter f1 IP 192.168.10.1
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

**Example 2:**

```
Filter f1 IP 192.168.10.1
begin f1
logFilenameFormat logfiles.log
end f1
```

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

**Sample configuration file (audit.conf)**

April 23, 2019

Following is a sample configuration file:

```
# This is the Auditserver configuration file
# Only the default filter is active
# Remove leading # to activate other filters
MYIP <NSAuditserverIP>
MYPORT 3023
# Filter filter_nsip IP <Specify the Citrix ADC IP address to filter on > ON
# begin filter_nsip
logInterval Hourly
logFileSizeLimit 10
logDirectory logdir\%A\%
logFilenameFormat nsip\%d\%m\%Y }
t.log
```
Web server logging

April 23, 2019

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the Citrix ADC.
- The Citrix ADC Web Logging (NSWL) client, which runs on the client system.

When you run the Citrix ADC Web Logging (NSWL) client:

1. It connects to the Citrix ADC.
2. The Citrix ADC buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the Citrix ADC and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the Citrix ADC IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the Citrix ADC for web server logging

April 23, 2019

To configure the Citrix ADC for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the Citrix ADC Web Logging (NSWL) client.
Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

**To configure web server logging by using the command line interface**

At the command prompt, perform the following operations:

- Enable the web server logging feature.

  ```
  enable ns feature WL
  ```

- [Optional] Modify the buffer size for storing the logged information.

  ```
  set ns weblogparam -bufferSizeMB <size>
  ```

  **Note:**
  To activate your modification, you must disable and then re-enable the Web server logging feature.

- [Optional] Specify the custom HTTP header names that you want to export.

  ```
  set ns weblogparam [-customReqHdrs <string> ...] [-customRspHdrs <string> ...]
  ```

```
1 > enable ns feature WL
  Done
2 > set ns weblogparam -bufferSizeMB 60
  Done
3 > show ns weblogparam
   Web Logging parameters:
   Log buffer size: 60MB
   Custom HTTP request headers: (none)
   Custom HTTP response headers: (none)
  Done
4 > set ns weblogparam -customReqHdrs req1 req2 -customRspHdrs res1 res2
  Done
5 > show ns weblogparam
   Web Logging parameters:
   Log buffer size: 60MB
   Custom HTTP request headers: req1, req2
   Custom HTTP response headers: res1, res2
  Done
```
To configure web server logging by using the GUI

1. Navigate to System > Settings and perform the following operations:
   a) To enable the web server logging feature, click Change Advanced Features and select Web Logging.
   b) To modify the buffer size, click Change Global System Settings and under Web Logging, enter the buffer size.
   c) To specify the custom HTTP headers to be exported, click Change Global System Settings and under Web Logging, specify the header values.

Installing the Citrix ADC web logging (NSWL) client

April 23, 2019

During installation, the NSWL client executable file (nswl) is installed along with other files. The nswl executable file provides a list of options that you can use. For details, see Configuring the NSWL Client.

Attention:
The version of the NSWL client must be the same as that of the Citrix ADC. For example, if the version of the Citrix ADC is 10.1 Build 125.9, the NSWL client must also be of the same version. Also, Citrix ADC web logging (NSWL) client works only on 32 bit appliance and not on 64 bit appliance.

The following table lists the operating systems on which the NSWL client can be installed.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Version</th>
<th>Hardware requirements</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mac OS</td>
<td>Mac OS 8.6 or later</td>
<td>-</td>
<td>Not supported on Citrix ADC 10.1 and later releases.</td>
</tr>
<tr>
<td>Linux</td>
<td>RedHat Linux 4 or later, SUSE Linux Enterprise 9.3 or later</td>
<td>Processor - Intel x86 ~501 MHz, RAM - 512 MB, Controller - SCSI</td>
<td></td>
</tr>
<tr>
<td>Operating system</td>
<td>Version</td>
<td>Hardware requirements</td>
<td>Remarks</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td>-----------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Solaris</td>
<td>Solaris Sun OS 5.6 or later</td>
<td>Processor - UltraSPARC-IIi 400 MHz, RAM - 512 MB, Controller - SCSI</td>
<td>Not supported on Citrix ADC 10.5 and later releases.</td>
</tr>
<tr>
<td>FreeBSD</td>
<td>FreeBSD 6.3 or later</td>
<td>Processor - Intel x86 ~501 MHz, RAM - 512 MB, Controller - SCSI</td>
<td>For Citrix ADC 10.5, use only FreeBSD 8.4.</td>
</tr>
<tr>
<td>AIX</td>
<td>AIX 6.1</td>
<td>-</td>
<td>Not supported on Citrix ADC 10.5 and later releases.</td>
</tr>
</tbody>
</table>

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

**Caution:**
Reinitiation of logging can result in loss of log transactions.

To temporarily solve a NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the Citrix ADC appliance. To solve the problem, you need a client system that can handle the site’s throughput.

**Downloading the NSWL client**

You can obtain the NSWL client package from either the Citrix ADC product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platforms.

**To download the NSWL client package from the Citrix site**

2. Log in to the site using your credentials.
3. Open the page for the required release number and build.
4. In the page, under Weblog Clients, click Download. The package has the name format as follows: `Weblog- <release number>-<build number>.zip`.  

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Installing the NSWL client on a Solaris system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_solaris-<release number>-<build number>.tar` file from the package.

2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.

3. Extract the files from the tar file with the following command:

   ```
   tar xvf nswl_solaris-<release number>-<build number>.tar
   ```

   A directory NSweblog is created in the temporary directory, and the files are extracted to the NSweblog directory.

4. Install the package with the following command:

   ```
   pkgadd -d
   ```

   The list of available packages appears. In the following example, one NSweblog package is shown:

   ```
   1 1 NSweblog Citrix ADC Weblogging (SunOS,sparc) 7.0
   ```

5. You are prompted to select the packages. Select the package number of the NSweblog to be installed.

   After you select the package number and press Enter, the files are extracted and installed in the following directories:
   
   • `/usr/local/netscaler/etc`
   • `/usr/local/netscaler/bin`
   • `/usr/local/netscaler/samples`

6. To check whether the NSWL package is installed, execute the following command:

   ```
   pkginfo | grep NSweblog
   ```

   **Note:** To uninstall the NSWL package, execute the following command:

   ```
   pkgrm NSweblog
   ```
Installing the NSWL client on a Linux system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_linux-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   ```
   rpm -i nswl_linux-9.3-51.5.rpm
   ```

   This command extracts the files and installs them in the following directories.
   - `/usr/local/netscaler/etc`
   - `/usr/local/netscaler/bin`
   - `/usr/local/netscaler/samples`

   **Note:** To uninstall the NSWL package, execute the following command:

   ```
   rpm -e NSweblog
   ```

   **Note:**
   To get more information about the NSweblog RPM file, execute the following command:

   ```
   rpm -qpi *.rpm
   ```

   **Note:**
   To view the installed Web server logging files, execute the following command:

   ```
   rpm -qpl *.rpm
   ```

Installing the NSWL client on a FreeBSD system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_bsd-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
1 pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```
1 pkg_info | grep NSweblog
```

**Installing the NSWL client on a Mac system**

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_macos-<release number>-<build number>.tgz` file from the package.
2. Copy the extracted file to a system, running Mac OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

```
1 pkg_add nswl_macos-9.3-51.5.tgz
```

This command extracts the files and installs them in the following directories:

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
1 pkg_delete NSweblog
```

4. To verify that the package is installed, execute the following command:

```
1 pkg_info | grep NSweblog
```
Installing the NSWL client on a Windows system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_win-<release number>-<build number>.zip` file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as `<NSWL-HOME>`). The following directories are extracted: bin, etc, and samples.
4. At the command prompt, run the following command from the `<NSWL-HOME>\bin` directory:

   ```bash
   1 nswl -install -f <directorypath>\log.conf
   ```

   where,

   `directorypath` refers to the path of the configuration file (log.conf). By default, the file is in the `<NSWL-HOME>` etc directory. However, you can copy the configuration file to any other directory.

   **Note:** To uninstall the NSWL client, at the command prompt, run the following command from the `<NSWL-HOME>\bin` directory:

   ```bash
   1 > nswl -remove
   ```

Installing the NSWL client on a AIX system

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the `nswl_aix-<release number>-<build number>.rpm` file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:

   ```bash
   1 rpm -i nswl_aix-9.3-51.5.rpm
   ```

   This command extracts the files and installs them in the following directories.

   - `/usr/local/netscaler/etc`
   - `/usr/local/netscaler/`
   - `/usr/local/netscaler/samples`
Configure NSWL client

April 23, 2019

After installing the NSWL client, you can configure the NSWL client using the nswl executable. These configurations are then stored in the NSWL client configuration file (log.conf).

**Note:**
You can further customize logging on the NSWL client system by making additional modifications to the NSWL configuration file (log.conf). For details, see Customizing Logging on the NSWL Client System.

The following table describes the commands that you can use to configure the NSWL client.

<table>
<thead>
<tr>
<th>NSWL command</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>nswl -help</td>
<td>The available NSWL help options.</td>
</tr>
<tr>
<td>nswl -addns -f  &lt;path-to-configuration-file&gt;</td>
<td>The system that gathers the log transaction data. You are prompted to enter the IP address of the Citrix ADC appliance. Enter a valid user name and password.</td>
</tr>
<tr>
<td>nswl -verify -f  &lt;path-to-configuration-file&gt;</td>
<td>Check for syntax or semantic errors in the configuration file.</td>
</tr>
<tr>
<td>NSWL command</td>
<td>Specifies</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------</td>
</tr>
<tr>
<td>nswl -start -f &lt;path-to-configuration-file&gt;</td>
<td>Start the NSWL client based on the settings in the configuration file. Note: For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&amp;) at the end of the command.</td>
</tr>
<tr>
<td>nswl -stop (Solaris and Linux only)</td>
<td>Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.</td>
</tr>
<tr>
<td>nswl -install -f &lt;path-to-configuration-file&gt; (Windows only)</td>
<td>Install the NSWL client as a service in Windows.</td>
</tr>
<tr>
<td>nswl -startservice (Windows only)</td>
<td>Start the NSWL client by using the settings in the configuration file specified in the nswl install option. You can also start NSWL client from Start &gt; Control Panel &gt; Services. Note: The NSWL log files will be created in C:\Windows\SysWOW64.</td>
</tr>
<tr>
<td>nswl -stopservice (Windows only)</td>
<td>Stops the NSWL client.</td>
</tr>
<tr>
<td>nswl -remove</td>
<td>Remove the NSWL client service from the registry.</td>
</tr>
</tbody>
</table>

Run the following commands from the directory in which the NSWL executable is located:

- **Windows**: `\ns\bin`
- **Solaris and Linux**: `\usr\local\netscaler\bin`

The Web server logging configuration files are located in the following directory path:

- **Windows**: `\ns\etc`
- **Solaris and Linux**: `\usr\local\netscaler\etc`

The NSWL executable is started as `.\nswl` in Linux and Solaris.

**Add the IP addresses of the Citrix ADC appliance**

In the NSWL client configuration file (log.conf), add the Citrix ADC IP address (NSIP) from which the NSWL client will start collecting logs.
To add the NSIP address of the Citrix ADC appliance

1. At the client system command prompt, type:

   nswl -addns -f <directorypath> \log.conf

   <directorypath>: Specifies the path to the configuration file (log.conf).

2. At the next prompt, enter the following information:

   - **NSIP**: Specify the IP address of the Citrix ADC appliance.
   - **Username and Password**: Specify the nsroot user credentials of the Citrix ADC appliance.

   **Note**:
   If you add multiple Citrix ADC IP addresses (NSIP), and later you do not want to log all of Citrix ADC system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the log.conf file. During a failover setup, you must add both primary and secondary Citrix ADC IP addresses to the log.conf by using the command. Before adding the IP address, make sure the user name and password exist on the Citrix ADC appliances.

Verify the NSWL configuration file

To make sure that logging works correctly, check the NSWL configuration file (log.conf) on the client system for syntax errors.

To verify the configuration in the NSWL configuration file

At the client system command prompt, type:

   nswl -verify -f <directorypath>\log.conf

   <directorypath>: Specifies the path to the configuration file (log.conf).

Running the NSWL Client

To start Web server logging

At the client system command prompt, type:

   nswl -start -f <directorypath>\log.conf

   <directorypath>: Specifies the path to the configuration file (log.conf).
To stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

```
nswl -stop
```

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

```
nswl -stop-service
```

Customize logging on the NSWL client system

April 23, 2019

You can customize logging on the NSWL client system by making additional modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

Sample configuration file

Following is a sample configuration file:

```
1  ############
2  # This is the NSWL configuration file
3  # Only the default filter is active
4  # Remove leading # to activate other filters
5  ############
6  ############
7  # Default filter (default on)
8  # W3C Format logging, new file is created every hour or on reaching 10 MB file size,
9  # and the file name is Exyymmdd.log
```
Filter default begin default

logFormat W3C
logInterval Hourly
logFileSizeLimit 10
logFilenameFormat Ex%{'%Sy%md%d'} }
t.log
end default

# Citrix ADC caches example
# CACHE_F filter covers all the transaction with HOST name www.netscaler.com and the listed server ip's
# Filter CACHE_F HOST www.netscaler.com IP 192.168.100.89 192.168.100.95
# 192.168.100.52 192.168.100.53 ON

# netscaler origin server example
# Not interested in Origin server to Cache traffic transaction logging
# Filter ORIGIN_SERVERS IP 192.168.100.64 192.168.100.65 192.168.100.66
# 192.168.100.67 192.168.100.225 192.168.100.226 192.168.100.228 OFF

# netscaler image server example
# all the image server logging.
# Filter IMAGE_SERVER HOST www.netscaler.images.com IP 192.168.100.71
# 192.168.100.72 192.168.100.169 192.168.100.170 192.168.100.171 ON

# NCSA Format logging, new file is created every day midnight or on
# reaching 20MB file size,
# and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmddyy.
# log.
# Exclude objects that ends with .gif .jpg .jar.

#begin ORIGIN_SERVERS
# logFormat NCSA
# logInterval Daily
# logFileSizeLimit 40
# logFilenameFormat /datadisk5/ORGIN/log/%v/NS%'{
't.log
```plaintext
# logExclude .gif .jpg .jar

## NCSA Format logging, new file is created every day midnight or on reaching 20MB file size,
and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmddyy.log with log record timestamp as GMT.

## W3C Format logging, new file on reaching 20MB and the log file path name is atadisk6/netscaler/log/server’s ip/Exmmyydd.log with log record timestamp as LOCAL.

# Virtual Host by Name firm, can filter out the logging based on the host name by,

#Filter VHOST_F IP 10.101.2.151 NETMASK 255.255.255.0
```
Creating filters

You can use the default filter definition located in the configuration file (log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

**Note:** Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.

If the server hosts multiple Web sites and each Web site has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each Web site. The following table displays the parameters for creating a filter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>filterName</td>
<td>Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.</td>
</tr>
<tr>
<td>HOST name</td>
<td>Host name of the server for which the transactions are being logged.</td>
</tr>
<tr>
<td>IP ip</td>
<td>IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).</td>
</tr>
<tr>
<td>IP ip 2…ip n:</td>
<td>Multiple IP addresses (for example, if the server domain has multiple IP addresses).</td>
</tr>
<tr>
<td>ip6 ip</td>
<td>IPv6 address of the server for which transactions are to be logged.</td>
</tr>
<tr>
<td>IP ip NETMASK mask</td>
<td>IP addresses and netmask combination to be used on a subnet.</td>
</tr>
</tbody>
</table>
## Parameters for Creating a Filter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON</td>
<td>OFF</td>
</tr>
</tbody>
</table>

### To create a filter

To create a filter, enter the following command in the log.conf file:

- `filter <filterName> <HOST name> | [IP<ip> ] | [IP<ip 2...ip n> ] | <IP ip NETMASK mask> [ON | OFF]`
- `filter <filterName> <HOST name> | [IP6 ip/<prefix length>] [ON | OFF]`

### To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

```
filter <filterName> <VirtualServer IP address>
```

### Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

```
1 Filter F1 HOST www.netscaler.com ON
2 Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
3 Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
4 Filter F4 IP 192.168.100.151
5 Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
7 Filter F7 IP 192.250.100.0 NETMASK 255.255.255.0
8 Filter F8 HOST www.xyz.com IP 192.250.100.0 NETMASK 255.255.255.0 OFF
9 For creating filters for servers having IPv6 addresses.
10 Filter F9 2002::8/112 ON
11 Filter F10 HOST www.abcd.com IP6 2002::8 ON

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Specifying log properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
logFormat ...
logFilenameFormat ...
logInterval ...
logFileSize ....
logExclude ....
logTime ....
END
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

  By default, the logformat property is w3c. To override, enter custom or NCSA in the configuration file, for example:

```
LogFormat NCSA
```

**Note:** For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.

```
**LogInterval** specifies the intervals at which new log files are created. Use one of the following values:

- Hourly: A file is created every hour.
- Daily: A file is created every day at midnight. Default value.
- Weekly: A file is created every Sunday at midnight.
- Monthly: A file is created on the first day of the month at midnight.
- None: A file is created only once, when Web server logging starts.</span>
```

Example:

```
LogInterval Daily
```

**LogFileSizeLimit** specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.
To override this behavior, specify the size as the loginterval property so that a file is created only when the log file size limit is reached.

The default LogFileSizeLimit is 10 MB.

**Example:**

```
LogFileSizeLimit 35
```

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: Specifies a constant string that contains the absolute path and file name.
  - Dynamic: Specifies an expression containing the following format:
    * Server IP address
    * Date (%{format}t)
    * URL suffix (%x)
    * Host name (%v)

**Example:**

```
LogFileFormatName Ex%'{
  %m%d%y }
  t.log
```

This command creates the first file name as Exmmddyy.log, then every hour creates a file with file name: Exmmddyy.log.0, Exmmddyy.log.1,…, Exmmddyy.log.n.

**Example:**

```
LogInterval size
LogFileSize 100
LogFileFormatName Ex%'{
  %m%d%y }
  t
```

**Caution:**

The date format %t specified in the LogFilenameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat.

- **LogExclude** prevents logging of transactions with the specified file extensions.

**Example:**

```
LogExclude .html
```
This command creates a log file that excludes log transactions for *.html files.

**LogTime** specifies log time as either GMT or LOCAL.

The defaults are:

```
1 - NCSA log file format: LOCAL
2 - W3C log file format: GMT.
```

**Understanding NCSA and W3C log formats**

The Citrix ADC supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

**NCSA Common Log Format**

If the log file format is NCSA, the log file displays log information in the following format:

```
Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object HTTP_version" HTTP_StatusCode BytesSent
```

To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client_IP_address</td>
<td>The IP address of the client computer.</td>
</tr>
<tr>
<td>User Name</td>
<td>The user name.</td>
</tr>
<tr>
<td>Date</td>
<td>The date of the transaction.</td>
</tr>
<tr>
<td>Time</td>
<td>The time when the transaction was completed.</td>
</tr>
<tr>
<td>Time Zone</td>
<td>The time zone (Greenwich Mean Time or local time).</td>
</tr>
<tr>
<td>Method</td>
<td>The request method (for example; GET, POST).</td>
</tr>
<tr>
<td>Object</td>
<td>The URL.</td>
</tr>
<tr>
<td>HTTP_version</td>
<td>The version of HTTP used by the client.</td>
</tr>
<tr>
<td>HTTP_StatusCode</td>
<td>The status code in the response.</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>The number of bytes sent from the server.</td>
</tr>
</tbody>
</table>
**W3C extended log format**

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line may contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

```plaintext
%{ '%Y-%m-%d %H:%M:%S }
t %a %u %S %A %m %q %s %j %T %H %+
user-agent
i %+
cookie
i %+
referer
i
```

You can also change the order or remove some fields in this W3C log format. For example:

```plaintext
logFormat W3C %{ '%Y-%m-%d %H:%M:%S }
t %m %U
```

W3C log entries are created with the following format:

```plaintext
```

**Entries**

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space; Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.
Directives

Refer to the Directives table for information about the logging process. Lines beginning with the pound sign (#) contain directives.

Example:

The following sample log file shows the log entries in W3C Extended log format:

```
#Version: 1.0 #Fields: time cs-method cs-uri #Date: 12-Jan-1996
00:00:00 00:34:23 GET /sports/football.html 12:21:16 GET /sports/football.html 12:45:52 GET /sports/football.html 12:57:34 GET /sports/football.html
```

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers may have one of the following forms:

- **identifier**: Relates to the transaction as a whole.
- **prefix-identifier**: Relates to information transfer between parties defined by the value prefix.
- **prefix (header)**: Specifies the value of the HTTP header field header for transfer between parties defined by the value prefix. Fields specified in this manner always have the type.

The following table describes defined prefixes.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Client</td>
</tr>
<tr>
<td>s</td>
<td>Server</td>
</tr>
<tr>
<td>r</td>
<td>Remote</td>
</tr>
<tr>
<td>cs</td>
<td>Client to server</td>
</tr>
<tr>
<td>sc</td>
<td>Server to client</td>
</tr>
<tr>
<td>sr</td>
<td>Server to remote server (prefix used by proxies)</td>
</tr>
<tr>
<td>rs</td>
<td>Remote server to server (prefix used by proxies)</td>
</tr>
<tr>
<td>x</td>
<td>Application-specific identifier</td>
</tr>
</tbody>
</table>

Examples:

The following examples are defined identifiers that use prefixes:
cs-method: The method in the request sent by the client to the server.

sc(Referer): The Referer field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date on which the transaction was done.</td>
</tr>
<tr>
<td>time</td>
<td>The time when the transaction is done.</td>
</tr>
<tr>
<td>time-taken</td>
<td>The time taken (in seconds) for the transaction to complete.</td>
</tr>
<tr>
<td>bytes</td>
<td>The number of bytes transferred.</td>
</tr>
<tr>
<td>cached</td>
<td>Records whether a cache hit has occurred. A zero indicates a cache miss.</td>
</tr>
</tbody>
</table>

Table 5. W3C Extended Log Format Identifiers (No Prefix Required)

The following table describes the W3C Extended log format identifiers that require a prefix.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>The IP address and the port number.</td>
</tr>
<tr>
<td>dns</td>
<td>The DNS name.</td>
</tr>
<tr>
<td>status</td>
<td>The status code.</td>
</tr>
<tr>
<td>comment</td>
<td>The comment returned with status code.</td>
</tr>
<tr>
<td>method</td>
<td>The method.</td>
</tr>
<tr>
<td>url</td>
<td>The URL.</td>
</tr>
<tr>
<td>url-stem</td>
<td>The stem portion of the URL.</td>
</tr>
<tr>
<td>url-query</td>
<td>The query portion of the URL.</td>
</tr>
</tbody>
</table>

Table 6. W3C Extended Log Format Identifiers (Requires a Prefix)

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the fol-
The following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>The date on which the transaction is done.</td>
</tr>
<tr>
<td>Time</td>
<td>The time when the transaction is done.</td>
</tr>
<tr>
<td>Client IP</td>
<td>The IP address of the client.</td>
</tr>
<tr>
<td>User Name</td>
<td>The user name.</td>
</tr>
<tr>
<td>Service Name</td>
<td>The service name, which is always HTTP.</td>
</tr>
<tr>
<td>Server IP</td>
<td>The server IP address.</td>
</tr>
<tr>
<td>Server Port</td>
<td>The server port number</td>
</tr>
<tr>
<td>Method</td>
<td>The request method (for example; GET, POST).</td>
</tr>
<tr>
<td>Url Stem</td>
<td>The URL stem.</td>
</tr>
<tr>
<td>Url Query</td>
<td>The query portion of the URL.</td>
</tr>
<tr>
<td>Http Status</td>
<td>The status code in the response.</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>The number of bytes sent to the server (request size, including HTTP headers).</td>
</tr>
<tr>
<td>Bytes Received</td>
<td>The number of bytes received from the server (response size, including HTTP headers).</td>
</tr>
<tr>
<td>Time Taken</td>
<td>The time taken for transaction to complete, in seconds.</td>
</tr>
<tr>
<td>Protocol Version</td>
<td>The version number of HTTP being used by the client.</td>
</tr>
<tr>
<td>User Agent</td>
<td>The User-Agent field in the HTTP protocol.</td>
</tr>
<tr>
<td>Cookie</td>
<td>The Cookie field of the HTTP protocol.</td>
</tr>
<tr>
<td>Referer</td>
<td>The Referer field of the HTTP protocol.</td>
</tr>
</tbody>
</table>

Table 7. W3C Extended Log File Format (Allows Log Fields)

**Creating a custom log format**

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.
Creating a custom log format by using the NSWL library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows**: The nswl.lib library located in \ns\bin directory on the system manager host computer.
- **Solaris**: The libnswl.a library located in /usr/local/netscaler/bin.

To create the custom log format by using the NSWL library

1. Add the following two C functions defined by the system in a C source file:
   - `ns_userDefFieldName()` : This function returns the string that must be added as a custom field name in the log record.
   - `ns_userDefFieldVal()` : This function implements the custom field value, then returns it as a string that must be added at the end of the log record.

2. Compile the file into an object file.

3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.

4. Add a `%d` string at the end of the logFormat string in the configuration file (log.conf).

Example:

```plaintext
1 # A new file is created every midnight or on reaching 20MB file size, # and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmdyy.log and create digital #signature field for each record. BEGIN CACHE_F logFormat custom "%a - "%
2 user-agent }
3 i" ["%d/%B/%Y %T-%g] "%x" %s %b%
4 referrer }
5 i" "%{
6 user-agent }
7 i" "%{
8 cookie }
9 i" %d ” logInterval Daily logFileSizeLimit 20 logFilenameFormat /datadisk5/netscaler/log/%v/NS'{
10 '{%m%m%d%y }
11 t.log END CACHE_F
```
Creating a Custom log format manually

To customize the format in which log file data should appear, specify a character string as the argument of the LogFormat log property definition. The following is an example where character strings are used to create a log format:

```
LogFormat Custom "%a - %user-agent
i %[d/m/Y]t %U %s %b %T"
```

- The string can contain the “c” type control characters \n and \t to represent new lines and tabs.
- Use the Esc key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

```
".*:/:<=>\
```

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:

%<ASCII value of character in hexadecimal>.

For example, the character with ASCII value 22 is replaced by %16.

**Caution:**

If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open should be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache log formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

- NCSA/combined: LogFormat custom "%h %l %u ["%t"] "%r" %s %B ""%{referer}i" ""%{user-agent}i"
- NCSA/Common: LogFormat custom "%h %l %u ["%t"] "%r" %s %B
- Referer Log: LogFormat custom ""%{referer}i" -> %U

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3875
Arguments for defining a custom log format

Refer to the Custom log format pdf table for more information about defining a custom log format.

Note:
For instructions on how to export custom HTTP headers, see Configuring the Citrix ADC for Web Server Logging

For example, if you define the log format as %+{user-agent}i, and if the user agent value is Citrix ADC system Web Client, then the information is logged as Citrix ADC system+Web+Client. An alternative is to use double quotation marks. For example, “%{user-agent}i” logs it as “Citrix ADC system Web Client.” Do not use the <Esc> key on strings from %.. .r, %.. .i and, %.. .o. This complies with the requirements of the Common Log Format. Note that clients can insert control characters into the log. Therefore, you should take care when working with raw log files.

Time format definition

Refer to the Time format definition table to know about the format part of the %{format}t string described in the Custom Log Format table. Values within brackets ([ ]) show the range of values that appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

Note:
If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.

The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

Displaying Server Logs

You can configure a Citrix ADC Web Logging (NSWL) feature to display server logs on the console or redirect server logs to a directory on the Citrix ADC appliance.
There are two ways to display logs on the console (standard output):
Option 1: Display all logs on the console.
Option 2: Display only selected logs on the console where filters with logfilenameformat as STDOUT.

Call Home

April 23, 2019

Appliances might sometimes fail to perform well because of software or hardware issues. In such cases, Citrix needs to collect data and perform issue resolution before a potential impact can occur at the customer site. By enabling Call Home on your Citrix ADC appliance, you can automate the error notification process. Not only you avoid calling Citrix Support, raising a service request, and uploading system data before Support team can troubleshoot the issue, but Support can identify and address an issue before it occurs. Call Home periodically monitors the appliance and automatically uploads data to the Citrix technical support server. In addition, the incoming Call Home data provide insights about Citrix ADC usage. Multiple teams within Citrix can use this data to better design, support, and implement Citrix ADC.

By default, Call Home is enabled on all platforms and all flavors of Citrix ADC (MPX, VPX, SDX). By having this feature enabled, you allow Citrix to collect Citrix ADC deployment and telemetry data for better implementation, and support service.

Note
You can also see the Call Home FAQ page for information pertaining to Call Home.

Benefits

Call Home provides the following benefits.

- Monitor hardware and software error conditions. For more information, see Monitor critical error conditions section.
- Notify critical events that impact your network.
- Send performance data and system usage details to Citrix to:
  - Analyze and improve product quality.
  - Provide real-time troubleshooting information for proactive issue identification, and faster issue resolution.
Platform support

Call Home feature is supported on all Citrix ADC platforms and all appliance models (MPX, VPX, and SDX).

- Citrix ADC MPX: All MPX models.
- Citrix ADC VPX: All VPX models, including VPX appliances that obtain their license from external or central licensing pools.
- Citrix ADC SDX: Monitors the disk drive and assigned SSL chips for any errors or failures. The VPX instances, however, do not have access to the Power Supply Unit (PSU) and therefore their status is not monitored. In an SDX platform, you can configure Call Home either directly on an individual instance or through the SVM.

Prerequisites

To use Call Home, Citrix ADC must have the following:

- **Internet connection.** Call Home requires an internet connection for Citrix ADC to connect to the Citrix support server for uploading a data archive.

How Call Home works

The following figure shows the basic workflow of Call Home in a Citrix ADC appliance deployed at a customer site.

Call Home workflow is as follows:

1. **Set up Internet Connectivity.** For Call Home to upload system data, your appliance must have an internet connectivity. If it does not, you can configure a proxy server configuration to provide internet connectivity. For more information, see Configuring Call Home section.

2. **Enable Call Home.** When upgrading your appliance to the latest software through either Citrix ADC command interface or GUI, Call Home is enabled by default and the system delays the registration process by 24 hours. During this period, you can choose to manually disable the feature, but Citrix recommends you to have it enabled.

   **Note:** If you are upgrading your appliance from an older version that explicitly has Call Home disabled, the system still enables the feature by default and displays a notification message on your first login.

   In addition, if you are doing any configuration changes for an internet connectivity, you must disable and enable Call Home. This enables Call Home to register with Citrix Insight Services (CIS) server without any failure errors.

3. **Register the Citrix ADC appliance on the Citrix Support Server.** When Call Home registers the appliance with the Citrix Support server, the server checks the database for the validity of appliance
serial number. If the serial number is valid, the server registers the appliance for Call Home service and sends a successful registration response. Otherwise, the server sends back a registration failure message. The basic system information is sent as a separate message. The data includes memory and CPU usage details along with the throughput numbers. The data is sent periodically as part of the heartbeat message every 7 days, by default. However, a value of less than 5 days is not recommended, because frequent uploads are usually not very useful.

4. **Monitor critical error conditions.** Once registered, Call Home starts monitoring the appliance. The following table lists the conditions Call Home can monitor on the appliance.

<table>
<thead>
<tr>
<th>Critical Error Condition</th>
<th>Description</th>
<th>Call Home Monitoring Interval</th>
<th>Corresponding SNMP Alarm Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compact flash drive errors</td>
<td>The compact flash drive on the appliance encountered read or write failures.</td>
<td>24 hours</td>
<td>COMPACT-FLASH-ERRORS</td>
</tr>
<tr>
<td>Hard disk drive errors</td>
<td>The hard drives on the appliance encountered read or write failures.</td>
<td>24 hours</td>
<td>HARD-DISK-DRIVE-ERRORS</td>
</tr>
<tr>
<td>Power supply unit failure</td>
<td>One of the power supply units on the Citrix ADC appliance has failed.</td>
<td>7 seconds</td>
<td>POWER-SUPPLY-FAILURE</td>
</tr>
<tr>
<td>SSL card failure</td>
<td>One of the SSL cards on the Citrix ADC appliance has failed.</td>
<td>7 seconds</td>
<td>SSL-CARD-FAILED</td>
</tr>
<tr>
<td>Warm restart</td>
<td>The appliance has warm restarted due to a failure of a system process.</td>
<td>After every restart of the Citrix ADC appliance.</td>
<td>WARM-RESTART-EVENT</td>
</tr>
<tr>
<td>Memory anomaly error</td>
<td>Memory utilization progressively increases above its normal limit and exceeds the threshold.</td>
<td>1 day</td>
<td>No SNMP alarm</td>
</tr>
</tbody>
</table>
5. **Upload Call Home data.** If Call Home identifies any one of the above critical condition on the appliance, the feature notifies Citrix support by automatically uploading the support archive to the Citrix support server. Additionally, you can configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home upload happens. The SNMP alert notifies the local administrator about the critical event.

   **Note**
   
   Call Home creates the Call Home tar file and uploads it to the Citrix tech support server for only the first occurrence of a particular error condition since the last reboot. If you want the appliance to send alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.

6. **Create Service Request.** For all critical hardware related events such as power supply failure, SSL card failure, hard disk drive errors, and compact flash errors Call Home automatically creates a service request. For other errors, after you review the System Logs, you can contact the Citrix support team to appear a service request for investigation. For more information, see [http://support.citrix.com/article/CTX126172](http://support.citrix.com/article/CTX126172).

### Configuring Call Home

To configure Call Home, verify the internet connectivity on the appliance and ensure a DNS name-server is configured. If there is no internet connection, configure a proxy server or service. Then, enable Call Home on the appliance and verify the registration status of the appliance with Citrix support server. Once registered, Call Home can monitor and upload data. In addition, you can configure SNMP alarms to notify the administrator at the customer site.

To configure Call Home, you can use either the Citrix ADC command interface or GUI to do the following tasks:

- Enable Call Home.
- Configure Call Home for optional proxy server parameters.
- Verify Call Home Registration Status.

<table>
<thead>
<tr>
<th>Critical Error Condition</th>
<th>Description</th>
<th>Call Home Monitoring Interval</th>
<th>Corresponding SNMP Alarm Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rate limit packet drop</td>
<td>The throughput limits or packets-per-second (pps) limits is reached.</td>
<td>7 seconds</td>
<td>PF-RL-PPS-PKTS-DROPPED, PF-RL-RATE-PKTS-DROPPED</td>
</tr>
</tbody>
</table>
To configure Call Home by using Citrix ADC command interface

The Citrix ADC command interface enables you to do the following:

**Enabling Call Home**

At the command prompt, type:

```
enable ns feature callhome
```

**Configuring Call Home for optional proxy server parameters**

Call Home enables you to configure the optional proxy server for internet connectivity. You can either configure a proxy server with IP address and port or configure a proxy authentication service with one-way or two-way authentication.

**To configure optional proxy server with IP address and port**

At the command prompt, type:

```
set callhome -proxyMode (YES | NO)[-IPAddress <ip_addr|ipv6_addr|*] [-port <port |*>]
```

Example:

```
set callhome -proxyMode YES -IPAddress 10.102.167.33 -port 80
```

**Note**

Call Home uses the proxy server only when you set the proxy-mode parameter to YES. If you set it to NO, the proxy functionality does not work, even if the IP address and port are configured.

The port number should be for an HTTP service, not for an HTTPS service.

**To configure optional proxy authentication service**

This mode provides two types of security authentication: one-way and two-way. To set up either type, you must configure an SSL service. For more information, see Configuring SSL Service topic.

In one-way authentication, only the Citrix ADC appliance authenticates the proxy server. In two-way authentication, the Citrix ADC appliance authenticates the proxy server and the proxy server, in turn, authenticates the appliance.

**To configure proxy authentication service**

At the command prompt, type:

```
set callhome -proxyMode (YES | NO)[-proxyAuthService <string>]
```

Example:

```
set callhome -proxyMode YES -proxyAuthService callhome_proxy
```
To configure one-way proxy server authentication

Do the following tasks to configure one-way proxy server authentication.

1. Create an SSL service.
2. Bind a CA certificate to the service.
3. Bind an HTTPS Monitor to the service.
4. Configure Call Home to use the SSL service.

To configure two-way proxy server authentication

Do the following tasks to configure two-way proxy server authentication.

1. Create an SSL service
2. Bind a CA certificate to the service.
4. Bind an HTTPS Monitor to the service.
5. Configure Call Home to use the SSL service.

Verifying Call Home Registration status

At the command prompt, type:

```
show callhome
show callhome
Registration with Citrix upload server SUCCESSFUL
Mode: Default
Contact email address: exampleadmin@example.com
Heartbeat Custom Interval (days): 7
Proxy Mode: Yes
Proxy IP Address: 10.102.29.200
Proxy Authentication Service:
Proxy Port: 80
Trigger event occurrence State Latest occurrence
-------------- ----- ---------------
```
Enabling SNMP Alarms

The Citrix ADC appliance provides a set of error condition entities called SNMP alarms. When an error condition in a SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the SSL-CARD-FAILED alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a SSL card failure on the appliance. For more information, see SNMP.**

At the command prompt, type:

```plaintext
enable snmp alarm <trapName>
show snmp alarm <trapName>
```

To configure Call Home by using GUI

To verify if Call Home feature is enabled by default in the GUI
1. Navigate to **Configuration > System > Settings**.
2. In the **details** pane, click **Configure Advanced features** link.
3. In the **Configure Advanced Features** page, **Call Home** option must display as enabled.

To enable Call Home by using GUI

1. Navigate to **Configuration > System > Settings**.
2. In the **details** pane, click **Configure Advanced features** link and select **Callhome** option.

To configure Call Home for optional proxy mode authentication by using GUI

1. You can use any of the two ways to access the Call Home page:
   a) Navigate to **System > System Information**.
   b) Navigate to **System > Diagnostics**.
      i. In the details pane, under **Technical Support Tools**, select **Call Home**.
2. On the **Configure Call Home** page, set the following parameters.
   a) **Mode**. Call Home mode of operation. Possible types: Default, Citrix Service Provider (CSP) deployment.
   b) **Email address**. Email address of the contact administrator at the customer site.
   c) **CallHome Heartbeats Interval (days)**. Monitoring interval (in days) between Call Home heartbeats. Minimum value=1 and Maximum value=7.
   d) **Enable Call Home**. Enable or disable the Call Home feature to view the status of appliance registration on the Citrix support server.
   e) **Proxy Mode**. If you do not have an internet connectivity, enable proxy mode and set the optional proxy parameters.
   f) **Proxy Server**. If you set the proxy mode by using a proxy server, specify the server IP address.
      i. **Proxy Service**. If you set the proxy mode by using a proxy service. Specify the service name.
      ii. **IP Address**. IP address of the proxy server.
      iii. **Port**. Port number of the proxy server.
      iv. **Proxy Authentication SSL Service**. Name of the proxy service that provides proxy-mode authentication.
3. Click **OK** and **Done**.

To configure SSL service for proxy server authentication by using GUI

For information about configuring SSL service by using the GUI, see **Configuring SSL Service** topic.

To verify Call Home registration status by using GUI

1. You can use any of the two ways to access the **Call Home** page:
   a) Navigate to **System > System Information**.
   b) Navigate to **System > Diagnostics**.
      i. In the details pane, under **Technical Support Tools**, select **Call Home**.
2. In the **Configure Call Home** page, the **Registration with Citrix upload server** field shows the registration status.

To configure an SNMP alarms

1. Navigate to **System > SNMP > Alarms**.
2. In the details pane, select an alarm and configure its parameters.
3. Click **OK** and **Close**.

**Citrix Service Provider (CSP) deployment support**

In a Citrix Service Provider (CSP) environment where Citrix ADC services are deployed on VPX instances, Call Home can monitor and track the license-specific information and securely send the information to Citrix Insight Services (CIS). CIS in turn sends the information to the License Usage Insights (LUI) portal for accounting purposes and for CSP customers to review their license usage. Currently, CSP environments support Citrix ADC services on VPX instances only, not on MPX or SDX appliances. The VPX instances can be deployed in either standalone or high availability mode.

**Reporting tool**

April 23, 2019

Use the Citrix® Citrix ADC® Reporting tool to view Citrix ADC performance statistics data as reports. Statistics data are collected by the nscollect utility and are stored in a database. When you want to view certain performance data over a period of time, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports as well as the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, nscollect, and stop or start its operation.

**Using the reporting tool**

The Reporting tool is a Web-based interface accessed from the Citrix® Citrix ADC® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports. You can create a custom report for any number of entities.
To invoke the reporting tool

1. Use the Web browser of your choice to connect to the IP address of the Citrix ADC (for example, http://10.102.29.170/). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the Citrix ADC.
3. In the Password text box, type the password.
4. In the Start in drop-down box, select Reporting. Click Login.

The following screen shots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. Report Toolbar

Figure 2. Chart Toolbar

Working with reports

You can plot and monitor statistics for the various functional groups configured on the Citrix ADC over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a tabular format. The graphical view consists of line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then clicking Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag-and-drop operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.
Using built-in reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, Citrix ADC Gateway, and Citrix ADC Application Firewall. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

Note:
You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report.

To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).
2. Click a report (for example, SSL > All Backend Ciphers).

Creating and deleting reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar.

By default, newly created custom reports contain one chart named System Overview that displays a CPU Usage counter plotted for the last day.

To create a custom report

1. In the Reporting tool, on the report toolbar, click Create, or if you want to create a new custom report based on an existing report, open the existing report, and then click Save As.
2. In Report Name box, type a name for the custom report.
3. Do one of the following:
   • To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click OK.
   • To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click OK.
You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to delete, and then click Delete.

Note:
When you delete a folder, all the contents of that folder are deleted.

Modifying the time interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click Duration, and then click a time interval.

Setting the data source and time zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report’s time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the Reporting tool, on the report toolbar, click Settings.
2. In the Settings dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
   - If you want the tool to remember the time period for which a chart is plotted, select the Remember time selection for charts check box.
   - If you want the reports to use the time settings of your Citrix ADC appliance, select the Use Appliance’s time zone check box.
Exporting and importing custom reports

You can share reports with other Citrix ADC administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the **Click to manage custom reports** icon.
2. Select the check box that corresponds with the report you want to export or import, and then click **Export** or **Import**.
   
   **Note:**
   When you export the file, it is exported in a .gz file format.

Working with charts

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats (for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day.

**Note:**
If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report.

Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.
Modifying a chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to Plot chart for, do one of the following:
   - To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
   - To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In Select group, click the desired entity.
6. Under Counters, in Available, click the counter name(s) that you want to plot, and then click the > button.
7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click the entity instance name(s) you want to plot, and then click the > button.
8. Click OK.

Viewing a chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.
To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click Customize.
3. On the Chart tab, under Category, click Plot type, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Zoom in, and do one or both of the following:
   - To refocus the chart to display data for a specific time window, drag and drop the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.
   - To refocus the chart to display data for a data point, simply click once on chart where you want to zoom in and get more detailed information.
3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click Graphical View.

   Note: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Scroll, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, click and drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the background color, click Background Color, and then select the options for color, transparency, and effects.
• To change the text color, click Text **Color**, and then select the options for color, transparency, and effects.

**To customize the axes of a chart**

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click **Customize**.
3. On the **Chart** tab, under Category, click one or more of the following:
   - To change the scale of the left y-axis, click **Left Y-Axis**, and then select the scale you want.
   - To change the scale of the right y-axis, click **Right Y-Axis**, in Data set to plot, select the date set, and then select the scale you want.

   **Note:**
   The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

   - To plot each data set in its own hidden y-axis, click **Multiple Axes**, and then click **Enable**.

**To change the background color, edge color, and gridlines for a plot area of a chart**

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click **Customize**.
3. On the **Plot Area** tab, under Category, click one or more of the following:
   - To change the background color and edge color of the chart, click **BackgroundColor** and **Edge Color**, and then select the options for color, transparency, and effects.
   - To change the horizontal or vertical grids of the chart, click **Horizontal Grids** or **Vertical Grids**, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

**To change the color and graph type of a data set**

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click **Customize**.
3. On the **Data Set** tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.

   **Note:** The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and
Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

4. Under Category, do one of more of the following:
   - To change the background color, click Color, and then select the options for color, transparency, and effects.
   - To change the graph type, click Plot type, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

**Exporting chart data to excel**

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click Export.

**Deleting a chart**

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the Delete icon.

**Examples**

**To display the trend report for CPU usage and memory usage for the last week**

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click Duration, and then click Last Week.
To compare the bytes received rate and the bytes transmitted rate between two interfaces for
the last week

1. In the right pane, on the report toolbar, click Create.
2. In the Report Name box, type a name for the custom report (for example, Custom_Interfaces),
   and then click OK. The report is created with the default System Overview chart, which displays
   the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click Counters.
4. In the counter selection pane, in Title, type a name for the chart (for example, Interfaces bytes
data).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the Entities tab, click the interface name(s) you want to plot (for example, 1/1 and 1/2), and
   then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the
   > button.
8. Click OK.
9. On the report toolbar, click Duration, and then click Last Week.

Stopping and starting the data collection utility

The data collection utility, nscollect, runs automatically when you start the Citrix ADC. This utility re-
trieves the application performance data and stores it in the form of data sources on the ADC. You can
create up to 32 data sources. The default data source is /var/log/db/default.

The data collection utility creates databases for global counters and entity-specific counters,
and uses this data to generate reports. Global-counter databases are created at /var/log
/db/<DataSourceName> . The entity-specific databases are created based on the entities
configured on the Citrix ADC, and a separate folder is created for each entity type in /var/log/db/<
DataSourceName/EntityNameDB>.

Nscollect retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day,
hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the
reports display corrupted data.

To stop nscollect

At the command prompt, type:

/netscaler/nscollect stop

To start nscollect on the current SSH session to the Citrix ADC:
At the command prompt, type:

```
/netscaler/nscollect start
```

**To start nscollect on the local system:**

At the command prompt, type:

```
/netscaler/nscollect start &
```

## CloudBridge Connector

July 29, 2019

**Note:** The current Citrix ADC 1000V release does not support this feature.

The CloudBridge Connector feature of the Citrix ADC appliance connects enterprise datacenters to external clouds and hosting environments, making the cloud a secure extension of your enterprise network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network. With Citrix CloudBridge Connector, you can augment your datacenters with the capacity and efficiency available from cloud providers.

The CloudBridge Connector enables you to move your applications to the cloud to reduce costs and increase reliability.

In addition to using CloudBridge Connector between a datacenter and a cloud, you can use it to connect two datacenters for a high-capacity secure and accelerated link.

### Understanding CloudBridge Connector

To implement the Citrix CloudBridge Connector solution, you connect a datacenter to another datacenter or an external cloud by setting up a tunnel called the CloudBridge Connector tunnel.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between two Citrix ADC appliances, one in each datacenter.

To connect a datacenter to an external cloud (for example, Amazon AWS cloud), you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual appliance (VPX) that resides in the Cloud. The remote end point can be a CloudBridge Connector or a Citrix ADC VPX with premium license.

The following illustration shows a CloudBridge Connector tunnel set up between a datacenter and an external cloud.
The appliances between which a CloudBridge Connector tunnel is set up are called the end points or peers of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel uses the following protocols:

- Generic Routing Encapsulation (GRE) protocol
- Open-standard IPSec Protocol suite, in transport mode

The GRE protocol provides a mechanism for encapsulating packets, from a wide variety of network protocols, to be forwarded over another protocol. GRE is used to:

- Connect networks running non-IP and non-routable protocols.
- Bridge across a wide area network (WAN).
- Create a transport tunnel for any type of traffic that needs to be sent unchanged across a different network.

The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

The Internet Protocol security (IPSec) protocol suite secures communication between peers in the CloudBridge Connector tunnel.

In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the transport mode in which the GRE encapsulated packet is encrypted. The encryption is done by the Encapsulating Security Payload (ESP) protocol. The ESP protocol ensures the integrity of the packet by using a HMAC hash function, and ensures confidentiality by using an encryption algorithm. After the packet is encrypted and the HMAC is calculated, an ESP header is generated. The ESP header is inserted after the GRE IP header and, an ESP trailer is inserted at the end of the encrypted payload.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version (IKE) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

- The two peers mutually authenticate with each other, using one of the following authentication methods:
  - Pre-shared key authentication. A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
- **Digital certificates authentication.** The initiator (sender) peer signs message inter-
change data by using its private key, and the other receiver peer uses the sender’s public key to verify the signature. Typically, the public key is exchanged in messages containing an X.509v3 certificate. This certificate provides a level of assurance that a peer’s identity as represented in the certificate is associated with a particular public key.

- The peers then negotiate to reach agreement on:
  - An encryption algorithm.
  - Cryptographic keys for encrypting data in one peer and decrypting the data in the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when two peers, CB1 and CB2, are communicating through a Connector tunnel, CB1 has two Security Associations. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets.

SAs expire after a specified length of time, which is called the *lifetime*. The two peers use the Internet Key Exchange (IKE) protocol (part of the IPSec protocol suite) to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

The following table lists some IPSec properties supported by a Citrix ADC appliance:

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Types Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKE Versions</td>
<td>V1, V2</td>
</tr>
<tr>
<td>IKE Authentication Methods</td>
<td>Pre-shared key authentication, Digital certificates authentication</td>
</tr>
<tr>
<td>Encryption Algorithm</td>
<td>AES (128 bits), AES 256 (256 bits), 3DES</td>
</tr>
<tr>
<td>Hash Algorithm</td>
<td>HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5</td>
</tr>
</tbody>
</table>

**Monitoring CloudBridge Connector tunnels**

April 23, 2019

You can display the statistics for monitoring the performance of a CloudBridge Connector tunnel. To display CloudBridge Connector tunnel statistics on a Citrix ADC appliance, use the GUI or the Citrix ADC command line.

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a Citrix ADC appliance.
### Statistical counter

<table>
<thead>
<tr>
<th>Counter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes Received</td>
<td>Total number of bytes received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Bytes Sent</td>
<td>Total number of bytes sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Packets Received</td>
<td>Total number of packets received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Packets Sent</td>
<td>Total number of packets sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.</td>
</tr>
<tr>
<td>Bytes Received Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Bytes Sent Rate</td>
<td>Number of bytes per second sent by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Packets Received Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
<tr>
<td>Packets Sent Rate</td>
<td>Number of bytes per second received by the Citrix ADC appliance through all the configured CloudBridge Connector tunnels.</td>
</tr>
</tbody>
</table>

All these counters are reset to 0 when the Citrix ADC appliance is restarted. They do not increment during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.
Citrix ADC 13.0

tunnel.

To display CloudBridge Connector tunnel statistics by using the Citrix ADC command line

At the command prompt, type:

- **stat ipsec counters**

To display CloudBridge Connector tunnel statistics by using the GUI

1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance.
2. On the **Configuration** tab, navigate to **System > CloudBridge Connector**.
3. On the CloudBridge Connector page, click **Create/Manage CloudBridge Connector**. The **IPSec Bytes** and **IPSec Packets** charts display the bytes received rate, bytes sent rate, packets received rate, and packets sent rate of all the CloudBridge Connector tunnels configured on the Citrix ADC appliance.

```
> stat ipsec counters
Secure tunnel(s) summary

<table>
<thead>
<tr>
<th>Rate (/s)</th>

**Configuring a CloudBridge Connector tunnel between two datacenters**

April 23, 2019

You can configure a CloudBridge Connector tunnel between two different datacenters to extend your network without reconfiguring it, and leverage the capabilities of the two datacenters. A CloudBridge Connector tunnel between the two geographically separated datacenters enables you to implement redundancy and safeguard your setup from failure. The CloudBridge Connector tunnel helps achieve optimal utilization of infrastructure and resources across datacenters. The applications available across the two datacenters appear as local to the user.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance in one datacenter and a Citrix ADC appliance in the other datacenter.

As an illustration of CloudBridge Connector tunnel between datacenters, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in datacenter DC1 and Citrix ADC appliance NS_Appliance-2 in datacenter DC2.
Both NS_Appliance-1 and NS_Appliance-2 function in L2 and L3 mode. They enable communication between private networks in datacenters DC1 and DC2. In L3 mode, NS_Appliance-1 and NS_Appliance-2 enable communication between client CL1 in datacenter DC1 and server S1 in the datacenter DC2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Because client CL1 and server S1 are on different private networks, L3 mode is enabled on NS_Appliance-1 and NS_Appliance-2, and routes are updated as follows:

- CL1 has a route to NS_Appliance-1 for reaching S1.
- NS_Appliance-1 has a route to NS_Appliance-2 for reaching S1.
- S1 has a route to NS_Appliance-2 for reaching CL1.
- NS_Appliance-2 has a route to NS_Appliance-1 for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-1 in datacenter DC1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-2 in datacenter DC2.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Points to consider for configuring CloudBridge Connector tunnel**

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Deploy and set up a Citrix ADC appliance in each of the two datacenters.
2. Make sure that the CloudBridge Connector tunnel endpoint IP addresses are accessible to each other.

Configuration procedure

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in one datacenter and another Citrix ADC appliance that resides in the other datacenter, use the GUI or the command line interface of one of the Citrix ADC appliances.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the first Citrix ADC appliance is automatically pushed to the other endpoint (the other Citrix ADC appliance) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI of the other Citrix ADC appliance to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on each of the Citrix ADC appliances consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies the local IP address (a public SNIP address configured on the local Citrix ADC appliance), remote IP address (a public SNIP address configured on the remote Citrix ADC appliance), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the first datacenter and is destined to a server on the subnet in the second datacenter. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the first datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSec profile by using the command line interface

At the command prompt, type:

```
add ipsec profile <name> [-ikeVersion ( V1 | V2 )] [-encAlgo ( AES | 3 DES )...][-hashAlgo <hashAlgo> ...][-lifetime <positive_integer>] [-psk | (-publickey<string> -privatekey<string>-peerPublicKey<string>)][-livenessCheckInterval <positive_integer>][-replayWindowSize ...]
```

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3901
To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- `add ipTunnel <name> <remote><remoteSubnetMask> <local> [-protocol < protocol>] [-ipsecProfileName <string>]`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- `add ns pbr <pbr_name> ALLOW -srcIP = <local_subnet_range> -destIP = <remote_subnet_range> -ipTunnel <tunnel_name>`
- `apply ns pbrs`
- `show ns pbr <pbr_name>`

Example

```
1  add ipsec profile Cloud_Connector_DC1-DC2 -encAlgo AES -hashAlgo HMAC_SHA1
   Done
2  > add ipTunnel Cloud_Connector_DC1-DC2 203.0.113.133 255.255.255.255 198.51.100.15 -protocol GRE -ipsecProfileName Cloud_Connector_DC1-DC2
   Done
3  > add ns pbr PBR-DC1-DC2 ALLOW -srcIP 198.51.100.15 -destIP 203.0.113.133 ipTunnel Cloud_Connector_DC1-DC2
   Done
4  > apply ns pbrs
   Done
```

To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.
2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.
3. Navigate to **System > CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.

5. On the Welcome screen click **Get Started**.

**Note:**

If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the CloudBridge Connector Setup pane, click **Citrix ADC**.

1. In the Citrix ADC pane, provide your account credentials for the remote Citrix ADC appliance. Click **Continue**.

2. In the CloudBridge Connector Setting pane, set the following parameter:

   - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.

3. Under **Local Setting**, set the following parameter:

   - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel.

4. Under **Remote Setting**, set the following parameter:

   - **Subnet IP**—IP address of the peer endpoint of the CloudBridge Connector tunnel.

5. Under **PBR Setting**, set the following parameters:

   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - **Source IP Low**—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
   - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   - **Destination IP Low**—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
   - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.

6. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:

   - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
• **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.

• **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
  
  – **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
  
  – **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
    
    * Pre Shared Security Key—The text string entered for pre-shared key based authentication.
  
  – **Upload Certificates**—Authentication based on digital certificates.
    
    * **Public Key**—A local digital certificate to be used to authenticate the local Citrix ADC appliance to the peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
    
    * **PrivateKey**—Private key of the local digital certificate.
    
    * **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

7. Click **Done**.

The new CloudBridge Connector tunnel configuration on both the Citrix ADC appliances appears on the Home tab of the respective GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge Connectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector Tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see [Monitoring CloudBridge Connector Tunnels](#).

**Configuring CloudBridge Connector between datacenter and AWS cloud**

July 20, 2019
You can configure a CloudBridge Connector tunnel between a datacenter and AWS cloud to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.

To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a Citrix ADC virtual appliance (VPX) that resides in AWS cloud.

As an illustration of a CloudBridge Connector tunnel between a datacenter and Amazon AWS cloud, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-DC, in datacenter DC, and Citrix ADC virtual appliance (VPX) NS_VPX_Appliance-AWS.

Both NS_Appliance-DC and NS_VPX_Appliance-AWS function in L3 mode. They enable communication between private networks in datacenter DC and the AWS cloud. NS_Appliance-DC and NS_VPX_Appliance-AWS enable communication between client CL1 in datacenter DC and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Note:
AWS does not support L2 mode, hence it is necessary to have only L3 mode enabled on both the endpoints.

For proper communication between CL1 and S1, L3 mode is enabled on NS_Appliance-DC and NS_VPX_Appliance-AWS and routes are updated as such:

- CL1 have a route to NS_Appliance-DC for reaching S1.
- NS_Appliance-DC have a route to NS_VPX_Appliance-AWS for reaching S1.
- S1 should have a route to NS_VPX_Appliance-AWS for reaching CL1.
- NS_VPX_Appliance-AWS have a route to NS_Appliance-DC for reaching CL1.

The following table lists the settings on Citrix ADC appliance NS_Appliance-DC in datacenter DC.

<table>

Prerequisites

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Install, configure, and launch an instance of Citrix ADC Virtual appliance (VPX) on AWS cloud. For instructions on installing Citrix ADC VPX on AWS, see Deploy a Citrix ADC VPX instance on AWS.
2. Deploy and configure a Citrix ADC physical appliance, or provisioning and configuring a Citrix ADC virtual appliance (VPX) on a virtualization platform in the datacenter.
3. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Citrix ADC VPX license

After the initial instance launch, Citrix ADC VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: http://support.citrix.com/article/CTX122426.

You have to:

1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a paid marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Configuration steps

To set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in a datacenter and a Citrix ADC virtual appliance (VPX) that resides on the AWS cloud, use the GUI of the Citrix ADC appliance.

When you use the GUI, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on AWS) of the CloudBridge Connector tunnel. Therefore, you do not have to access the GUI (GUI) of the Citrix ADC VPX on AWS to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on both peers (the Citrix ADC appliance that resides in the datacenter and the Citrix ADC virtual appliance (VPX) that resides on the AWS cloud) consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in both the peers of the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies a local IP address (a public SNIP address configured on the local peer), remote IP address (a public SNIP address configured on the remote peer), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the datacenter and is destined to a server on the subnet in the AWS cloud. If this packet matches the source and destination IP address range of the PBR entity on the Citrix ADC appliance in the datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:
```
add ipsec profile <name> [-**ikeVersion** (V1 | V2)] [-**encAlgo** (AES | 3DES)...][-**hashAlgo** <hashAlgo> ...][-**lifetime** <positive_integer>] [-**psk** | (**publickey** <string> -**privatekey** <string> -**peerPublickey** <string>)][-**livenessCheckInterval** <positive_integer>][-**replayWindowSize** <positive_integer>][-**ikeRetryInterval** <positive_integer>][-**retransmissiontime** <positive_integer>]
**show ipsec profile** <name>
```

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:
```
add ipTunnel <name> <remote><remoteSubnetMask> <local> [-**protocol** <protocol>] [-**ipsecProfileName** <string>]
show ipTunnel <name>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:
```
add ns pbr <pbr_name> ALLOW -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
apply ns pbrs
show ns pbr <pbr_name>
```

**Example**
```
> add ipsec profile CC_Tunnel_DC-AWS -encAlgo AES -hashAlgo HMAC_SHA1
```

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3908
To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Type the NSIP address of a Citrix ADC appliance in the address line of a web browser.

2. Log on to the GUI of the Citrix ADC appliance by using your account credentials for the appliance.

3. Navigate to **System > CloudBridge Connector**.

4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.

5. The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.

6. On the **Welcome** screen click **Get Started**.

**Note:**

If you already have a CloudBridge Connector tunnel configured on the Citrix ADC appliance, the Welcome screen does not appear, so you do not click Get Started.

1. In the **CloudBridge Connector Setup** pane, click **amazon web services**

1. In the **Amazon** pane, provide your AWS account credentials: AWS Access Key ID and AWS Secret Access Key. You can obtain these access keys from the AWS GUI console. Click **Continue**.

**Note**

Earlier, the Setup wizard always connects to the same AWS region even when another region is selected. As a result, configuring CloudBridge Connector tunnel to a Citrix ADC VPX running on the selected AWS region used to fail. This issue has been fixed now.

1. In the **Citrix ADC** pane, select the NSIP address of the Citrix ADC virtual appliance running on AWS. Then, provide your account credentials for the Citrix ADC virtual appliance. Click **Continue**.

2. In the **CloudBridge Connector Setting** pane, set the following parameter:
• **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.

3. Under **Local Setting**, set the following parameter:

   • **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.

4. Under **Remote Setting**, set the following parameter:

   • **Subnet IP**—IP address of the CloudBridge Connector tunnel end point on the AWS side. Must be an IP address of type SNIP on the Citrix ADC VPX instance on AWS.
   
   • **NAT**—Public IP address (EIP) in AWS that is mapped to the SNIP configured on the Citrix ADC VPX instance on AWS.

5. Under **PBR Setting**, set the following parameters:

   • **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   
   • **Source IP Low**—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
   
   • **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
   
   • **Operation**—Either the equals (=) or does not equal (!=) logical operator.
   
   • **Destination IP Low**—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
   
   • **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.

6. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:

   • **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   
   • **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
   
   • **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
     
     - **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
     
     - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
* **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.

- **Upload Certificates**—Authentication based on digital certificates.
  * **Public Key**—A local digital certificate to be used to authenticate the local peer to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
  * **Private Key**—Private key of the local digital certificate.
  * **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

7. Click **Done**.

The new CloudBridge Connector tunnel configuration on the Citrix ADC appliance in the datacenter appears on the Home tab of the GUI. The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC VPX appliance in the AWS cloud appears on the GUI. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see **Monitoring CloudBridge Connector Tunnels**.

**Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and virtual private gateway on AWS**

April 23, 2019

To connect a datacenter to Amazon Web Services (AWS), you can configure a CloudBridge Connector tunnel between a Citrix ADC appliance in the datacenter and a virtual private gateway on AWS. The Citrix ADC appliance and the virtual private gateway form the endpoints of the CloudBridge Connector tunnel and are called peers.

**Note:**
You can also set up a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and a Citrix ADC VPX instance (instead of a virtual private gateway) on AWS. For more
Virtual private gateways on AWS support the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.

<table>
<thead>
<tr>
<th>IPSec Properties</th>

</tbody>
</table>

**Example of CloudBridge Connector tunnel configuration and data flow**

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance NS_Appliance-1 in a datacenter and virtual private gateway gateway AWS-Virtual-Private-Gateway-1 on AWS cloud.

NS_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the AWS cloud through the CloudBridge Connector tunnel. As a router, NS_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named NS_AWS_IPSec_Profile, a CloudBridge Connector tunnel entity named NS_AWS_Tunnel, and a policy based routing (PBR) entity named NS_AWS_Pbr.

The IPSec profile entity NS_AWS_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. NS_AWS_IPSec_Profile is bound to IP tunnel entity NS_AWS_Tunnel.

CloudBridge Connector tunnel entity NS_AWS_Tunnel specifies the local IP address (a public IP—SNIP—address configured on the Citrix ADC appliance), the remote IP address (the IP address of the AWS-Virtual-Private-Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. NS_AWS_Tunnel is bound to policy based routing (PBR) entity NS_AWS_Pbr.

The PBR entity NS_AWS_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (NS_AWS_Tunnel). The source IP address range and the destination IP address range are the condi-
tions for NS_AWS_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the AWS cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the AWS cloud matches the conditions in NS_AWS_Pbr. This packet is then considered for CloudBridge Connector processing and is sent across the CloudBridge Connector tunnel (NS_AWS_Tunnel) bound to the PBR entity.

The following table lists the settings used in this example.

| IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in the datacenter side | 66.165.176.15 |
| IP address of the CloudBridge Connector tunnel end point (AWS-Virtual-Private-Gateway-1) in the AWS | 168.63.252.133 |
| Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel | 10.102.147.0/24 |
| AWS Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel | 10.20.20.0/24 |

Settings on Amazon AWS

| Customer Gateway | AWS-Customer-Gateway-1 | Routing = Static, IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side = 66.165.176.15 |

Points to consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, consider the following points:

1. AWS supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the Citrix ADC appliance for the CloudBridge Connector tunnel.
   - IKE version = v1
   - Encryption algorithm = AES
   - Hash algorithm = HMAC SHA1

2. You must configure the firewall at the Citrix ADC end to allow the following.
   - Any UDP packets for port 500
   - Any UDP packets for port 4500
   - Any ESP (IP protocol number 50) packets

3. You must configure Amazon AWS before specifying the tunnel configuration on the Citrix ADC, because the public IP address of the AWS end (gateway) of the tunnel and the PSK are automatically generated when you set up the tunnel configuration in AWS. You need this information for specifying the tunnel configuration on the Citrix ADC appliance.

4. AWS gateway supports static routes and the BGP protocol for route updates. The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. There-
fore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.

**Configuring Amazon AWS for the CloudBridge Connector tunnel**

To create a CloudBridge Connector tunnel configuration on Amazon AWS, use the Amazon AWS Management Console, which is a web based graphical interface for creating and managing resources on Amazon AWS.

Before you begin the CloudBridge Connector tunnel configuration on AWS cloud, make sure that:

- You have a user account for Amazon AWS cloud.
- You have a virtual private cloud whose networks you want to connect to the networks at the Citrix ADC side through the CloudBridge Connector tunnel.
- You are familiar with the Amazon AWS Management Console.

**Note:**

The procedures for configuring Amazon AWS for a CloudBridge Connector tunnel might change over time, depending on the Amazon AWS release cycle. Citrix recommends you refer Amazon AWS documentation for the latest procedures.

To configure a CloudBridge connector tunnel between a Citrix ADC and AWS gateway perform the following tasks on the AWS Management Console:

- **Create a Customer Gateway.** A customer gateway is an AWS entity that represents a CloudBridge Connector tunnel endpoint. For a CloudBridge Connector tunnel between a Citrix ADC appliance and AWS gateway, the customer gateway represents the Citrix ADC appliance on AWS. The customer gateway specifies a name, the type of routing (static or BGP) used in the tunnel, and the CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

- **Create a Virtual Private Gateway and attach it to a VPC.** A virtual private gateway is a CloudBridge Connector tunnel endpoint at the AWS side. When you create a virtual private gateway, you assigned it a name or allow AWS to assign the name. You then associate the virtual private gateway with a VPC. This association enables the subnets of the VPC to connect to the subnets at the Citrix ADC side through the CloudBridge Connector tunnel.

- **Create a VPN Connection.** A VPN connection specifies a customer gateway and a virtual private gateway between which a CloudBridge Connector tunnel is to be created. It also specifies an IP prefix for the networks at the Citrix ADC side. Only IP prefixes that are known to the virtual private gateway (through static route entry) can receive traffic from the VPC through the tunnel. Also, the virtual private gateway does not route any traffic not destined to the specified...
IP prefixes through the tunnel. After configuring a VPN connection, you might have to wait few minutes for it to be created.

- **Configure Routing Options.** For the VPC’s network to reach the networks at the Citrix ADC side through the CloudBridge Connector tunnel, you must configure the VPC’s routing table to include routes for the networks at the Citrix ADC side and point those routes to the virtual private gateway. You can include routes in a VPC’s routing table in one of the following ways:
  - **Enable Route Propagation.** You can enable route propagation for your routing table, so that routes are automatically propagated to the table. The static IP prefixes that you specify for VPN configuration are propagated to the routing table after you’ve created the VPN connection.
  - **Enter Static Routes Manually.** If you do not enable route propagation, you must manually enter the static routes for the networks at the Citrix ADC side.

- **Download Configuration.** After the CloudBridge Connector tunnel (VPN connection) configuration is created on AWS, download the configuration file of the VPN connection to your local system. You might need the information in the configuration file for configuring the CloudBridge Connector tunnel on the Citrix ADC appliance.

To create a customer gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Navigate to **VPN Connections > Customer Gateways** and click on **Create Customer Gateway**.
3. In the **Create Customer Gateway** dialog box, set the following parameters and then click Yes, Create:
   - **Name tag.** A name for the customer gateway.
   - **Routing list.** Type of routing between Citrix ADC appliance and AWS virtual private gateway for advertising routes to each other through the CloudBridge Connector tunnel. Select **Static Routing** from the Routing list. **Note:** The Citrix ADC appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.
   - **IP Address.** Internet-routable CloudBridge Connector tunnel endpoint IP address on the Citrix ADC side. The IP address can be an Internet-routable Citrix ADC owned subnet IP (SNIP) address or, if the Citrix ADC appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.

To create a virtual private gateway and attach it to a VPC

1. Navigate to **VPN Connections > Virtual Private Gateways**, and then click Create Virtual Private Gateway.
2. Enter a name for the virtual private gateway, and then click Yes, Create.
3. Select the virtual private gateway that you created, and then click Attach to VPC.
4. In the **Attach to VPC** dialog box, select your VPC from the list, and then choose Yes, Attach.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To create a VPN connection:

1. Navigate to VPN Connections > VPN Connections and then click Create VPN Connection.
2. In the Create VPN Connection dialog box set the following parameters and then choose Yes, Create:
   - Name tag. A name for the VPN connection.
   - Virtual Private Gateway. Select the virtual private gateway that you created earlier.
   - Customer Gateway. Select Existing. Then, from the drop down list, select the customer gateway that you created earlier.
   - Routing Options. Type of routing between the virtual private gateway and customer gateway (Citrix ADC appliance). Select Static. In the Static IP Prefixes field, specify the IP prefixes for the subnet on the Citrix ADC side, separated by commas.

To enable route propagation:

1. Navigate to Route Tables and select the routing table that’s associated with the subnet whose traffic is to traverse the CloudBridge Connector tunnel.
   
   **Note**
   By default, this is the main routing table for the VPC.

   1. On the Route Propagation tab in the details pane, choose Edit, select the virtual private gateway, and then choose Save.

To manually enter static routes:

1. Navigate to Route Tables and select your routing table.
2. On the Routes tab, click Edit.
3. In the Destination field, enter the static route used by your CloudBridge Connector tunnel (VPN connection).
4. Select the virtual private gateway ID from the Target list, and then click Save.

To download the configuration file:

1. Navigate to VPN Connection, select a VPN connection, and then click Download Configuration.
2. In the Download Configuration dialog box, set the following parameters, and then click Yes, Download.
   - Vendor. Select Generic.
   - Platform. Select Generic.
   - Software. Select Vendor Agnostic.
Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a virtual private gateway on AWS cloud, perform the following tasks on the Citrix ADC appliance.
You can use either the Citrix ADC command line or the GUI.

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm and PSK to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel that uses IPSec protocol and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (a SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the virtual private gateway in AWS), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to traverse the tunnel, and set the destination IP address range to specify the AWS VPC subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet that originates from a client in the subnet on the Citrix ADC side and is destined to a server in the AWS cloud subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the Citrix ADC command line

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion** v1`
- `show ipsec profile** <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the Command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `show ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the Command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP** <subnet-range> -ipTunnel <tunnelName>`
The following commands create all settings of Citrix ADC appliance NS_Appliance-1 used in “Example of CloudBridge Connector Configuration and Data Flow.”

```
> add ipsec profile NS_AWS_IPSec_Profile -psk DkiMgMdcqvYREEuIvxsbKkW0Foyabcd -ikeVersion v1 -lifetime 31536000
Done
> add iptunnel NS_AWS_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 - protocol IPSEC -ipsecProfileName NS_AWS_IPSec_Profile
Done
> add pbr NS_AWS_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_AWS_Tunnel
Done
> apply pbrs
Done
```

To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version (select V1)
4. Select the Pre-shared Key Authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
• Local IP Type (In the Local IP Type drop down list, select Subnet IP).
• Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select
  the desired IP from the list.)
• Protocol
• IPSec Profile

4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR dialog box, set the following parameters:
   • Name
   • Action
   • Next Hop Type (Select IP Tunnel)
   • IP Tunnel Name
   • Source IP Low
   • Source IP High
   • Destination IP Low
   • Destination IP High
4. Click Create, and then click Close.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance ap-
pears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Con-
nectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by us-
ing CloudBridge Connector tunnel statistical counters.
For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appli-
ance, see Monitoring CloudBridge Connector Tunnels.
Configuring a CloudBridge Connector tunnel between a datacenter and Azure cloud

April 23, 2019

The Citrix ADC appliance provides connectivity between your enterprise datacenters and the Microsoft cloud hosting provider, Azure, making Azure a seamless extension of the enterprise network. Citrix ADC encrypts the connection between the enterprise datacenter and Azure cloud so that all data transferred between the two is secure.

How CloudBridge Connector tunnel works

To connect a datacenter to Azure cloud, you set up a CloudBridge Connector tunnel between a Citrix ADC appliance that resides in the datacenter and a gateway that resides in the Azure cloud. The Citrix ADC appliance in the datacenter and the gateway in Azure cloud are the end points of the CloudBridge Connector tunnel and are called peers of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel between a datacenter and Azure cloud uses the open-standard Internet Protocol security (IPSec) protocol suite, in tunnel mode, to secure communications between peers in the CloudBridge Connector tunnel. In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the tunnel mode in which the complete IP packet is encrypted and then encapsulated. The encryption uses the Encapsulating Security Payload (ESP) protocol, which ensures the integrity of the packet by using a HMAC hash function and ensures confidentiality by using an encryption algorithm. The ESP protocol, after encrypting the payload and calculating the HMAC, generates an ESP header and inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and inserts it at the end of the packet.

The IPSec protocol then encapsulates the resulting packet by adding an IP header before the ESP header. In the IP header, the destination IP address is set to the IP address of the CloudBridge Connector peer.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version 1 (IKEv1) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

1. The two peers mutually authenticate with each other, using pre-shared key authentication, in which the peers exchange a text string called a pre-shared key (PSK). The pre-shared keys are
matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.

2. The peers then negotiate to reach agreement on:
   - An encryption algorithm
   - Cryptographic keys for encrypting data on one peer and decrypting it on the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when a CloudBridge Connector tunnel is set up between a Citrix ADC appliance in a datacenter and a gateway in an Azure cloud, both the datacenter appliance and the Azure gateway have two SAs. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets. SAs expire after a specified interval of time, which is called the lifetime.

Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of CloudBridge Connector Tunnel, consider an example in which a CloudBridge Connector tunnel is set up between Citrix ADC appliance CB_Appliance-1 in a datacenter and gateway Azure_Gateway-1 in Azure cloud.

CB_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the Azure cloud through the CloudBridge Connector tunnel. As a router, CB_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the Azure cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On CB_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named CB_Azure_IPSec_Profile, a CloudBridge Connector tunnel entity named CB_Azure_Tunnel, and a policy based routing (PBR) entity named CB_Azure_Pbr.

The IPSec profile entity CB_Azure_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. CB_Azure_IPSec_Profile is bound to IP tunnel entity CB_Azure_Tunnel.

CloudBridge Connector tunnel entity CB_Azure_Tunnel specifies the local IP address (a public IP address configured on the Citrix ADC appliance), the remote IP address (the IP address of the Azure_Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. CB_Azure_Tunnel is bound to the PBR entity CB_Azure_Pbr.

The PBR entity CB_Azure_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (CB_Azure_Tunnel). The source IP address range and the destination IP address range are the conditions for CB_Azure_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the Azure cloud, respectively. Any request
packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the Azure cloud matches the conditions in CB_Azure_Pbr. This packet is then considered for CloudBridge processing and is sent across the CloudBridge Connector tunnel (CB_Azure_Tunnel) bound to the PBR entity.

On Microsoft Azure, the CloudBridge Connector tunnel configuration includes a local network entity named My-Datacenter-Network, a virtual network entity named Azure-Network-for-CloudBridge-Tunnel, and a gateway named Azure_Gateway-1.

The local (local to Azure) network entity My-Datacenter-Network specifies the IP address of the Citrix ADC appliance on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network entity Azure-Network-for-CloudBridge-Tunnel defines a private subnet named Azure-Subnet-1 in Azure. The traffic of the subnet traverses the CloudBridge Connector tunnel. The server S1 is provisioned in this subnet.

The local network entity My-Datacenter-Network is associated with the virtual network entity Azure-Network-for-CloudBridge-Tunnel. This association defines the remote and local network details of the CloudBridge Connector tunnel configuration in Azure. Gateway Azure_Gateway-1 was created for this association to become the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel.

For more information about the settings, refer to the CloudBridge Connector Tunnel Settings pdf.

**Points to consider for a CloudBridge Connector tunnel configuration**

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Microsoft Azure, consider the following points:

1. The Citrix ADC appliance must have a public facing IPv4 address (type SNIP) to use as a tunnel end-point address for the CloudBridge Connector tunnel. Also, the Citrix ADC appliance should not be behind a NAT device.
2. Azure supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings while configuring the Citrix ADC for the CloudBridge Connector tunnel.
   - IKE version = v1
   - Encryption algorithm = AES
   - Hash algorithm = HMAC SHA1
3. You must configure the firewall in the datacenter edge to allow the following.
   - Any UDP packets for port 500
   - Any UDP packets for port 4500
   - Any ESP (IP protocol number 50) packets
4. IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge Connector tunnel end points to establish new SAs, is not supported. When the Security Associations
(SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for
the lifetimes of SAs.
5. You must configure Microsoft Azure before specifying the tunnel configuration on the Citrix ADC,
because the public IP address of the Azure end (gateway) of the tunnel, and the PSK, are auto-
matically generated when you set up the tunnel configuration in Azure. You need this informa-
tion for specifying the tunnel configuration on the Citrix ADC.

Configuring the CloudBridge Connector tunnel

For setting up a CloudBridge Connector tunnel between your datacenter and Azure, you must install
CloudBridge VPX/MPX in your datacenter, configure Microsoft Azure for the CloudBridge Connector
tunnel, and then configure the Citrix ADC appliance in the data center for the CloudBridge Connector
tunnel.

Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance in datacenter and Mi-
crosoft Azure consists of the following tasks:

1. **Setting up the Citrix ADC appliance in the datacenter.** This task involves deploying and config-
uring a Citrix ADC physical appliance (MPX), or provisioning and configuring a Citrix ADC virtual
appliance (VPX) on a virtualization platform in the datacenter.

2. **Configuring Microsoft Azure for the CloudBridge Connector tunnel.** This task involves creat-
ing local network, virtual network, and gateway entities in Azure. The local network entity spec-
ifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC appliance)
on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge
Connector tunnel. The virtual network defines a network on Azure. Creating the virtual network
includes defining a subnet whose traffic is to traverse the CloudBridge Connector tunnel to be
formed. You then associate the local network with the virtual network. Finally, you create a
gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel.

3. **Configuring the Citrix ADC appliance in the datacenter for the CloudBridge Connector tun-
nel.** This task involves creating an IPSec profile, an IP tunnel entity, and a PBR entity in the
Citrix ADC appliance in datacenter. The IPSec profile entity specifies the IPSec protocol param-
eters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used in the
CloudBridge Connector tunnel. The IP tunnel specifies the IP address of both the CloudBridge
Connector tunnel end points (the Citrix ADC appliance in datacenter and the gateway in Azure)
and the protocol to be used in the CloudBridge Connector tunnel. You then associate the IPSec
profile entity with the IP tunnel entity. The PBR entity specifies the two subnets, in the datacen-
ter and in the Azure cloud, that are to communicate with each other through the CloudBridge
Connector tunnel. You then associate the IP tunnel entity with the PBR entity.
Configuring Microsoft Azure for the CloudBridge Connector tunnel

To create a CloudBridge Connector tunnel configuration on Microsoft Azure, use the Microsoft Windows Azure Management Portal, which is a web based graphical interface for creating and managing resources on Microsoft Azure.

Before you begin the CloudBridge Connector tunnel configuration on Azure cloud, make sure that:

- You have a user account for Microsoft Azure.
- You have a conceptual understanding of Microsoft Azure.
- You are familiar with the Microsoft Windows Azure Management Portal.

Note:
The procedures for configuring Microsoft Azure for a CloudBridge Connector tunnel might change over time, depending on the Microsoft Azure release cycle. Citrix recommends the following Microsoft Azure documentation for the latest procedures.

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on Microsoft Azure by using the Microsoft Windows Azure Management Portal:

- **Create a local network entity.** Create a local network entity in Windows Azure for specifying the network details of the datacenter. A local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the Citrix ADC) on the datacenter side and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel.

- **Create a Virtual Network.** Create virtual network entity that defines a network on Azure. This task includes defining a private address space, where you provide a range of private addresses and subnets belonging to the range specified in the address space. The traffic of the subnets will traverse the CloudBridge Connector tunnel. You then associate a local network entity with the virtual network entity. This association lets Azure create a configuration for a CloudBridge Connector tunnel between the virtual network and the data center network. A gateway (to be created) in Azure for this virtual network will be the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel. You then define a private subnet for the gateway to be created. This subnet belongs to the range specified in the address space in the virtual network entity.

- **Create a gateway in Windows Azure.** Create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel. Azure, from its pool of public IP addresses, assigns an IP address to the gateway created.

- **Gather the public IP address of the gateway and the pre-shared key.** For a CloudBridge Connector tunnel configuration on Azure, the public IP address of the gateway and the pre-shared Key (PSK) are automatically generated by Azure. Make a note of this information. You will need it for configuring the CloudBridge Connector tunnel on the Citrix ADC in datacenter.
1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + NEW.
3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click REGISTER LOCAL NETWORK.
4. In the ADD A LOCAL NETWORK wizard, in the specify your local network details screen, set the following parameters:
   - NAME
   - VPN DEVICE IP ADDRESS
5. In the lower right corner of the screen, click -> (forward arrow mark).
6. On the Specify the address space screen, set the following parameter:
   - ADDRESS SPACE
7. In the lower right corner of the screen, click the check mark.
8. The local network entity is created in Windows Azure. You can verify it on the portal’s LOCAL NETWORK tab.

To create a virtual network in Azure by using the Microsoft Windows Azure Management Portal

1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + New.
3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click CUSTOM CREATE.
4. In the CREATE A VIRTUAL NETWORK wizard, in the Virtual Network Details screen, set the following parameters:
   - NAME
   - AFFINITY GROUP
   - REGION
   - AFFINITY GROUP NAME
5. Click -> (forward arrow mark) in the lower right-hand corner of the screen.
6. In the DNS Servers and VPN Connectivity screen, in SITE-TO-SITE CONNECTIVITY, select Configure Site-To-Site VPN and set the following parameter:
   - LOCAL NETWORK
7. In the Address Space and Subnets screen, set the following parameters:
   a) Address space
8. Click the check mark in the lower right-hand corner of the screen.

9. The virtual network is created in Windows Azure and is listed on the VIRTUAL NETWORK tab.

To create a gateway by using the Microsoft Windows Azure Management Portal

1. In the left pane, click **NETWORKS**.

2. On the **Virtual Network** tab, in the Name column, click the virtual network entity for which you want to create a gateway.

3. On the DASHBOARD page of the virtual network, at the bottom of the page, click **+ Create Gateway**.

4. When prompted to confirm you want the gateway created, click **YES**. Creating the gateway can take up to 15 minutes.

5. When the gateway is created, the DASHBOARD page displays the gateway IP address, which is a public IP address.

To gather public IP address of the gateway and the pre-shared key information by using the Microsoft Windows Azure Management Portal

1. In the left pane, click **NETWORKS**.

2. On the **Virtual Network** tab, in the Name column, click **virtual network entity**.

3. On the **DASHBOARD** page of the virtual network, copy the Gateway IP Address.

4. For the Pre Shared Key (PSK), at the bottom of the page, click **MANAGE KEY**.

5. In the **MANAGE SHARED KEY** dialog box, copy the **SHARED KEY**.

**Configuring the Citrix ADC Appliance in the datacenter for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on the Citrix ADC in the datacenter. You can use either the Citrix ADC command line or the GUI:

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel with IPSec protocol and associate the IPSec profile to it.** An IP tunnel specifies the local IP address (a public SNIP address configured on the Citrix ADC appliance), remote IP address (the public IP address of the gateway in Azure), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
• **Create a PBR rule and associate the IP tunnel to it.** A PBR entity specifies a set of conditions and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range to specify the datacenter subnet whose traffic is to traverse the tunnel, and the destination IP address range to specify the Azure subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet originated from a client in the subnet on the datacenter and destined to a server in the subnet on the Azure cloud matches the source and destination IP range of the PBR entity. This packet is then considered for CloudBridge Connector tunnel processing and is sent across the CloudBridge Connector tunnel associated with the PBR entity.

The GUI combines all these tasks in a single wizard called the CloudBridge Connector wizard.

To create an IPSEC profile by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipsec profile <name> -psk <string> -ikeVersion v1
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line:

At the Command prompt, type:

```
add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line:

```
add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> ipTunnel <tunnelName> apply pbrs
```

**Sample Configuration**

The following commands create all settings of Citrix ADC appliance CB_Appliance-1 used in “Example of CloudBridge Connector Configuration and Data Flow”.

```bash
1 > add ipsec profile CB_Azure_IPSec_Profile -psk DkiMgMdcbqyYREEuIvxsbKkW0FOyDiLM -ikeVersion v1 -lifetime 31536000
2    Done
3
4 > add ipTunnel CB_Azure_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 -protocol IPSEC -ipsecProfileName CB_Azure_IPSec_Profile
5    Done
6

To configure a CloudBridge Connector tunnel in a Citrix ADC appliance by using the GUI

1. Access the GUI by using a web browser to connect to the IP address of the Citrix ADC appliance in the datacenter.

2. Navigate to System > CloudBridge Connector.

3. In the right pane, under Getting Started, click Create/Monitor CloudBridge.

4. Click Get Started.

   **Note:** If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

5. In the CloudBridge Setup pane, click Microsoft Windows Azure.

6. In the Azure Settings pane, in the Gateway IP Address* field, type the IP address of the Azure gateway. The CloudBridge Connector tunnel is then set up between the Citrix ADC appliance and the gateway. In the Subnet (IP Range)* text boxes, specify a subnet range (in Azure cloud), the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.

7. In the Citrix ADC Settings pane, from the Local Subnet IP* drop-down list, select a publicly accessible SNIP address configured on the Citrix ADC appliance. In Subnet (IP Range)* text boxes, specify a local subnet range, the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.

8. In the CloudBridge Setting pane, in the CloudBridge Name text box, type a name for the CloudBridge that you want to create.

9. From the Encryption Algorithm and Hash Algorithm drop-down lists, select the AES and HMAC_SHA1 algorithms, respectively. In the Pre Shared Security Key text box, type the security key.

10. Click Done.

**Monitoring the CloudBridge Connector tunnel**

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the Citrix ADC appliance in the datacenter and Microsoft Azure. To view CloudBridge Connector tunnel statistics on the Citrix ADC appliance, use GUI or Citrix ADC command line. To view CloudBridge Connector tunnel statistics in Microsoft Azure, use the Microsoft Windows Azure Management Portal.
Displaying CloudBridge Connector tunnel Statistics in the Citrix ADC appliance

For information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

Displaying CloudBridge Connector tunnel Statistics in Microsoft Azure

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels in Microsoft Azure.

<table>
<thead>
<tr>
<th>Statistical counter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA IN</td>
<td>Total number of kilobytes received by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.</td>
</tr>
<tr>
<td>DATA OUT</td>
<td>Total number of kilobytes sent by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.</td>
</tr>
</tbody>
</table>

To display CloudBridge Connector tunnel statistics by using the Microsoft Windows Azure Management Portal

1. Log on to the Windows Azure Management Portal by using your Microsoft Azure account credentials.
2. In the left pane, click NETWORKS.
3. On the Virtual Network tab, in the Name column, select the virtual network entity associated with a CloudBridge Connector tunnel whose statistics you want to display.
4. On the DASHBOARD page of the virtual network, view the DATA IN and DATA OUT counters for the CloudBridge Connector tunnel.

Configuring CloudBridge Connector tunnel between datacenter and softlayer enterprise cloud

April 23, 2019

The GUI includes a wizard that helps you to easily configure a CloudBridge Connector tunnel between a Citrix ADC appliance in a datacenter and Citrix ADC VPX instances on the SoftLayer enterprise cloud.
When you use the wizard of the Citrix ADC appliance in the datacenter, the CloudBridge Connector tunnel configuration created on the Citrix ADC appliance, is automatically pushed to the other endpoint or peer (the Citrix ADC VPX on SoftLayer) of the CloudBridge Connector tunnel.

Using the wizard of the Citrix ADC appliance in the datacenter, you perform the following steps to configure a CloudBridge Connector tunnel.

1. Connect to the Softlayer enterprise cloud by providing the user log on credentials.
2. Select the Citrix XenServer that is running the Citrix ADC VPX appliance.
3. Select the Citrix ADC VPX appliance.
4. Provide CloudBridge Connector tunnel parameters to:
   - Configure a GRE Tunnel.
   - Configure IPsec on the GRE tunnel.
   - Create a netbridge, which is a logical representation of the CloudBridge connector, by specifying a name.
   - Bind the GRE Tunnel to the netbridge.

To configure a CloudBridge Connector tunnel by using the GUI

1. Log on to the GUI of the Citrix ADC appliance in the datacenter by using your account credentials for the appliance.
2. Navigate to System > CloudBridge Connector.
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge Connector.
4. Click Get Started.

Note:

If you already have any CloudBridge Connector tunnel configured on the Citrix ADC appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

1. In the CloudBridge Connector Setup pane, click Softlayer, and then follow the instructions in the wizard.

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.
Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device

April 23, 2019

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco device to connect two datacenters or extend your network to a Cloud provider. The Citrix ADC appliance and the Cisco IOS device form the end points of the CloudBridge Connector tunnel and are called peers.

Example of CloudBridge Connector tunnel configuration and data flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco IOS device Cisco-IOS-Device-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco_Tunnel, and policy based routing (PBR) entity NS_Cisco_Pbr.

For more information, refer to the CloudBridge Connector tunnel between a Citrix ADC appliance and Cisco IOS device settings pdf.

Points to Consider for a CloudBridge Connector tunnel configuration

Before configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, consider the following points:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec mode</td>
<td>Tunnel mode</td>
</tr>
</tbody>
</table>
IPSec Properties | Setting
--- | ---
IKE version | Version 1
IKE authentication method | Pre-Shared Key
IKE encryption algorithm | AES, 3DES
IKE hash algorithm | HMAC SHA1, HMAC SHA256, HMAC SHA384, HMAC SHA512, HMAC MD5
ESP encryption algorithm | AES, 3DES
ESP hash algorithm | HMAC SHA1, HMAC SHA256, HMAC SHA256, HMAC MD5

- You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco IOS device at the two ends of the CloudBridge Connector.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another, and a common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore on the Cisco device, you must specify the same hash algorithm and same encryption algorithm for IKE (while creating IKE policy) and ESP (while creating IPSec transform set).
- You must configure the firewall at the Citrix ADC end and Cisco device end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

### Configuring Cisco IOS device for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a Cisco IOS device, use the Cisco IOS command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco devices.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco IOS device, make sure that:

- You have a user account with administrator credentials on the Cisco IOS device.
- You are familiar with the Cisco IOS command line interface.
- The Cisco IOS device is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
Note:
The procedures for configuring CloudBridge Connector tunnel on a Cisco IOS device might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco product documentation for more information, see Configuring IPSec VPN tunnels topic.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Cisco device’s IOS command line:

- **Create an IKE Policy.** An IKE policy defines a combination of security parameters to be used during the IKE negotiation. For example, parameters such as hash algorithm, encryption algorithm, Diffie-Hellman group, and authentication method to be used in the IKE negotiation are set in this task.

- **Configure a Pre-shared key for IKE authentication.** A pre-shared key is a text string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco device and the Citrix ADC appliance.

- **Define a transform set and configure IPSec in tunnel mode.** A transform set defines a combination of security parameters to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful. Parameters such as hash algorithm and encryption algorithm are set in this task. This task also specifies that IPSec in tunnel mode be used for the CloudBridge tunnel.

- **Create a crypto access List.** Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco device side and Citrix ADC side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from a device in the Cisco device side subnet and is destined to a device in the Citrix ADC side subnet, and that matches the source and destination parameters of the access list, is sent across the CloudBridge Connector tunnel.

- **Create a crypto map.** Crypto maps define the IPSec parameters to be negotiated with peer. They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (Citrix ADC) identification by IP address, and transform set to match the peer security settings.

- **Apply the crypto Map to an interface.** In this task, you apply a crypto map to an interface through which CloudBridge Connector tunnel traffic will flow. Applying the crypto map to an interface instructs the Cisco IOS device to evaluate all the interface traffic against the crypto map set, and to use the specified policy during connection or SA negotiation on behalf of subnet’s traffic to be protected.

The examples in the following procedures create settings of Cisco IOS device Cisco-IOS-Device-1 used
To create an IKE policy, refer to the IKE policy pdf.

To configure a pre-shared key by using the Cisco IOS command line

At the Cisco IOS device’s command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto isakmp identity address</td>
<td>Cisco-ios-device-1(config)# crypto isakmp identity address</td>
<td>Specify the ISAKMP identity (address) for the Cisco IOS device to use when communicating with the peer (Citrix ADC appliance) during IKE negotiations. This example specifies the address keyword, which uses IP address 203.0.113.200 (Gigabit Ethernet interface 0/1 of Cisco-IOS-Device-1) as the identity for the device.</td>
</tr>
<tr>
<td>crypto isakmp key keystringaddress peer-address</td>
<td>Cisco-ios-device-1(config)# crypto isakmp key examplepresharedkey address 198.51.100.100</td>
<td>Specify a pre-shared key for the IKE authentication. This example configures shared key examplepresharedkey to be used with the Citrix ADC appliance NS_Appliance-1 (198.51.100.100). The same pre-shared key must be configured on the Citrix ADC appliance for IKE authentication to be successful between the Cisco IOS device and the Citrix ADC appliance.</td>
</tr>
</tbody>
</table>

To create a crypto access list by using the Cisco IOS command line

At the Cisco IOS device’s command prompt, type the following command in global configuration mode:
mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-listaccess-list-number permit IPsource source-wildcard destination destination-wildcard</td>
<td>Cisco-ios-device-1(config)# access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255</td>
<td>Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-IOS-Device-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).</td>
</tr>
</tbody>
</table>

To define a transform and configure IPSec tunnel mode by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ipsec transform-setname ESP_Authentication_Transform ESP_Encryption_Transform</td>
<td>Cisco-ios-device-1(config)# crypto ipsec transform-set NS-CISCO-TS esp-sha256-hmac esp-3des</td>
<td>Define a transform set and specify the ESP hash algorithm (for authentication) and the ESP encryption algorithm to be used during exchange of data between the CloudBridge Connector tunnel peers. This example defines transform set NS-CISCO-TS and specifies ESP authentication algorithm as esp-sha256-hmac, and ESP encryption algorithm as esp-3des.</td>
</tr>
<tr>
<td>mode tunnel</td>
<td>Cisco-ios-device-1(config-crypto-trans)# mode tunnel</td>
<td>Set IPSec in tunnel mode.</td>
</tr>
<tr>
<td>exit</td>
<td>Cisco-ios-device-1 (config-crypto-trans)# exit, Cisco-ios-device-1 (config)#</td>
<td>Exit back to global configuration mode.</td>
</tr>
</tbody>
</table>

<td></td>
<td>exit, Cisco-ios-device-1 (config)#</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco IOS device, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method (Pre-Shared key) to be used by the IPSec protocol in the CloudBridge Connector tunnel.
• **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the Cisco IOS device), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

• **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the Cisco IOS device side subnet whose traffic is to be protected over the tunnel. Any request packet that originates from a client in the subnet on the Citrix ADC side and is destined to a server in the Cisco IOS device side subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity. Apply the PBR rule to make it functional.

To create an IPSEC profile by using the Citrix ADC command line

At the Command prompt, type:

- `add ipsec profile <name> -psk <string> -ikeVersion v1`
- `show ipsec profile <name>`

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the Command prompt, type:

- `add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>`
- `add ipTunnel <name>`

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the Command prompt, type:

- `add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>`
- `apply pbrs`
- `show pbrs <pbrName>`

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of CloudBridge Connector Configuration and Data Flow.”

```
1 > add ipsec profile NS_Cisco_IPSec_Profile -psk examplepresharedkey -ikeVersion v1 -lifetime 315360 -encAlgo 3 DES
Done
```
To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
   - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI
1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR dialog box, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click Create, and then click Close.

To apply a PBR by using the GUI
1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

**Monitoring the CloudBridge Connector Tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

**Configuring a CloudBridge Connector tunnel between a Citrix ADC appliance and fortinet fortiGate appliance**

April 23, 2019

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Fortinet FortiGate appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the FortiGate appliance form the end points of the CloudBridge Connector tunnel and are called peers.
**Example of a CloudBridge Connector Tunnel Configuration**

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- FortiGate appliance FortiGate-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and FortiGate-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and FortiGate-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Fortinet_IPSec_Profile, CloudBridge Connector tunnel entity NS_Fortinet_Tunnel, and policy based routing (PBR) entity NS_Fortinet_Pbr.

For more information, see [CloudBridge Connector tunnel configuration table](#) pdf.

For information about Settings on Fortinet FortiGate-Appliance-1 in Datacenter-2, see [table](#).

**Points to consider for a CloudBridge Connector tunnel configuration**

The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec mode</td>
<td>Tunnel mode</td>
</tr>
<tr>
<td>IKE version</td>
<td>Version 1</td>
</tr>
<tr>
<td>IKE authentication method</td>
<td>Pre-Shared Key</td>
</tr>
<tr>
<td>IKE encryption algorithm</td>
<td>AES</td>
</tr>
<tr>
<td>IKE hash algorithm</td>
<td>HMAC SHA1</td>
</tr>
<tr>
<td>ESP encryption algorithm</td>
<td>AES</td>
</tr>
<tr>
<td>ESP hash algorithm</td>
<td>HMAC SHA1</td>
</tr>
</tbody>
</table>

- You must specify the same IPSec settings on the Citrix ADC appliance and the FortiGate appliance at the two ends of the CloudBridge Connector.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algo-
Citrix ADC 13.0

rithm and an ESP hash algorithm. It also provides another common parameter for specifying an
IKE encryption algorithm and an ESP encryption algorithm. Therefore in the FortiGate appli-
cance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase
1 configuration) and ESP (phase 2 configuration).

• You must configure the firewall at the Citrix ADC end and FortiGate end to allow the following.
  – Any UDP packets for port 500
  – Any UDP packets for port 4500
  – Any ESP (IP protocol number 50) packets

• FortiGate appliance supports two types of VPN tunnels: Policy-based and Route-based. Only
  policy-based VPN tunnel is supported between a FortiGate appliance and a Citrix ADC appliance.

**Configuring FortiGate appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel on a FortiGate appliance, use the Fortinet Web-based
Manager, which is the primary user interface for configuring, monitoring, and maintaining FortiGate
appliances.

Before you begin the CloudBridge Connector tunnel configuration on a FortiGate appliance, make
sure that:

• You have a user account with administrator credentials on the FortiGate appliance.
• You are familiar with the Fortinet Web-based Manager.
• The FortiGate appliance is UP and running, is connected to the Internet, and is also connected
to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

**Note**

The procedures for configuring CloudBridge Connector tunnel on a FortiGate appliance might
change over time, depending on the Fortinet release cycle. Citrix recommends that you follow
the official Fortinet product documentation for Configuring IPSec VPN tunnels.

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a FortiGate appli-
cance, perform the following tasks on the FortiGate appliance by using the Fortinet Web-based man-
ger:

• **Enable Policy-based IPSec VPN feature.** Enable this feature for creating policy-based VPN tun-
nels on the FortiGate appliance. Only policy-based type of VPN tunnel is supported between a
FortiGate appliance and a Citrix ADC appliance. A policy-based VPN tunnel configuration on a
FortiGate appliance includes phase 1 settings, phase 2 settings, and an IPSec security policy.

• **Define phase 1 parameters.** Phase 1 parameters are used by the FortiGate appliance for IKE
  Authentication before forming a secure tunnel to the Citrix ADC appliance.

• **Define phase 2 parameters.** Phase 2 parameters are used by the FortiGate appliance for form-
ing a secure tunnel to the Citrix ADC appliance by establishing IKE security associations (SA).
• **Specify private subnets.** Define the FortiGate-side and the Citrix ADC-side private subnets whose IP traffic is to be transported through the tunnel.

• **Define an IPSec security policy for the tunnel.** A security policy allow IP traffic to pass between interfaces on a FortiGate appliance. An IPSec security policy specifies the interface to the private subnet and the interface connecting the Citrix ADC appliance through the tunnel.

To enable Policy-based IPSec VPN feature by using the Fortinet Web-based Manager

1. Navigate to **System > Config > Features**.
2. On the **Feature Settings** page, select **Show More** and turn on **Policy-based IPSec VPN**.

To define phase 1 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN > IPsec > Auto Key (IKE)** and click **Create Phase1**.
2. On the **New Phase 1** page, set the following parameters:
   - Name: Enter a name for this phase 1 configuration.
   - Remote Gateway: Select **Static IP Address**.
   - Mode: Select **Main (ID Protection)**.
   - Authentication Method: Select **Preshared Key**.
   - Pre-Shared Key: Enter a pre-shared key. The same pre-shared key must be configured on the Citrix ADC appliance.
   - Peer Options: Set the following IKE parameters for authenticating a Citrix ADC appliance.
     - IKE Version: Select 1.
     - Mode Config: Clear this option if it is selected.
     - Local Gateway IP: Select **Main Interface IP**.
     - P1 Proposal: Select the encryption and authentication algorithms for IKE Authentication before forming a secure tunnel to the Citrix ADC appliance.
       * 1 - Encryption: Select **AES128**.
       * Authentication: Select **SHA1**.
       * Keylife: Enter an amount of time (in seconds) for the phase 1 key life.
       * DH Group: Select 2.
     - X-Auth: Select **Disable**.
     - Deed Peer Detection: Select this option.
3. Click **OK**.

To specify private subnets by using the Fortinet Web-based Manager

1. Navigate to **Firewall Objects > Address > Addresses** and select **Create New**.
2. On the **New Address** page, set the following parameters:
   - Name: Enter a name for FortiGate-side subnet.
   - Type: Select **Subnet**.
   - Subnet / IP Range: Enter the address of the FortiGate-side subnet.
   - Interface: Select the local interface to this subnet.
3. Click **OK**.
4. Repeat steps 1-3 to specify the Citrix ADC-side subnet.

To define phase 2 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN > IPsec > Auto Key (IKE)** and click **Create Phase 2**.
2. On the **New Phase 2** page, set the following parameters:
   - Name: Enter a name for this phase 2 configuration.
   - Phase 1: Select the Phase 1 configuration from the drop-down list.
3. Click **Advanced** and set the following parameters:
   - P2 Proposal: Select the encryption and authentication algorithms for forming a secure tunnel to the Citrix ADC appliance.
     - 1 - Encryption: Select **AES128**.
     - Authentication: Select **SHAI**.
     - Enable replay detection: Select this option.
     - Enable perfect forward secrecy (PFS): Select this option.
     - DH Group: Select **2**.
   - Keylife: Enter an amount of time (in seconds) for the phase 2 key life.
   - Autokey Keep Alive: Select this option.
   - Auto-negotiate: Select this option.
   - Quick Mode Selector: Specify the FortiGate-side and the Citrix ADC-side private subnets whose traffic is to be traversed through the tunnel.
     - Source Address: Select the FortiGate-side subnet from the drop-down list.
     - Source Port: Enter **0**.
     - Destination Address: Select the Citrix ADC-side subnet from the drop-down list.
     - Destination Port: Enter **0**.
     - Protocol: Enter **0**.
4. Click **OK**.

To define an IPSec security policy by using the Fortinet Web-based Manager

1. Navigate to **Policy > Policy > Policy** and click **Create New**.
2. On the **Edit Policy** page, set the following parameters:
   - Policy Type: Select **VPN**.
   - Policy Subtype: Select **IPSec**.
   - Local Interface: Select the local interface to the internal (private) network.
   - Local Protected Subnet: Select the FortiGate-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   - Outgoing VPN Interface: Select the local interface to the external (public) network.
   - Remote Protected Subnet: Select the Citrix ADC-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   - Schedule: Keep the default setting (**always**) unless changes are needed to meet specific requirements.
• **Service:** Keep the default setting *(ANY)* unless changes are needed to meet your specific requirements.
• **VPN Tunnel:** Select *Use Existing* and select the tunnel from the drop-down list.
• **Allow traffic to be initiated from the remote site:** Select if traffic from the remote network will be allowed to initiate the tunnel.

3. Click **OK**.

### Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a FortiGate appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel endpoint IP address configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the FortiGate appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the FortiGate appliance side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```
• add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE
• show ipsec profile <name>
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

```
• add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName** <string>
• show ipTunnel <name>
```
To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

• add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
• apply pbrs
• show pbr <pbrName>

To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSec Profile page, set the following parameters:
   • Name
   • Encryption Algorithm
   • Hash Algorithm
   • IKE Protocol Version
   • Perfect Forward Secrecy (Enable this parameter)
4. Configure the IPsec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel page, set the following parameters:
   • Name
   • Remote IP
   • Remote Mask
   • Local IP Type (In the Local IP Type drop-down list, select Subnet IP).
   • Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop-down list. Select the desired IP from the list.)
   • Protocol
   • IPSec Profile
4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR page, set the following parameters:
   • Name
Citrix ADC 13.0

- Action
- Next Hop Type (Select IP Tunnel)
- IP Tunnel Name
- Source IP Low
- Source IP High
- Destination IP Low
- Destination IP High

4. Click Create, and then click Close.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in "Example of a CloudBridge Connector Configuration."

```
> add ipsec profile NS_Fortinet_IPSec_Profile -psk examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
Done
> add iptunnel NS_Fortinet_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 -protocol IPSEC -ipsecProfileName NS_Fortinet_IPSec_Profile
Done
> add pbr NS_Fortinet_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_Fortinet_Tunnel
Done
> apply pbtrs
Done
```

**Monitoring the CloudBridge Connector tunnel**

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.
CloudBridge Connector tunnel diagnostics and troubleshooting

April 23, 2019

If you have problems with a CloudBridge Connector tunnel configuration, make sure that all prerequisites were observed before the tunnel was set up. If they were, the problem might be with the tunnel end-point IP addresses, a NAT configuration, the way the tunnel was set up, or with the data traffic.

Troubleshooting a CloudBridge Connector tunnel

If your CloudBridge Connector tunnel does not function properly, the issue could be with tunnel establishment or with the data traffic. If you are unsure which type of problem you have, look for an error message in the log file and see if the error message is in the list of tunnel-establishment issues. If you do not find your error message, check the list of possible issues related to data traffic.

Issues Related to tunnel establishment

After the requirements for configuring the IPSec tunnel are met and the CloudBridge Connector tunnel is configured, if the status of the tunnel is not UP, look for debugging information in the iked.log file on one or both Citrix ADC appliances configured as the tunnel end points.

On either appliance, type the following command at the Citrix ADC shell prompt:

```
cat /tmp/iked.debug tee /var/iked.log
```

The Troubleshooting pdf lists some common errors and their solutions.

Issues related to data traffic

If the data in the CloudBridge Connector tunnel are not exchanged properly between the tunnel end points, do the following.

- For a CloudBridge Connector tunnel that uses GRE and IPSec protocols:
  - Make sure that L2 mode is enabled on both of the CloudBridge Connector tunnel end points. To enable L2 mode, type the following command at the Citrix ADC command line interface:
    ```
    enable mode L2
    ```
  - If one of the CloudBridge Connector tunnel end points is a CloudBridge virtual appliance (VPX) and is provisioned on a VMware ESXi hypervisor, make sure that Promiscu-
ous mode is set to Accept for the vSwitch associated with the CloudBridge VPX appliance.

- If a VLAN is extended through a CloudBridge Connector tunnel, verify one-to-one mapping on the extended VLAN entity on each of the tunnel end points.
- Make sure that the IP tunnel entity is bound to the correct netbridge entity in each of the tunnel end points.
- Verify that the ARP entry for the peer CloudBridge Connector tunnel end point exists on the local tunnel end point, by typing the following command at the Citrix ADC command line interface:
  `show arp`
- If the output shows an incomplete ARP entry, bidirectional traffic is not flowing through the tunnel. If bidirectional traffic is flowing, the ARP entry shows the name of tunnel interface for the devices on the other side of the tunnel.
- Remove the IP tunnel entities from both tunnel end points and add them again with the same parameters, but with the IPSec profile set to NONE, so that the tunnel uses only the GRE protocol.

After verifying the following in the IP tunnel (that uses GRE protocol), configure the tunnel with IPSec parameters by specifying a valid IPSec profile to the respective IP tunnel entities on each of the tunnel end points.

Proper PING or TCP flow through the tunnel.
Proper flow of data traffic through the tunnel.

After the configured tunnel (that uses GRE and IPSec protocols) is in UP state, if the data traffic does not flow properly through the tunnel, and if a NAT device was deployed in front of any or both of the tunnel end points, analyze the ingress and egress packets on the NAT devices.

- If a Citrix ADC appliance is used as Router or Gateway.
  
  - Make sure that L3 mode is enabled on the Citrix ADC appliance. To enable L3 mode, run the following command in the CloudBridge command line.
  - `enable mode L3`
  - If subnets are bound to a netbridge entity, make sure that correct IP tunnel entity is also bound to the netbridge.
  - Run the following command in the Citrix ADC command line to see where the packets (Input and Output) are getting dropped:

    `stat ipsec counters`
  - Make sure that the correct routes are configured on both the tunnel end points.
  - If no NAT device is deployed in front of the Citrix ADC appliance, make sure that the firewalls are configured to allow any ESP (IP protocol number 50) packets and any UDP packets for port 4500.

If none of the above measures result in successful exchange of traffic between the tunnel end points,
contact Citrix Technical Support.

**Checklist before contacting Citrix technical Support**

For a speedy resolution, make sure that you have the following items ready before contacting Citrix Technical Support.

- Details of the deployment and network topology.
- Log file collected by typing the following command at the Citrix ADC shell prompt.
  
  ```
  cat /tmp/iked.debug | tee /var/log/iked.log
  ```
- Tech support bundle captured by typing the following command at the Citrix ADC command line.
  
  ```
  show techsupport
  ```
- Packet traces captured on both CloudBridge Connector tunnel end points. To start a packet trace, type the following command at the Citrix ADC command line.
  
  ```
  start nstrace -size 0
  ```
  To stop packet trace, type the following command at the Citrix ADC command line.
  
  ```
  stop nstrace
  ```
- Output of the following command typed at the Citrix ADC command prompt.
  
  ```
  show arp
  ```

**CloudBridge Connector interoperability – StrongSwan**

April 23, 2019

StrongSwan is an opensource IPSec implementation for Linux platforms. You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the StrongSwan appliance form the end points of the CloudBridge Connector tunnel and are called peers.

**Example of a CloudBridge Connector tunnel configuration**

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- StrongSwan appliance StrongSwan-Appliance-1 in a datacenter designated as Datacenter-2
NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and StrongSwan-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_StrongSwan_IPSec_Profile, CloudBridge Connector tunnel entity NS_StrongSwan_Tunnel, and policy based routing (PBR) entity NS_StrongSwan_Pbr.

The following table lists the settings used in this example.

Main settings of the CloudBridge Connector tunnel setup

<table>
<thead>
<tr>
<th>Entity</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in Datacenter-1</td>
<td>198.51.100.100</td>
</tr>
<tr>
<td>IP address of the CloudBridge Connector tunnel end point (StrongSwan-Appliance-1) in Datacenter-2</td>
<td>203.0.113.200</td>
</tr>
<tr>
<td>Datacenter–1’s subnet whose traffic is to be protected over the CloudBridge Connector tunnel</td>
<td>10.102.147.0/24</td>
</tr>
<tr>
<td>Datacenter–2’s subnet whose traffic is to be protected over the CloudBridge Connector tunnel</td>
<td>10.20.20.0/24</td>
</tr>
</tbody>
</table>

Settings on Citrix ADC appliance NS_Appliance-1 in Datacenter-1

<table>
<thead>
<tr>
<th>SNIP1 (for reference purposes only)</th>
<th>198.51.100.100</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec profile</td>
<td>NS_StrongSwan_IPSec_Profile</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>
psk = examplepresharedkey
(Note: This is an example of a
pre-share key, for illustration.
Citrix does not recommend to
use this string in your
CloudBridge Connector
configuration)

<table>
<thead>
<tr>
<th>CloudBridge Connector tunnel</th>
<th>NS_StrongSwan_Tunnel</th>
<th>Remote IP = 203.0.113.200, Local IP= 198.51.100.100, Tunnel protocol = IPSEC, IPSec profile = NS_StrongSwan_IPSec_Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy based route</td>
<td>NS_StrongSwan_Pbr</td>
<td>Source IP range = Subnet in the Datacenter-1=10.102.147.0-10.102.147.255, Destination IP range =Subnet in Datacenter-2=10.20.20.0-10.20.20.255, IP Tunnel = NS_StrongSwan_Tunnel</td>
</tr>
</tbody>
</table>

**Points to consider for a CloudBridge Connector tunnel configuration**

Before you begin configuring CloudBridge connector tunnel, make sure that:

- You have a basic knowledge about linux configurations.
- You have a basic Knowledge about IPSec protocol suite.
- The StrongSwan appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
- IKE encryption algorithm: AES
- IKE hash algorithm: HMAC SHA1
- ESP encryption algorithm: AES
- ESP hash algorithm: HMAC SHA1

- You must specify the same IPSec settings on the Citrix ADC appliance and the StrongSwan appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the StrongSwan appliance, you must specify the same hash algorithm and same encryption algorithm in IKE and ESP parameters in the IPSec.conf file.
- You must configure the firewall at the Citrix ADC end and StrongSwan end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

**Configure StrongSwan for the CloudBridge Connector tunnel**

To configure a CloudSwan connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the StrongSwan appliance:

- **Specify IPsec connection information in ipsec.conf file.** ipsec.conf file defines all control and configuration information for IPsec connections in the strongSwan appliance.
- **Specify pre-shared key in ipsec.secrets file.** ipsec.secrets file defines secrets for IKE/IPsec authentication for IPsec connections in the strongSwan appliance.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on a StrongSwan appliance might change over time, depending on the StrongSwan release cycle. Citrix recommends that you follow the official StrongSwan documentation for Configuring IPSec VPN tunnels.

Following sample excerpt of ipsec.conf file specifies IPsec information for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic. For more information, see CloudBridge Connector Configuration pdf.

Following sample excerpt of ipsec.secrets file specifies the IKE authentication pre-shared key for setting up the IPsec VPN tunnel, described in Example of a CloudBridge Connector Configuration topic.

/etc/ipsec.secrets  PSK 'examplepresharedkey' #pre-shared key for IPsec IKE authentication'

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a StrongSwan appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC
command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile.** An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.

- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel endpoint IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the StrongSwan appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

- **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the StrongSwan side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```
• add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1
• show ipsec profile <name>
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

```
• add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
• show ipTunnel <name>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

```
• add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
• apply pbrs
• show pbr <pbrName>
```

To create an IPSEC profile by using the GUI

1. Navigate to **System > CloudBridge Connector > IPSec Profile.**
2. In the details pane, click **Add.**
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication method** and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSec profile to it by using the GUI

1. Navigate to **System > CloudBridge Connector > IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select **Subnet IP**).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop-down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSec tunnel to it by using the GUI

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select **IP Tunnel**)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the
tunnel is down.
The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration:

```
> add ipsec profile NS_StrongSwan_IPSec_Profile -psk examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo HMAC_SHA1

Done

> add iptunnel NS_StrongSwan_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 -protocol IPSEC -ipsecProfileName NS_StrongSwan_IPSec_Profile

Done

> add pbr NS_StrongSwan_Pbr -srcIP 10.102.147.0-10.102.147.255 -destIP 10.20.0.0-10.20.255.255 -ipTunnel NS_StrongSwan_Tunnel

Done

> apply pbrs

Done
```

Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector interoperability – F5 BIG-IP

April 23, 2019

© 1999-2018 Citrix Systems, Inc. All rights reserved.
You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the F5 BIG-IP appliance form the end points of the CloudBridge Connector tunnel and are called peers.

**Example of a CloudBridge Connector tunnel configuration**

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- F5 BIG-IP appliance F5-BIG-IP-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and F5-BIG-IP-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_F5-BIG-IP_IPSec_Profile, CloudBridge Connector tunnel entity NS_F5-BIG-IP_Tunnel, and policy based routing (PBR) entity NS_F5-BIG-IP_Pbr.

For more information, refer to [F5 big IP pdf.](#)

**Points to consider for a CloudBridge Connector tunnel configuration**

- The Citrix ADC appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The F5 BIG-IP appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.
- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance.
  - IPSec mode: Tunnel mode
  - IKE version: Version 1
  - IKE authentication method: Pre-Shared Key
  - IKE encryption algorithm: AES
  - IKE hash algorithm: HMAC SHA1
  - ESP encryption algorithm: AES
  - ESP hash algorithm: HMAC SHA1
- You must specify the same IPSec settings on the Citrix ADC appliance and the F5 BIG-IP appliance at the two ends of the CloudBridge Connector tunnel.
Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the F5 BIG-IP appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).

You must configure the firewall at the Citrix ADC end and F5 BIG-IP end to allow the following.
- Any UDP packets for port 500
- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

**Configuring F5 BIG-IP for the CloudBridge Connector tunnel**

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and an F5 BIG-IP appliance, perform the following tasks on the F5 BIG-IP appliance:

- **Create a forwarding virtual server for IPsec.** A forwarding virtual server intercepts IP traffic for the IPsec tunnel.
- **Create an IKE peer.** An IKE peer specifies the local and remote IPsec tunnel endpoints. It also specifies algorithms and credentials to be used for IPsec IKE phase 1.
- **Create a custom IPsec policy.** A policy specifies the IPsec protocol (ESP) and the mode (tunnel) to be used for forming the IPsec tunnel. It also specifies the algorithms and security parameters to be used for IKE IPsec phase 2.
- **Create a bidirectional IPsec traffic selector.** A traffic selector specifies the F5 BIG-IP side and Citrix ADC side subnets whose IP traffic is to be traversed through the IPsec tunnel.

The procedures for configuring IPsec VPN (CloudBridge Connector tunnel) on an F5 BIG-IP appliance might change over time, depending on the F5 release cycle. Citrix recommends that you follow the official F5 BIG-IP documentation for configuring IPSec VPN tunnels, at:

https://f5.com

To create a forwarding virtual server for IPsec by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Local Traffic > Virtual Servers**, and then click **Create**.
2. On **New Virtual Server List** screen, set the following parameters:
   - **Name.** Type a unique name for the virtual server.
   - **Type.** Select **Forwarding (IP)**.
   - **Destination Address.** Type a wildcard network address in CIDR format, for example, 0.0.0.0/0 for IPv4 to accept any traffic.
   - **Service Port.** Select **All Ports** from the list.
   - **Protocol list.** Select **All Protocols** from the list.
   - **VLAN and Tunnel Traffic.** Retain the default selection, **All VLANS and Tunnels**.
3. Click **Finished**.
To create a custom IPsec policy by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network > IPsec > IPsec Policies**, and then click **Create**.
2. On the **New Policy** screen, set the following parameters:
   - **Name**: Type a unique name for the policy.
   - **IPsec Protocol**: Retain the default selection, ESP.
   - **Mode**: Select Tunnel. The screen refreshes to show additional related settings.
   - **Tunnel Local Address**: Type the local IPsec tunnel endpoint IP address (Configured on the F5 BIG-IP appliance).
   - **Tunnel Remote Address**: Type the remote IPsec tunnel endpoint IP address (Configured on the Citrix ADC appliance).
3. For the IKE Phase 2 parameters, retain the default values, or select the options that are appropriate for your deployment.
4. Click **Finished**.

To create a bidirectional IPsec traffic selector by using the F5 BIG-IP GUI

1. On the **Main** tab, click **Network > IPsec > Traffic Selectors**, and then click **Create**.
2. On the **New Traffic Selector** screen, set the following parameters:
   - **Name**: Type a unique name for the traffic selector.
   - **Order**: Retain the default value (First). This setting specifies the order in which the traffic selector appears on the Traffic Selector List screen.
3. From the **Configuration** list, select **Advanced**, and set the following parameters:
   - **Source IP Address**: Click **Host** or **Network**, and in the **Address** field, type the address of the F5 BIG-IP side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Source Port**: Select *All Ports*.
   - **Destination IP Address**: Click **Host**, and in the **Address** field, type the address of the Citrix ADC side subnet whose traffic is to be protected over the IPsec tunnel.
   - **Destination Port**: Select *All Ports*.
   - **Protocol**: Select *All Protocols*.
   - **Direction**: Select Both.
   - **Action**: Select Protect. The **IPsec Policy Name** setting appears.
   - **IPsec Policy Name**: Select the name of the custom IPsec policy that you created.
4. Click **Finished**.

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a F5 BIG-IP appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC command line or the Citrix ADC graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPsec protocol parameters, such
as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.

• **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.** An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the Citrix ADC appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the F5 BIG-IP appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.

• **Create a PBR rule and associate it with the IP tunnel.** A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the Citrix ADC-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the F5 BIG-IP side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```
• add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecyENABLE
• show ipsec profile** <name>
```

To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

At the command prompt, type:

```
• add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
• show ipTunnel <name>
```

To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

At the command prompt, type:

```
• add pbr <pbrName> ALLOW -srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
• apply pbrs
• show pbr <pbrName>
```

To create an IPSEC profile by using the GUI

1. Navigate to **System > CloudBridge Connector > IPSecProfile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   • Name
   • Encryption Algorithm
• Hash Algorithm
• IKE Protocol Version

4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication method** and set the **Pre-Shared Key Exists** parameter.

5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to **System > CloudBridge Connector > IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   • Name
   • Remote IP
   • Remote Mask
   • Local IP Type (In the Local IP Type drop-down list, select **Subnet IP**).
   • Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   • Protocol
   • IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to **System > Network > PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   • Name
   • Action
   • Next Hop Type (Select **IP Tunnel**)
   • IP Tunnel Name
   • Source IP Low
   • Source IP High
   • Destination IP Low
   • Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.”: 

© 1999-2018 Citrix Systems, Inc. All rights reserved. 3962
Monitoring the CloudBridge Connector tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector interoperability – Cisco ASA

April 23, 2019

You can configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance to connect two datacenters or extend your network to a cloud provider. The Citrix ADC appliance and the Cisco ASA appliance form the end points of the CloudBridge Connector tunnel and are called peers.
Example of a CloudBridge Connector tunnel configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following appliances:

- Citrix ADC appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco ASA appliance Cisco-ASA-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-ASA-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco-ASA_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco-ASA_Tunnel, and policy based routing (PBR) entity NS_Cisco-ASA_Pbr.

Points to consider for a CloudBridge Connector tunnel configuration

Before you begin configuring CloudBridge connector tunnel, make sure that:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance.

<table>
<thead>
<tr>
<th>IPSec Properties</th>
<th>Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec mode</td>
<td>Tunnel mode</td>
</tr>
<tr>
<td>IKE version</td>
<td>Version 1</td>
</tr>
<tr>
<td>IKE authentication method</td>
<td>Pre-Shared Key</td>
</tr>
<tr>
<td>IKE encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>IKE hash algorithm</td>
<td>HMAC SHA1, HMAC MD5</td>
</tr>
<tr>
<td>ESP encryption algorithm</td>
<td>AES, 3DES</td>
</tr>
<tr>
<td>ESP hash algorithm</td>
<td>HMAC SHA1, HMAC MD5</td>
</tr>
</tbody>
</table>

- You must specify the same IPSec settings on the Citrix ADC appliance and the Cisco ASA appliance at the two ends of the CloudBridge Connector tunnel.
- Citrix ADC provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore, in the Cisco ASA appli-
You must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).

- You must configure the firewall at the Citrix ADC end and Cisco ASA end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

### Configuring Cisco ASA for the CloudBridge Connector tunnel

To configure a CloudBridge Connector tunnel on a Cisco ASA appliance, use the Cisco ASA command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco ASA appliances.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco ASA appliance, make sure that:

- You have a user account with administrator credentials on the Cisco ASA appliance.
- You are familiar with the Cisco ASA command line interface.
- The Cisco ASA appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

**Note**

The procedures for configuring CloudBridge Connector tunnel on a Cisco ASA appliance might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco ASA product documentation for Configuring IPSec VPN tunnels, at:

- http://www.cisco.com

To configure a CloudBridge connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Cisco ASA appliance’s command line:

- **Create an IKE Policy.** An IKE policy defines a combination of security parameters to be used during the IKE negotiation (phase 1). For example, parameters such as hash algorithm, encryption algorithm, and authentication method to be used in the IKE negotiation are set in this task.

- **Enable IKE on the outside interface.** Enable IKE on the outside interface through which the tunnel traffic will flow to the tunnel peer.

- **Create a tunnel group.** A tunnel group specifies the type of tunnel and the pre-shared key. The tunnel type must be set to ipsec-l2l, which stands for IPsec LAN to LAN. A pre-shared key is a text string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco ASA appliance and the Citrix ADC appliance.
• **Define a transform set.** A transform set defines a combination of security parameters (phase 2) to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful.

• **Create an access list.** Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco appliance side and Citrix ADC side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from an appliance in the Cisco appliance side subnet and is destined to an appliance in the Citrix ADC side subnet, and that matches the source and destination parameters of the access list, is sent across the CloudBridge Connector tunnel.

• **Create a crypto map.** Crypto maps define the IPSec parameters for security associations (SAs). They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (Citrix ADC) identification by IP address, and transform set to match the peer security settings.

• **Apply the crypto Map to the outside interface.** In this task, you apply the crypto map to the outside interface through which the tunnel traffic will flow to the tunnel peer. Applying the crypto map to an interface instructs the Cisco ASA appliance to evaluate all interface traffic against the crypto map set and to use the specified policy during connection or security association negotiations.

The examples in the following procedures create settings of Cisco ASA appliance Cisco-ASA-Appliance-1 used in Example of CloudBridge Connector Configuration and Data Flow.

To create an IKE policy by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following commands, starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ikev1 policy priority</td>
<td>Cisco-ASA-appliance-1(config)# crypto ikev1 policy 1</td>
<td>Enter IKE policy configuration mode and identify the policy to create. (Each policy is uniquely identified by the priority number you assign.) This example configures policy 1.</td>
</tr>
<tr>
<td>Command</td>
<td>Example</td>
<td>Command Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>encryption (3des)</td>
<td>aes</td>
<td>Specify the encryption algorithm. This example configures the 3DES algorithm.</td>
</tr>
<tr>
<td>hash (sha)</td>
<td>md5</td>
<td>Specify the hash algorithm. This example configures SHA.</td>
</tr>
<tr>
<td>authentication</td>
<td>pre-share</td>
<td>Specify the pre-share authentication method.</td>
</tr>
<tr>
<td>group 2</td>
<td></td>
<td>Specify 1024-bit Diffie-Hellman group identifier (2).</td>
</tr>
<tr>
<td>lifetime seconds</td>
<td></td>
<td>Specify the security association’s lifetime in seconds. This example configures 28800 seconds, which is the default value of lifetime in a Citrix ADC appliance.</td>
</tr>
</tbody>
</table>

To enable IKE on the outside interface by using the Cisco ASA command line

At the Cisco ASA appliance’s command prompt, type the following commands, starting in global configuration mode, in the order shown:
To create a tunnel group by using the Cisco ASA command line
At the Cisco ASA appliance’s command prompt, type the following commands, starting in global con-
figuration mode, as show in the attached pdf Tunnel Group using Cisco ASA command line:

To create a crypto access list by using the Cisco ASA command line
At the Cisco ASA appliance’s command prompt, type the following command in global configuration
mode, in the order shown:

To define a transform set by using the Cisco ASA command line
At the Cisco ASA appliance’s command prompt, type the following commands, starting in global con-
figuration mode. See Transform set using ASA command line table pdf.

To create a crypto map by using the Cisco ASA command line
At the Cisco ASA appliance’s command prompt, type the following commands starting in global con-
figuration mode, in the order shown:
<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto map map-name seq-num match address access-list-name</td>
<td>Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 match address 111</td>
<td>Create a crypto map and specify an access list to it. This example configures crypto map NS-CISCO-CM with sequence number 1 and assigns access list 111 to NS-CISCO-CM.</td>
</tr>
<tr>
<td>crypto map map-name seq-num set peer ip-address</td>
<td>Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 set peer 198.51.100.100</td>
<td>Specify the peer (Citrix ADC appliance) by its IP address. This example specifies 198.51.100.100, which is the tunnel endpoint IP address on the Citrix ADC appliance.</td>
</tr>
<tr>
<td>crypto map map-name seq-num set ikev1 transform-set transform-set-name</td>
<td>Cisco-ASA-appliance-1 (config)# crypto map NS-CISCO-CM 1 set ikev1 transform-set NS-CISCO-TS</td>
<td>Specify which transform set is allowed for this crypto map entry. This example specifies transform set NS-CISCO-TS.</td>
</tr>
</tbody>
</table>

To apply a crypto map to an interface by using the Cisco ASA command line

At the Cisco ASA appliance's command prompt, type the following commands starting in global configuration mode, in the order shown:

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
<th>Command Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto map map-name interface interface-name</td>
<td>Cisco-ASA-appliance-1(config)# crypto map NS-CISCO-CM interface outside</td>
<td>Apply the crypto map to the interface through which CloudBridge Connector tunnel traffic will flow. This example applies crypto map NS-CISCO-CM to interface outside.</td>
</tr>
</tbody>
</table>

**Configuring the Citrix ADC appliance for the CloudBridge Connector tunnel**

To configure a CloudBridge Connector tunnel between a Citrix ADC appliance and a Cisco ASA appliance, perform the following tasks on the Citrix ADC appliance. You can use either the Citrix ADC com-
mand line or the Citrix ADC graphical user interface (GUI):

- Create an IPSec profile.
- Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it.
- Create a PBR rule and associate it with the IP tunnel.

To create an IPSEC profile by using the Citrix ADC command line

At the command prompt, type:

```bash
add ipsec profile <name> -psk <string> -ikeVersion v1 -encAlgo AES -hashAlgo HMAC_SHA1 -perfectForwardSecrecy ENABLE
```

```
show ipsec profile <name>
```

**To create an IPSEC tunnel and bind the IPSEC profile to it by using the Citrix ADC command line

**At the command prompt, type:

```bash
add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC -ipsecProfileName <string>
```

```
show ipTunnel <name>
```

**To create a PBR rule and bind the IPSEC tunnel to it by using the Citrix ADC command line

**At the command prompt, type:

```bash
**add pbr** <pbrName> **ALLOW** -**srcIP** <subnet-range> -**destIP** <subnet-range>
```

```
**ipTunnel** <tunnelName>
```

```
**apply pbrs**
```

```
**show pbr** <pbrName>
```

To create an IPSEC profile by using the GUI

1. Navigate to System > CloudBridge Connector > IPSec Profile.
2. In the details pane, click Add.
3. In the Add IPSEC Profile page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
   - Perfect Forward Secrecy (Enable this parameter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click Create, and then click Close.

To create an IP tunnel and bind the IPSEC profile to it by using the GUI

1. Navigate to System > CloudBridge Connector > IP Tunnels.
2. On the IPv4 Tunnels tab, click Add.
3. In the Add IP Tunnel page, set the following parameters:
   • Name
   • Remote IP
   • Remote Mask
   • Local IP Type (In the Local IP Type drop-down list, select Subnet IP).
   • Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop
     down list. Select the desired IP from the list.)
   • Protocol
   • IPSec Profile
4. Click Create, and then click Close.

To create a PBR rule and bind the IPSEC tunnel to it by using the GUI

1. Navigate to System > Network > PBR.
2. On the PBR tab, click Add.
3. In the Create PBR page, set the following parameters:
   • Name
   • Action
   • Next Hop Type (Select IP Tunnel)
   • IP Tunnel Name
   • Source IP Low
   • Source IP High
   • Destination IP Low
   • Destination IP High
4. Click Create, and then click Close.

The corresponding new CloudBridge Connector tunnel configuration on the Citrix ADC appliance appears in the GUI. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

The following commands create settings of Citrix ADC appliance NS_Appliance-1 in “Example of a CloudBridge Connector Configuration.”:

```
1 > add ipsec profile NS_Cisco-ASA_IPSec_Profile -psk examplepresharedkey -ikeVersion v1 -encAlgo AES -hashalgo HMAC_SHA1 -lifetime 315360 -perfectForwardSecrecy ENABLE
2
3 Done
4
5 > add iptunnel NS_Cisco-ASA_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 -protocol IPSEC -ipsecProfileName NS_Cisco-ASA_IPSec_Profile
```
Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a Citrix ADC appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a Citrix ADC appliance, see Monitoring CloudBridge Connector Tunnels.

High Availability

April 23, 2019

A high availability (HA) deployment of two Citrix ADC appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.
With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.

The following figure shows a network configuration with an HA pair.

Figure 1. Citrix ADC Appliances in a High Availability Configuration

To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept Citrix ADC gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Points to consider for a high availability setup

April 23, 2019

Note

The following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary Citrix ADC appliances should be of the same model. Different Citrix ADC models are not supported in an HA pair (for example, you cannot configure a 10010 model and a 7000 model as an HA pair).

- In an HA setup, both nodes must run the same version of Citrix ADC, for example, nCore/nCore or classic/classic. If the nodes are running Citrix ADC classic and you want to migrate to Citrix ADCs nCore of the same Citrix ADC release, prop and sync are not supported during the migration process. Once migration is complete, prop and sync are auto-enabled. The same applies if you migrate from Citrix ADC nCore to Citrix ADC classic.

- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
  - The primary and the secondary systems must each be configured with their own unique IP addresses (NSIPs.)
In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.

- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.

- Initially, all Citrix ADC appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

One RPC node exists on each Citrix ADC. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each Citrix ADC requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

**Note:**

If the Citrix ADC appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.

For an IPv6 HA configuration, the following considerations apply:

- You must install the IPv6PT license on both Citrix ADC appliances.
- After installing the IPv6PT license, enable the IPv6 feature by using the GUI or the command line interface.
- Both Citrix ADC appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

**Configuring high availability**

April 23, 2019

To set up a high availability configuration, you create two nodes, each of which defines the other's Citrix ADC IP (NSIP) address as a remote node. Begin by logging on to one of the two Citrix ADC appliances that you want to configure for high availability, and add a node. Specify the other appliance's
Citrix ADC IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

**Note:**

The Citrix ADC GUI provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

**Figure 1. Two Citrix ADC Appliances Connected in a High Availability Configuration**

### Adding a remote node

To add a remote Citrix ADC appliance as a node in a high availability setup, you specify a unique node ID and the appliance’s NSIP. The maximum number of node IDs in an HA setup is 64. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

**Note:**

To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

### To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress>`
- `show ha node`

**Example**

```
1 > add ha node 10 203.0.113.32
```

### To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [-haMonitor ( ON | OFF )]`
- `show interface <ifNum>`

**Example**
To add a remote node by using the GUI

Navigate to System > High Availability and, on the Nodes tab, add a new remote node, or edit an existing node.

Disabling or Enabling a Node

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.

To disable or enable a node by using the command line interface

At the command prompt, type one of the following commands:

- `set ha node -hastatus DISABLED`
- `set ha node -hastatus ENABLED`

To disable or enable a node by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. In the High Availability Status list, select ENABLED (Actively Participate in HA) or DISABLED (Do not participate in HA).

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

`rm ha node <id>`

Example
To remove a node by using the GUI

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Configuring the communication intervals

April 23, 2019

The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair. Dead interval must be set as a multiple of hello interval.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- set HA node [-helloInterval <msecs>] [-deadInterval <secs>]
- show HA node <id>

To set the hello and dead intervals by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Set the following parameters:
   - Hello Interval (msecs)
   - Dead Interval (secs)

Configuring synchronization

April 23, 2019

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information.
between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.

Automatic synchronization is enabled by default. You can also force synchronization.

**Disabling or enabling synchronization**

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

**To disable or enable automatic synchronization by using the command line interface**

At the command prompt, type:

- `set HA node -haSync DISABLED`
- `set HA node -haSync ENABLED`

**To disable or enable synchronization by using the GUI**

1. Navigate to **System > High Availability**.
2. Under HA Synchronization, clear or select the **Secondary node will fetch the configuration from Primary** option.

**Forcing the secondary node to synchronize with the primary node**

In addition to automatic synchronization, the Citrix ADC supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.
- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.
To force synchronization by using the command line interface

At the command prompt, type:

```
force HA sync
```

To force synchronization by using the GUI

1. Navigate to System > High Availability.
2. On the Nodes tab, in the Action list, click Force Synchronization.

Synchronizing configuration files in a high availability setup

April 23, 2019

In a high availability setup, all configuration files are synchronised automatically from the primary node to the secondary node at an interval of one minute. Synchronizing configuration files can be performed manually by using the command line interface or the GUI at either the primary or the secondary node.

Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type:

```
sync HA files <mode>
```

Example

```
1 > Sync HA files all
2   Done
```
```
1 > Sync HA files ssl
2   Done
```

Parameter descriptions (of the command listed in the CLI procedure)

```
sync ha files <mode>
```
mode

Specify one of the following modes of synchronization.

- **all** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, and Application Firewall XML objects.
- **bookmarks** - Synchronize all Access Gateway bookmarks.
- **ssl** - Synchronize all certificates, keys, and CRLs for the SSL feature.
- **htmlinjection** - Synchronize all scripts configured for the HTML injection feature.
- **imports** - Synchronize all XML objects (for example, WSDLs, schemas, error pages) configured for the application firewall.
- **misc** - Synchronize all license files and the rc.conf file.
- **all_plus_misc** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, application firewall XML objects, licenses, and the rc.conf file.

**To synchronize files in a high availability setup by using the GUI**

Navigate to **System > Diagnostics** and, in the **Utilities** group, click **Start HA files synchronization**.

**Configuring command propagation**

April 23, 2019

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.

**Note**

After reenabling propagation, remember to force synchronization.

If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.
To disable or enable command propagation by using the command line interface

At the command prompt, type:

- `set HA node -haProp DISABLED`
- `set HA node -haProp ENABLED`

To disable or enable command propagation by using the GUI

1. Navigate to **System > High Availability** and, on the **Nodes** tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

Restricting high availability synchronization traffic to a VLAN

June 4, 2019

In a high availability (HA) deployment, traffic related to maintaining the HA configuration flows between the two HA nodes. This traffic is of the following types:

- Config synchronization
- Config propagation
- Connection mirroring
- Load balancing persistency config synchronization
- Persistent session synchronization
- Session state synchronization

Proper flow of this HA related traffic between the two nodes is critical for the functioning of the HA deployment. Typically, the HA related traffic is small in volume but can become very high during a failover. It becomes very high if stateful connection failover is enabled and the node that was primary before the failover was handling a large number of connections.

By default, the HA related traffic flows through the VLANs to which the NSIP address is bound. To accommodate a potential surge in this traffic, you can separate the HA related traffic from the management traffic and restrict its flow to a separate VLAN. This VLAN is called the HA SYNC VLAN.

Points to consider before Configuring an HA SYNC VLAN

- The configuration of an HA SYNC VLAN is neither propagated nor synchronized. In other words, the HA SYNC VLAN is node specific and is configured independently on each nodes.
- HA SYNC VLAN configuration is removed when you clear the configuration in only FULL mode.
- HA MON must be set to OFF for interfaces that are part of the HA SYNC VLAN, to avoid a situation in which both nodes function as the primary node.

- Management interfaces (for example, 0/1 and 0/2) must not be part of the HA SYNC VLAN, so that HA related traffic does not flow through management interfaces.

- Citrix recommends disabling high availability heartbeat messages on management interfaces and enabling on HA SYNC VLAN interfaces. After meeting these recommendations, high availability heartbeat messages can also be enabled on data interfaces.

For more information on disabling high availability heartbeat messages on interfaces, see Managing high availability heartbeat messages on a Citrix ADC appliance.

To configure an HA SYNC VLAN on a Citrix ADC node, specify a configured VLAN with the HA SYNC VLAN parameter of the local node entity.

To configure an HA SYNC VLAN on a local node by using the command line

At the command prompt, type:

- `set node -hasyncvlan <VLANID>`
- `show node`

Parameter Description

Hasyncvlan (Sync VLAN)

VLAN on which HA related traffic is sent. This includes traffic for synchronization, propagation, connection mirroring, load balancing persistency, configuration synchronization, persistent session synchronization, and session state synchronization. However, HA heartbeats can use any interface.

To configure an HA SYNC VLAN on a node by using the GUI

1. Navigate to System > High Availability.
2. Set the Sync VLAN parameter while modifying the local node.

Configuring fail-safe mode

April 23, 2019

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.
<table>
<thead>
<tr>
<th>Node A (Primary) Health State</th>
<th>Node B (Secondary) Health State</th>
<th>Default HA Behavior</th>
<th>Fail-Safe Enabled HA Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT_UP (failed last)</td>
<td>NOT_UP (failed first)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If both nodes fail, one after the other, the node that was the last primary remains primary.</td>
</tr>
<tr>
<td>NOT_UP (failed first)</td>
<td>NOT_UP (failed last)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Secondary), B (Primary)</td>
<td>If both nodes fail, one after the other, the node that was the last primary remains primary.</td>
</tr>
<tr>
<td>UP</td>
<td>UP</td>
<td>A (Primary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If both nodes pass the health check, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>UP</td>
<td>NOT_UP</td>
<td>A (Primary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If only the secondary node fails, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>NOT_UP</td>
<td>UP</td>
<td>A (Secondary), B (Primary)</td>
<td>A (Secondary), B (Primary)</td>
<td>If only the primary fails, no change in behavior with fail-safe enabled.</td>
</tr>
<tr>
<td>Node A (Primary) Health State</td>
<td>Node B (Secondary) Health State</td>
<td>Default HA Behavior</td>
<td>Fail-Safe Enabled HA Behavior</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------</td>
<td>---------------------</td>
<td>-----------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>NOT_UP</td>
<td>UP (STAYSECONDARY)</td>
<td>A (Secondary), B (Secondary)</td>
<td>A (Primary), B (Secondary)</td>
<td>If the secondary is configured as STAYSECONDARY, the primary remains primary even if it fails.</td>
</tr>
</tbody>
</table>

To enable fail-safe mode by using the command line interface

At the command prompt, type:

```
set HA node [-failsafe ( **ON** | **OFF** )]
```

Example

```
set ha node -failsafe ON
```

To enable fail-safe mode by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under Fail-Safe Mode, select the Maintain one Primary node even when both nodes are unhealthy option.

Configuring Virtual MAC Addresses

May 16, 2019

A virtual MAC address is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node’s MAC address.
When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the Citrix ADC appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a virtual MAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a virtual MAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a virtual MAC with the VRID as the last octet.

This section includes the following details:

- Configuring IPv4 virtual MACs
- Configuring IPv6 virtual MACs

### Configuring IPv4 virtual MACs

When you create a IPv4 virtual MAC address and bind it to a interface, any IPv4 packet sent from the interface uses the virtual MAC address that is bound to the interface. If there is no IPv4 virtual MAC bound to an interface, the interface's physical MAC address is used.

The generic virtual MAC is of the form 00:00:5e:00:01:<VRID>. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting virtual MAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

### Creating or modifying an IPv4 virtual MAC

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then bind the virtual MAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the virtual MAC configuration, you should display and examine the virtual MACs and the interfaces bound to the virtual MACs.

### To add a virtual MAC by using the command line interface

At the command prompt, type:

- `add vrID`
To bind interfaces to a virtual MAC by using the command line interface

At the command prompt, type:

- `bind vrid <id> -ifnum <interface_name>`
- `show vrID`

Example

```
1 > add vrID 100
2 Done
3 > bind vrid 100 -ifnum 1/1 1/2 1/3
4 Done
```

To unbind interfaces from a virtual MAC by using the command line interface

At the command prompt, type:

- `unbind vrid <id> -ifnum <interface_name>`
- `show vrID`

To configure a virtual MAC by using the GUI

Navigate to System > Network > VMAC and, on the VMAC tab, add a new virtual MAC, or edit an existing virtual MAC.

Removing an IPv4 virtual MAC

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove an IPv4 virtual MAC by using the command line interface

At the command prompt, type:

```
rm vrid <id>
```

Example

```
1 rm vrid 100s
```

To remove an IPv4 virtual MAC by using the GUI

Navigate to System > Network > VMAC and, on the VMAC tab, delete the IPv4 virtual MAC.
Configuring IPv6 virtual MAC6s

The Citrix ADC supports virtual MAC6 for IPv6 packets. You can bind any interface to a virtual MAC6, even if an IPv4 virtual MAC is bound to the interface. Any IPv6 packet sent from the interface uses the virtual MAC6 bound to that interface. If there is no virtual MAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a virtual MAC6

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then bind the virtual MAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the virtual MAC6 configuration, you should display and examine the virtual MAC6s and the interfaces bound to the virtual MAC6s.

To add a virtual MAC6 by using the command line interface

At the command prompt, type:

- `add vrID6 <id>`
- `bind vrID6 <id> -ifnum <interface_name>`
- `show vrID6`

Example

```
1 > add vrID6 100
2  Done
3 > bind vrID6 100 -ifnum 1/1 1/2 1/3
4  Done
```

To unbind interfaces from a virtual MAC6 by using the command line interface

At the command prompt, type:

- `unbind vrID6 <id> -ifnum <interface_name>`
- `show vrID6`

To configure a virtual MAC6 by using the GUI

Navigate to System > Network > VMAC and, on the VMAC6 tab, add a new virtual MAC6, or edit an existing virtual MAC6.
Removing a virtual MAC6

To remove an IPv4 virtual MAC, you delete its virtual router ID.

To remove a virtual MAC6 by using the command line interface

At the command prompt, type:

```
rm vrid6 <id>
```

Example

```
1  rm vrid6 100
```

To remove a virtual MAC6 by using the GUI

Navigate to System > Network > VMAC and, on the VMAC6 tab, delete the virtual router ID.

Configuring high availability nodes in different subnets

April 23, 2019

The following figure shows an HA deployment with the two systems located in different subnets:

Figure 1. High Availability over a Routed Network

In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The Citrix ADC appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

Note:

If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as SNIPs, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.
### NetScaler entities

<table>
<thead>
<tr>
<th>NetScaler entities</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPs (NSIP/SNIPs)</td>
<td>Node-specific. Active only on that node.</td>
</tr>
<tr>
<td>VIPs</td>
<td>Floating.</td>
</tr>
<tr>
<td>VLANs</td>
<td>Node-specific. Active only on that node.</td>
</tr>
<tr>
<td>Routes</td>
<td>Node-specific. Active only on that node. Link load balancing routes are floating.</td>
</tr>
<tr>
<td>ACLs</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>Dynamic routing</td>
<td>Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.</td>
</tr>
<tr>
<td>L2 mode</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>L3 mode</td>
<td>Floating (Common). Active on both nodes.</td>
</tr>
<tr>
<td>Reverse NAT (RNAT)</td>
<td>Node-specific. RNAT with VIP, because NATIP is floating.</td>
</tr>
</tbody>
</table>

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two Citrix ADC appliances and add a remote node representing the other appliance.

### Adding a Remote Node

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

### To add a node by using the command line interface

At the command prompt, type:

- `add ha node <id> <IPAddress> -inc ENABLED`
- `show ha node`

**Example**

```plaintext
1 > add ha node 3 10.102.29.170 -inc ENABLED
2 Done
```
To disable an HA monitor by using the command line interface

At the command prompt, type:

- `set interface <ifNum> [haMonitor ( **ON** | **OFF** )]
- `show interface <ifNum>

Example

1 > set interface 1/3 -haMonitor OFF
2 Done

To add a remote node by using the GUI

1. Navigate to System > High Availability and, on the Nodes tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.

Removing a Node

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

`rm ha node <id>

Example

1 > rm ha node 2
2 Done

To remove a node by using the GUI

Navigate to System > High Availability and, on the Nodes tab, delete the node.
Note:
You can use the Network Visualizer to view the Citrix ADC appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks.

Configuring route monitors

April 23, 2019

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a Citrix ADC appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

<table>
<thead>
<tr>
<th>Route Monitors in HA in non-INC mode</th>
<th>Route Monitors in HA in INC mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Route monitors are propagated by nodes and exchanged during synchronization.</td>
<td>Route monitors are neither propagated by nodes nor exchanged during synchronization.</td>
</tr>
<tr>
<td>Route monitors are active only in the current primary node.</td>
<td>Route monitors are active on both the primary and the secondary node.</td>
</tr>
<tr>
<td>The Citrix ADC appliance always displays the state of a route monitor as UP irrespective of the whether the route entry is present or not in the internal routing table.</td>
<td>The Citrix ADC appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.</td>
</tr>
</tbody>
</table>
Route Monitors in HA in non-INC mode

A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: reboot, failover, set route6 command for v6 routes, set route msr enable/disable command for v4 routes, adding a new route monitor.

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-Inc mode HA setup in a two-arm topology that has Citrix ADC appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

Figure 1.

With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1’s internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.
2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges heartbeat messages through switch SW3 at regular intervals.
3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

Adding a route monitor to a high availability node

A single procedure creates a route monitor and binds it to an HA node.

To add a route monitor by using the command line interface

At the command prompt, type:
Citrix ADC 13.0

- bind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [netmask])
- show HA node

Example

```plaintext
1 > bind HA node 0 -routeMonitor 10.102.71.0 255.255.255.0
2   Done
3 > bind HA node 0 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888
4   Done
```

To add a route monitor by using the GUI

Navigate to System > High Availability and, on the Route Monitors tab, click Configure.

Removing route monitors

To remove a route monitor by using the command line interface

At the command prompt, type:

- unbind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [netmask])
- show ha node

Example

```plaintext
1 unbind HA node 3 -routeMonitor 10.102.71.0 255.255.255.0
2 unbind HA node 3 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888
```

To remove a route monitor by using the GUI

Navigate to System > High Availability and, on the Route Monitors tab, delete the route monitor.

Limiting failovers caused by route monitors in non-INC mode

June 7, 2019

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.
However, for a node, you can limit the number of failovers for a given interval by setting the Maximum Number of Flips and Maximum Flip Time parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary (but node state as NOT UP) even if any route monitor fails on that node. This combination of HA state as Primary and Node state as NOT UP is called Stick Primary state.

If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the Maximum Number of Flips and Maximum Flip Time parameters on the node and starting the time specified in the Maximum Flip Time parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

- Parameters for limiting the number of failovers

  **Maximum Number of Flips (maxFlips)**

  Maximum number of failovers allowed, within the Maximum Flip Time interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

  **Maximum Flip Time (maxFlipTime)**

  Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:

- `set ha node [-maxFlips < positive_integer>] [-maxFlipTime <positive_integer>]
- `show ha node [<id>]`

To limit the number of failovers by using the GUI

1. Navigate to **System > High Availability** and, on the **Nodes** tab, open the local node.
2. Set the following parameters:
   - Maximum Number of Flips
   - Maximum Flip Time

   ```
   > set ha node -maxFlips 30 -maxFlipTime 60
   Done
   > sh ha node
   1) Node ID: 0
   IP: 10.102.169.82 (NS)
   Node State: UP
   Master State: Primary
   Fail-Safe Mode: OFF
   ```
SNMP Alarm for Sticky Primary State

Enable HA-STICKY-PRIMARY SNMP alarm in a node of a high availability set up if you want to be alerted of the node becoming sticky primary. When the node becomes sticky primary, it alerts by generating a trap message (stickyPrimary (1.3.6.1.4.1.5951.1.1.0.138)) and sends it to all the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see configuring the Citrix ADC to Generate SNMPv1 and SNMPv2 Traps.
Frequently Asked Questions

Consider an example of a high availability setup of two Citrix ADC appliances NS-1 and NS-2 in non-INC mode. Maximum numbers of flips and maximum flip time in both the nodes have been set with the same values.

The following table lists the settings used in this example:

<table>
<thead>
<tr>
<th>Entity</th>
<th>Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address of NS-1</td>
<td>10.102.173.211</td>
</tr>
<tr>
<td>IP address of NS-2</td>
<td>10.102.173.212</td>
</tr>
<tr>
<td>Maximum number of flips</td>
<td>2</td>
</tr>
<tr>
<td>Maximum flip time</td>
<td>200</td>
</tr>
</tbody>
</table>

For information about the maximum number of flips and maximum flip time settings, refer to the pdf.

Configuring failover interface set

April 23, 2019

A Failover Interface Set (FIS) is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. A FIS can also be configured for the nodes of a Citrix ADC cluster.

HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

Note:

An FIS does not create an active and standby configuration. It also does not prevent bridging loops when connecting to links to the same VLAN.

Note

An FIS does not create an active and standby Interfaces or channels. It also does not prevent bridging loops when connecting to links to the same VLAN
Creating or Modifying an FIS

To add an FIS and bind interfaces to it by using the command line interface

At the command prompt, type:

```
• add fis <name>
• bind fis \<name\> \<ifnum\> ...
• show fis \<name\>
```

Example

```
1 > add fis fis1
2   Done
3 > bind fis fis1 1/3 1/5
4   Done
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

To unbind an interface from an FIS by using the command line interface

At the command prompt, type:

```
• unbind fis \<name\> \<ifnum\> ...
• show fis \<name\>
```

Example

```
1 > unbind fis fis1 1/3
2   Done
```

To configure an FIS by using the GUI

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Removing an FIS

When the FIS is removed, its interfaces are marked as critical interfaces.
To remove an FIS by using the command line interface

At the command prompt, type:

```
rm fis <name>
```

Example

```
1  > rm fis fis1
2  Done
```

To remove an FIS by using the GUI

Navigate to **System > High Availability** and, on the **Failover Interface Set** tab, delete the FIS.

Understanding the causes of failover

April 23, 2019

The following events can cause failover in an high availability configuration:

1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note: 1.)

2. The primary node experiences a hardware failure of its SSL card.

3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.

4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note: 2.)

5. On the primary node, all interfaces in an FIS fail. (See Note: 2.)

6. On the primary node, an LA channel with HAMON enabled fails. (See Note: 2.)

7. On the primary node, all interfaces fail (see Note: 2). In this case, failover occurs regardless of the HAMON configuration.

8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.

9. You force a failover by issuing the force failover command on either node.

10. A route monitor that is bound to the primary node goes DOWN.
For more information about setting the dead interval, see Configuring the Communication Intervals. Possible causes for a node not receiving heartbeat packets from a peer node include:

- A network configuration problem prevents heartbeats from traversing the network between the HA nodes.
- The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.

In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the GUI. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

Forcing a node to fail over

April 23, 2019

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The Citrix ADC appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node.**

  If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.
If the secondary node is DOWN, the force failover command returns the following error message: “Operation not possible due to invalid peer state. Rectify and retry.”

If the secondary system is in the claiming state or inactive, it returns the following error message: “Operation not possible now. Please wait for system to stabilize before retrying.”

• **Forcing Failover on the Secondary Node.**

If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node’s health is good and it is not configured to stay secondary.

If the secondary node cannot become the primary node, or if secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message: “Operation not possible as my state is invalid. View the node for more information.”

• **Forcing Failover When Nodes Are in Listen Mode.**

When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

Before upgrading the system software on both nodes, you should test the new version on one of the nodes. To do this, you need to force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections need to be re-established.

To force failover on a node by using the command line interface

At the command prompt, type:

```plaintext
force HA failover
```

To force failover on a node by using the GUI

Navigate to **System > High Availability** and, on the **Nodes** tab, select the node, in the Action list, select **Force Failover.**

---

**Forcing the secondary node to stay secondary**

April 23, 2019

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the
secondary node to take over; you want it to remain the secondary node even if it detects a failure in
the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary
node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not
participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone
node, you must use this option before you can add a node to create an HA pair. When you add the
new node, the existing node continues to function as the primary node, and the new node becomes
the secondary node.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>
| When you force a system to remain secondary, the forcing process is not propagated or synchro-
| nized. It affects only the node on which you run the command. |

**To force the secondary node to stay secondary by using the command line interface**

At the command prompt, type:

```
set ha node -hastatus STAYSECONDARY
```

**To force the secondary node to stay secondary by using the GUI**

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY SEC-
ONDARY.

**Forcing the primary node to stay primary**

April 23, 2019

In an HA setup, you can force the primary node to remain primary even after a failover. You can enable
this option either on a primary node in an HA pair or on a standalone system.

On a standalone system, you must run this command before you can add a node to create an HA pair.
When you add the new node, it becomes the primary node. The existing node stops processing traffic
and becomes the secondary node in the HA pair.
To force the primary node to stay primary by using the command line interface

At the command prompt, type:

```
set ha node -hastatus STAYPRIMARY
```

To force the primary node to stay primary by using the GUI

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY PRIMARY.

Understanding the high availability health check computation

June 7, 2019

The following table summarizes the factors examined in a health check computation:

- State of the failover interface sets
- State of the critical interfaces
- State of the route monitors

The following table summarizes the health check computation.

<table>
<thead>
<tr>
<th>Failover interface sets</th>
<th>Critical interfaces</th>
<th>Route monitor</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Y</td>

## High Availability FAQs

April 23, 2019

1. **What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?**

   In an HA configuration, both nodes use the following ports to exchange HA related information:
   - UDP Port 3003, to exchange heartbeat packets.
   - Port 3010, for synchronization and command propagation.

2. **What are the conditions that trigger synchronization?**

   Synchronization is triggered by any of the following conditions:
   - The incarnation number of the primary node, received by the secondary, does not match that of the secondary node.
     
     Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
     a) All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
     b) All interface related commands. For example, set interface and unset interface.
     c) All channel-related commands. For example, add channel, set channel, and bind channel.
   - The secondary node comes up after a restart.
   - The primary node becomes secondary after a failover.

3. **What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?**
The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

4. What configurations are not synced nor propagated in an HA configuration in INC mode?

The following configurations are not synced or propagated. Each node has its own.

- MIPs
- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations.

5. Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

6. What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

7. Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

- The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
- After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
- Similar considerations apply to any time related decisions on the nodes.

8. What are the conditions for failure of the force HA sync command?

Forced synchronization fails in any of the following circumstances:

- You force synchronization when synchronization is already in progress.
- You force synchronization on a standalone Citrix ADC appliance.
• The secondary node is disabled.
• HA synchronization is disabled on the current secondary node.
• HA propagation is disabled on the current primary node and you force synchronization from the primary.

9. What are the conditions for failure of the `sync HA files` command?

Synchronizing configuration files fail in either of the following circumstances:
  • On a standalone system.
  • With the secondary node disabled.

10. In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the `force failover` command.

11. What are the conditions for failure of the force failover command?

A forced failover fails in any of the following circumstances:
  • You force failover on a standalone system.
  • The secondary node is disabled.
  • The secondary node is configured to remain secondary.
  • The primary node is configured to remain primary.
  • The state of the peer node is unknown.

**Troubleshooting high availability issues**

May 16, 2019

The most common high availability issues involve the high availability feature not working at all, or working only intermittently. Following are common high availability issues, and probable causes and resolutions.

• **Issue**
  The inability of the Citrix ADC appliances to pair the Citrix ADC appliances in a high availability setup.
  
  • **Cause**
    Network connectivity
  
  • **Resolution**
    Verify that both the appliances are connected to the switch and the interfaces are enabled.
- **Cause**
  Mismatch in the Password for the default Administrator account

  **Resolution**
  Verify that the password on both the appliances is the same.

- **Cause**
  IP conflict

  **Resolution**
  Verify that both the appliances have unique Citrix ADC IP (NSIP) address. The appliances should not have the same NSIP address.

- **Cause**
  Node ID mismatch

  **Resolution**
  Verify that the Node ID Configuration on both the appliances is unique. The appliances should not have the same Node ID configuration. Additionally, you must assign value for a Node ID between 1 and 64.

- **Cause**
  Mismatch in the password of the RPC node

  **Resolution**
  Verify that both the nodes have the same RPC node password.

- **Cause**
  An administrator has disabled the remote node

  **Resolution**
  Enable the remote node.

- **Cause**
  The Firewall application has blocked the heartbeat packets

  **Resolution**
  Verify that the UDP port 3003 is allowed.

- **Issue**
  Both the appliances claim to be the primary appliance.

  - **Cause**
    Missing heartbeat packets between the appliances

    **Resolution**
    Verify that the UDP port 3003 is not blocked for communication between the appliances.

- **Issue**
  The Citrix ADC appliance is not able to synchronize the configuration.

  - **Cause**
    A Firewall application is blocking the required port.

    **Resolution**
    Verify that the UDP port 3010 (or UDP port 3008 with secure synchronization) is not blocked.
for communication between the appliances.

- **Cause**
  An administrator has disabled synchronization.

  **Resolution**
  Enable synchronization on the appliance that has the issue.

- **Cause**
  Different Citrix ADC releases or builds are installed on appliances.

  **Resolution**
  Upgrade the appliances to the same Citrix ADC release or build.

**Issue**

Command propagation fails between the appliances.

- **Cause**
  A Firewall application is blocking the port.

  **Resolution**
  Verify that the UDP port 3011 (or UDP port 3009 with secure propagation) is not blocked for communication between the appliances.

- **Cause**
  An administrator has disabled command propagation.

  **Resolution**
  Enable command propagation on the appliance that has the issue.

- **Cause**
  Different Citrix ADC releases or builds are installed on appliances.

  **Resolution**
  Upgrade the appliances to the same Citrix ADC release or build.

**Issue**

The Citrix ADC appliances in the high availability pair are unable to run the force failover process.

- **Cause**
  The Secondary node is disabled.

  **Resolution**
  Enable the secondary node.

- **Cause**
  The Secondary node is configured to stay secondary.

  **Resolution**
  Set the secondary high availability status of the secondary node to Enable from Stay Secondary.

**Issue**

The secondary appliance does not receive any traffic after the failover process.

- **Cause**
  The upstream router does not understand GARP messages of Citrix ADC appliance.
Resolution
Configure virtual MAC address on the secondary appliance.

Managing high availability heartbeat messages on a Citrix ADC appliance

April 23, 2019

The two nodes in a high availability configuration send and receive heartbeat messages to and from each other on all interfaces that are enabled. The heartbeat messages flow regardless of the HA MON setting on these interfaces. If NSVLAN or both (NSVLAN and SYNC) are configured on an appliance, the heartbeat messages flow only through the enabled interfaces that are part of the NSVLAN and SYNCVLAN.

If a node does not receive the heartbeat messages on an enabled interface, it sends critical alerts to the specified Command Center and SNMP managers. These critical alerts give false alarms and draw unnecessary attention from the administrators for interfaces that are not configured as part of the connections to the peer node.

To resolve this issue, the HAHeartBeat option for interfaces and channels is used for enabling or disabling HA heartbeat-message flow on them.

To manage the high availability heartbeat messages on an interface by using the command line interface

At the command prompt, type:

- set interface <ID> [ -HAHeartBeat ( ON | OFF ) ]
- show interface <ID>

To manage the high availability heartbeat messages on a channel by using the command line interface

At the command prompt, type:

- set channel <ID> [ -HAHeartBeat ( ON | OFF ) ]
- show channel <ID>

To manage the high availability heartbeat messages for an interface by using the GUI

1. Navigate to System > Network > Interfaces.
2. Enable or disable the HA Heart Beat parameter.

To manage the high availability heartbeat messages on a channel by using the GUI

1. Navigate to System > Network > Channels.
2. Enable or disable the HA Heart Beat parameter.
Remove and Replace a Citrix ADC in a High Availability Setup

July 20, 2019

This topic helps you to address RMA replacements. Also, this topic has instructions on how to backup configurations, upgrade or downgrade shipped software version, and setup of RPC password on ADC.

Points to Consider

The following configurations are not synchronized or propagated in a high availability configuration in INC (Independent Network Configuration) or non-INC mode:

• All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
• All Interface related configuration commands. For example, set interface and unset interface.
• All channel related configuration commands. For example, add channel, set channel, and bind channel.
• All Interface HA Monitoring configuration commands.

The following configurations are not synced nor propagated in an HA configuration in INC mode (Independent Network Configuration):

• SNIPs
• VLANs
• Routes (except LLB routes)
• Route monitors
• RNAT rules (except any RNAT rule with VIP as the NAT IP)
• Dynamic routing configurations

Instructions

Complete the following steps to replace a Citrix ADC in high availability setup:

• Remove an Active Citrix ADC secondary node
• Configure Replacement secondary node
• Verify and Update the Software Build on Replacement ADC
• Set Password on New secondary to Match primary
• Add Licenses to Replacement ADC
• Creating HA Pair between primary and New secondary node
Remove an Active Secondary Node

1. Log on to both ADCs and run the following command to confirm which node is primary and which node is secondary:

```
1 show ha node
```

2. Log on to the primary ADC, backup the configurations on the primary node, and copy the files off of the ADC prior to the changes. These files are located under “/var/ns_sys_backup/” directory.

The steps are as follows:

a) Save the ADC running configurations to memory:

```
1 save ns config
```

b) Create the full backup file package:

```
1 create system backup -level full
```

c) Create the basic backup file package:

```
1 create system backup -level basic
```

3. After all backup files have been generated, be sure to copy them off of the device before proceeding.

From a windows terminal, open a Command Prompt and copy the backup files off of the ADC and onto your local hard drive. This can be done using the following command:

```
1 pscp <username>@<NSIP>:/<Target file source> <Target file destination>
```

Example:

```
1 pscp nsroot@10.125.245.78:/var/ns_sys_backup/backup_basic_10.125.245.78_2016_09_14_15_08.tgz c:\nsbackup\backup_basic_10.125.245.78_2016_09_14_15_08.tgz
```

When prompted, enter the password for the specified administrator account, then hit Enter. Repeat these steps until all backup bundles are copied to the local PC before proceeding.

4. SSH into the secondary ADC, and set the unit to the “STAYSECONDARY” status. This will force the unit to not attempt to assume the primary role in the event of a detected failure during the swap. Confirm that you are connected to the secondary ADC before executing this step.
5. Once the secondary ADC’s **Node State** successfully displays STAYSECONDARY, switch to the primary ADC and delete the secondary node and run the following command:

```
set ha node - haStatus <state>
set ha node - haStatus STAYSECONDARY
```

While logged into the primary ADC, run the following commands:

   a) Run the following command to identify which numerical value represents the secondary HA node:

```
show ha node
```

   b) Run the following command to remove the secondary ADC from the primary HA pair;

```
rm ha node <node ID>
```

c) Run the following command to save the configuration:

```
save ns config
```

d) With the secondary ADC now removed, shutdown, disconnect, and remove the secondary ADC from the network.

   **Note.** Be sure to label all connections before disconnecting.

### Configure Replacement Secondary Node

1. With the replacement ADC in place, power up the new device. DO NOT CONNECT the network connections at this point.

2. With boot-up complete, use the console port to connect to the ADC and configure the NSIP that you will use to connect to the unit.

   **Note.** In this example, we are using a different NSIP for the replacement ADC. If you wish to use the original secondary unit’s IP, You may change it on the replacement before binding the new ADC to the primary HA unit.

4. The ADC should now be booted. Now connect the network interface that will be used for Management traffic, and confirm that the IP address is reachable from your network.
Verify and Update the Software Build on Replacement ADC

Before syncing the new unit to the primary ADC, we need to ensure that both ADCs are running the same build.

1. To verify the version on ADC run the following command:

   ```
   show version
   ```

2. While on the new secondary ADC, create a subfolder in `/var` to be used for the upgrade.

3. Go to Citrix Downloads and download the appropriate package that matches the build version running on the primary ADC.

4. Download and extract the .tgz file:

   ```
   tar -xvzf "file.tgz"
   ```

5. Copy the extracted files to the secondary ADC. On your windows terminal, open a “Command Prompt” and navigate to the directory containing the extracted .tgz build package and run the following `pscp` command:

   ```
   pscp <Target file source> <username>@<NSIP>:<Target file destination>
   ```

   Example:

   ```
   C:\inetpub>pscp c:\inetpub\build-12.1-47.14_nc.tgz nsroot@10.20.245.80:/var/NS_upg_12.1_47.14/build-12.1-47.14_nc.tgz
   ```

6. After the file has been transferred, return to the secondary ADC and upgrade. For detailed instructions, see Upgrading a Citrix ADX Standalone Appliance.

7. Once the new secondary has rebooted, SSH back into the unit and confirm that the upgrade is successful and the build matches that of the primary.

Set Password on Replacement Secondary Node to Match Primary

Note: If at this point you want to change the management IP (NSIP) address of the new secondary ADC, you may do so before moving forward.

Change the password on the new secondary ADC to match the password that is currently on the primary ADC.

1. Make that the default administrator (nsroot) account password is the same as the primary ADC. This is accomplished using the following command while logged in through SSH into the new secondary unit:
**Add Licenses to Replacement Secondary Node**

With the new ADC updated and ready for pairing, download and install the appropriate licensing for the replacement node.

1. Navigate to https://www.mycitrix.com to request and download licenses for the new replacement unit.

2. Once you have all appropriate licenses downloaded, SSH into the new secondary ADC and type the following command to see the current state of licensing:

   ```
   show license
   ```

3. From the Windows terminal command prompt you must now upload the license files to the new secondary ADC using the following command:

   **Note.** If you have multiple licenses, repeat this step until all licenses are uploaded.

   ```
   pscp <Target file source> <username>@<NSIP>:<Target file destination>
   ```

   **Example:**

   ```
   \C:\inetpub> pscp c:\inetpub\NS-VPX-3K-LIC-020030ad0024.lic nsroot@10.125.245.80:/nsconfig/license/NS-VPX-3K-LIC-020030ad0024.lic
   ```

4. SSH into the new secondary ADC and perform a warm reboot using the following command:

   ```
   reboot -w
   ```

   After the unit is restarted, SSH into the unit and run show license command once again. At this point, the licenses should be applied.

**Set up High Availability between primary and New Secondary Node**

At this point, we are now ready to join the Citrix ADC units into a high availability pair. For more information, see Configuring high availability.
TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.

**Congestion Control Strategies**

The Transmission Control Protocol (TCP) has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

**Proportional Rate Recovery (PRR) algorithm**

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

**TCP Fast Open (TFO)**

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP's initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a Citrix ADC appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the Citrix ADC appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using this TFO mechanism, you can reduce an application's network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

**How TFO works**

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the Citrix ADC appliance can include data in the SYN-ACK segment even though it has not received the final ACK.
A client and a backend server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the Citrix ADC appliance.
2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client’s IP address under a secret key) and responds to the client with a SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.
4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached Fast Open Cookie (as a TCP option) along with HTTP data.
5. The Citrix ADC appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with a SYN-ACK, TFO Cookie, and HTTP Response.

**Note:**
If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the Citrix ADC appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.
2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the backend server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same backend server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the backend server.
6. The backend server acknowledges the event with both data and a SYN.

**Note:** If the server acknowledges the event with only a SYN segment, the Citrix ADC appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.
Configuring TCP fast open

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

Enable or disable TFO by using the CLI

At the command prompt, type one of the following commands to enable or disable TFO in a new or existing profile.

Note: The default value is DISABLED.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add tcpprofile</td>
<td>Enable TFO</td>
</tr>
<tr>
<td>set tcpprofile</td>
<td>Disable TFO</td>
</tr>
<tr>
<td>unset tcpprofile</td>
<td>Remove TFO from profile</td>
</tr>
</tbody>
</table>

Examples

1. add tcpprofile Profile1 - tcpFastOpen
2. set tcpprofile Profile1 - tcpFastOpen Enabled
3. unset tcpprofile Profile1 - tcpFastOpen

To set TCP Fast Open cookie timeout value by using the command line interface

At the command prompt, type:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>set tcpparam - tcpfastOpenCookieTimeout</td>
<td>Set TCP Fast Open Cookie Timeout</td>
</tr>
<tr>
<td>Example</td>
<td></td>
</tr>
</tbody>
</table>

Example

1. set tcpparam - tcpfastOpenCookieTimeout 30 secs

To configure the TCP Fast Open by using the GUI

1. Navigate to Configuration > System > Profiles > and then click Edit to modify a TCP profile.
2. On the Configure TCP Profile page, select the TCP Fast Open checkbox.
3. Click OK and then Done.

To configure the TCP Fast Cookie timeout value by using the GUI

Navigate to Configuration > System > Settings > Change TCP Parameters and then Configure TCP Parameters page to set the TCP Fast Open Cookie timeout value.
TCP Hystart

A new TCP profile parameter, hystart, enables the Hystart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

If congestion is detected, Hystart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.

Configuring TCP Hystart

To use the Hystart feature, enable the Cubic Hystart option in the relevant TCP profile.

To configure Hystart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable Hystart in a new or existing TCP profile.

```
1  add tcpprofile <profileName> -hystart ENABLED
2  set tcpprofile <profileName> -hystart ENABLED
3  unset tcprofile <profileName> -hystart
```

Examples:

```
1  add tcpprofile profile1 -hystart ENABLED
2  set tcpprofile profile1 -hystart ENABLED
3  unset tcprofile profile1 -hystart
```

To configure Hystart support by using the GUI

1. Navigate to Configuration > System > Profiles > and click Edit to modify a TCP profile.
2. On the Configure TCP Profile page, select the Cubic Hystart check box.
3. Click OK and then Done.

TCP burst rate control

It is observed that TCP control mechanisms can lead to a bursty traffic flow on high speed mobile networks with a negative impact on the overall network efficiency. Due to mobile network conditions such as congestion or Layer-2 retransmission of data, TCP acknowledgements arrive clumped at the sender triggering a burst of transmission. These group of consecutive packets sent with a short inter-packet gaps it is called TCP packet burst. To overcome traffic burst, the Citrix ADC appliance uses a
TCP Burst Rate Control technique. This technique evenly spaces data into the network for an entire round-trip-time so that the data is not sent into a burst. By using this burst rate control technique, you can achieve better throughput and lower packet drop rates.

**How TCP burst rate control works**

In a Citrix ADC appliance, this technique evenly spreads the transmission of a packets across the entire duration of the round-trip-time (RTT). This is achieved by using a TCP stack and network packet scheduler that identifies the various network conditions to output packets for ongoing TCP sessions in order to reduce the bursts.

At the sender, instead of transmitting packets immediately upon receipt of an acknowledgment, the sender can delay transmitting packets to spread them out at the rate defined by scheduler (Dynamic configuration) or by the TCP profile (Fixed configuration).

**Configuring TCP burst rate control**

To use the TCP Burst Rate Control option in the relevant TCP profile and set the burst rate control parameters.

**To set TCP burst rate control by using the command line**

At the command prompt, set one of the following TCP Burst Rate Control commands are configured in a new or existing profile.

**Note:** The default value is DISABLED.

```
1 add tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed
2 set tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed
4 unset tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed
```

where,

Disabled – If the Burst rate control is disabled, then a Citrix ADC appliance does not perform burst management other than the maxBurst setting.

Fixed – If the TCP burst rate control is Fixed, the appliance uses the TCP Connection Payload Send Rate value mentioned in the TCP Profile.
Dynamic – If the Burst Rate Control is “Dynamic” the connection is being regulated based on various network conditions to reduce TCP bursts. This mode works only when the TCP connection is in END-POINT mode. When Dynamic Burst Rate control is enabled the maxBurst parameter of the TCP profile is not in effect.

```
1 add tcpProfile profile1 -burstRateControl Disabled
2 set tcpProfile profile1 -burstRateControl Dynamic
3 unset tcpProfile profile1 -burstRateControl Fixed
```

**To set TCP Burst Rate Control parameters by using the command line interface**

At the command prompt, type:

```
1 set ns tcpprofile nstcp_default_profile -burstRateControl <type of burst rate control> -tcprate <TCP rate> -rateqmax <maximum bytes in queue>
2 T1300-10-2> show ns tcpprofile nstcp_default_profile
3 Name: nstcp_default_profile
4 Window Scaling status: ENABLED
5 Window Scaling factor: 8
6 SACK status: ENABLED
7 MSS: 1460
8 MaxBurst setting: 30 MSS
9 Initial cwnd setting: 16 MSS
10 TCP Delayed-ACK Timer: 100 millisecc
11 Nagle’s Algorithm: DISABLED
12 Maximum out-of-order packets to queue: 15000
13 Immediate ACK on PUSH packet: ENABLED
14 Maximum packets per MSS: 0
15 Maximum packets per retransmission: 1
16 TCP minimum RTO in millisecc: 1000
17 TCP Slow start increment: 1
18 TCP Buffer Size: 8000000 bytes
19 TCP Send Buffer Size: 8000000 bytes
20 TCP Syncookie: ENABLED
21 Update Last activity on KA Probes: ENABLED
22 TCP flavor: BIC
23 TCP Dynamic Receive Buffering: DISABLED
24 Keep-alive probes: ENABLED
25 Connection idle time before starting keep-alive probes: 900 seconds
```
Keep-alive probe interval: 75 seconds
Maximum keep-alive probes to be missed before dropping connection: 3
Establishing Client Connection: AUTOMATIC
TCP Segmentation Offload: AUTOMATIC
TCP Timestamp Option: DISABLED
RST window attenuation (spoof protection): ENABLED
Accept RST with last acknowledged sequence number: ENABLED
SYN spoof protection: ENABLED
TCP Explicit Congestion Notification: DISABLED
Multipath TCP: DISABLED
Multipath TCP drop data on pre-established subflow: DISABLED
Multipath TCP fastopen: DISABLED
Multipath TCP session timeout: 0 seconds
DSACK: ENABLED
ACK Aggregation: DISABLED
FRTO: ENABLED
TCP Max CWND : 4000000 bytes
FACK: ENABLED
TCP Optimization mode: ENDPOINT
TCP Fastopen: DISABLED
HYSTART: DISABLED
TCP dupack threshold: 3
Burst Rate Control: Dynamic
TCP Rate: 0
TCP Rate Maximum Queue: 0

To configure the TCP Burst Rate Control by using the GUI

1. Navigate to Configuration > System > Profiles > and then click Edit to modify a TCP profile.
2. On the Configure TCP Profile page, select TCP Burst Control option from the drop-down list:
   a) BurstRateCtrl
   b) CreditBytePrms
   c) RateBytePerms
   d) RateSchedulerQ
3. Click OK and then Done.

Protection against wrapped sequence (PAWS) algorithm

If you enable the TCP timestamp option in the default TCP profile, the Citrix ADC appliance uses the Protection Against Wrapped Sequence (PAWS) algorithm to identify and reject old packets whose se-
quence numbers are within the current TCP connection's receive window because the sequence has “wrapped” (reached its maximum value and restarted from 0).

If network congestion delays a non-SYN data packet and you open a new connection before the packet arrives, sequence-number wrapping might cause the new connection to accept the packet as valid, leading to data corruption. But if the TCP timestamp option is enabled, the packet is discarded.

By default, the TCP timestamp option is disabled. If you enable it, the appliance compares the TCP timestamp (SEG.TSval) in a packet's header with the recent timestamp (Ts.recent) value. If SEG.TSval is equal to or greater than Ts.recent, the packet is processed. Otherwise, the appliance drops the packet and sends a corrective acknowledgement.

**How PAWS works**

The PAWS algorithm processes all the incoming TCP packets of a synchronized connection as follows:

1. If SEG.TSval < Ts.recent: The incoming packet is not acceptable. PAWS sends an acknowledgement (as specified in RFC-793) and drops the packet. Note: Sending an ACK segment is necessary in order to retain TCP's mechanisms for detecting and recovering from half-open connections.
2. If packet is outside the window: PAWS rejects the packet, as in normal TCP processing.
3. If SEG.TSval > Ts.recent: PAWS accepts the packet and processes it.
4. If SEG.TSval <= Last.ACK.sent (arriving segment satisfies): PAWS must copies SEG.TSval value to Ts.recent (is it copied to Ts.Recent field in the db?).
5. If packet is in sequence: PAWS accepts the packet.
6. If packet is not in sequence: The packet is treated as a normal in-window, out-of-sequence TCP segment. For example, it might be queued for later delivery.
7. If Ts.recent value is idle for more than 24 days: The validity of Ts.recent is checked if the PAWS timestamp check fails. If the Ts.recent value is found to be invalid, the segment is accepted and the PAWS rule updates Ts.recent with the TSval value from the new segment.

**To enable or disable TCP timestamp by using the command line interface**

At the command prompt, type:

```
set nstcpprofile nstcp_default_profile -TimeStamp (ENABLED | DISABLED)
```

**To enable or disable TCP timestamp by using the GUI**

Navigate to System > Profile > TCP Profile, select the default TCP profile, click Edit, and select or clear the TCP timestamp check box.
Optimization Techniques

TCP uses the following optimization techniques and methods for optimized flow controls.

Policy based TCP Profile Selection

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server’s traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

For information about using subscriber attributes to perform TCP optimization, see Policy-based TCP Profile.

Configuring policy based TCP profile selection

Configuring policy based TCP profile selection consists of the following tasks:

- Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.
- Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
- Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your Citrix ADC ADC can distinguish the connections and bind the correct AppQoE action to each policy.
- Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

- `enable ns feature appqoe`
- `show ns feature`
To bind a TCP profile while creating an AppQoE action using the command line interface

At the command prompt, type the following AppQoE action command with tcpprofiletobind option.

```
add appqoe action <name> [-priority <priority>] [-respondWith ( ACS | NS ) [<CustomFile>]] [-altContentSvcName <string>] [-altContentPath <string>] [-maxConn <positive_integer>] [-delay <usecs>] [-polqDepth <positive_integer>] [-priqDepth <positive_integer>] [-dosTrigExpression <expression>] [-dosAction ( SimpleResponse | HICResponse )] [-tcpprofiletobind <string>]
```

To configure an AppQoE policy by using the command line interface

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:

```
bind cs vserver <name> -policyName <appqoe_policy_name> -priority <priority>
bind lb vserver <name> -policyName <appqoe_policy_name> -priority <priority>
bind cr vserver <name> -policyName <appqoe_policy_name> -priority <priority>
```

Example

```
1 add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle ENABLED -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 500 -slowStartIncr 1 -bufferSize 4194304 -flavor BIC -KA ENABLED -sendBuffsize 4194304 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -dsack enabled -frto ENABLED -maxcwnd 4000000 -fack ENABLED -tcpmode ENDPOINT
2 add appqoe action appact1 -priority HIGH -tcpprofile tcp1
3 add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -action appact1
4 bind lb vserver lb2 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST
5 bind cs vserver cs1 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST
```
Configuring policy based TCP profiling using the GUI

To enable AppQoE by using the GUI

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the AppQoE check box.
4. Click OK.

To configure AppQoE policy by using the GUI

1. Navigate to App-Expert > AppQoE > Actions.
2. In the details pane, do one of the following:
3. To create a new action, click Add.
4. To modify an existing action, select the action, and then click Edit.
5. In the Create AppQoE Action or the Configure AppQoE Action screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring the AppQoE Action” as follows (asterisk indicates a required parameter):
   a) Name—name
   b) Action type—respondWith
   c) Priority—priority
   d) Policy Queue Depth—polqDepth
   e) Queue Depth—priqDepth
   f) DOS Action—dosAction
6. Click Create.

To bind AppQoE policy by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, select a server and then click Edit.
2. In the Policies section and click (+) to bind an AppQoE policy.
3. In the Policies slider, do the following:
   a) Select a policy type as AppQoE from the drop-down list.
   b) Select a traffic type from the drop-down list.
4. In the Policy Binding section, do the following:
   a) Click New to create a new AppQoE policy.
   b) Click Existing Policy to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click Bind to the policy to the virtual server.
6. Click Done.
SACK block generation

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgement (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

Note: A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

Client reneging

A Citrix ADC appliance can handle client reneging during SACK based recovery.

Memory checks for marking end_point on PCB is not considering total available memory

In a Citrix ADC appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

Unnecessary retransmissions due to missing SACK blocks

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers additional retransmissions from the server.

SNMP for number of connections bypassed optimization because of overload

The following SNMP ids have been added to a Citrix ADC appliance to track number of connections bypassed TCP optimization due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.131 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.
**Dynamic receive buffer**

To maximize TCP performance, a Citrix ADC appliance can now dynamically adjust the TCP receive buffer size.

**Tail Loss Probe algorithm**

A retransmission timeout (RTO) is a loss of segments at the tail end of a transaction. An RTO occurs if there are application latency issues, especially in short web transactions. To recover loss of segments at the end of a transaction, TCP uses Tail Loss Probe (TLP) algorithm. TLP is a sender only algorithm. If a TCP connection is not receiving any acknowledgement for a certain period, TLP transmits the last unacknowledged packet (loss probe). In the event of a tail loss in original transmission, acknowledge from loss probe triggers a SACK or FACK recovery.

**Configuring Tail Loss Probe**

To use the Tail Loss Probe (TLP) algorithm, you must enable the TLP option in the TCP profile and set the parameter to a value that suits the security requirement for that profile.

**Enable TLP by using the command line**

At the command prompt, type one of the following commands to enable or disable TLP in a new or existing profile.

```
add tcpprofile <TCP Profile Name> - taillossprobe ENABLED | DISABLED
set tcpprofile <TCP Profile Name> - taillossprobe ENABLED | DISABLED
unset tcpprofile <TCP Profile Name> - taillossprobe
```

**Examples:**

```
add tcpprofile nstcp_default_profile - taillossprobe
set tcpprofile nstcp_default_profile -taillossprobe Enabled
unset tcpprofile nstcp_default_profile -taillossprobe
```

**Configure Tail Loss Probe algorithm by using the Citrix ADC GUI**

1. Navigate to **Configuration > System > Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Tail Loss Probe** checkbox.
3. Click **OK** and then **Done**.

**Troubleshooting Citrix ADC**

April 23, 2019

This topic gives you some basic troubleshooting solutions needed to resolve issues that occur in your appliance. It gives you an understanding of NetScaler appliance, how it integrates with the network, and what issues you can expect in basic system features.

**How to record a packet trace on Citrix ADC**

April 23, 2019

This troubleshooting article explains how an administrator can record a network packet trace using the Citrix ADC GUI.

**Points to remember**

- Citrix recommends you to use the recent Wireshark version from the “automated build section” available in the following web page: [http://www.wireshark.org/download/automated](http://www.wireshark.org/download/automated).
- In Citrix ADC software release 10.5 and later, to decrypt the capture, ensure that ECC (Elliptic Curve Cryptography), Session Reuse and DH Param are disabled/removed from the virtual server before the trace is captured. Refer to the Additional Resources section of this article before making these changes.

**Record packet trace on NetScaler 11.1 appliance**

To record a packet trace on a NetScaler 11.1 appliance, you must complete the following procedure.

1. Sign into NetScaler GUI and navigate to **System > Diagnostics** page.
2. Click the **Start new trace** link in the **Diagnostics** page, as shown in the following screenshot.
3. Update the packet size to 0 in the **Packet size** field.
4. Click **Start** to start recording the network packet trace.
5. Click **Stop and Download** to stop recording the network packet trace after the test is complete.

6. Select the required file and click **Select** and click **Download**.

7. Open the network packet trace file with the Wireshark utility to display the content of the file.

**Record packet trace on NetScaler 10.5 appliance**

To record a packet trace on a NetScaler 10.5 appliance, you must complete the following procedure:

1. Sign into NetScaler GUI and navigate to **System > Diagnostics** page.

2. Click the **Start new trace** link under **Technical Support Tools** as shown in the following screenshot.

3. Update the packet size to 0 in the **Packet Size** field.

   **Note:** If NetScaler headers are not required then select Capture trace in .pcap format.

4. Click **Start** to start recording the network packet trace.

5. Click **OK** to stop recording the network packet trace after the test is complete.

   An nstrace.cap file is generated, which contains the network packet trace.

6. Highlight the required file and click **Download**.

7. Specify a destination and save the packet trace.

8. Open the network packet trace file with the Wireshark utility to display the content of the file.

   **Note:** Select Decrypted SSL packets (SSLPLAIN) to decrypt the packet trace without the private key.

**Capture SSL master keys**

In the latest 11.0 and 11.1 version and above there is an option to capture the session keys which will be valid for only for that particular session/nstrace and this option can be used if you donot want to share the private key or use SSLPLAIN mode. For more information please refer to **How to use the new “capsslkeys” option when trying to capture nstrace on Netscaler**.

**Export Session Keys without sharing Private key**

In most of the scenarios the private key is not available or shared. In such scenarios we can suggest to export the SSL session keys instead of the private key. Please refer to the below article for more information.

**How to Export and Use SSL Session Keys to Decrypt SSL Traces Without Sharing the SSL Private Key**.
**Filters**

Additionally, it is always recommended to add IP based filters while taking traces. This will ensure that you will capture only interested traffic which will further ease your troubleshooting. Adding filters will also decrease the load on NetScaler while taking traces.

You will find the option to configure filters on the same page:

```
screenshot
```

Simple IP based filters are enough to get the right captures. For a detailed list of filters and examples, refer to Citrix Documentation - nstrace.

**Use case to capture a packet trace with virtual server IP filter (both frontend and backend)**

With a filter of the virtual server IP address and enabling the option “-link” in CLI or select the option “Trace filtered connection peer traffic” in GUI (available 10.1 and above), you will be able to capture both the front end and backend traffic for that particular IP address. With this option it is not recommended to mention a source IP or destination IP filter.

```
start nstrace -size 0 -filter "CONNECTION.IP.EQ(1.1.1.1)" -link ENABLED
```

```
State: RUNNING Scope: LOCAL TraceLocation:
"/var/nstrace/24Mar2017_16_00_19/..." Nf: 24
Time: 3600 Size: 0
Mode: TXB NEW_RX
```

```
Traceformat: NSCAP PerNIC: DISABLED FileName: 24 Mar2017_16_00_19 Filter: "CONNECTION.IP.EQ(1.1.1.1)" Link: ENABLED Merge: ONSTOP Runtimecleanup: ENABLED
```

```
TraceBuffers: 5000 SkipRPC: DISABLED Capsslkeys: DISABLED InMemoryTrace: DISABLED
```

**Capturing cyclic traces**

It is always challenging to troubleshoot an intermittent issue. Cyclic tracing is best suited for issues which are intermittent. These traces can be run over a span of few hours or days based on the occurrence of the issue. Also a specific filter can be used as mentioned above. Please evaluate the size of the trace files that are being generated before running it for a longer time (as this can fill up the var space).

Run the following command from CLI:
**Best Practices**

On a unit handling gigabytes of traffic per second, capturing traffic is a very resource intensive process. The impact to resources is mainly in terms of CPU and Disk Space. Disk Space impact can be reduced by using filtering expressions (capturing traffic only related to a particular IP). However the impact on CPU remains despite using expressions and in some cases might cause a slight further increase as NetScaler now needs to process packets according to the filter before capturing them.

The best practice with regards to tracing are:

1. The duration for which the trace is run should be as limited as possible while still ensuring the packets of interest are captured.
2. Schedule the tracing activity to happen at a time when the number of users (and hence the traffic) is greatly reduced, such as during off hours.

**Additional resources**

**Disable session reuse on virtual server from NetScaler GUI**

Session reuse is disabled while capturing a trace in order to capture a complete SSL handshake in the trace. When it is enabled it is likely that you will only capture a partial handshake in the trace. Ensure to enable the option after trace collection.

Do not disable SSL session reuse when the persistence method is ssslsession, as it will break the persistence for existing connections. For more information refer to [CTX121925- SSL Renegotiation Process and Session Reuse on NetScaler appliance](#).

1. Open the virtual server and navigate to SSL Parameters.
2. Disable Enable Session Reuse if enabled.

**Disable session reuse on virtual server from NetScaler CLI**

1. SSH to the NetScaler.

---

```
1  start nstrace -nf 60 -time 30 -size 0
2  This particular trace will create 60 files each of them for 30 sec. This means the files will start getting overwritten after 60 trace files or 30 mins
3  Show nstrace à To check the status of the nstrace
4  Stop nstrace à To stop the nstrace.
```
2. Run the following command to disable DH Param from the virtual server:

```
set ssl vserver "vServer_Name"-sessReuse DISABLED
```

**Disable DH parameter on virtual server from NetScaler GUI**

Refer to CTX213335 - How do I setup a Diffie-Hellman key on NetScaler? to understand about DH Parameter.

1. Open the virtual server and navigate to SSL Parameters.
2. Disable DH Param if enabled.

**Disable DH parameter on virtual server from NetScaler CLI**

1. SSH to the NetScaler.
2. Run the following command to disable DH Param from the virtual server:

```
set ssl vserver "vServer_Name"-dh DISABLED
```

**Disable ECC curve on virtual server from NetScaler GUI**

ECC curve are disabled in order to decrypt the captured SSL trace with private key. These keys should not be disabled if the related SSL ciphers are used. For more information on ECC curve refer to CTX20 - How Do I Setup ECC on NetScaler?

1. Open the virtual server and navigate to ECC Curve.
2. If no ECC Curve is bound to the virtual server then no other action is required.
3. If any ECC Curve is bound to the virtual server then click the ECC Curve and Unbind it from the virtual server.

**Disable ECC curve on virtual server from NetScaler CLI**

1. SSH to the NetScaler.
2. Run the following command for each ECC Curve bound to the virtual server:

```
unbind ssl vserver "vServer_Name"-eccCurveName "ECC_Curve_Name"
```
How to free space on /var directory for logging issues with a Citrix ADC appliance

April 23, 2019

This troubleshooting article explains how an administrator can free space from the /var directory of a Citrix ADC appliance when you are unable to log on to the Citrix GUI.

When the amount of disk space is low in /var directory of the appliance, you might not be able to sign in to the Citrix GUI. In this scenario, you can remove the old log files to create free space in /var directory.

Points to remember

- Ensure that you back up the files before removing the files from the appliance.

To free space in the /var directory of a NetScaler appliance, complete the following procedure:

1. Log on to the Command Line Interface (CLI) of NetScaler by using SSH. For more information to complete this task, refer to Citrix ADC Documentation.
2. After you log on to NetScaler CLI, switch to the shell prompt using the following command.
3. Run the following command to see the availability of space on NetScaler appliance.
4. If the capacity of the /var directory is less than 90 percent or very low, then you must delete few files from this directory.
   - Run the following commands to view the contents of the /var directory:
     ```
     cd /var
     ls -l
     ```
   The directories that are usually of interest are as follows:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var/ntrace</td>
<td>This directory contains trace files. This is the most common reason for HDD being filled on the NetScaler. This is due to an ntrace being left running for indefinite amount of time. All traces that are not of interest can and should be deleted. To stop an ntrace, go back to the CLI and issue stop ntrace command.</td>
</tr>
<tr>
<td>/var/log</td>
<td>This directory contains system specific log files.</td>
</tr>
<tr>
<td>/var/nslog</td>
<td>This directory contains NetScaler log files.</td>
</tr>
</tbody>
</table>
/var/tmp/support - This directory contains technical support files, also known as, support bundles. All files not of interest should be deleted.

/var/core - Core dumps are stored in this directory. There will be directories within this directory and they will be labeled with numbers starting with 1. These files can be quite large in size. Clear all files unless the core dumps are recent and investigation is required.

/var/crash - Crash files, such as process crashes are stored in this directory. Clear all files unless the crashes are recent and investigation is required.

/var/nsinstall - Firmware is placed in this directory when upgrading. Clear all files, except the firmware that is currently being used.

- Verify if any of the directories are using more space:

du -hs *
44k cache
2.0k clustered
2.0k configdb
6.0k core
989M crash
4.0k cron
2.0k dev
6.0k download
2.0k gui
2.0k install
2.0k krb
2.0k learnt_data
122M log
366M netscaler
14k ns_gui
86k ns_sys_backup
631M nsinstall
883M nslog
32k nsproflog
2.0k nssynclog
16k nstemplates
36k nstmp
4.5G nstrace
8.1M opt
6.0k pubkey
52k run
28M safenet
72M tmp
2.0k vmtools
14k vpn

- Delete the files which are not required:

```
$ rm -r nstrace/*
```

For more help on deleting files refer to FreeBSD Man Pages.

- If the log or nslog directory is using more space, then run the following commands to open the log directory and view its contents:
  - Delete the files which are not required.
    ```
    $ rm -r nstrace/*
    
    For more help on deleting files refer to FreeBSD Man Pages.
    
    - If the log or nslog directory is using more space, then run the following commands to open the log directory and view its contents:
      ```
      1. cd /var/log
      2. ls -l
      3. cd /var/nslog
      4. ls -l
      ```

1. Ensure that all files are compressed. This is indicated by the .tar.gz file extension.
2. If you are using NetScaler MAS or Command Center, then verify the /var/ns_system_backup directory. Ensure that NetScaler MAS or Command Center clears the backup files it creates.

**Additional Resources**

For information on any of the commands mentioned in the preceding procedure, refer to [ss64.com/bash/](http://ss64.com/bash/)

**How to download core or crashed files from Citrix ADC appliance**

April 23, 2019
This troubleshooting article explains how an administrator can download core or crash files from the Citrix ADC GUI.

**Download core or crash files from Citrix ADC appliance**

To download files, you must complete the following procedure.

1. Sign into NetScaler GUI and navigate to **System > Diagnostics** page.
2. click the **Download core files** link in the **Diagnostic** page, as shown in the following screenshot.
   
   **Note:** You must download the latest core or crash files generated by the appliance that are relevant to the time-stamp of your issue. The files can be located either in the core or crash directory.
3. Select the relevant file and click **Download**.

**Download core or crash files from Citrix ADC appliance using SFTP client**

To download the core or crash files from a NetScaler appliance, complete the following procedure:

1. Open WinSCP and log on to the NetScaler Management IP.
2. Navigate to the `/var/core/1` to download the files.

**Reference Material**
