For improved performance while using callouts, you can use the integrated caching feature to cache callout responses. The responses are stored in an integrated caching content group named callout-ContentGroup for a specified time duration.
Note: To cache callout responses, make sure that the integrated caching feature is enabled.

**To set the cache duration by using the command line interface**

At the command prompt, type:

```
set policy httpCallout <name> -cacheForSecs <secs>
```

**Example:**

```
> set httpcallout httpcallout1 -cacheForSecs 120
```

**To set the cache duration by using the configuration utility**

1. Navigate to **AppExpert > HTTP Callouts**.
2. In the details pane, select the HTTP callout for which you want to set the cache duration and click **Open**.
3. In the **Configure HTTP Callout** dialog box, specify the **Cache Expiration Time**.
4. Verify that you have entered the correct time duration, and then click **OK**.

**Use Case: Filtering clients by using an IP blacklist**

July 8, 2020

HTTP callouts can be used to block requests from clients that are blacklisted by the administrator. The list of clients can be a publicly known blacklist, a blacklist that you maintain for your organization, or a combination of both.

The Citrix ADC appliance checks the IP address of the client against the pre-configured blacklist and blocks the transaction if the IP address has been blacklisted. If the IP address is not in the list, the appliance processes the transaction.

To implement this configuration, you must perform the following tasks:

1. Enable responder on the Citrix ADC appliance.
2. Create an HTTP callout on the Citrix ADC appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response to the HTTP callout, and then bind the policy globally.
4. Create an HTTP callout agent on the remote server.

**Enabling responder**

You must enable responder before you can use it.

**To enable responder by using the GUI**

1. Make sure that you have installed the responder license.
2. In the configuration utility, expand AppExpert, and right-click **Responder**, and then click **Enable Responder** feature.

**Creating an HTTP callout on the Citrix ADC appliance**

Create an HTTP callout, HTTP_Callout, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see [Configuring an HTTP Callout](#).pdf.

**Configuring a responder policy and binding it globally**

After you configure the HTTP callout, verify the callout configuration, and then configure a responder policy to invoke the callout. While you can create a responder policy in the Policies sub-node and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

**To create a responder policy and bind it globally by using**

1. Navigate to **AppExpert > Responder**.
2. In the details pane, under **Policy Manager**, click **Policy Manager**.
3. In the **Responder Policy Manager** dialog box, click **Override Global**.
4. Click **Insert Policy**, and then, under **Policy Name**, click **New Policy**.
5. In the **Create Responder Policy** dialog box, do the following:
   a) In Name, type **PolicyResponder1**.
   b) In **Action**, select **RESET**.
   c) In **Undefined-Result Action**, select **Global undefined-result** action.
d) In Expression, type the following default syntax expression:

```
"HTTP.REQ.HEADER("Request").EQ("Callout Request").NOT & SYS.
HTTP_CALLOUT(HTTP_Callout).CONTAINS("IP Matched")"
```

e) Click Create, and then click Close.

6. Click Apply Changes, and then click Close.

**Creating an HTTP callout agent on the remote server**

You must now create an HTTP callout agent on the remote callout server that will receive callout requests from the Citrix ADC appliance and respond appropriately. The HTTP callout agent is a script that is different for each deployment and must be written with the server specifications in mind, such as the type of database and the scripting language supported.

Following is a sample callout agent that verifies whether the given IP address is part of an IP blacklist. The agent has been written in the Perl scripting language and uses a MYSQL database.

The following CGI script checks for a given IP address on the callout server.

```
#!/usr/bin/perl -w
print "Content-type: text/html\n\n";
use DBI();
use CGI qw(:standard);
# Take the Client IP address from the request query
my $ip_to_check = param('cip');
# Where a MYSQL database is running
my $dsn = 'DBI:mysql:BAD_CLIENT=localhost';
# Database username to connect with
my $db_user_name = 'dbuser';
# Database password to connect with
my $db_password = 'dbpassword';
my ($id, $password);
# Connecting to the database
my $dbh = DBI->connect($dsn, $db_user_name, $db_password);
my $sth = $dbh->prepare(qq{
select * from bad_clnt 
});
$sth->execute();
while (my ($ip_in_database) = $sth->fetchrow_array()) {
chomp($ip_in_database);
# Check for IP match
if ($ip_in_database eq $ip_to_check) {
```
Use Case: ESI support for fetching and updating content dynamically

July 8, 2020

Edge Side Includes (ESI) is a markup language for edge-level dynamic Web content assembly. It helps in accelerating dynamic Web-based applications by defining a simple markup language to describe cacheable and non-cacheable Web page components that can be aggregated, assembled, and delivered at the network edge. By using HTTP callouts on the Citrix ADC appliance, you can read through the ESI constructs and aggregate or assemble content dynamically.

To implement this configuration, you must perform the following tasks:

1. Enable rewrite on the Citrix ADC appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a rewrite action to replace the ESI content with the callout response body.
4. Configure a rewrite policy to specify the conditions under which the action is performed, and then bind the rewrite policy globally.

Enabling rewrite

Rewrite must be enabled before it is used on the Citrix ADC appliance. The following procedure describes the steps to enable the rewrite feature.
To enable rewrite by using the GUI

1. Make sure that you have installed the rewrite license.
2. In the configuration utility, expand AppExpert, and right-click Rewrite, and then click Enable Rewrite feature.

Creating an HTTP Callout on the Citrix ADC Appliance

For more information about creating an HTTP callout, see Configuring an HTTP Callout.
For more information about the parameter values, see Parameters and Values for HTTP-Callout-2 pdf.

Configuring the Rewrite Action

Create a rewrite action, Action-Rewrite-1, to replace the ESI content with the callout response body.
Use the parameter settings shown in the following table.

Table 2. Parameters and Values for Action-Rewrite-1

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Action-Rewrite-1</td>
</tr>
<tr>
<td>Type</td>
<td>Replace</td>
</tr>
<tr>
<td>Expression to choose target text reference</td>
<td>“HTTP.RES.BODY(500).AFTER_STR(&quot; &lt;example&gt;&quot;).BEFORE_STR(&quot; &lt;/example&gt;&quot;)”</td>
</tr>
<tr>
<td>String expression for replacement text</td>
<td>“SYS.HTTP_CALLOUT(HTTP-Callout-2)”</td>
</tr>
</tbody>
</table>

To configure the rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, in Name, type Action-Rewrite-1.
4. In Type, select REPLACE.
5. In Expression to choose target text reference, type the following default syntax expression:

```
"HTTP.RES.BODY(500).AFTER_STR("<example>").BEFORE_STR("</example>")"
```

6. In the String expression for replacement text, type the following string expression:
Creating the Rewrite Policy and Binding it Globally

Create a rewrite policy, Policy-Rewrite-1, with the parameter settings shown in the following table. You can create a rewrite policy in the Policies subnode and then bind it globally by using the Rewrite Policy Manager. Alternatively, you can use the Rewrite Policy Manager to perform both these tasks simultaneously. This demonstration uses the Rewrite Policy Manager to perform both tasks.

Table 3. Parameters and Values for Policy-Rewrite-1

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Policy-Rewrite-1</td>
</tr>
<tr>
<td>Action</td>
<td>Action_Rewrite-1</td>
</tr>
<tr>
<td>Undefined Result Action</td>
<td>-Global undefined-result action-</td>
</tr>
<tr>
<td>Expression</td>
<td>“HTTP.REQ HEADER(&quot;Name&quot;).CONTAINS(&quot;Callout&quot;).NOT”</td>
</tr>
</tbody>
</table>

To configure a rewrite policy and bind it globally by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Policy Manager, click Rewrite Policy Manager.
3. In the Rewrite Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Rewrite Policy dialog box, do the following:
   1. In Name, type Policy-Rewrite-1.
   3. In Undefined-Result Action, select Global undefined-result action.
   4. In Expression, type the following default syntax expression:

   "SYS.HTTP_CALLOUT(HTTP-Callout-2)"

   a) Click Create, and then click Close.
5. Click Apply Changes, and then click Close.
Use Case: Access control and authentication

August 19, 2020

In high security zones, it is mandatory to externally authenticate the user before a resource is accessed by clients. On the Citrix ADC appliance, you can use HTTP callouts to externally authenticate the user by evaluating the credentials supplied. In this example, the assumption is that the client is sending the user name and password through HTTP headers in the request. However, the same information could be fetched from the URL or the HTTP body.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the Citrix ADC appliance.
2. Create an HTTP callout on the appliance and configure it with details about the external server and other required parameters.
3. Configure a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling Responder

The responder feature must be enabled before it is used on the Citrix ADC appliance.

To enable responder by using the configuration utility

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP callout on the Citrix ADC appliance

Create an HTTP callout, HTTP-Callout-3, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see Configuring an HTTP Callout.

Table 1. Parameters and Values for HTTP-Callout-3
Parameter | Value | Name
--- | --- | ---
Name | Policy-Responder-3 |  

Parameter
Value
Name
HTTP-Callout-3

**Server to receive callout request:**

IP Address
10.103.9.95

Port
80

**Request to send to the server:**

Method
GET

Host Expression
10.102.3.95

URL Stem Expression
“/cgi-bin/authenticate.pl”

**Headers:**

Name
Request
Value-expression
Callout Request

**Parameters:**

Name
Username
Value-expression

HTTP.REQ.HEADER(“Username”).VALUE(0)
Citrix ADC 13.0

Name
Password
Value-expression
HTTP.REQ.HEADER("Password").VALUE(0)

**Server Response:**
Return Type
TEXT
Expression to extract data from the response
HTTP.RES.BODY(100)

### Creating a Responder Policy to Analyze the Response

Create a responder policy, Policy-Responder-3, that will check the response from the callout server and RESET the connection if the source IP address has been blacklisted. Create the policy with the parameters settings shown in the following table. While you can create a responder policy in the Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind the policy globally.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Policy-Responder-3</td>
</tr>
<tr>
<td>Action</td>
<td>RESET</td>
</tr>
<tr>
<td>Undefined-Result-Action</td>
<td>-Global undefined-result action-</td>
</tr>
<tr>
<td>Expression</td>
<td>“HTTP.REQ.HEADER(&quot;Request&quot;)).EQ(&quot;Callout Request&quot;)).NOT &amp;&amp; SYS.HTTP_CALLOUT(HTTP-Callout-3).CONTAINS(&quot;Authentication Failed&quot;)”</td>
</tr>
</tbody>
</table>

**To create a responder policy and bind it globally by using the configuration utility**

1. Navigate to **AppExpert > Responder**.
2. In the details pane, under **Policy Manager**, click **Responder Policy Manager**.

© 1999-2020 Citrix Systems, Inc. All rights reserved. 1573
3. In the **Responder Policy Manger** dialog box, click **Override Global**.

4. Click **Insert Policy**, and then, in the **Policy Name** column, click **New Policy**.

5. In the **Create Responder Policy** dialog box, do the following:
   a) In Name, type Policy-Responder-3.
   b) In Action, select **RESET**.
   c) In Undefined-Result Action, select Global undefined-result action.
   d) In the Expression text box, type:

   ```
   "HTTP.REQ.HEADER("Request")".EQ("Callout Request") .NOT & & SYS.
   HTTP_CALLOUT(HTTP-Callout-3).CONTAINS("Authentication Failed")
   ```

   a) Click **Create**, and then click **Close**.

6. Click **Apply Changes**, and then click **Close**.

**Creating an HTTP Callout Agent on the Remote Server**

You now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the Citrix ADC appliance and responds appropriately. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

Following is sample callout agent pseudo-code that verifies whether the supplied user name and password are valid. The agent can be implemented in any programming language of your choice. The pseudo-code is to be used only as a guideline for developing the callout agent. You can build additional functionality into the program.

**To verify the supplied user name and password by using pseudo-code**

1. Accept the user name and password supplied in the request and format them appropriately.
2. Connect to the database that contains all the valid user names and passwords.
3. Check the supplied credentials against your database.
4. Format the response as required by the HTTP callout.
5. Send the response to the Citrix ADC appliance.
Use Case: OWA-based spam filtering

July 8, 2020

Spam filtering is the ability to dynamically block emails that are not from a known or trusted source or that have inappropriate content. Spam filtering requires an associated business logic that indicates that a particular kind of message is spam. When the Citrix ADC appliance processes Outlook Web Access (OWA) messages based on the HTTP protocol, HTTP callouts can be used to filter spam.

You can use HTTP callouts to extract any portion of the incoming message and check with an external callout server that has been configured with rules that are meant for determining whether a message is legitimate or spam. In case of spam email, for security reasons, the Citrix ADC appliance does not notify the sender that the email is marked as spam.

The following example conducts a very basic check for various listed keywords in the email subject. These checks can be more complex in a production environment.

To implement this configuration, you must perform the following tasks:

1. Enable the responder feature on the Citrix ADC appliance.
2. Create an HTTP callout on the Citrix ADC appliance and configure it with details about the external server and other required parameters.
3. Create a responder policy to analyze the response, and then bind the policy globally.
4. Create a callout agent on the remote server.

Enabling responder

The responder feature must be enabled before it can be used on the Citrix ADC appliance.

To enable responder by using the GUI

1. Make sure that the responder license is installed.
2. In the configuration utility, expand AppExpert, and right-click Responder, and then click Enable Responder feature.

Creating an HTTP callout on the Citrix ADC appliance

Create an HTTP callout, HTTP-Callout-4, with the parameter settings shown in the following table. For more information about creating an HTTP callout, see Configuring an HTTP Callout.

For more information, see Parameters and Values for HTTP-Callout-4 pdf.
Creating a responder action

Create a responder action, Action-Responder-4. Create the action with the parameter settings shown in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Action-Responder-4</td>
</tr>
<tr>
<td>Type</td>
<td>Respond with</td>
</tr>
</tbody>
</table>
| Target    | ""HTTP/1.1 200 OK\r\nServer: Microsoft-IIS/6.0\r\nX-Powered-By: ASP.NET\r\nContent-Length: 0\r\nMS-WebStorage: 6.5.6944\r\nCache-Control: no-cache\r\n\n"

Table 2. Parameters and Values for Action-Responder-4

To create a responder action by using the configuration utility

2. In the details pane, click Add.
3. In the Create Responder Action dialog box, in Name, type Action-Responder-4.
4. In Type, click Respond with.
5. In Target, type:

   ""HTTP/1.1 200 OK\r\nServer: Microsoft-IIS/6.0\r\nX-Powered-By: ASP.NET\r\nContent-Length: 0\r\nMS-WebStorage: 6.5.6944\r\nCache-Control: no-cache\r\n\n"

6. Click Create, and then click Close.

Creating a Responder Policy to Invoke the HTTP Callout

Create a responder policy, Policy-Responder-4, that will check the request body and, if the body contains the word “subject,” invoke the HTTP callout to verify the email. Create the policy with the parameter settings shown in the following table. While you can create a responder policy in the
Citrix ADC 13.0

Policies subnode and then bind it globally by using the Responder Policy Manager, this demonstration uses the Responder Policy Manager to create the responder policy and bind it globally.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Policy-Responder-4</td>
</tr>
<tr>
<td>Action</td>
<td>Action-Responder-4</td>
</tr>
<tr>
<td>Undefined-Result-Action</td>
<td>-Global undefined-result action-</td>
</tr>
<tr>
<td>Expression</td>
<td>“HTTP.REQ.BODY(1000).CONTAINS(&quot;urn:schemas:httpmail:subject&quot;) &amp;&amp; SYS.HTTP_CALLOUT(HTTP-Callout-4)”</td>
</tr>
</tbody>
</table>

**To create a responder policy by using the configuration utility**

1. Navigate to AppExpert > Responder.
2. In the details pane, under Policy Manager, click Responder policy manager.
3. In the Responder Policy Manager dialog box, click Override Global.
4. Click Insert Policy, and then, in the Policy Name column, click New Policy.
5. In the Create Responder Policy dialog box, do the following:
   a) In Name, type Policy-Responder-4.
   b) In Action, click Action-Responder-4.
   c) In Undefined-Result Action, click Global undefined-result action.
   d) In the Expression text box, type:

   ```
   "HTTP.REQ.BODY(1000).CONTAINS("urn:schemas:httpmail:subject") && SYS.HTTP_CALLOUT(HTTP-Callout-4)"
   ```

   e) Click Create, and then click Close.
6. Click Apply Changes, and then click Close.

**Creating an HTTP callout agent on the remote server**

You will now need to create an HTTP callout agent on the remote callout server. The HTTP callout agent receives callout requests from the Citrix ADC appliance and responds accordingly. The callout agent is a script that is different for each deployment and must be written with server specifications in mind, such as the type of database and the scripting language supported.

The following pseudo-code provides instructions for creating a callout agent that checks a list of words that are generally understood to indicate spam mails. The agent can be implemented in any program-
ming language of your choice. The pseudo-code is to be used only as a guideline for developing the
callout agent. You can build additional functionality into the program.

To identify spam email by using pseudo-code

1. Accept the email subjecta provided by the Citrix ADC appliance.
2. Connect to the database that contains all the terms against which the email subject is checked.
3. Check the words in the email subject against the spam word list.
4. Format the response as required by the HTTP callout.
5. Send the response to the Citrix ADC appliance.

Use Case: Dynamiccontent switching

February 13, 2020

This use case provides dynamic content switching by using an HTTP callout to get the name of the
load balancing virtual server to which the request is forwarded.

1. Add a content switching virtual server.

   ```
   add cs vserver cs_vserver1 HTTP 10.102.29.196 80
   ```

2. Create an HTTP callout.

   ```
   add policy httpCallout http_callout1
   ```

3. Configure the HTTP callout to respond with the name of the load balancing virtual server from
   a request that contains the client IP address in the HTTP header “X-CLIENT-IP”.

   ```
   ```

4. Configure the content switching action to retrieve the callout response.

   ```
   add cs action cs_action1 -targetVserverExpr 'SYS.HTTP_CALLOUT(http_callout1)'
   ```
Note:
You must bind a load balancing virtual server to the content switching virtual server to account for:

- The non-availability of the load balancing virtual server that the callout resolves to.
- A UNDEF condition that results from the execution of the callout.

```
1 > bind cs vserver cs_vserver1 -lbvserver default_lbvip
```

5. Configure the content switching policy.

```
1 add cs policy cs_policy1 -rule true -action cs_action1
```

6. Binding the content switching policy to the content switching virtual server.

```
1 bind cs vserver cs_vserver1 -policyName cs_policy1 -priority 10
```

Pattern sets and data sets

February 12, 2020

Policy expressions for string matching operations on a large set of string patterns tend to become long and complex. Resources consumed by the evaluation of such complex expressions are significant in terms of processing cycles, memory, and configuration size. You can create simpler, less resource-intensive expressions by using pattern matching.

Depending on the type of patterns that you want to match, you can use one of the following features to implement pattern matching:

- A pattern set is an array of indexed patterns used for string matching during default syntax policy evaluation. Example of a pattern set: imagetypes {svg, bmp, png, gif, tiff, jpg}.
- A data set is a specialized form of pattern set. It is an array of patterns of types number (integer), IPv4 address, or IPv6 address.

In many cases, you can use either pattern sets or data sets. However, in cases where you want specific matches for numerical data or IPv4 and IPv6 addresses, you must use data sets.

Note:
Pattern sets and data sets can be used only in default syntax policies.

To use pattern sets or data sets, first create the pattern set or data set and bind patterns to it. Then, when you configure a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

---

**How string matching works with pattern sets and data sets**

April 23, 2019

A pattern set or data set contains a set of patterns, and each pattern is assigned a unique index. When a policy is applied to a packet, an expression identifies a string to be evaluated, and the operator compares the string to the patterns defined in the pattern set or data set until a match is found or all patterns have been compared. Then, depending on its function, the operator returns either a boolean value that indicates whether or not a matching pattern was found or the index of the pattern that matches the string.

**Note:** This topic explains the working of a pattern set. Data sets work the same way. The only difference between pattern sets and data sets is the type of patterns defined in the set.

Consider the following use case to understand how patterns can be used for string matching.

You want to determine whether the URL suffix (target text) contains any of the image file extensions. Without using pattern sets, you would have to define a complex expression, as follows:

1. \( \text{HTTP.REQ.URL.SUFFIX.CONTAINS("svg") || HTTP.REQ.URL.SUFFIX.CONTAINS("bmp") || HTTP.REQ.URL.SUFFIX.CONTAINS("png") ||} \)
2. \( \text{HTTP.REQ.URL.SUFFIX.CONTAINS("gif") || HTTP.REQ.URL.SUFFIX.CONTAINS("tiff") || HTTP.REQ.URL.SUFFIX.CONTAINS("jpg")} \)

If the URL has a suffix of “jpg,” with the above compound expression, the Citrix ADC appliance has to iterate through the entire compound expression sequentially, from one sub expression to the next, to determine that the request refers to a jpg image. The following figure shows the steps in the process.
When a compound expression includes hundreds of sub expressions, the above process is resource intensive. A better alternative is an expression that invokes a pattern set, as shown in the following figure.

During policy evaluation as shown above, the operator (CONTAINS_ANY) compares the string identified in the request with the patterns defined in the pattern set until a match is found. With the Sample_Patset expression, the multiple iterations through six sub expressions are reduced to just one.

By eliminating the need to configure compound expressions that perform string matching with multiple OR operations, pattern sets or data sets simplify configuration and accelerate processing of requests and responses.
Configuring a Pattern Set

November 25, 2019

To configure a pattern set, you must specify the strings that are to serve as patterns. You can manually assign a unique index value to each of these patterns, or you can allow the index values to be assigned automatically.

Note: Pattern sets are case sensitive (unless you specify the expression to ignore case). Therefore, the string pattern “product1,” for example, is not the same as the string pattern “Product1.”

Points to remember about index values:

- You cannot bind the same index value to more than one pattern.
- An automatically assigned index value is one number larger than the highest index value of the existing patterns within the pattern set. For example, if the highest index value of existing patterns in a pattern set is 104, the next automatically assigned index value will be 105.
- If you do not specify an index for the first pattern, index value 1 is automatically assigned to that pattern.
- Index values are not regenerated automatically if one or more patterns are deleted or modified. For example, if the set contains five patterns, with indexes from 1 through 5, and if the pattern with an index of 3 is deleted, the other index values in the pattern set are not automatically regenerated to produce values from 1 through 4.
- The maximum index value that can be assigned to a pattern is 4294967290. If that value is already assigned to a pattern in the set, you must manually assign index values to any newly added patterns. An unused index value that is lower than a currently used value cannot be assigned automatically.

To configure a pattern set by using the command line interface

At the command prompt, do the following:

1. Create a pattern set.

   add policy patset <name>

Example:

add policy patset samplepatset
1. Bind patterns to the pattern set.

   bind policy patset <name> <string> [-index <positive_integer>][-charset ( ASCII | UTF_8 )] [-comment <string>]

Example:

bind policy patset samplepatset product1 -index 1 -comment short description about the pattern bound to the pattern set

Note: Repeat this step for all the patterns you want to bind to the pattern set.

   1. Verify the configuration.

      show policy patset <name>

To configure a pattern set by using the configuration utility

1. Navigate to AppExpert > Pattern Sets.
2. In the details pane, click Add to open the Create Pattern Set dialog box.
3. Specify a name for the pattern set in the Name text box.
4. Under Specify Pattern, type the first pattern and, optionally, specify values for the following parameters:
   - Treat back slash as escape character—Select this check box to specify that any backslash characters that you might include in the pattern are to be treated as escape characters.
   - Index—A user assigned index value, from 1 through 4294967290.
5. Verify that you have entered the correct characters, and then click Add.
6. Repeat steps 4 and 5 to add additional patterns, and then click Create.

Copied!
Failed!

Configuring a data set

May 26, 2020

To configure a data set, you must specify the strings that server as a pattern, assign a type (number, IPv4 address, or IPv6 address) and configure the dataset range. You can manually assign a unique index value to the pattern, or you can allow the index values to be assigned automatically. Dataset is not related to HTTP or any 7 layer protocol. It works only on text or string. There are different types of dataset such as NUM, ULONG, IPv4, IPv6, MAC, DOUBLE. You can select a type and define the dataset range based on the specified type.
Note:
Policy data sets are case sensitive (unless you specify the expression to ignore case). Therefore, the MAC address ff:ff:ff:ff:ff:ff for example, is not the same as the MAC address FF:FF:FF:FF:FF.

The rules applied for index values of data sets are similar to pattern sets. For information about index values, see Configuring a Pattern Set.

To configure a data set

You must complete the following steps to configure a data set:

1. Add a policy dataset
2. Bind pattern to a policy dataset
3. Add a policy expression
4. Verify the policy configuration

Add a policy dataset

At the command prompt, do the following:

`add policy dataset <name> <type>
``

Example:
`add policy dataset ds1 ipv4 -comment numbers``

Bind a pattern to the data set

At the command prompt, type:

`bind policy dataset <name> <value> [-index <positive_integer>] [-endRange <string>] [-comment <string>]
``

Example:
`bind policy dataset ds1 1.1.1.1 endRange 1.1.1.10 -comment short description about the pattern bound to the data set``

Note:
You must repeat this step for all the patterns you want to bind to the data set. You can bind only up to 5000 patterns to a dataset.
And, a dataset range must not overlap with other ranges bound to a dataset and cannot include single values bound to the dataset. If you bind a dataset with an overlapping range results in an
error.

**Example:**

```plaintext
1  add policy dataset ip_set ipv4
2  Done
3  bind policy dataset ip_set 2.2.2.25
4  Done
5  bind policy dataset ip_set 2.2.2.20 -endRange 2.2.2.30
6  ERROR: The range overlaps an existing range or includes a value bound to the dataset.
```

A value is considered to be in the dataset if it is either equal to a single value bound to the data set or is between the lower-value and upper-value (lower-value <= value && value <= upper-value), for a range bound to the data set.

**Use policy expression in a policy data set**

At the command prompt, type:

```
add policy expression exp1 http.req.body(100).contains_any("ds1")
```

Where,

The expression checks whether there is any pattern (or pattern within the range) bound to the dataset ds1 is present in the first 100 bytes of the HTTP request body.

**Verify dataset configuration**

At the command prompt, type:

```
show policy dataset ds1
```

Example:

```
Dataset: ds1
Type: IPV4
1) Bound Dataset Range from: 1.1.1.1 through: 1.1.1.10
   Index: 1
```

**To configure a data set by using the configuration utility**

Follow the steps given below to configure a policy dataset:
1. Navigate to AppExpert > Data Sets.

2. In the details pane, under Data Sets, click Add.

3. In the Configure Data Set page, set the following parameters.
   a) Name. Name of the policy data set.
   b) Type. Type of value to bind to the dataset.

Configuring data set

4. Click Insert to bind the dataset value of specific type.
   a) Value. Value of the specified type associated with the dataset.
   b) Index. The index value of the dataset.
   c) End range. The dataset entry. This is a range <value> to <end_range>.
   d) Comments. A short description about the data set.

dataset binding

5. Click Insert and Close.

6. Enter comments.

7. Click Create and Close.

Using pattern sets and data sets

July 8, 2020

Default syntax policy expressions that take pattern sets or data sets as an argument can be used to perform string matching operations.

The usage is as follows:

```
1 <text>.<operator>("<name>")
```

where,

- `<text>` is the expression that identifies a string in a packet. Example: HTTP.REQ.HEADER("Host").
- `<operator>` is one of the operators described in the Pattern Set Types table pdf.

For sample usage, see Sample Usage.
Sample usage

April 23, 2019

To understand the usage of pattern sets in expressions, consider the example of a pattern set named “imagetypes.”

<table>
<thead>
<tr>
<th>Patterns</th>
<th>Index value</th>
</tr>
</thead>
<tbody>
<tr>
<td>svg</td>
<td>1</td>
</tr>
<tr>
<td>bmp</td>
<td>2</td>
</tr>
<tr>
<td>png</td>
<td>3</td>
</tr>
<tr>
<td>gif</td>
<td>4</td>
</tr>
<tr>
<td>tiff</td>
<td>5</td>
</tr>
<tr>
<td>jpg</td>
<td>6</td>
</tr>
</tbody>
</table>

Table 1. Pattern set “imagetypes”

**Example 1:** Determine whether the suffix of an HTTP request is one of the file extensions defined in the “imagetypes” pattern set.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_ANY(“imagetypes”)
- **Sample URL.** http://www.example.com/homepageicon.jpg
- **Result.** TRUE

**Example 2:** Determine whether the suffix of an HTTP request is one of the file extensions defined in the “imagetypes” pattern set, and return the index of that pattern.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX(“imagetypes”)
- **Sample URL.** http://www.example.com/mylogo.png
- **Result.** 4 (The index value of the pattern “gif”.)

**Example 3:** Use the index value of a pattern to determine whether the URL suffix is within a specified index-value range.

- **Expression.** HTTP.REQ.URL.SUFFIX.EQUALS_INDEX(“imagetypes”).GE(3) && HTTP.REQ.URL.SUFFIX.EQUALS_INDEX(“imagetypes”).LE(5)
- **Sample URL.** http://www.example.com/mylogo.png
- **Result.** TRUE (The index value of gif file types is 4.)

**Example 4:** Implement one set of policies for file extensions bmp, jpg, and png, and a different set of policies for gif, tiff, and svg files.
An expression that returns the index of a matched pattern can be used to define traffic subsets for a web application. The following two expressions could be used in content switching policies for a content switching virtual server:

- HTTP.REQ.URL.SUFFIX.EQUALS_INDEX(“imagetypes”).LE(3)
- HTTP.REQ.URL.SUFFIX.EQUALS_INDEX(“imagetypes”).GE(4)

Variables

February 12, 2020

Variables are named objects that store information in the form of tokens. These tokens are used within and across different transactions on the Citrix ADC Appliance for internal computation and policy processing.

The Citrix ADC appliance supports creation of variables of the following types:

- **Singleton variables.** Can have a single value of one of the following types: ulong and text (max-size). The ulong type is an unsigned 64-bit integer, the text type is a sequence of bytes, and max-size is the maximum number of bytes in the sequence.

- **Map variables.** Maps hold values associated with keys: each key-value pair is called a map entry. The key for each entry is unique within the map. Maps are specified as follows:

  map (key_type, value_type, max-values).

  where,

  - **key_type** is the data type of the key. It is of type text (max-size).
  - **value_type** is the data type of the values of the map. It can be of type ulong or text (max-size).
  - **max-values** is the maximum number of entries that the map can contain. It is of type ulong.

Values for these variables are set using assignments which must be invoked on policy actions.

**Note:** Variables are not yet supported in a high-availability setup or in a cluster.

Variables Scope

A map variable or a singleton variable can have a global scope. Alternatively, the scope of a singleton variable can be limited to a single transaction.
• **Global Scope Variable** - A variable with global scope (the default) has only one instance, and that instance has the same value(s) across all cores of a Citrix ADC appliance and across all nodes of a cluster or HA configuration. Global variable values exist until they are explicitly deleted, until they expire, or until a standalone appliance is restarted or all nodes of a cluster or HA configuration are restarted.

• **Transaction Scope Variable** - A variable with transaction scope has a separate instance, with its own value, for each transaction processed by the Citrix ADC appliance. When the transaction processing is complete, the transaction variable value is deleted.

**Note**: Transaction scope variables are available in Citrix ADC release 10.5.e or later.

---

### Configuring and Using Variables

February 13, 2020

You must first create a variable and then assign a value or specify the operation that must be performed on the variable. After performing these operations, you can use the assignment as a policy action.

**Note**: Once configured, a variable's settings cannot be modified or reset. If the variable needs to be changed, the variable and all references to the variable (expressions and assignments) must be deleted. The variable can then be re-added with new settings, and the references (expressions and assignments) can be re-added.

### To configure variables by using the command line interface

1. Create a variable.

```bash
add ns variable <name> -type <string> [-scope global] [-ifFull ( undef | lru )] [-ifValueTooBig ( undef | truncate )] [-ifNoValue ( undef | init )] [-init <string>] [-expires <positive_integer>] [-comment <string>]
```

**Note**: Refer to the man page “man add ns variable” for description of the command parameters.

Example 1: Create a ulong variable named “my_counter” and initialize it to 1.

```bash
add ns variable my_counter -type ulong -init 1
```
Example 2: Create a map named “user_privilege_map”. The map will contain keys of maximum length 15 characters and text values of maximum length 10 characters, with a maximum of 10000 entries.

```plaintext
add ns variable user_privilege_map -type map(text(15),text(10),10000)
```

Note: If the map contains 10000 unexpired entries, assignments for new keys reuse one of the least recently used entries. By default, an expression trying to get a value for a non-existent key will initialize an empty text value.

Assign the value or specify the operation to be performed on the variable. This is done by creating an assignment.

```plaintext
add ns assignment <name> -variable <expression> [-set <expression> | -add <expression> | -sub <expression> | -append <expression> | -clear ] [-comment <string>]
```

Note: A variable is referenced by using the variable selector ($). Therefore, `$variable1` is used to refer to text or ulong variables. Similarly, `$variable2[key-expression]` is used to refer to map variables.

Example 1: Define an assignment named “inc_my_counter” that automatically adds 1 to the “my_counter” variable.

```plaintext
add ns assignment inc_my_counter -variable $my_counter -add 1
```

Example 2: Define an assignment named “set_user_privilege” that adds to the “user_privilege_map” variable an entry for the client’s IP address with the value returned by the “get_user_privilege” HTTP callout.

```plaintext
add ns assignment set_user_privilege -variable $user_privilege_map[client.ip.src.typecast_text_t] -set sys.http.callout(get_user_privilege)
```

Note: If an entry for that key already exists, the value will be replaced. Otherwise a new entry for the key and value will be added. Based on the previous declaration for user_privilege_map, if the map already has 10000 entries, one of the least recently used entries will be reused for the new key and value.

1. Invoke the variable assignment in a policy.

There are two functions that can operate on map variables.

- `$name.valueExists(key-expression)`. Returns true if there is a value in the map selected by the key-expression. Otherwise returns false. This function will update the expiration and LRU information if the map entry exists, but will not create a new map entry if the value does not exist.
• $name.valueCount. Returns the number of values currently held by the variable. This is the number of entries in a map. For a singleton variable, this is 0 if the variable is uninitialized or 1 otherwise.

Example: Invoke the assignment named “set_user_privilege” with a compression policy.

```
add cmp policy set_user_privilege_pol -rule $user_privilege_map.valueExists(client.ip.src.typecast_text_t).not -resAction set_user_privilege
```

Use Case to Insert HTTP header in the Response Side

The following example shows an example of a singleton variable.

Add a singleton variable of type text. This variable can hold maximum 100 Bytes data.

```
add ns variable http_req_data -type text(100) -scope transaction
```

Add an assignment action, which will be used to store the HTTP request data into the variable.

```
add ns assignment set_http_req_data -variable $http_req_data -set http.req.body(100)
```

Add a rewrite action to insert HTTP header, whose value will be fetched from the variable.

```
add rewrite action act_ins_header insert_http_header user_name $http_req_data.after_str("user_name").before_str("password")
```

Add a rewrite policy which will evaluate in the request time, and take assignment action to store data. When we hit this policy, we’ll take assignment action and store the data into the ns variable (http_req_data)

```
add rewrite policy pol_set_variable true set_http_req_data
bind rewrite global pol_set_variable 10 -type req_DEFAULT
```

Add a rewrite policy which will evaluate in the response time, and add an HTTP header in the response.

```
add rewrite policy pol_ins_header true act_ins_header
bind rewrite global pol_ins_header 10 -type res_DEFAULT
```
Assignment action

In a Citrix ADC appliance, an assignment action bound to the policy is triggered when the policy rule evaluates to true. The action updates the value in the variable which can be used in subsequent policy rule evaluations. This way, the same variable can be updated and used for subsequent policy evaluations in the same feature. Previously, the appliance executed assignment actions only after evaluating all of the policies in the feature when the policies of the associated assignment actions evaluated to true. Therefore, the variable value set by the assignment action cannot be used in the subsequent policy rule evaluations within the feature.

This functionality can be understood better with a use case that controls access list for clients on a Citrix ADC appliance. The access decision is provided by a separate web service, with the request `GET /client-access?<client-IP-address>` which returns a response with “BLOCK” or “ALLOW” in the body. The HTTP callout is configured to include the IP address of the client that is associated with an incoming request. When the Citrix ADC appliance receives a request from a client, the appliance generates the callout request and sends it to the callout server, which hosts a database of blacklisted IP addresses and an HTTP callout agent that checks whether the client’s IP address is listed in the database. The HTTP callout agent receives the callout request, checks whether the client’s IP address is listed, and sends a response. The response is a status code, 200, 302 along with “BLOCK” or “ALLOW” in the body. Based on the status code, the appliance performs the policy evaluation. If the policy evaluation is true, the assignment action is triggered immediately and action sets the value to the variable. The appliance uses and sets this variable value for subsequent policy evaluation in the same module.

Use case for configuring assignment action

Follow the steps below to configure assignment action and use variable for subsequent policies:

1. The access decision is provided by a separate web service, with the request which returns a response with BLOCK or ALLOW in the body.
   
   `GET /url-service?url-allowed?<URL path>`

2. Set up a map variable to hold the access decisions for URLs.
   
   ```
   add ns variable url_list_map -type 'map(text(1000),text(10),10000)'
   ```

3. Set up an HTTP callout to send the access request to the web service.
   
   ```
   add policy httpCallout url_list_callout -vserver url_vs -returnType TEXT -urlStemExpr '/url-allowed?' + HTTP.REQ.URL.PATH'-resultExpr 'HTTP.RES.BODY(10)'
   ```

4. Set up an assignment action to invoke the callout to get the access decision and assign it to the map entry for the URL.
add ns assignment client_access_assn -variable '$client_access_map[CLIENT.IP.SRC.TYPECAST_TEXT_T]'-set SYS.HTTP_CALLOUT(client_access_callout)

5. Set up a responder action to send a 403 response if a URL request is blocked.

add responder action url_list_block_act respondwith "HTTP/1.1 403 Forbidden\r\n\n"

6. Set up a responder policy to set the map entry for the URL if it is not already set. With the immediate action enhancement, the map entry value is set when this policy is evaluated. Prior to the enhancement, the assignment was not done until all responder policies had been evaluated
decision is provided by a separate web service.

add responder policy url_list_assn_pol '!'$url_list_map.VALUEEXISTS(HTTP.REQ.URL.PATH)'url_list_assn

7. Set up a responder policy to block access to a URL if its map entry value is BLOCK. With the immediate action enhancement, the map entry set by the preceding policy is available for use in this policy. Prior to the enhancement, the map entry would still be unset at this point.

add responder policy client_access_block_pol '$client_access_map[CLIENT.IP.SRC.TYPECAST_TEXT_T] == "BLOCK"'client_access_block_act

8. Bind the responder policies to the virtual server. **Note**: We cannot globally bind the policies because we don’t want to execute them for the HTTP callout on a separate virtual server.

bind lb vserver vs -policyName client_access_assn_pol -priority 10 -gotoPriorityExpression NEXT -type REQUEST
bind lb vserver vs -policyName client_access_block_pol -priority 20 -gotoPriorityExpression END -type REQUEST

To configure variables by using the configuration utility

1. Navigate to **AppExpert > NS Variables**, to create a variable.
2. Navigate to **AppExpert > NS Assignments**, to assign value(s) to the variable.
3. Navigate to the appropriate feature area where you want to configure the assignment as an action.

**Copied!**
**Failed!**
Use Case: Caching User Privileges

April 23, 2019

In this use case, user privileges ("GOLD", "SILVER", and so on) must be retrieved from an external web service.

To achieve this use case, perform the following operations

Create an HTTP callout to fetch the user privileges from the external web service.

```plaintext
```

Store the privileges in a variable.

```plaintext
add ns variable <name> -type <string> [-scope (global | transaction)] [-ifFull (undef | lru)] [-ifValueTooBig (undef | truncate)] [-ifNoValue (undef | init)] [-init <string>] [-expires <positive_integer>] [-comment <string>]
```

Create a policy to check if there is already a cached entry for the client’s IP address; if not, it calls the HTTP callout to set a map entry for the client.

```plaintext
add cmp policy <name> -rule <expression> -resAction <string>
add cmp policy set_user_privilege_pol -rule $user_privilege_map.valueExists(client.ip.src).not -resAction set_user_privilege
```
Create a policy that compresses if the cached privilege entry for the client is “GOLD”.

```plaintext
1  add cmp policy <name> -rule <expression> -resAction <string>
2 3 add cmp policy compress_if_gold_privilege_pol -rule '
   $user_privilege_map[client.ip.src].eq("GOLD")' -resAction compress
```

Bind the compression policies globally.

```plaintext
1  bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-gotoPriorityExpression <expression>] [-type <type>] [-invoke (<labelType> <labelName>)]
2 3 bind cmp global set_user_privilege_pol -priority 10 NEXT
4 5 bind cmp global compress_if_gold_privilege_pol -priority 20 END
```

Use Case: Limiting the Number of Sessions

April 23, 2019

In this use case, the requirement is to limit the number of active backend sessions. In the deployment, each session login has login in the URL and each session logout has logout in the URL. On successful login, the backend sets a sessionid cookie with a unique 10 character value.

To achieve this use case, perform the following operations:

1. Create a map variable that can store each active session. The key of the map is the sessionid. The expiry time for the variable is set to 600 seconds (10 minutes).

```plaintext
1  > add ns variable session_map -type map(text(10),ulong,100) -expires 600
```

2. Create the following assignments for the map variable:

   • Create an entry for the sessionid and set that value to 1 (this value is not actually used).

```plaintext
1  > add ns assignment add_session -variable '$session_map[http.req.cookie.value("sessionid")]' -set 1
```
• Deallocate the entry for a session ID, which implicitly decrements the value count for session_map.

```bash
$session_map[http.req.cookie.value("sessionid")]' -clear
```

3. Create responder policies for the following:

• To check if a map entry exists for that sessionid in the HTTP request. The add_session assignment is executed if the map entry does not exist.

```bash
$session_map
```

Note: The valueExists() function in the add_session_pol policy counts as a reference to the session's map entry, so each request resets the expiration timeout for its session. If no requests for a session are received after 10 minutes, the session's entry will be deallocated.

• To check when the session is logged out. The delete_session assignment is executed.

```bash
delete_session
```

• To check for login requests and if the number of active sessions exceed 100. If these conditions are satisfied, in order to limit the number of sessions, the user is redirected to a page that indicates that the server is busy.

```bash
redirect_too_busy
```

4. Bind the responder policies globally.

```bash
bind responder global add_session_pol 30 next
bind responder global delete_session_pol 10
bind responder global check_login_pol 20
```
Policies and expressions

August 19, 2020

The following topics provide the conceptual and reference information that you require for configuring advanced policies on the Citrix® Citrix ADC® appliance.

To know about all the advanced policy expressions supported on the Citrix ADC appliance, see Policy Expressions

## Introduction to policies and expressions

September 25, 2019

For many Citrix ADC features, policies control how a feature evaluates data. A policy uses a logical expression, called as rule, to evaluate data, and applies one or more actions based on evaluation. Alternatively, a policy can apply a profile, which defines a complex action.

Some Citrix ADC features use default syntax policies, which provide greater capabilities than older classic policies. If you have migrated to a newer release of the Citrix ADC software and have configured classic policies for features that use default syntax policies, you have to manually migrate policies to advanced policy infrastructure.
Warning

Classic policy expressions are deprecated from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies.

Classic policies evaluate basic characteristics of traffic and other data. For example, classic policies can identify whether an HTTP request or response contains a particular type of header or URL.

Advanced policies can perform the same type of evaluations as classic policies. In addition, default syntax policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, transforming data in the body of a request into an HTTP header).

In addition to assigning a policy an action or profile, you bind the policy to a particular point in the processing associated with the Citrix ADC features. The bind point is one factor that determines when the policy will be evaluated.

Benefits of using advanced policies

Default syntax policies use a powerful expression language that is built on a class-object model, and they offer several options that enhance your ability to configure the behavior of various Citrix ADC features. With default syntax policies, you can do the following:

- Perform fine-grained analyses of network traffic from layers 2 through 7.
- Evaluate any part of the header or body of an HTTP or HTTPS request or response.
- Bind policies to the multiple bind points that the default syntax policy infrastructure supports at the default, override, and virtual server levels.
- Use goto expressions to transfer control to other policies and bind points, as determined by the result of expression evaluation.
- Use special tools such as pattern sets, policy labels, rate limit identifiers, and HTTP callouts, which enable you to configure policies effectively for complex use cases.

Also, the configuration utility extends robust graphical user interface support for default syntax policies and expressions and enables users who have limited knowledge of networking protocols to con-
figure policies quickly and easily. The configuration utility also includes a policy evaluation feature for default syntax policies. You can use this feature to evaluate a default syntax policy and test its behavior before you commit it, thus reducing the risk of configuration errors.

**Basic components of an advanced policy**

Following are a few characteristics of an Advanced policy:

- **Name.** Each policy has a unique name.
- **Rule.** The rule is a logical expression that enables the Citrix ADC feature to evaluate a piece of traffic or another object. For example, a rule can enable the Citrix ADC to determine whether an HTTP request originated from a particular IP address, or whether a Cache-Control header in an HTTP request has the value “No-Cache.”

Advanced policies can use all of the expressions that are available in a classic policy, with the exception of classic expressions for the SSL VPN client. In addition, Advanced policies enable you to configure more complex expressions.

- **Bindings.** To ensure that the Citrix ADC can invoke a policy when it is needed, you associate the policy, or bind it, to one or more bind points.

You can bind a policy globally or to a virtual server. For more information, see About policy bindings.

- **An associated action.** An action is a separate entity from a policy. Policy evaluation ultimately results in the Citrix ADC performing an action.

For example, a policy in the integrated cache can identify HTTP requests for .png or .jpeg files. An action that you associate with this policy determines that the responses to these types of requests are served from the cache.

For some features, you configure actions as part of a more complex set of instructions known as a profile.

**How different Citrix ADC features use policies**

The Citrix ADC supports various features that rely on policies for operation. The following table summarizes how the Citrix ADC features use policies.
<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Policy Type</th>
<th>How You Use Policies in the Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>System</td>
<td>Classic</td>
<td>For the Authentication function, policies contain authentication schemes for different authentication methods. For example, you can configure LDAP and certificate-based authentication schemes. You also configure policies in the Auditing function.</td>
</tr>
<tr>
<td>DNS</td>
<td>Advanced</td>
<td>To determine how to perform DNS resolution for requests.</td>
</tr>
<tr>
<td>SSL</td>
<td>Classic and Advanced</td>
<td>To determine when to apply an encryption function and add certificate information to clear text. To provide end-to-end security, after a message is decrypted, the SSL feature re-encrypts clear text and uses SSL to communicate with Web servers.</td>
</tr>
<tr>
<td>Compression</td>
<td>Classic and Advanced</td>
<td>To determine what type of traffic is compressed.</td>
</tr>
<tr>
<td>Integrated Caching</td>
<td>Advanced</td>
<td>To determine whether HTTP responses are cacheable.</td>
</tr>
<tr>
<td>Responder</td>
<td>Advanced</td>
<td>To configure the behavior of the Responder function.</td>
</tr>
<tr>

<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Content Switching</td>
<td>Classic and Advanced</td>
<td>To determine what server or group of servers is responsible for serving responses, based on characteristics of an incoming request. Request characteristics include device type, language, cookies, HTTP method, content type, and associated cache server.</td>
</tr>
<tr>
<td>AAA - Traffic Management</td>
<td>Classic. Exceptions: Traffic policies support only default syntax policies and authorization policies support both classic and default syntax policies.</td>
<td>To check for client-side security before users log in and establish a session. Traffic policies, which determine whether single sign-on (SSO) is required, use only the default syntax. Authorization policies authorize users and groups that access intranet resources through the appliance.</td>
</tr>
<tr>
<td>Cache Redirection</td>
<td>Classic</td>
<td>To determine whether responses are served from a cache or from an origin server.</td>
</tr>
<tr>
<td>Feature Name</td>
<td>Policy Type</td>
<td>How You Use Policies in the Feature</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Rewrite</td>
<td>Advanced</td>
<td>To identify HTTP data that you want to modify before serving. The policies provide rules for modifying the data. For example, you can modify HTTP data to redirect a request to a new home page, or a new server, or a selected server based on the address of the incoming request, or you can modify the data to mask server information in a response for security purposes. The URL Transformer function identifies URLs in HTTP transactions and text files for the purpose of evaluating whether a URL should be transformed.</td>
</tr>
<tr>
<td>Application Firewall</td>
<td>Classic and Advanced</td>
<td>To identify characteristics of traffic and data that should or should not be admitted through the firewall.</td>
</tr>
<tr>
<td>Citrix Gateway, Clientless Access function</td>
<td>Advanced</td>
<td>To define rewrite rules for general Web access using the Citrix Gateway.</td>
</tr>
<tr>
<td>Citrix Gateway</td>
<td>Classic</td>
<td>To determine how the Citrix Gateway performs authentication, authorization, auditing, and other functions.</td>
</tr>
</tbody>
</table>
About actions and profiles

Policies do not themselves take action on data. Policies provide read-only logic for evaluating traffic. To enable a feature to perform an operation based on a policy evaluation, you configure actions or profiles and associate them with policies.

Note: Actions and profiles are specific to particular features. For information about assigning actions and profiles to features, see the documentation for the individual features.

About actions

Actions are steps that the Citrix ADC takes, depending on the evaluation of the expression in the policy. For example, if an expression in a policy matches a particular source IP address in a request, the action that is associated with this policy determines whether the connection is permitted.

The types of actions that the Citrix ADC can take are feature specific. For example, in Rewrite, actions can replace text in a request, change the destination URL for a request, and so on. In Integrated Caching, actions determine whether HTTP responses are served from the cache or an origin server.

In some Citrix ADC features actions are predefined, and in others they are configurable. In some cases, (for example, Rewrite), you configure the actions using the same types of expressions that you use to configure the associated policy rule.

About profiles

Some Citrix ADC features enable you to associate profiles, or both actions and profiles, with a policy. A profile is a collection of settings that enable the feature to perform a complex function. For example, in the application firewall, a profile for XML data can perform multiple screening operations, such as examining the data for illegal XML syntax or evidence of SQL injection.

Use of actions and profiles in particular features

The following table summarizes the use of actions and profiles in different Citrix ADC features. The table is not exhaustive. For more information about specific uses of actions and profiles for a feature, see the documentation for the feature.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Use of an Action</th>
<th>Use of a Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application firewall</td>
<td>Synonymous with a profile</td>
<td>All application firewall features use profiles to define complex behaviors, including pattern-based learning. You add these profiles to policies.</td>
</tr>
<tr>
<td>Citrix Gateway</td>
<td>The following features of the Citrix Gateway use actions: Pre-Authentication. Uses Allow and Deny actions. You add these actions to a profile, Authorization. Uses Allow and Deny actions. You add these actions to a policy. TCP Compression. Uses various actions. You add these actions to a policy.</td>
<td>The following features use a profile: Pre-Authentication, Session, Traffic, and Clientless Access. After configuring the profiles, you add them to policies.</td>
</tr>
<tr>
<td>Rewrite</td>
<td>You configure URL rewrite actions and add them to a policy.</td>
<td>Not used.</td>
</tr>
<tr>
<td>Integrated Caching</td>
<td>You configure caching and invalidation actions within a policy</td>
<td>Not used.</td>
</tr>
<tr>
<td>AAA - Traffic Management</td>
<td>You select an authentication type, set an authorization action of ALLOW or DENY, or set auditing to SYSLOG or NSLOG.</td>
<td>You can configure session profiles with a default timeout and authorization action.</td>
</tr>
<tr>
<td>Protection Features</td>
<td>You configure actions within policies for the following functions: Filter, Compression, Responder, and SureConnect.</td>
<td>Not used.</td>
</tr>
<tr>
<td>SSL</td>
<td>You configure actions within SSL policies</td>
<td>Not used.</td>
</tr>
</tbody>
</table>
### About policy bindings

A policy is associated with, or bound to, an entity that enables the policy to be invoked. For example, you can bind a policy to request-time evaluation that applies to all virtual servers. A collection of policies that are bound to a particular bind point constitutes a policy bank.

Following is an overview of different types of bind points for a policy:

- Request time global. A policy can be available to all components in a feature at request time.
- Response time global. A policy can be available to all components in a feature at response time.
- Request time, virtual server-specific.

A policy can be bound to request-time processing for a particular virtual server. For example, you

<table>
<thead>
<tr>
<th>Feature</th>
<th>Use of an Action</th>
<th>Use of a Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>System</td>
<td>The action is implied. For the Authentication function, it is either Allow or Deny. For Auditing, it is Auditing On or Auditing Off.</td>
<td>Not used.</td>
</tr>
<tr>
<td>DNS</td>
<td>The action is implied. It is either Drop Packets or the location of a DNS server.</td>
<td>Not used.</td>
</tr>
<tr>
<td>SSL Offload</td>
<td>The action is implied. It is based on a policy that you associate with an SSL virtual server or a service.</td>
<td>Not used.</td>
</tr>
<tr>
<td>Compression</td>
<td>Determine the type of compression to apply to the data</td>
<td>Not used.</td>
</tr>
<tr>
<td>Content Switching</td>
<td>The action is implied. If a request matches the policy, the request is directed to the virtual server associated with the policy.</td>
<td>Not used.</td>
</tr>
<tr>
<td>Cache Redirection</td>
<td>The action is implied. If a request matches the policy, the request is directed to the origin server.</td>
<td>Not used.</td>
</tr>
</tbody>
</table>
can bind a request-time policy to a cache redirection virtual server to ensure that particular requests are forwarded to a load balancing virtual server for the cache, and other requests are sent to a load balancing virtual server for the origin.

- Response time, virtual server-specific. A policy can also be bound to response-time processing for a particular virtual server.
- User-defined policy label. For default syntax policies, you can configure custom groupings of policies (policy banks) by defining a policy label and collecting a set of related policies under the policy label.
- Other bind points. The availability of additional bind points depends on type of policy (classic or default syntax), and specifics of the relevant Citrix ADC feature. For example, classic policies that you configure for the Citrix Gateway have user and group bind points.

For additional information about advanced policy bindings, see Bind policies that use the advanced policies and Configure a policy bank for a virtual server. For additional information about classic policy bindings, see Configure a classic policy.

About evaluation order of policies

For classic policies, policy groups and policies within a group are evaluated in a particular order, depending on the following:

- The bind point for the policy, for example, whether the policy is bound to request-time processing for a virtual server or global response-time processing. For example, at request time, the Citrix ADC evaluates all request-time classic policies before evaluating any virtual server-specific policies.
- The priority level for the policy. For each point in the evaluation process, a priority level that is assigned to a policy determines the order of evaluation relative to other policies that share the same bind point. For example, when the Citrix ADC evaluates a bank of request-time, virtual server-specific policies, it starts with the policy that is assigned to the lowest priority value. In classic policies, priority levels must be unique across all bind points.

For Advanced policies, as with classic policies, the Citrix ADC selects a grouping, or bank, of policies at a particular point in overall processing. Following is the order of evaluation of the basic groupings, or banks, of Advanced policies:

1. Request-time global override
2. Request-time, virtual server-specific (one bind point per virtual server)
3. Request-time global default
4. Response-time global override
5. Response-time virtual server-specific
6. Response-time global default
However, within any of the preceding banks of policies, the order of evaluation is more flexible than in classic policies. Within a policy bank, you can point to the next policy to be evaluated regardless of the priority level, and you can invoke policy banks that belong to other bind points and user-defined policy banks.

**Order of evaluation based on traffic flow**

As traffic flows through the Citrix ADC and is processed by various features, each feature performs policy evaluation. Whenever a policy matches the traffic, the Citrix ADC stores the action and continues processing until the data is about to leave the Citrix ADC. At that point, the Citrix ADC typically applies all matching actions. Integrated Caching, which only applies a final Cache or NoCache action, is an exception.

Some policies affect the outcome of other policies. Following are examples:

- If a response is served from the integrated cache, some other Citrix ADC features do not process the response or the request that initiated it.
- If the Content Filtering feature prevents a response from being served, no subsequent features evaluate the response.

If the application firewall rejects an incoming request, no other features can process it.

**Classic and advanced policy expressions**

February 12, 2020

One of the most fundamental components of a policy is its rule. A policy rule is a logical expression that enables the policy to analyze traffic. Most of the policy's functionality is derived from its expression.

An expression matches characteristics of traffic or other data with one or more parameters and values. For example, an expression can enable the Citrix ADC to accomplish the following:

- Determine whether a request contains a certificate.
- Determine the IP address of a client that sent a TCP request.
- Identify the data that an HTTP request contains (for example, a popular spreadsheet or word processing application).
- Calculate the length of an HTTP request.
About classic expressions

Classic expressions enable you to evaluate basic characteristics of data. They have a structured syntax that performs string matching and other operations.

Following are a few simple examples of classic expressions:

- An HTTP response contains a particular type of Cache Control header.
  res.http.header Cache-Control contains public
- An HTTP response contains image data.
  res.http.header Content-Type contains image
- An SSL request contains a certificate.
  req.ssl.client.cert exists

About advanced policy expressions

Any feature that uses default syntax policies also uses Advanced expressions. For information about which features use Advanced policies, see the table Citrix ADC Feature, Policy Type, and Policy Usage.

Advanced policy expressions have a few other uses. In addition to configuring Advanced expressions in policy rules, you configure Advanced expressions in the following situations:

- Integrated Caching:
  You use Advanced policy expressions to configure a selector for a content group in the integrated cache.
- Load Balancing:
  You use Advanced policy expressions to configure token extraction for a load balancing virtual server that uses the TOKEN method for load balancing.
- Rewrite:
  You use Advanced policy expressions to configure rewrite actions.
- Rate-based policies:
  You use Advanced policy expressions to configure limit selectors when configuring a policy to control the rate of traffic to various servers.

Following are a few simple examples of Advanced policy expressions:

- An HTTP request URL contains no more than 500 characters.
  http.req.url.length <= 500
An HTTP request contains a cookie that has fewer than 500 characters.

\[
\text{http.req.cookie.length} \ < 500
\]

An HTTP request URL contains a particular text string.

\[
\text{http.req.url.contains("\.html")}
\]

**Converting policy expressions using NSPEPI tool**

July 8, 2020

Classic policy-based features and functionalities are deprecated from NetScaler 12.0 build 56.20 onwards. As an alternative, Citrix recommends you to use the Advanced policy infrastructure. As part of this effort, when you upgrade to Citrix ADC 12.1 build 56.20 or later, you must replace the Classic policy-based features and functionalities to its corresponding non-deprecated features and functionalities. Also, you must convert Classic policies and expressions to Advanced policies and expressions. Also, all new Citrix ADC features support only Advanced policy infrastructure.

The nspepi tool can perform the following:

1. Convert Classic policy expressions to Advanced policy expressions.
2. Convert certain Classic policies and their entity bindings to Advanced policies and bindings.
3. Convert a few additional deprecated features to their corresponding non-deprecated features.
4. Convert classic filter commands to advanced filter commands.
5. Convert classic filter features to advanced features for goto expression as END or use_innovation

**Note:**

After the nspepi tool successfully converts the ns.conf config file, the tool displays the converted file as a new file with a prefix, “new_”. If the converted config file has errors or warnings, you must manually fix them as part of the conversion process. Once converted, you must test the file in test environment and then use it to replace the actual ns.conf config file. After testing, you must reboot the appliance for the newly converted or fixed ns.conf config file.

Features that only support Classic policies or expressions are deprecated and they need to be replaced by the corresponding non-deprecated features.

**Note:**
Conversion warnings and error files

Before you use the tool for your conversion, there are few warnings to keep in mind:

1. All warnings and errors are output to the console. There is a warning file created where the configuration files are stored.
2. The warnings and error file has the same name as the input file but with a prefix “warn_” added to the file name. During expression conversion (when using -e), the warnings will show up in the current directory with a name “warn_expr”.

Note:
This file is in a standard log file format, with date/time stamp and log level. Previous instances of the file are kept with suffixes like “.1”, “.2”, etc. as the tool is run multiple times. At most 10 instances will be kept.

 Converted file format

When converting a configuration file (using “-f”), the converted file will be put into the same directory as where the input configuration file exists with the same name but a prefix “new_”.

Commands handled by the nspepi conversion tool

Following are the commands handled during the auto conversion process.

- The following Classic policies and their expressions are converted to Advanced policies and expressions. This includes conversion of entity bindings including global bindings.
  1. add appfw policy
  2. add authorization policy
  3. add cmp policy
  4. add cr policy
  5. add cs policy
  6. add tm sessionPolicy
  7. add vpn trafficPolicy
  8. add filter action
  9. add filter policy
  10. filter policy binding to load balancing, content switching, cache redirection, and global.
Note:
However, for “add tm sessionPolicy” and “add vpn trafficPolicy”, you cannot bind to global override in Advanced policies.

- The rule parameter configured in “add lb vserver” is converted from Classic expression to Advanced expression.
- The SPDY parameter configured in “add ns httpProfile” or “set ns httpProfile” command is changed to “-http2 ENABLED”.
- Named expressions (“add policy expression” commands). Each Classic named policy expression is converted to its corresponding Advanced named expression with “nspepi_adv_” set as the prefix. In addition, usage of named expressions for the converted Classic expressions is changed to the corresponding Advanced named expressions. In addition, every named expression will have two named expressions, where one is Classic and the other one is Advanced (as shown below).

For example:

1. `add policy expression classic_expr ns_true`
2. Converts to:
3. `add policy expression classic_expr ns_true`
4. `add policy expression nspepi_adv_classic_expr TRUE`

- The policyType parameter configured in the “set cmp parameter” command is changed to Advanced policy type.

Convert classic filter commands to advanced filter commands

The nspepi tool can convert commands based on classic filter actions such as add, bind and so forth to advanced filter commands.

However, the nepepi tool does not support the following filter commands.

1. `add filter action <action Name> FORWARD <service name>`
2. `add filter action <action name> ADD prebody`
3. `add filter action <action name> ADD postbody`

Note:

1. If there are existing rewrite or responder features in ns.conf and their policies are bound globally with GOTO expression as END or USER_INVOCATION_RESULT and bind type is REQ_X or RES_X then the tool converts bind filter commands partially and comments out. Warning will be displayed to put manual effort.
2. If there are existing rewrite or responder features and their policies are bound to virtual...
servers (for example, load balancing, content switching or cache redirect) of type HTTPS
with GOTO - END or USER_INVOCATION_RESULT, the tool converts bind filter commands
partially and then comments out. Warning will be displayed to put manual effort.

Example

Following is a sample input:

```
1 add lb vserver v1 http 1.1.1.1 80 -persistenceType NONE -cltTimeout 9000
2 add cs vserver csv1 HTTP 1.1.1.2 80 -cltTimeout 180 -persistenceType NONE
3 add cr vserver crv1 HTTP 1.1.1.3 80 -cacheType FORWARD
4 add service svc1 1.1.1.4 http 80
5 add filter action fact_add add 'header:value'
6 add filter action fact_variable add 'H1:%HTTP.TRANSID%'
7 add filter action fact_prebody add prebody
8 add filter action fact_error_act1 ERRORCODE 200 "<HTML>Good URL</HTML>"
9 add filter action fact_forward_act1 FORWARD svc1
10 add filter policy fpol_add_res -rule ns_true -resAction fact_add
11 add filter policy fpol_error_res -rule ns_true -resAction
   fact_error_act1
12 add filter policy fpol_error_req -rule ns_true -reqAction
   fact_error_act1
13 add filter policy fpol_add_req -rule ns_true -reqAction fact_add
14 add filter policy fpol_variable_req -rule ns_true -reqAction
   fact_variable
15 add filter policy fpol_variable_res -rule ns_true -resAction
   fact_variable
16 add filter policy fpol_prebody_req -rule ns_true -reqAction
   fact_prebody
17 add filter policy fpol_prebody_res -rule ns_true -resAction
   fact_prebody
18 add filter policy fpol_forward_req -rule ns_true -reqAction
   fact_forward_act1
19 bind lb vserver v1 -policyName fpol_add_res
20 bind lb vserver v1 -policyName fpol_add_req
21 bind lb vserver v1 -policyName fpol_error_res
22 bind lb vserver v1 -policyName fpol_error_req
23 bind lb vserver v1 -policyName fpol_variable_res
24 bind lb vserver v1 -policyName fpol_variable_req
25 bind lb vserver v1 -policyName fpol_forward_req
26 bind cs vserver csv1 -policyName fpol_add_req
27 bind cs vserver csv1 -policyName fpol_add_res
```
Following is a sample output. All converted commands are commented.

```
 28 bind cs vserver csv1 -policyName fpol_error_res
 29 bind cs vserver csv1 -policyName fpol_error_req
 30 bind cr vserver crv1 -policyName fpol_add_req
 31 bind cr vserver crv1 -policyName fpol_add_res
 32 bind cr vserver crv1 -policyName fpol_error_res
 33 bind cr vserver crv1 -policyName fpol_error_req
 34 bind cr vserver crv1 -policyName fpol_forward_req
 35 bind filter global fpol_add_req
 36 bind filter global fpol_add_res
 37 bind filter global fpol_error_req
 38 bind filter global fpol_error_res
 39 bind filter global fpol_variable_req
 40 bind filter global fpol_variable_res -state DISABLED
 41 bind filter global fpol_prebody_req
 42 bind filter global fpol_forward_req
 43 bind filter global fpol_variable_res
 44 After conversion, warning/error messages will be displayed for manual effort.
 45 Warning files:
 46 cat warn_<input file name>:
 52 2019-11-07 17:13:39,060: WARNING - Following bind command is commented out because state is disabled. Advanced expressions only have a fixed ordering of the types of bindings without interleaving, except that global bindings are allowed before all other bindings and after all bindings. If you have global bindings in the middle of non-global bindings or any other interleaving then you will need to reorder all your bindings for that feature and direction. Refer to nspepi documentation. If command is required please take a backup because comments will not be saved in ns.conf after triggering 'save ns config': bind filter global fpol_variable_res -state DISABLED
```
1 cat new_<input file name>
2 add rewrite action fact_add insert_http_header header "\\"value\\""
3 add filter action fact_prebody add prebody
4 add filter action fact_forward_act1 FORWARD svc1
5 add filter policy fpol_prebody_req -rule ns_true -reqAction fact_prebody
6 add filter policy fpol_prebody_res -rule ns_true -resAction fact_prebody
7 add filter policy fpol_forward_req -rule ns_true -reqAction fact_forward_act1
8 bind lb vserver v1 -policyName fpol_forward_req
9 bind cr vserver crv1 -policyName fpol_forward_req
10 #bind filter global fpol_variable_res -state DISABLED
11 bind filter global fpol_prebody_req
12 bind filter global fpol_forward_req
13 add rewrite action nspepi_adv_fact_variable insert_http_header H1 HTTP. RES.TXID
14 add rewrite action fact_variable insert_http_header H1 HTTP.REQ.TXID
15 add responder action fact_error_act1 respondwith "HTTP.REQ.VERSION. APPEND(\" 200 OK\r\n\n)"
16 nConnection: close\r\n17 nContent-Length: 21\r\n\n" HTTP.
18 <HTML>Good URL</HTML>"
19 add rewrite action nspepi_adv_fact_error_act1 replace_http_res "HTTP. REQ.VERSION. APPEND(\" 200 OK\r\n\n)"
20 nConnection: close\r\n21 nContent-Length: 21\r\n\n" HTTP.
22 <HTML>Good URL</HTML>"
23 add rewrite policy fpol_add_res TRUE fact_add
24 add rewrite policy fpol_error_res TRUE nspepi_adv_fact_error_act1
25 add responder policy fpol_error_req TRUE fact_error_act1
26 add rewrite policy fpol_add_req TRUE fact_add
27 add rewrite policy fpol_variable_req TRUE fact_variable
28 add rewrite policy fpol_variable_res TRUE nspepi_adv_fact_variable
29 set cmp parameter -policyType ADVANCED
30 bind rewrite global fpol_add_req 100 NEXT -type REQ_DEFAULT
31 bind rewrite global fpol_variable_req 200 NEXT -type REQ_DEFAULT
32 bind rewrite global fpol_add_res 100 NEXT -type RES_DEFAULT
33 bind rewrite global fpol_error_res 200 NEXT -type RES_DEFAULT
34 bind rewrite global fpol_variable_res 300 NEXT -type RES_DEFAULT
35 bind responder global fpol_error_req 100 END -type REQ_DEFAULT
36 bind lb vserver v1 -policyName fpol_add_res -type RESPONSE -priority 100 -gotoPriorityExpression NEXT
37 bind lb vserver v1 -policyName fpol_error_res -type RESPONSE -priority
200 -gotoPriorityExpression NEXT
38 bind lb vserver v1 -policyName fpol_variable_res -type RESPONSE -priority 300 -gotoPriorityExpression NEXT
39 bind lb vserver v1 -policyName fpol_add_req -type REQUEST -priority 100 -gotoPriorityExpression NEXT
40 bind lb vserver v1 -policyName fpol_variable_req -type REQUEST -priority 200 -gotoPriorityExpression NEXT
41 bind lb vserver v1 -policyName fpol_error_req -type REQUEST -priority 100 -gotoPriorityExpression END
42 bind cs vserver csv1 -policyName fpol_add_req -type REQUEST -priority 100 -gotoPriorityExpression NEXT
43 bind cs vserver csv1 -policyName fpol_add_res -type RESPONSE -priority 100 -gotoPriorityExpression NEXT
44 bind cs vserver csv1 -policyName fpol_error_res -type RESPONSE -priority 200 -gotoPriorityExpression NEXT
45 bind cs vserver csv1 -policyName fpol_error_req -type REQUEST -priority 100 -gotoPriorityExpression END
46 bind cr vserver crv1 -policyName fpol_add_req -type REQUEST -priority 100 -gotoPriorityExpression NEXT
47 bind cr vserver crv1 -policyName fpol_add_res -type RESPONSE -priority 200 -gotoPriorityExpression NEXT
48 bind cr vserver crv1 -policyName fpol_error_res -type RESPONSE -priority 200 -gotoPriorityExpression NEXT
49 bind cr vserver crv1 -policyName fpol_error_req -type REQUEST -priority 100 -gotoPriorityExpression END

Convert classic filter commands to advanced feature commands if existing rewrite or responder policy bindings have goto expression END or USE_INVOCATION

In this conversion, if a rewrite policy bound to one or more virtual server and if the server has END or USE_INVOCATION_RESULT, the tool comments out the commands.

Example

Following is a sample input command:

1 COPY
2 add filter policy fpoll -rule ns_true -resAction reset
3 add filter policy fpol2 -rule ns_true -reqAction reset
4 add rewrite policy poll true NOREWRITE
5 add rewrite policylabel pl http_res
6 bind rewrite policylabel pl poll 1
Following is a sample output command:

```
COPY
add rewrite policy pol1 true NOREWRITE
add rewrite policylabel pl http_res
bind rewrite policylabel pl pol1 1
add responder policy pol2 true NOOP
add responder policylabel pl -policylabeltype HTTP
bind responder global NOPOLICY 1 USE_INVOCATION_RESULT -type RES_DEFAULT
  -invoke policylabel pl
```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Commands not handled by the nspepi conversion tool

Following are some commands that are not handled as part of the auto conversion process.

- Some bindings cannot be converted if there are certain interleaving of priorities between global and non-global bind points, between users and groups, and also among bindings to different entities. These will have the affected configuration commented out and an error produced. Such configurations must be converted manually.
- Both Classic and Advanced policies can be bound to cmp global. There are many cases where the functionality will change once Classic policies are converted to Advanced policies. We have converted commands that can be solved by commenting out some policies. Still there are some commands that cannot be converted; in such cases an error will be produced and conversion has to be done manually.
- Classic content switching policies that are bound to multiple bind points are not handled.
- Built-in Classic policy bindings in all features are not handled.
- Not all uses of Classic built-in named expressions are converted to equivalent Advanced named expressions.
- Named expressions in a load balancing rule are not handled.
- Client security expressions are not handled.
- Bindings to GSLB virtual servers are not handled.
- The “-precedence” option for content switching and cache redirection virtual servers is not handled.

Known Issues

The following errors can be produced by the nspepi tool:

- If there is an issue when converting an expression.
Citrix ADC 13.0

- If a named policy expression uses the -clientSecurityMessage parameter because this parameter is not supported in Advanced policy expression.

Note:
All classic policy bindings with -state option disabled are commented out. The -state option is not available for Advanced policy bindings.

Running the nspepi tool

The following is a command line example for running the nspepi tool. This tool is run from the command line of the shell (you will need to type the “shell” command to the NetScaler “CLI” to get to that). Either “-f” or “-e” must be specified to perform a conversion. Use of “-d” is mainly intended for Citrix personnel to analyze for support purposes.

```
1 usage: nspepi [-h]
2 (-e <classic policy expression> | -f <path to ns config file>)
3 [-d] [-v] [-V]
4
5 Convert classic policy expressions to advanced policy expressions and deprecated commands to non-deprecated commands.
6 optional arguments:
7 -h, --help show this help message and exit
8 -e <classic policy expression>, --expression <classic policy expression>
9 convert classic policy expression to advanced policy expression (maximum length of 8191 allowed)
10 -f <path to ns config file>, --infile <path to ns config file>
11 convert netscaler config file
12 -d, --debug show debug output
13 -v, --verbose show verbose output
14 -V, --version show program's version number and exit
```

Following are few examples of running nspepi tool from the command line interface:

**Example output for –e parameter:**

```
1 root@ns# nspepi -e "req.http.header foo == \"bar\""
2 "HTTP.REQ.HEADER("\"foo\")\".EQ\"\"\"\"bar\"")"
```

**Example output for -f parameter:**
1 root@ns# cat sample.conf
2 add c**Input**r vserver cr_vs HTTP -cacheType TRANSPARENT -cltTimeout 180 -originUSIP OFF
3 add cr policy cr_poll1 -rule ns_true
4 bind cr vserver cr_vs -policyName cr_poll

Running nspepi with -f parameter:

1 root@ns# nspepi -f sample.conf
2 root@ns#

Example output of -f parameter along with -v parameter

1 root@ns# nspepi -f sample.conf -v
2 INFO - add cr vserver cr_vs HTTP -cacheType TRANSPARENT -cltTimeout 180 -originUSIP OFF
3 INFO - add cr policy cr_poll1 -rule TRUE -action ORIGIN
4 INFO - set cmp parameter -policyType ADVANCED
5 INFO - bind cr vserver cr_vs -policyName cr_poll1 -priority 100 -gotoPriorityExpression END -type REQUEST
6 root@ns#

Example output with converted file and warning files generated

Converted Config file:

1 root@ns# cat new_sample.conf
2 add cr vserver cr_vs HTTP -cacheType TRANSPARENT -cltTimeout 180 -originUSIP OFF
3 add cr policy cr_poll1 -rule TRUE -action ORIGIN
4 set cmp parameter -policyType ADVANCED
5 bind cr vserver cr_vs -policyName cr_poll1 -priority 100 -gotoPriorityExpression END -type REQUEST

Example output of a sample configuration with no errors or warnings:

1 root@ns# cat warn_sample.conf
2 root@ns#

Example output of a sample configuration with warnings:

1 root@ns# cat sample_2.conf
Example of running nspepi with -f parameter:

```bash
root@ns# nspepi -f sample_2.conf
ERROR - Error in converting expression security_expr : conversion of clientSecurityMessage based expression is not supported.
WARNING - Following bind command is commented out because state is disabled. Advanced expressions only have a fixed ordering of the types of bindings without interleaving, except that global bindings are allowed before all other bindings and after all bindings. If you have global bindings in the middle of non-global bindings or any other interleaving then you will need to reorder all your bindings for that feature and direction. Refer to nspepi documentation. If command is required please take a backup because comments will not be saved in ns.conf after triggering 'save ns config': bind cmp global cmp_pol2 -state DISABLED

Warning - Bindings of advanced CMP policies to cmp global are commented out, because initial global cmp parameter is classic but advanced policies are bound. Now global cmp parameter policy type is set to advanced. If commands are required please take a backup because comments will not be saved in ns.conf after triggering 'save ns config'. Advanced expressions only have a fixed ordering of the types of bindings without interleaving, except that global bindings are allowed before all other bindings and after all bindings. If you have global bindings in the middle of non-global bindings or any other interleaving then you will need to reorder all your bindings for that feature and direction. Refer to nspepi documentation.

root@ns#
```

Converted file:

```bash
root@ns# cat new_sample_2.conf
add policy expression security_expr "req.tcp.destport == 80" -
```
clientSecurityMessage "Not allowed"

set cmp parameter -policyType ADVANCED
add cmp policy cmp_pol1 -rule TRUE -resAction COMPRESS
add cmp policy cmp_pol2 -rule TRUE -resAction COMPRESS
add cmp policy cmp_pol3 -rule TRUE -resAction COMPRESS
#bind cmp global cmp_pol2 -state DISABLED
#bind cmp global cmp_pol3 -priority 1 -gotoPriorityExpression END -type RES_DEFAULT
bind cmp global cmp_pol1 -priority 100 -gotoPriorityExpression END -type RES_DEFAULT
bind lb vserver lb_vs -policyName cmp_pol2 -priority 100 -gotoPriorityExpression END -type RESPONSE

Binding Priorities

Advanced policies do not allow arbitrary interleaving by priority between global and non-global and between different binding types. If you rely on such interleaving of Classic policy priorities, you will need to adjust the priorities to conform to the Advanced policy rules and to get the behavior you desire.

Priorities in Advanced policies are local to a bind point. A bind point is a unique combination of protocol, feature, direction, and entity (entities are specific virtual servers, users, groups, services, and either global override or global default). Policy priorities are not followed across bind points.

For a given protocol, feature, and direction the order of evaluation of Advanced policies is given below:

- Global override.
- (Current) AAA user.
- AAA groups (that the user is a member of) in order of weight - ordering is undefined if two or more groups have the same weight.
- LB virtual server that either the request was received on or that Content Switching selected.
- Content switching virtual server, cache redirection virtual server that the request was received on.
- Service selected by load balancing.
- Global default.

For authorization policy evaluation, the order is:

- System override.
- Load balancing virtual server that either the request was received on or that CS selected.
- Content switching virtual server that the request was received on.
- System default.

Within each bind point, the polices are evaluated in order of priority from lowest numbered to highest numbered. Of course policies are only evaluated for the protocol used and direction that the message was received from.

Classic policy bindings that require manual reprioritization

Here are some types of Classic policy bindings that will require manual reprioritization to accomplish your needs. All these are for a given feature and direction.

- Classic priorities that increase in priority number opposite to the direction of the above entity type lists. For example a content switching virtual server binding lower than a load balancing virtual server binding.
- Classic priorities that interleave AAA groups. One part of one group is before some other group and yet another part is after part of that other group.
• Classic priorities that increase in number other than the order of weights of AAA groups.
• Classic global priorities that are less than some non-global priority and the same global priorities are greater than some other non-global priority (in other words, any segment of priorities that are a non-global, followed by one or more globals, followed by a non-global).

Classic Policy Deprecation FAQs

July 8, 2020

• What are the classic policies deprecated from Citrix ADC 12.0 release onwards?

All features and functionalities mentioned in the below table are deprecated from Citrix ADC 12.1 build 51.16. The features that are deprecated in Citrix ADC 12.1 build 51.16 onwards will be removed in a future release. Citrix recommends you to use the alternative features mentioned in the deprecated table.

• How can I convert Classic policy based feature and functionalities to Advanced policy?

You can use the Citrix ADC proprietary nspepi tool to convert commands, expressions, and configurations. nspepi tool helps to convert all the Classic expressions in the Citrix ADC configuration to the Advanced policy. For more information about nspepi tool, see Converting policy expressions using NSPEPI tool.

• From which release onwards are Classic policy based features and functionalities deprecated?

Citrix ADC 12.0 build 56.20 onwards.

• What steps should I take when I upgrade my appliance to a build that does not support the features listed in the table (example, Citrix ADC 13.0)?

Citrix recommends replacing the Classic policy based features and functionalities with the replacement features and functionalities mentioned in Table 1 above before upgrading to 13.0.

• How long will the deprecated features be supported on Citrix ADC appliance??

Citrix supports the policy based features and functionalities as per current software support guidelines. For more details refer to Citrix ADC Product Matrix.

• Do I have to reboot my appliance after converting the configuration file?

Yes, you have to reboot the Citrix ADC instance after successful conversion of ns.config file.
**Before you proceed**

May 14, 2019

Before configuring expressions and policies, be sure you understand the relevant Citrix ADC feature and the structure of your data, as follows:

- Read the documentation on the relevant feature.
- Look at the data stream for the type of data that you want to configure.

You may want to run a trace on the type of traffic or content that you want to configure. This will give you an idea of the parameters and values, and operations on these parameters and values, that you need to specify in an expression.

**Note:** The Citrix ADC supports either classic or Advanced policy within a feature. You cannot have both types in the same feature. Over the past few releases, some Citrix ADC features have migrated from using classic policies and expressions to Advanced policy and expressions. If a feature of interest to you has changed to the Advanced policy format, you may have to manually migrate the older information. Following are guidelines for deciding if you need to migrate your policies:

- If you configured classic policies in a version of the Integrated Caching feature prior to release 9.0 and then upgrade to version 9.0 or later, there is no impact. All legacy policies are migrated to the Advanced policy format.
- For other features, you need to manually migrate classic policies and expressions to the Advanced syntax if the feature has migrated to the Advanced policy.

**Configure advanced policy infrastructure**

May 16, 2019

You can create advanced policies for various Citrix ADC features, including DNS, Rewrite, Responder, and Integrated Caching, and the clientless access function in the Citrix Gateway. Policies control the behavior of these features.
When you create a policy, you assign it a name, a rule (an expression), feature-specific attributes, and an action that is taken when data matches the policy. After creating the policy, you determine when it is invoked by binding it globally or to either request-time or response-time processing for a virtual server.

Policies that share the same bind point are known as a policy bank. For example, all policies that are bound to a virtual server constitute the policy bank for the virtual server. When binding the policy, you assign it a priority level to specify when it is invoked relative to other policies in the bank. In addition to assigning a priority level, you can configure an arbitrary evaluation order for policies in a bank by specifying Goto expressions.

In addition to policy banks that are associated with a built-in bind point or a virtual server, you can configure policy labels. A policy label is a policy bank that is identified by an arbitrary name. You invoke a policy label, and the policies in it, from a global or virtual-server-specific policy bank. A policy label or a virtual-server policy bank can be invoked from multiple policy banks.

For some features, you can use the policy manager to configure and bind policies.

Rules for names in identifiers used in policies

February 12, 2020

The names of identifiers in the named expression, HTTP callout, pattern set, and rate limiting features must begin with an ASCII alphabet or an underscore (_). The remaining characters can be ASCII alphanumeric characters or underscores (_).

The names of these identifiers must not begin with the following reserved words:

- The words ALT, TRUE, or FALSE or the Q or S one-character identifier.
- The special-syntax indicator RE (for regular expressions) or XP (for XPath expressions).
- Expression prefixes, which currently are the following:
  - CLIENT
  - EXTEND
  - HTTP
  - SERVER
  - SYS
  - TARGET
  - TEXT
Additionally, the names of these identifiers cannot be the same as the names of enumeration constants used in the policy infrastructure. For example, the name of an identifier cannot be IGNORE-CASE, YEAR, or LATIN2_CZECH_CS (a MySQL character set).

**Note:** The Citrix ADC appliance performs a case-insensitive comparison of identifiers with these words and enumeration constants. For example, names of the identifiers cannot begin with TRUE, True, or true.

Create or modify a policy

February 18, 2020

All policies have some common elements. Creating a policy consists, at minimum, of naming the policy and configuring a rule. The policy configuration tools for the various features have areas of overlap, but also differences. For the details of configuring a policy for a particular feature, including associating an action with the policy, see the documentation for the feature.

To create a policy, begin by determining the purpose of the policy. For example, you may want to define a policy that identifies HTTP requests for image files, or client requests that contain an SSL certificate. In addition to knowing the type of information that you want the policy to work with, you need to know the format of the data that the policy is analyzing.

Next, determine whether the policy is globally applicable, or if it pertains to a particular virtual server. Also consider the effect that the order in which your policies are evaluated (which will be determined by how you bind the policies) will have on the policy that you are about to configure.

Create a policy by using the CLI

At the command prompt, type the following commands to create a policy and verify the configuration:

```bash
1 - add responder|dns|cs|rewrite|cache policy <policyName> -rule <expression> [<feature-specific information>]
2
3 - show rewrite policy <name>
```
Example 1:

```
1 add rewrite policy "pol_remove-ae" true "act_remove-ae"
2 Done
3 > show rewrite policy pol_remove-ae
4   Name: pol_remove-ae
5   Rule: true
6   RewriteAction: act_remove-ae
7   UndefAction: Use Global
8   Hits: 0
9   Undef Hits: 0
10  Bound to: GLOBAL RES_OVERRIDE
11  Priority: 90
12  GotoPriorityExpression: END
13 Done
```

Example 2:

```
1 add cache policy BranchReportsCachePolicy -rule q{
2   http.req.url.query.value("actionoverride").contains("branchReports")
3   -action cache
4 } Done
5 show cache policy BranchReportsCachePolicy
6   Name: BranchReportsCachePolicy
7   Rule: http.req.url.query.value("actionoverride").contains("branchReports")
8   CacheAction: CACHE
9   Stored in group: DEFAULT
10  UndefAction: Use Global
11   Hits: 0
12   Undef Hits: 0
13 Done
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see Configure advanced policy expressions: Get started.

Create or modify a policy by using the GUI

1. In the navigation pane, expand the name of the feature for which you want to configure a policy, and then click Policies. For example, you can select Content Switching, Integrated Caching, DNS, Rewrite, or Responder.
2. In the details pane, click Add, or select an existing policy and click Open. A policy configuration dialog box appears.

3. Specify values for the following parameters. (An asterisk indicates a required parameter. For a term in parentheses, see the corresponding parameter in “Parameters for creating or modifying a policy.”)

4. Click Create, and then click Close.

5. Click Save. A policy is added.

   Note: After you create a policy, you can view the policy’s details by clicking the policy entry in the configuration pane. Details that are highlighted and underlined are links to the corresponding entity (for example, a named expression).

---

Policy configuration examples

May 31, 2019

These examples show how policies and their associated actions are entered at the command line interface. In the configuration utility, the expressions would appear in the Expression window of the feature-configuration dialog box for the integrated caching or rewrite feature.

Following is an example of creating a caching policy. Note that actions for caching policies are built in, so you do not need to configure them separately from the policy.

```plaintext
add cache policy BranchReportsCachePolicy -rule q{
  http.req.url.query.value("actionoverride").contains("branchReports") }
```

Following is an example of a rewrite policy and action:

```plaintext
add rewrite action myAction1 INSERT_HTTP_HEADER "myHeader" "valueForMyHeader"
add rewrite policy myPolicy1 "http.req.url.contains("myURLstring")" myAction1
```

Note: At the command line, quote marks within a policy rule (the expression) must be escaped or delimited with the q delimiter. For more information, see Configure advanced policy expressions: Get started.

Configure and bind policies with the policy manager

September 2, 2020

Warning:
Classic policy expressions are no longer supported from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies.

Some applications provide a specialized Policy Manager in the Citrix ADC configuration utility to simplify configuring policy banks. It also lets you find and delete policies and actions that are not being used.

The Policy Manager is currently available for the Rewrite, Integrated Caching, Responder, and Compression features.

The following are keyboard equivalents for the procedures in this section:

- For editing a cell in the Policy Manager, you can tab to the cell and click F2 or press the SPACE bar on the keyboard.
- To select an entry in a drop-down menu, you can tab to the entry, press the space bar to view the drop-down menu, use the UP and DOWN ARROW keys to navigate to the entry that you want, and press the space bar again to select the entry.
- To cancel a selection in a drop-down menu, press the Escape key.
- To insert a policy, tab to the row above the insertion point and press Control + Insert, or click Insert Policy.
- To remove a policy, tab to the row that contains the policy and press Delete.

Note: Note that when you delete the policy, the Citrix ADC searches the Goto Expression values of other policies in the bank. If any of these Goto Expression values match the priority level of the deleted policy, they are removed.

Configure policy bindings by using the policy manager

1. In the navigation pane, click the feature for which you want to configure policies. The choices are Responder, Integrated Caching, Rewrite or Compression.

2. In the details pane, click Policy Manager.

3. If you are configuring classic policy bindings for compression, in the Compression Policy Manager dialog box, click Switch to Classic Syntax. The dialog box switches to the classic syntax view and displays the Switch to Advanced Policy button. At any time before you complete con-
figuring policy bindings, if you want to configure bindings for policies that use the Advanced
Policy click the Switch to Advanced Policy button.

4. For features other than Responder, to specify the bind point, click Request or Response, and
then click one of the request-time or response-time bind points. The options are Override
Global, LB Virtual Server, CS Virtual Server, Default Global, or Policy Label. If you are configuring
the Responder, the Request and Response flow types are not available.

5. To bind a policy to this bind point, click Insert Policy, and select a previously configured policy,
a NOPOLICY label, or the New policy option. Depending on the option that you select, you have
the following choices:

- **New policy**: Create the policy as described in “Create or modify a policy,” and then con-
figure the priority level, GoTo expression, and policy invocation as described in the table,
“Format of each entry in a policy bank.”

- **Existing policy, NOPOLICY, or NOPOLICY\<feature name\>**: Configure the priority
level, GoTo expression, and policy invocation as described in the table, “Format of each
entry in a policy bank.” The NOPOLICY or NOPOLICY\<feature name\> options are
available only for policies that use Advanced Policies.

6. Repeat the preceding steps to add entries to this policy bank.

7. To modify the priority level for an entry, you can do any of the following:

- Double-click the Priority field for an entry and edit the value.
- Click and drag a policy to another row in the table.
- Click Regenerate Priorities.

In all three cases, priority levels of all other policies are modified as needed to accommodate the
new value. Goto Expressions with integer values are also updated automatically. For example,
if you change a priority value of 10 to 100, all policies with a Goto Expression value of 10 are
updated to the value 100.

8. To change the policy, action, or policy bank invocation for a row in the table, click the down
arrow to the right of the entry and do one of the following:

- To change the policy, select another policy name or select New Policy and follow the steps
  in Create or modify a policy.
- To change the Goto Expression, select Next, End, USE_INVOCATION_RESULT, or select
  more and enter an expression whose result returns the priority level of another entry in
  this policy bank.
- To modify an invocation, select an existing policy bank, or click New Policy Label and fol-
  low the steps in Bind a policy to a policy label.

9. To unbind a policy or a policy label invocation from this bank, click any field in the row that
contains the policy or policy label, and then click Unbind Policy.
10. When you are done, click Apply Changes. A message in the status bar indicates that the policy is bound successfully.

**Remove unused policies by using the policy manager**

1. In the navigation pane, click the feature for which you want to configure the policy bank. The choices are Responder, Integrated Caching, or Rewrite.
2. In the details pane, click `<Feature Name>` policy manager.
3. In the Feature Name > Policy Manager dialog box, click Cleanup Configuration.
4. In the Cleanup Configuration dialog box, select the items that you want to delete, and then click Remove.
5. In the Remove dialog box, click Yes.
6. Click Close. A message in the status bar indicates that the policy is removed successfully.

© 1999-2020 Citrix Systems, Inc. All rights reserved.

**Unbind a policy**

February 12, 2020

If you want to re-assign a policy or delete it, you must first remove its binding.

**Unbind an integrated caching, rewrite, or compression advanced policy globally by using the CLI**

At the command prompt, type the following commands to unbind an integrated caching, rewrite, or compression Advanced policy globally and verify the configuration:

```
1 - unbind cache|rewrite|cmp global <policyName> [-type req_override| req_default|res_override|res_default] [-priority <positiveInteger>]
2
3 - show cache|rewrite|cmp global
```

**Example:**

```
1 > unbind cache global_nonPostReq
2 Done
3 > show cache global
4   1) Global bindpoint: REQ_DEFAULT
```
The priority is required only for the “dummy” policy named NOPOLICY.

**Unbind a responder policy globally by using the CLI**

At the command prompt, type the following commands to unbind a responder policy globally and verify the configuration:

```
1 - unbind responder global <policyName> [-type override|default] [-priority <positiveInteger>]
2
3 - show responder global
```

**Example:**

```
1 > unbind responder global pol404Error
2 Done
3 > show responder global
4 1) Global bindpoint: REQ_DEFAULT
5 Number of bound policies: 1
6 Done
```

The priority is required only for the “dummy” policy named NOPOLICY.

**Unbind a DNS policy globally by using the CLI**

At the command prompt, type the following commands to unbind a DNS policy globally and verify the configuration:

```
1 - unbind responder global <policyName>
2
3 - unbind responder global
```

**Example:**

```
1 unbind dns global dfgdfg
2 Done
```
Unbind an advanced policy from a virtual server by using the CLI

At the command prompt, type the following commands to unbind an Advanced policy from a virtual server and verify the configuration:

```
1 - unbind cs vserver <name> -policyName <policyName> [-priority <positiveInteger>] [-type REQUEST|RESPONSE]
2
3 - show lb vserver <name>
```

Example:

```
1 unbind cs vserver vs-cont-switch -policyName poll
2 Done
3 > show cs vserver vs-cont-switch
4 vs-cont-switch (10.102.29.10:80) - HTTP Type: CONTENT
5 State: UP
6 Last state change was at Wed Aug 19 08:56:55 2009 (+18 ms)
7 Time since last state change: 0 days, 02:47:55.750
8 Client Idle Timeout: 180 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down: DISABLED
11 Port Rewrite: DISABLED
12 State Update: DISABLED
13 Default: Content Precedence: RULE
14 Vserver IP and Port insertion: OFF
15 Case Sensitivity: ON
16 Push: DISABLED Push VServer:
17 Push Label Rule: none
18 Done
```

The priority is required only for the “dummy” policy named NOPOLICY.
Unbind an integrated caching, responder, rewrite, or compression Advanced policy
globally by using the GUI

1. In the navigation pane, click the feature with the policy that you want to unbind (for example, Integrated Caching).
2. In the details pane, click <Feature Name> policy manager.
3. In the Policy Manager dialog box, select the bind point with the policy that you want to unbind, for example, Advanced Global.
4. Click the policy name that you want to unbind, and then click Unbind Policy.
5. Click Apply Changes.
6. Click Close. A message in the status bar indicates that the policy is unbound successfully.

Unbind a DNS policy globally by using the GUI

1. Navigate to Traffic Management **> **DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Global Bindings dialog box, select policy and click unbind policy.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

Unbind an advanced policy from a load balancing or content switching virtual server
by using the GUI

1. Navigate to Traffic Management, and expand Load Balancing or Content Switching, and then click Virtual Servers.
2. In the details pane, double-click the virtual server from which you want to unbind the policy.
3. On the Policies tab, in the Active column, clear the check box next to the policy that you want to unbind.
4. Click OK. A message in the status bar indicates that the policy is unbinded successfully.

Create policy labels

February 12, 2020

In addition to the built-in bind points where you set up policy banks, you can also configure user-defined policy labels and associate policies with them.
Within a policy label, you bind policies and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. The Citrix ADC also permits you to define an arbitrary evaluation order as follows:

- You can use “goto” expressions to point to the next entry in the bank to be evaluated after the current one.
- You can use an entry in a policy bank to invoke another bank.

Each feature determines the type of policy that you can bind to a policy label, the type of load balancing virtual server that you can bind the label to, and the type of content switching virtual server from which the label can be invoked. For example, a TCP policy label can only be bound to a TCP load balancing virtual server. You cannot bind HTTP policies to a policy label of this type. And you can invoke a TCP policy label only from a TCP content switching virtual server.

After configuring a new policy label, you can invoke it from one or more banks for the built-in bind points.

**Create a caching policy label by using the CLI**

At the command prompt, type the following commands to create a Caching policy label and verify the configuration:

```
1 - add cache policylabel <labelName> -evaluates req|res
2
3 - show cache policylabel<labelName>
```

**Example:**

```
1 > add cache policylabel lbl-cache-pol -evaluates req
2 Done
3
4 > show cache policylabel lbl-cache-pol
5    Label Name: lbl-cache-pol
6    Evaluates: REQ
7    Number of bound policies: 0
8    Number of times invoked: 0
9 Done
```

**Create a content switching policy label by using the CLI**

At the command prompt, type the following commands to create a Content Switching policy label and verify the configuration:
Create a rewrite policy label by using the CLI

At the command prompt, type the following commands to create a Rewrite policy label and verify the configuration:

```
1 - add rewrite policylabel <labelName> http_req|http_res|url|text|
   clientless_vpn_req|clientless_vpn_res
2
3 - show rewrite policylabel <labelName>
```

Example:

```
1 > add rewrite policylabel lbl-rewrt-pol http_req
Done
3
4 > show rewrite policylabel lbl-rewrt-pol
   Label Name: lbl-rewrt-pol
   Transform Name: http_req
   Number of bound policies: 0
   Number of times invoked: 0
9 Done
```

Create a responder policy label by using the CLI

At the command prompt, type the following commands to create a Responder policy label and verify the configuration:
<table>
<thead>
<tr>
<th></th>
<th><strong>add responder policylabel &lt;labelName&gt;</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>show responder policylabel &lt;labelName&gt;</strong></td>
</tr>
</tbody>
</table>

**Example:**

```plaintext
1 > add responder policylabel lbl-respndr-pol
2 Done
3 4 > show responder policylabel lbl-respndr-pol
5   Label Name: lbl-respndr-pol
6   Number of bound policies: 0
7   Number of times invoked: 0
8 Done
```

**Note:** Invoke this policy label from a policy bank. For more information, see the “Binding a Policy to a Policy Label” section.

**Create a policy label by using the GUI**

1. In the navigation pane, expand the feature for which you want to create a policy label, and then click **Policy Labels**. The choices are Integrated Caching, Rewrite, Content Switching, or Responder.
2. In the details pane, click **Add**.
3. In the Name box, enter a unique name for this policy label.
4. Enter feature-specific information for the policy label. For example, for Integrated Caching, in the Evaluates drop-down menu, you would select REQ if you want this policy label to contain request-time policies, or select RES if you want this policy label to contain response-time policies. For Rewrite, you would select a Transform name.
5. Click **Create**.
6. Configure one of the built-in policy banks to invoke this policy label. For more information, see the “Binding a Policy to a Policy Label” section. A message in the status bar indicates that the policy label is created successfully.

**Bind a policy to a policy label**

As with policy banks that are bound to the built-in bind points, each entry in a policy label is a policy that is bound to the policy label. As with policies that are bound globally or to a vserver, each policy that is bound to the policy label can also invoke a policy bank or a policy label that is evaluated after the current entry has been processed. The following table summarizes the entries in a policy label.
- **Name.** The name of a policy, or, to invoke another policy bank without evaluating a policy, the “dummy” policy name NOPOLICY.

You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.

- **Priority.** An integer. This setting can work with the Goto expression.

- **Goto Expression.** Determines the next policy to evaluate in this bank. You can provide one of the following values:
  - **NEXT.** Go to the policy with the next higher priority.
  - **END.** Stop evaluation.
  - **USE_INVOCATION_RESULT.** Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT.
  - **Positive number:** The priority number of the next policy to be evaluated.
  - **Numeric expression.** An expression that produces the priority number of the next policy to be evaluated.

The Goto can only proceed forward in a policy bank.

If you omit the Goto expression, it is the same as specifying END.

- **Invocation Type.** Designates a policy bank type. The value can be one of the following:
  - **Request Vserver.** Invokes request-time policies that are associated with a virtual server.
  - **Response Vserver.** Invokes response-time policies that are associated with a virtual server.
  - **Policy label.** Invokes another policy bank, as identified by the policy label for the bank.

- **Invocation Name.** The name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

**Configure a policy label or virtual server policy bank**

February 18, 2020

After you have created policies, and created policy banks by binding the policies, you can perform additional configuration of policies within a label or policy bank. For example, before you configure invocation of an external policy bank, you might want to wait until you have configured that policy bank.
This topic includes the following sections:

- Configure a policy label
- Configure a policy bank for a virtual server

**Configure a policy label**

A policy label consists of a set of policies and invocations of other policy labels and virtual server-specific policy banks. An Invoke parameter enables you to invoke a policy label or a virtual server-specific policy bank from any other policy bank. A special-purpose NoPolicy entry enables you to invoke an external bank without processing an expression (a rule). The NoPolicy entry is a “dummy” policy that does not contain a rule.

For configuring policy labels from the Citrix ADC command line, note the following elaborations of the command syntax:

- gotoPriorityExpression is configured as described in Table 2. Format of Each Entry in a Policy Bank of the section “Entries in a Policy Bank” in Bind policies using advanced policy.
- The type argument is required. This is unlike binding a conventional policy, where this argument is optional.
- You can invoke the bank of policies that are bound to a virtual server by using the same method as you use for invoking a policy label.

**Configure a policy label by using the CLI**

At the command prompt, type the following commands to configure a policy label and verify the configuration:

1. `bind cache|rewrite|responder policylabel <policylabelName> - policyName <policyName> -priority <priority> [- gotoPriorityExpression <gotopriorityExpression> ] [-invoke reqvserver |resvserver|policylabel <policyLabelName>|<vserverName>]

2. `show cache|rewrite|responder policylabel <policylabelName>

**Example:**

```
bind cache policylabel _reqBuiltinDefaults -policyName _nonGetReq - priority 100
Done
```

```
show cache policylabel _reqBuiltinDefaults
Label Name: _reqBuiltinDefaults
Evaluates: REQ
```
**Invoke a policy label from a rewrite policy bank with a NOPOLICY entry by using the CLI**

At the command prompt, type the following commands to invoke a policy label from a Rewrite policy bank with a NOPOLICY entry and verify the configuration:

```
1 - bind rewrite global <policyName> <priority> <gotoPriorityExpression> -type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT -invoke reqvserver|resvserver|policylabel <policyLabelName>|<vserverName>
2
3 - show rewrite global
```

**Example:**

```
1 > bind rewrite global NOPOLICY 100 -type REQ_DEFAULT -invoke policylabel lbl-rewrt-pol
2 Done
3 > show rewrite global
4 1) Global bindpoint: REQ_DEFAULT
5    Number of bound policies: 1
6 7 2) Global bindpoint: REQ_OVERRIDE
8    Number of bound policies: 1
9 Done
```

**Invoke a policy label from an Integrated Caching policy bank by using the CLI**

At the command prompt, type the following commands to invoke a policy label from an Integrated Caching policy bank and verify the configuration:
Invoke a policy label from a Responder policy bank by using the CLI

At the command prompt, type the following commands to invoke a policy label from a Responder policy bank and verify the configuration:

```
1 - bind responder global NOPOLICY <priority> <gotopriorityExpression> -
type OVERRIDE|DEFAULT -invoke vserver|policylabel <policyLabelName>|
<vserverName>
2
3 - show responder global
```

Example:

```
1 > bind responder global NOPOLICY 100 NEXT -type DEFAULT -invoice
policylabel lbl-respndr-pol
2 Done
3 > show responder global
4 1) Global bindpoint: REQ_DEFAULT
5 Number of bound policies: 2
6
7 Done
```
Configure a policy label by using the GUI

1. In the navigation pane, expand the feature for which you want to configure a policy label, and then click Policy Labels. The choices are Integrated Caching, Rewrite, or Responder.

2. In the details pane, double-click the label that you want to configure.

3. If you are adding a new policy to this policy label, click Insert Policy, and in the Policy Name field, select New Policy. For more information about adding a policy, see Create or modify a policy. Note that if you are invoking a policy bank, and do not want a rule to be evaluated prior to the invocation, click Insert Policy, and in the Policy Name field select NOPOLICY.

4. For each entry in this policy label, configure the following:
   - **Policy Name:**
     This is already determined by the Policy Name, new policy, or NOPOLICY entry that you inserted in this bank.
   - **Priority:**
     A numeric value that determines either an absolute order of evaluation within the bank, or is used in conjunction with a Goto expression.
   - **Expression:**
     The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see Configure advanced policy expressions: Get started.
   - **Action:**
     The action to be taken if this policy evaluates to TRUE.
   - **Goto Expression:**
     Optional. Used to augment the Priority level to determine the next policy or policy bank to evaluate. For more information on possible values for a Goto expression, see Table 2. Format of Each Entry in a Policy Bank of the section “Entries in a Policy Bank” in Bind policies using advanced policy.
   - **Invoke:**
     Optional. Invokes another policy bank.

5. Click OK. A message in the status bar indicates that the policy label is configured successfully.

Configure a policy bank for a virtual server

You can configure a bank of policies for a virtual server. The policy bank can contain individual policies, and each entry in the policy bank can optionally invoke a policy label or a bank of policies that you
configured for another virtual server. If you invoke a policy label or policy bank, you can do so without triggering an expression (a rule) by selecting a NOPOLICY “dummy” entry instead of a policy name.

Add policies to a virtual server policy bank by using the CLI

At the command prompt, type the following commands to add policies to a virtual server policy bank and verify the configuration:

```
1 - bind lb|cs vserver <virtualServerName> <serviceType> [-policyName <policyName>] [-priority <positiveInteger>] [-gotoPriorityExpression <expression>] [-type REQUEST|RESPONSE]
2
3 - show lb|cs vserver <virtualServerName>
```

Example:

```
1 add lb vserver vs-cont-sw TCP
2 Done
3 show lb vserver vs-cont-sw
4 vs-cont-sw (0.0.0.0:0) - TCP Type: ADDRESS
5 State: DOWN
6 Last state change was at Wed Aug 19 10:04:02 2009 (+279 ms)
7 Time since last state change: 0 days, 00:02:14.420
8 Effective State: DOWN
9 Client Idle Timeout: 9000 sec
10 Down state flush: ENABLED
11 Disable Primary Vserver On Down : DISABLED
12 No. of Bound Services : 0 (Total) 0 (Active)
13 Configured Method: LEASTCONNECTION
14 Mode: IP
15 Persistence: NONE
16 Connection Failover: DISABLED
17 Done
```

Invoke a policy label from a virtual server policy bank with a NOPOLICY entry by using the CLI

At the command prompt, type the following commands to invoke a policy label from a virtual server policy bank with a NOPOLICY entry and verify the configuration:

```
1 - bind lb|cs vserver <virtualServerName> -policyName NOPOLICY_REWRITE|NOPOLICY_CACHE|NOPOLICY_RESPONDER -priority <integer> -type REQUEST|RESPONSE -gotoPriorityExpression <gotoPriorityExpression> -invoke reqVserver|resVserver|policyLabel <vserverName>|<labelName>
```
Configure a virtual server policy bank by using the GUI

1. In the left navigation pane, expand **Traffic Management > Load Balancing, Traffic Management > Content Switching, Traffic Management > SSL Offload, Security > AAA - Application Traffic, or Citrix Gateway**, as appropriate, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to configure, and then click Open.

3. In the Configure Virtual Server dialog box click the Policies tab.

4. To create a new policy in this bank, click the icon for the type of policy or policy label that you want to add to the virtual server's bank of policies, click Insert Policy. Note that if you want to invoke a policy label without evaluating a policy rule, select the NOPOLICY “dummy” policy.

5. To configure an existing entry in this policy bank, enter the following:

   - **Priority:**
     A numeric value that determines either an absolute order of evaluation within the bank or is used in conjunction with a Goto expression.

   - **Expression:**
     The policy rule. Policy expressions are described in detail in the following chapters. For an introduction, see Configuring Advanced Policy Expressions: Getting Started.

   - **Action:**
     The action to be taken if this policy evaluates to TRUE.

   - **Goto Expression:**
     Optional. Determines the next policy or policy bank evaluate. For more information on possible values for a Goto expression, see the section “Entries in a Policy Bank” in Bind policies using advanced policy.

   - **Invoke:**
     Optional. To invoke another policy bank, select the name of the policy label or virtual server policy bank that you want to invoke.
6. Click OK. A message in the status bar indicates that the policy is configured successfully.

Invoke or remove a policy label or virtual server policy bank

June 2, 2020

Unlike a policy, which can only be bound once, you can use a policy label or a virtual server’s policy bank any number of times by invoking it. Invocation can be performed from two places:

- From the binding for a named policy in a policy bank.
- From the binding for a NOPOLICY “dummy” entry in a policy bank.

Typically, the policy label must be of the same type as the policy from which it is invoked. For example, you would invoke a responder policy label from a responder policy.

Note: When binding or unbinding a global NOPOLICY entry in a policy bank at the command line, you specify a priority to distinguish one NOPOLICY entry from another.

Invoke a rewrite or integrated caching policy label by using the CLI

At the command prompt, type the one of the following commands to invoke a rewrite or integrated caching policy label and verify the configuration:

1. `bind cache global <policy> -priority <positive_integer> [-gotoPriorityExpression <expression>] -type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] -invoke reqvserver|resvserver|policylabel <label_name>`
2. `bind rewrite global <policy> -priority <positive_integer> [-gotoPriorityExpression <expression>] -type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] -invoke reqvserver|resvserver|policylabel <label_name>`
3. `show cache global|show rewrite global`

Example:

```
1 > bind cache global _nonPostReq2 -priority 100 -type req_override -invoke
2 policylabel lbl-cache-pol
```
Invoke a responder policy label by using the CLI

At the command prompt, type the following commands to invoke a responder policy label and verify the configuration:

```
1 - bind responder global <policy_Name> <priority_as_positive_integer> [ <gotoPriorityExpression> ] -type REQ_OVERRIDE|REQ_DEFAULT|OVERRIDE|DEFAULT -invoke vserver|policylabel <label_name>
```

Example:

```
1 > bind responder global pol404Error1 300 -invoke policylabel lbl-respndr-pol
2 Done
3 > show responder global
4 1) Global bindpoint: REQ_DEFAULT
5 Number of bound policies: 2
6
7 Done
```

Invoke a virtual server policy bank by using the CLI

At the command prompt, type the following commands to invoke a Virtual Server Policy Bank and verify the configuration:

```
1 - bind lb vserver <vserver_name> -policyName <policy_Name> -priority <positive_integer> [ <gotoPriorityExpression <expression> ] -type
```
REQUEST|RESPONSE - invoke reqvserver|resvserver|policylabel < policy_Label_Name>
- bind lb vserver <vserver_name>

Example:

```bash
> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 100
Done

> show lb vserver lbvip
  lbvip (8.7.6.6:80) - HTTP Type: ADDRESS
  State: DOWN
  Last state change was at Wed Jul 15 05:54:24 2009 (+166 ms)
  Time since last state change: 28 days, 06:37:49.250
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 0 (Total) 0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none

  1) CSPolicy: pol-cont-sw CSVserver: vs-cont-sw Priority: 100 Hits: 0
  2) Policy : pol-ssl Priority:0
  3) Policy : ns_cmp_msapp Priority:100
  4) Policy : cf-pol Priority:1 Inherited
Done
```

**Remove a rewrite or integrated caching policy label by using the CLI**

At the command prompt, type one of the following commands to remove a rewrite or integrated caching policy label and verify the configuration:

```bash
- unbind rewrite global <policyName> -priority <positiveInteger> -type REQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT
```
Example:

```
1 > unbind rewrite global NOPOLICY -priority 100 -type REQ_OVERRIDE
2 > show rewrite global
3 Done
4 1) Global bindpoint: REQ_DEFAULT
5 Number of bound policies: 1
6
7 Done
```

**Remove a responder policy label by using the CLI**

At the command prompt, type the following commands to remove a responder policy label and verify the configuration:

```
- unbind responder global <policyName> -priority <positiveInteger> -type OVERRIDE|DEFAULT
- show responder global
```

Example:

```
1 > unbind responder global NOPOLICY -priority 100 -type REQ_DEFAULT
2 Done
3 > show responder global
4 1) Global bindpoint: REQ_DEFAULT
5 Number of bound policies: 1
6
7 Done
```

**Remove a virtual server policy label by using the CLI**

At the command prompt, type one of the following commands to remove a Virtual Server policy label and verify the configuration:
unbind lb vserver <virtualServerName> -policyName NOPOLICY-REWRITE|NOPOLICY-RESPONDER|NOPOLICY-CACHE -type REQUEST|RESPONSE -priority <positiveInteger>
unbind cs vserver <virtualServerName> -policyName NOPOLICY-REWRITE|NOPOLICY-RESPONDER|NOPOLICY-CACHE -type REQUEST|RESPONSE -priority <positiveInteger>

Example:

> unbind lb vserver lbvip -policyName ns_cmp_msapp -priority 200
Done
> show lb vserver lbvip

  lbvip (8.7.6.6:80) - HTTP     Type: ADDRESS
  State: DOWN
  Last state change was at Wed Jul 15 05:54:24 2009 (+161 ms)
  Time since last state change:  28 days,  06:47:54.600
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services :  0 (Total)    0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none

  1) CSPolicy: pol-cont-sw  CSVserver: vs-cont-sw  Priority: 100  Hits: 0

  2) Policy : cs-pol  Priority: 0

Done
Invoke a policy label or virtual server policy bank by using the GUI

1. Bind a policy, as described in Bind a policy globally, Bind a policy to a virtual server, or Bind a policy to a policy label. Alternatively, you can enter a NOPOLICY “dummy” entry instead of a policy name. You do this if you do not want to evaluate a policy before evaluating the policy bank.
2. In the Invoke field, select the name of the policy label or virtual server policy bank that you want to evaluate if traffic matches the bound policy. A message in the status bar indicates that the policy label or virtual server policy bank is invoked successfully.

Remove a policy label invocation by using the GUI

1. Open the policy and clear the Invoke field. Unbinding the policy also removes the invocation of the label. A message in the status bar indicates that the policy label is removed successfully.

Configuring advanced policy expression: getting started

February 12, 2020

Advanced policies evaluate data based on information that you supply in Advanced policy expressions. An Advanced policy expression analyzes data elements (for example, HTTP headers, source IP addresses, the Citrix ADC system time, and POST body data). In addition to configuring an Advanced policy expression in a policy, in some Citrix ADC features, you configure Advanced policy expression outside of the context of a policy.

To create an Advanced policy expression, you select a prefix that identifies a piece of data that you want to analyze, and then you specify an operation to perform on the data. For example, an operation can match a piece of data with a text string that you specify, or it can transform a text string into an HTTP header. Other operations match a returned string with a set of strings or a string pattern. You configure compound expressions by specifying Boolean and arithmetic operators, and by using parentheses to control the order of evaluation.

Advanced policy expression can also contain classic expressions. You can assign a name to a frequently used expression to avoid having to build the expression repeatedly.

Policies and a few other entities include rules that the Citrix ADC uses to evaluate a packet in the traffic flowing through it, to extract data from the Citrix ADC system itself, to send a request (a “callout”) to an
external application, or to analyze another piece of data. A rule takes the form of a logical expression that is compared against traffic and ultimately returns values of TRUE or FALSE.

The elements of the rule can themselves return TRUE or FALSE, string, or numeric values.

Before configuring an Advanced policy expression, you need to understand the characteristics of the data that the policy or other entity is to evaluate. For example, when working with the Integrated Caching feature, a policy determines what data can be stored in the cache. With Integrated Caching, you need to know the URLs, headers, and other data in the HTTP requests and responses that the Citrix ADC receives. With this knowledge, you can configure policies that match the actual data and enable the Citrix ADC to manage caching for HTTP traffic. This information helps you determine the type of expression that you need to configure in the policy.

**Basic elements of an advanced policy expression**

February 12, 2020

An Advanced policy expression consists of, at a minimum, a prefix (or a single element used in place of a prefix). Most expressions also specify an operation to be performed on the data that the prefix identifies. You format an expression of up to 1,499 characters as follows:

```
<prefix>.<operation> [ <compound-operator> <prefix>.<operation> . . . ]
```

where

- `<prefix>`
  
is an anchor point for starting an expression.

  The prefix is a period-delimited key that identifies a unit of data. For example, the following prefix examines HTTP requests for the presence of a header named Content-Type:

  `http.req.header("Content-Type")`

  Prefixes can also be used on their own to return the value of the object that the prefix identifies.

- `<operation>`
  
  identifies an evaluation that is to be performed on the data identified by the prefix.

  For example, consider the following expression:

  `http.req.header("Content-Type").eq("text/html")`

  In this expression, the following is the operator component:
eq("text/html")

This operator causes the Citrix ADC to evaluate any HTTP requests that contain a Content-Type header, and in particular, to determine if the value of this header is equal to the string “text/html.” For more information, see “Operations.”

• `<compound-operator>`

is a Boolean or arithmetic operator that forms a compound expression from multiple prefix or prefix.operation elements.

For example, consider the following expression:

http.req.header("Content-Type").eq("text/html") && http.req.url.contains("html")

### Prefixes

An expression prefix represents a discrete piece of data. For example, an expression prefix can represent an HTTP URL, an HTTP Cookie header, or a string in the body of an HTTP POST request. An expression prefix can identify and return a wide variety of data types, including the following:

• A client IP address in a TCP/IP packet
• Citrix ADC system time
• An external callout over HTTP
• A TCP or UDP record type

In most cases, an expression prefix begins with one of the following keywords:

• **CLIENT:**
  - Identifies a characteristic of the client that is either sending a request or receiving a response, as in the following examples:
  - The prefix client.ip.dst designates the destination IP address in the request or response.
  - The prefix client.ip.src designates the source IP address.

• **HTTP:**
  - Identifies an element in an HTTP request or a response, as in the following examples:
  - The prefix http.req.body(integer) designates the body of the HTTP request as a multiline text object, up to the character position designated in integer.
  - The prefix http.req.header("header_name") designates an HTTP header, as specified in header_name.
  - The prefix http.req.url designates an HTTP URL in URL-encoded format.

• **SERVER:**

Identifies an element in the server that is either processing a request or sending a response.
• SYS:
  Identifies a characteristic of the Citrix ADC that is processing the traffic.

  **Note:** Note that DNS policies support only SYS, CLIENT, and SERVER objects.

In addition, in the Citrix Gateway, the Clientless VPN function can use the following types of prefixes:

• TEXT:
  Identifies any text element in a request or a response.

• TARGET:
  Identifies the target of a connection.

• URL:
  Identifies an element in the URL portion of an HTTP request or response.

As a general rule of thumb, any expression prefix can be a self-contained expression. For example, the following prefix is a complete expression that returns the contents of the HTTP header specified in the string argument (enclosed in quotation marks):

```
http.res.header.("myheader")
```

Or you can combine prefixes with simple operations to determine TRUE and FALSE values. For example, the following returns a value of TRUE or FALSE:

```
http.res.header.("myheader").exists
```

You can also use complex operations on individual prefixes and multiple prefixes within an expression, as in the following example:

```
http.req.url.length + http.req.cookie.length <= 500
```

Which expression prefixes you can specify depends on the Citrix ADC feature. The following table describes the expression prefixes that are of interest on a per-feature basis:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Types of Expression Prefix Used in the Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>SYS, CLIENT, SERVER</td>
</tr>
<tr>
<td>Responder in Protection Features</td>
<td>HTTP, SYS, CLIENT</td>
</tr>
<tr>
<td>Content Switching</td>
<td>HTTP, SYS, CLIENT</td>
</tr>
<tr>
<td>Rewrite</td>
<td>HTTP, SYS, CLIENT, SERVER, URL, TEXT, TARGET, VPN</td>
</tr>
<tr>
<td>Integrated Caching</td>
<td>HTTP, SYS, CLIENT, SERVER</td>
</tr>
</tbody>
</table>

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Table 1. Permitted Types of Expression Prefixes in Various Citrix ADC Features

**Note:** For details on the permitted expression prefixes in a feature, see the documentation for that feature.

### Single-element expressions

The simplest type of Advanced policy expression contains a single element. This element can be one of the following:

- **true.** An Advanced policy expression can consist simply of the value true. This type of expression always returns a value of TRUE. It is useful for chaining policy actions and triggering Goto expressions.
- **false.** An Advanced policy expression can consist simply of the value false. This type of expression always returns a value of FALSE.
- A prefix for a compound expression. For example, the prefix HTTP.REQ.HOSTNAME is a complete expression that returns a host name and HTTP.REQ.URL is a complete expression that returns a URL. The prefix could also be used in conjunction with operations and additional prefixes to form a compound expression.

### Operations

In most expressions, you also specify an operation on the data that the prefix identifies. For example, suppose that you specify the following prefix:

**http.req.url**

This prefix extracts URLs in HTTP requests. This expression prefix does not require any operators to be used in an expression. However, when you configure an expression that processes HTTP request URLs, you can specify operations that analyze particular characteristics of the URL. Following are a few possibilities:

- Search for a particular host name in the URL.
- Search for a particular path in the URL.
- Evaluate the length of the URL.
- Search for a string in the URL that indicates a time stamp and convert it to GMT.
The following is an example of a prefix that identifies an HTTP header named Server and an operation that searches for the string IIS in the header value:

```
http.res.header("Server").contains("IIS")
```

Following is an example of a prefix that identifies host names and an operation that searches for the string “www.mycompany.com” as the value of the name:

```
http.req.hostname.eq("www.mycompany.com")
```

### Basic operations on expression prefixes

The following table describes a few of the basic operations that can be performed on expression prefixes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Determines Whether or Not</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTAINS(&lt;string&gt;)</td>
<td>The object matches &lt;string&gt;. Following is an example: http.req.header(&quot;Cache-Control&quot;).contains(&quot;no-cache&quot;)</td>
</tr>
<tr>
<td>EXISTS</td>
<td>A particular item is present in an object. Following is an example: http.res.header(&quot;MyHdr&quot;).exists</td>
</tr>
<tr>
<td>EQ(&lt;text&gt;)</td>
<td>A particular non-numeric value is present in an object. Following is an example: http.req.method.eq(post)</td>
</tr>
<tr>
<td>EQ(&lt;integer&gt;)</td>
<td>A particular numeric value is present in an object. Following is an example: client.ip.dst.eq(10.100.10.100)</td>
</tr>
<tr>
<td>LT(&lt;integer&gt;)</td>
<td>An object’s value is less than a particular value. Following is an example: http.req.content_length.lt(5000)</td>
</tr>
<tr>
<td>GT(&lt;integer&gt;)</td>
<td>An object’s value is greater than a particular value. Following is an example: http.req.content_length.gt(5)</td>
</tr>
</tbody>
</table>

The following table summarizes a few of the available types of operations.
Operation Type | Description
--- | ---
Text operations | Match individual strings and sets of strings with any portion of a target. The target can be an entire string, the start of a string, or any portion of text in between the start and the end of the string. For example, you can extract the string “XYZ” from “XYZSomeText”. Or, you can compare an HTTP header value with an array of different strings. You can also transform text into another type of data. Following are examples: Transform a string into an integer value, create a list from the query strings in a URL, and transform a string into a time value.

Numeric operations | Numeric operations include applying arithmetic operators, evaluating content length, the number of items in a list, dates, times, and IP addresses.

**Compound advanced policy expressions**

February 12, 2020

You can configure an Advanced policy expression that contains Boolean or arithmetic operators and multiple atomic operations. The following compound expression contains a boolean AND:

`http.req.hostname.eq("mycompany.com") && http.req.method.eq(post)`

The following expression adds the value of two targets, and compares the result to a third value:

`http.req.url.length + http.req.cookie.length <= 500`

A compound expression can contain any number of logical and arithmetic operators. The following expression evaluates the length of an HTTP request on the basis of its URL and cookie, evaluates text in the header, and performs a Boolean AND on these two results:

`http.req.url.length + http.req.cookie.length <= 500 && http.req.header.contains("some text")`
You can use parentheses to control the order of evaluation in a compound expression.

**Booleans in compound expressions**

You configure compound expressions with the following operators:

- **&&.**
  
  This operator is a logical AND. For the expression to evaluate to TRUE, all components that are joined by the And must evaluate to TRUE. Following is an example:
  
  http.req.url.hostname.eq("myHost") && http.req.header("myHeader").exists
  
- **||.**
  
  This operator is a logical OR. If any component of the expression that is joined by the OR evaluates to TRUE, the entire expression is TRUE.
  
- **!**
  
  Performs a logical NOT on the expression.

In some cases, the Citrix ADC configuration utility offers AND, NOT, and OR operators in the Add Expression dialog box. However, these are of limited use. Citrix recommends that you use the operators &&, ||, and ! to configure compound expressions that use Boolean logic.

**Parentheses in compound expressions**

You can use parentheses to control the order of evaluation of an expression. The following is an example:

http.req.url.contains("myCompany.com") || (http.req.url.hostname.eq("myHost") && http.req.header("myHeader").exists)

The following is another example:

(http.req.header("Content-Type").exists && http.req.header("Content-Type").eq("text/html")). || (http.req.header("Transfer-Encoding").exists || http.req.header("Content-Length").exists)

**Compound operations for strings**

The following table describes operators that you can use to configure compound operations on string data.
<table>
<thead>
<tr>
<th>Operations that produce a string value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str + str</code></td>
<td>Concatenates the value of the expression on the left of the operator with the value on the right. Following is an example: http.req.hostname + http.req.url.protocol</td>
</tr>
<tr>
<td><code>str + num</code></td>
<td>Concatenates the value of the expression on the left of the operator with a numeric value on the right. Following is an example: http.req.hostname + http.req.url.content_length</td>
</tr>
<tr>
<td><code>num + str</code></td>
<td>Concatenates the numeric value of the expression on the left side of the operator with a string value on the right. Following is an example: http.req.url.content_length + http.req.hostname</td>
</tr>
<tr>
<td><code>str + ip</code></td>
<td>Concatenates the string value of the expression on the left side of the operator with an IP address value on the right. Following is an example: http.req.hostname + 10.00.000.00</td>
</tr>
<tr>
<td><code>ip + str</code></td>
<td>Concatenates the IP address value of the expression on the left of the operator with a string value on the right. Following is an example: client.ip.dst + http.req.url.hostname</td>
</tr>
<tr>
<td><code>str1 ALT str2</code></td>
<td>Uses the string1 or string2 value that is derived from the expression on either side of the operator, as long as neither of these expressions is a compound expressions. Following is an example: http.req.hostname alt client.ip.src</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operations on strings that produce a result of TRUE or FALSE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str == str</code></td>
<td>Evaluates whether the strings on either side of the operator are the same. Following is an example: http.req.header(&quot;myheader&quot;) == http.res.header(&quot;myheader&quot;)</td>
</tr>
</tbody>
</table>
## Operations on strings that produce a result of TRUE or FALSE

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str &lt;= str</code></td>
<td>Evaluates whether the string on the left side of the operator is the same as the string on the right, or precedes it alphabetically.</td>
</tr>
<tr>
<td><code>str &gt;= str</code></td>
<td>Evaluates whether the string on the left side of the operator is the same as the string on the right, or follows it alphabetically.</td>
</tr>
<tr>
<td><code>str &lt; str</code></td>
<td>Evaluates whether the string on the left side of the operator precedes the string on the right alphabetically.</td>
</tr>
<tr>
<td><code>str &gt; str</code></td>
<td>Evaluates whether the string on the left side of the operator follows the string on the right alphabetically.</td>
</tr>
<tr>
<td><code>str != str</code></td>
<td>Evaluates whether the strings on either side of the operator are different.</td>
</tr>
</tbody>
</table>

## Logical operations on strings

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bool &amp;&amp; bool</code></td>
<td>This operator is a logical AND. When evaluating the components of the compound expression, all components that are joined by the AND must evaluate to TRUE. Following is an example: http.req.method.eq(GET) &amp;&amp; http.req.url.query.contains(“viewReport &amp;&amp; my_pagelabel”)</td>
</tr>
<tr>
<td>`bool</td>
<td></td>
</tr>
<tr>
<td><code>bool</code></td>
<td>Performs a logical NOT on the expression.</td>
</tr>
</tbody>
</table>
**Compound operations for numbers**

You can configure compound numeric expressions. For example, the following expression returns a numeric value that is the sum of an HTTP header length and a URL length:

\[ \text{http.req.header.length + http.req.url.length} \]

The following tables describes operators that you can use to configure compound expressions for numeric data.

<table>
<thead>
<tr>
<th>Arithmetic operations on numbers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num + num</td>
<td>Add the value of the expression on the left of the operator to the value of the expression on the right. Following is an example: http.req.content_length + http.req.url.length</td>
</tr>
<tr>
<td>num – num</td>
<td>Subtract the value of the expression on the right of the operator from the value of the expression on the left.</td>
</tr>
<tr>
<td>num * num</td>
<td>Multiply the value of the expression on the left of the operator with the value of the expression on the right. Following is an example: client.interface.rxthroughput * 9</td>
</tr>
<tr>
<td>num / num</td>
<td>Divide the value of the expression on the left of the operator by the value of the expression on the right.</td>
</tr>
<tr>
<td>num % num</td>
<td>Calculate the modulo, or the numeric remainder on a division of the value of the expression on the left of the operator by the value of the expression on the right. For example, the values “15 mod 4” equals 3, and “12 mod 4” equals 0.</td>
</tr>
<tr>
<td>Arithmetic operations on numbers</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>~number</td>
<td>Returns a number after applying a bitwise logical negation of the number. The following example assumes that numeric.expression returns 12 (binary 1100): ~numeric.expression. The result of applying the ~ operator is -11 (a binary 1110011, 32 bits total with all ones to the left). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</td>
</tr>
<tr>
<td>number ^ number</td>
<td>Compares two bit patterns of equal length and performs an XOR operation on each pair of corresponding bits in each number argument, returning 1 if the bits are different, and 0 if they are the same. Returns a number after applying a bitwise XOR to the integer argument and the current number value. If the values in the bitwise comparison are the same, the returned value is a 0. The following example assumes that numeric.expression1 returns 12 (binary 1100) and numeric.expression2 returns 10 (binary 1010): numeric.expression1 ^ numeric.expression2The result of applying the ^ operator to the entire expression is 6 (binary 0110). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</td>
</tr>
<tr>

<tbody>
<tr>
<td>num &gt; num</td>
<td>Determine if the value of the expression on the left of the operator is greater than the value of the expression on the right.</td>
</tr>
<tr>
<td>num &lt; num</td>
<td>Determine if the value of the expression on the left of the operator is less than the value of the expression on the right.</td>
</tr>
<tr>
<td>num &gt;= num</td>
<td>Determine if the value of the expression on the left of the operator is greater than or equal to the value of the expression on the right.</td>
</tr>
<tr>
<td>num &lt;= num</td>
<td>Determine if the value of the expression on the left of the operator is less than or equal to the value of the expression on the right.</td>
</tr>
</tbody>
</table>

Functions for data types in the policy infrastructure

The Citrix ADC policy infrastructure supports the following numeric data types:

- Integer (32 bits)
- Unsigned long (64 bits)
- Double (64 bits)

Simple expressions can return all of these data types. Therefore, you can create compound expressions that use arithmetic operators and logical operators to evaluate or return values of these data types. Additionally, you can use all of these values in policy expressions. Literal constants of type unsigned long can be specified by appending the string ul to the number. Literal constants of type double contain a period (.), an exponent, or both.

Arithmetic Operators, Logical Operators, and Type Promotion

In compound expressions, the following standard arithmetic and logical operators can be used for the double and unsigned long data types:

- +, -, *, and /
- %, ~, ^, &, <<, and >> (do not apply to double)
• ==, !=, >, <, >=, and <=

All of these operators have the same meaning as in the C programming language.

In all cases of mixed operations between operands of type integer, unsigned long, and double, type promotion is performed so that the operation can be performed on operands of the same type. A type of lower precedence is automatically promoted to the type of the operand with the highest precedence involved in the operation. The order of precedence (higher to lower) is as follows:

- Double
- Unsigned long
- Integer

Therefore, an operation that returns a numeric result returns a result of the highest type involved in the operation.

For example, if the operands are of type integer and unsigned long, the integer operand is automatically converted to type unsigned long. This type conversion is performed even in simple expressions in which the type of data identified by the expression prefix does not match the type of data that is passed as the argument to the function. To illustrate such an example, in the operation HTTP.REQ.CONTENT_LENGTH.DIV(3ul), the integer returned by the prefix HTTP.REQ.CONTENT_LENGTH is automatically converted to unsigned long (the type of the data passed as the argument to the DIV() function), and an unsigned long division is performed. Similarly, the argument can be promoted in an expression. For example, HTTP.REQ.HEADER("myHeader").TYPECAST_DOUBLE_AT.DIV(5) promotes the integer 5 to type double and performs double-precision division.

For information about expressions for casting data of one type to data of another type, see Typecasting data.

Specify the character set in expressions

May 26, 2020

The policy infrastructure on the Citrix ADC appliance supports ASCII and UTF-8 character sets. The default character set is ASCII. If the traffic for which you are configuring an expression consists of only ASCII characters, you need not specify the character set in the expression. The appliance allows all string and character literals which include binary characters. However, the UTF-8 character sets still require the string and character literals to be a valid UTF-8.

CLIENT.TCP.PAYLOAD(100).CONTAINS("\xff\x02")
In an expression, the SET_CHAR_SET() function must be introduced at the point in the expression after which data processing must be carried out in the specified character set. For example, in the expression HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).CONTAINS_ANY("Greek_ alphabet"), if the strings stored in the pattern set “Greek_alphabet” are in UTF-8, you must include the SET_CHAR_SET(UTF_8) function immediately before the CONTAINS_ANY("<strings>") function, as follows:

HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).SET_CHAR_SET(UTF_8).CONTAINS_ANY("Greek_ alphabet")

The SET_CHAR_SET() function sets the character set for all further processing (that is, for all subsequent functions) in the expression unless it is overridden later in the expression by another SET_CHAR_SET() function that changes the character set. Therefore, if all the functions in a given simple expression are intended for UTF-8, you can include the SET_CHAR_SET(UTF_8) function immediately after functions that identify text (for example, the HEADER("<name>") or BODY(<int>) functions). In the second example that follows the first paragraph above, if the ASCII arguments passed to the AFTER_REGEX() and BEFORE_REGEX() functions are changed to UTF-8 strings, you can include the SET_CHAR_SET(UTF_8) function immediately after the BODY(1000) function, as follows:

HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).AFTER_REGEX(re/Bücher/).BEFORE_REGEX(re/Wörterbuch/).CONTAINS_ANY("Greek_alphabet")

The UTF-8 character set is a superset of the ASCII character set, so expressions configured for the ASCII character set continue to work as expected if you change the character set to UTF-8.

**Compound expressions with different character sets**

In a compound expression, if one subset of expressions is configured to work with data in the ASCII character set and the rest of the expressions are configured to work with data in the UTF-8 character set, the character set specified for each individual expression is considered when the expressions are evaluated individually. However, when processing the compound expression, just before processing the operators, the appliance promotes the character set of the returned ASCII values to UTF-8. For example, in the following compound expression, the first simple expression evaluates data in the ASCII character set while the second simple expression evaluates data in the UTF-8 character set:

HTTP.REQ.HEADER("MyHeader")== HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8)

However, when processing the compound expression, just before evaluating the “is equal to” Boolean operator, the Citrix ADC appliance promotes the character set of the value returned by HTTP.REQ.HEADER("MyHeader") to UTF-8.

The first simple expression in the following example evaluates data in the ASCII character set. However, when the Citrix ADC appliance processes the compound expression, just before concatenating
the results of the two simple expressions, the appliance promotes the character set of the value returned by HTTP.REQ.BODY(10) to UTF-8.

\[ \text{HTTP.REQ.BODY(10)} + \text{HTTP.REQ.HEADER("MyHeader")}. \text{SET_CHAR_SET(UTF\_8)} \]

Therefore, the compound expression returns data in the UTF-8 character set.

**Specify the character set based on the character set of traffic**

You can set the character set to UTF-8 based on traffic characteristics. If you are not sure whether the character set of the traffic being evaluated is UTF-8, you can configure a compound expression in which the first expression checks for UTF-8 traffic and subsequent expressions set the character set to UTF-8. Following is an example of a compound expression that first checks the value of “charset” in the request’s Content-Type header for “UTF-8” before checking whether the first 1000 bytes in the request contain the UTF-8 string Bücher:

\[ \text{HTTP.REQ.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).TYPECAST_NVLIST_T(\{'=', ';', ','\}).VALUE("charset").EQ("UTF-8") \&\& HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF\_8).CONTAINS("Bücher")} \]

If you are sure that the character set of the traffic being evaluated is UTF-8, the second expression in the example is sufficient.

**Character and string literals in expressions**

During expression evaluation, even if the current character set is ASCII, character literals and string literals, which are enclosed in single quotation marks (‘”) and quotation marks (“”), respectively, are considered to be literals in the UTF-8 character set. In a given expression, if a function is operating on character or string literals in the ASCII character set and you include a non-ASCII character in the literal, an error is returned.

**Note:**

The string literals in advanced policy expressions are now as long as the policy expression. The expression is allowed to be 1499 bytes or 8191 bytes long.

**Values in hexadecimal and octal formats**

When configuring an expression, you can enter values in octal and hexadecimal formats. However, each hexadecimal or octal byte is considered a UTF-8 byte. Invalid UTF-8 bytes result in errors regardless of whether the value is entered manually or pasted from the clipboard. For example, “\xc8\x20” is an invalid UTF-8 character because “c8” cannot be followed by “20” (each byte in a multi-byte UTF-8
string must have the high bit set). Another example of an invalid UTF-8 character is “\xce \xa9,” since the hexadecimal characters are separated by a white-space character.

Functions that return UTF-8 strings

Only the <text>.XPATH and <text>.XPATH_JSON functions always return UTF-8 strings. The following MYSQL routines determine at runtime which character set to return, depending on the data in the protocol:

- MYSQL_CLIENT_T.USER
- MYSQL_CLIENT_T.DATABASE
- MYSQL_REQ_QUERY_T.COMMAND
- MYSQL_REQ_QUERY_T.TEXT
- MYSQL_REQ_QUERY_T.TEXT(<unsigned int>)
- MYSQL_RES_ERROR_T.SQLSTATE
- MYSQL_RES_ERROR_T.MESSAGE
- MYSQL_RES_FIELD_T.CATALOG
- MYSQL_RES_FIELD_T.DB
- MYSQL_RES_FIELD_T.TABLE
- MYSQL_RES_FIELD_T.ORIGINAL_TABLE
- MYSQL_RES_FIELD_T.NAME
- MYSQL_RES_FIELD_T.ORIGINAL_NAME
- MYSQL_RES_OK_T.MESSAGE
- MYSQL_RES_ROW_T.TEXT_ELEM(<unsigned int>)

Terminal connection settings for UTF-8

When you set up a connection to the Citrix ADC appliance by using a terminal connection (by using PuTTY, for example), you must set the character set for transmission of data to UTF-8.

Minimum and maximum functions in an advanced policy expression

The advanced policy expressions support the below minimum and maximum functions.

1. (<expression1>.max(<expression2>)) - returns the maximum of the two values.
2. (<expression1>.min(<expression2>)) - returns the minimum of the two values.
Classic expressions in advanced policy expressions

February 12, 2020

Warning

Classic policy expressions are no longer supported from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Configure advanced policy expressions: Get started.

Classic expressions describe basic characteristics of traffic. In some cases, you may want to use a classic expression in an Advanced policy expression and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies topic. You can do so with the Advanced policy expression configuration tool. This can be helpful when manually migrating the older classic expressions to the Advanced policy.

Note that when you upgrade the Citrix ADC to version 9.0 or higher, Integrated Caching policies are automatically upgraded to Advanced policies, and the expressions in these policies are upgraded to the Advanced policies.

The following is the syntax for all Advanced policy expressions that use a classic expression:

SYS.EVAL_CLASSIC_EXPR("expression")

Note

The syntax and the metadata for the SYS.EVAL_CLASSIC_EXPR expression is getting deprecated. You can manually convert or use nspepi tool to convert the Classic expression to advanced expression.

Following are examples of the SYS.EVAL_CLASSIC_EXPR("expression") expression:

```plaintext
1  sys.eval_classic_expr("req.ssl.client.cipher.bits > 1000")
2  sys.eval_classic_expr("url contains abc")
3  sys.eval_classic_expr("req.ip.sourceip == 10.102.1.61 -netmask 255.255.255.255")
4  sys.eval_classic_expr("time >= *:30:00GMT")
5  sys.eval_classic_expr("e1 || e2")
6  sys.eval_classic_expr("req.http.urllen > 50")
7  sys.eval_classic_expr("dayofweek == wedGMT")
```
Configure advanced policy expressions in a policy

May 14, 2019

You can configure an Advanced policy expression of up to 1,499 characters in a policy. The user interface for Advanced policy expressions depends to some extent on the feature for which you are configuring the expression, and on whether you are configuring an expression for a policy or for another use.

When configuring expressions on the command line, you delimit the expression by using quotation marks ("..."). Within an expression, you escape additional quotation marks by using a back-slash (\). For example, the following are standard methods for escaping quotation marks in an expression:

"\"abc\"

'\"abc\''

You must also use a backslash to escape question marks and other backslashes on the command line. For example, the expression http.req.url.contains("?") requires a backslash so that the question mark is parsed. Note that the backslash character will not appear on the command line after you type the question mark. On the other hand, if you escape a backslash (for example, in the expression 'http.req.url.contains("\http")'), the escape characters are echoed on the command line.

To make an entry more readable, you can escape the quotation marks for an entire expression. At the start of the expression you enter the escape sequence "q" plus one of the following special characters: />{~$ˆ+=&%@'?.

You enter only the special character at the end of the expression, as follows:

```plaintext
1 q@http.req.url.contains("sometext") && http.req.cookie.exists@
2
3 q~http.req.url.contains("sometext") && http.req.cookie.exists~
```

Note that an expression that uses the { delimiter is closed with }.

For some features (for example, Integrated Caching and Responder), the policy configuration dialog box provides a secondary dialog box for configuring expressions. This dialog enables you to choose from drop-down lists that show the available choices at each point during expression configuration. You cannot use arithmetic operators when using these configuration dialogs, but most other advanced
policy expression features are available. To use arithmetic operators, write your expressions in free-form format.

**Configure an Advanced policy syntax rule by using the CLI**

1. **Note:**
   Default syntax policy is now renamed as Advanced policy.

At the command prompt, type the following commands to configure a default syntax rule and verify the configuration:

1. `add cache|dns|rewrite|cs policy policymame **-rule** expression featureSpecificParameters **-action**`
2. `show cache|dns|rewrite|cs policy policymame`

Following is an example of configuring a caching policy:

**Example:**

```bash
1 > add cache policy pol-cache -rule http.req.content_length.le(5) -action INVAL
2   Done
3
4 > show cache policy pol-cache
5   Name: pol-cache
6     Rule: http.req.content_length.le(5)
7     CacheAction: INVAL
8     Invalidate groups: DEFAULT
9     UndefAction: Use Global
10    Hits: 0
11    Undef Hits: 0
12
13   Done
```

**Configure a default syntax policy expression by using the GUI**

1. In the navigation pane, click the name of the feature where you want to configure a policy, for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching, and then click **Policies**.
2. Click **Add**.
3. For most features, click in the **Expression** field. For content switching, click **Configure**.
4. Click the **Prefix** icon (the house) and select the first expression prefix from the drop-down list. For example, in Responder, the options are HTTP, SYS, and CLIENT. The next set of applicable options appear in a drop-down list.

5. Double-click the next option to select it, and then type a period (.). Again, a set of applicable options appears in another drop-down list.

6. Continue selecting options until an entry field (signalled by parentheses) appears. When you see an entry field, enter an appropriate value in the parentheses. For example, if you select GT(int) (greater-than, integer format), you specify an integer in the parentheses. Text strings are delimited by quotation marks. Following is an example:

   `HTTP.REQ.BODY(1000).BETWEEN("this","that")`

7. **To insert an operator between two parts of a compound expression**, click the **Operators** icon (the sigma), and select the operator type. Following is an example of a configured expression with a Boolean OR (signalled by double vertical bars):

   `HTTP.REQ.URL.EQ("www.mycompany.com") || HTTP.REQ.BODY(1000).BETWEEN("this", "that")`

8. To insert a named expression, click the down arrow next to the Add icon (the plus sign) and select a named expression.

9. To configure an expression using drop-down menus, and to insert built-in expressions, click the Add icon (the plus sign). The Add Expression dialog box works in a similar way to the main dialog box, but it provides drop-down lists for selecting options, and it provides text fields for data entry instead of parentheses. This dialog box also provides a Frequently Used Expressions drop-down list that inserts commonly used expressions. When you are done adding the expression, click **OK**.

10. When finished, click **Create**. A message in the status bar indicates that the policy expression is configured successfully.
Test a default syntax expression by using the GUI

1. In the navigation pane, click the name of the feature for which you want to configure a policy (for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching), and then click Policies.
2. Select a policy and click Open.
3. To test the expression, click the Evaluate icon (the check mark).
4. In the expression evaluator dialog box, select the Flow Type that matches the expression.
5. In the HTTP Request Data or HTTP Response Data field, paste the HTTP request or response that you want to parse with the expression, and click Evaluate. Note that you must supply a complete HTTP request or response, and the header and body should be separated by blank line. Some programs that trap HTTP headers do not also trap the response. If you are copying and pasting only the header, insert a blank line at the end of the header to form a complete HTTP request or response.
6. Click Close to close this dialog box.

Configure named advanced policy expressions

February 12, 2020

Instead of retyping the same expression multiple times in multiple policies, you can configure a named expression and refer to the name any time you want to use the expression in a policy. For example, you could create the following named expressions:

- **ThisExpression:**
  ```java
  http.req.body(100).contains("this")
  ```

- **ThatExpression:**
  ```java
  http.req.body(100).contains("that")
  ```

You can then use these named expressions in a policy expression. For example, the following is a legal expression based on the preceding examples:

<table>
<thead>
<tr>
<th>ThisExpression</th>
<th>ThatExpression</th>
</tr>
</thead>
</table>

You can use the name of an advanced policy expression as the prefix to a function. The named expression can be either a simple expression or a compound expression. The function must be one that can
operate on the type of data that is returned by the named expression.

**Example 1: Simple Named Expression as a Prefix**

The following simple named expression, which identifies a text string, can be used as a prefix to the `AFTER_STR(<string>)` function, which works with text data:

```
HTTP.REQ.BODY(1000)
```

If the name of the expression is `top1KB`, you can use `top1KB.AFTER_STR("username")` instead of `HTTP.REQ.BODY(1000).AFTER_STR("username")`.

**Example 2: Compound named expression as a prefix**

You can create a compound named expression called `basic_header_value` to concatenate the user name in a request, a colon (:), and the user's password, as follows:

```
add policy expression basic_header_value "HTTP.REQ.USER.NAME + ":" + HTTP.REQ.USER.PASSWD"
```

You can then use the name of the expression in a rewrite action, as shown in the following example:

```
add rewrite action insert_b64encoded_authorization insert_http_header authorization '"Basic " + basic_header_value.b64encode'-bypassSafetyCheck YES
```

In the example, in the expression that is used to construct the value of the custom header, the B64 encoding algorithm is applied to the string returned by the compound named expression.

You can also use a named expression (either by itself or as a prefix to a function) to create the text expression for the replacement target in a rewrite.

**Configure a named default syntax expression by using the CLI**

At the command prompt, type the following commands to configure a named expression and verify the configuration:

```
1 - add policy expression \<name\>\<value\>
2
3 - show policy expression \<name\>
```

**Example:**
The expression can be up to 1,499 characters.

Configure a named expression by using the GUI

1. In the navigation pane, expand AppExpert, and then click Expressions.
2. Click Advanced Expressions.
3. Click Add.
4. Enter a name and a description for the expression.
5. Configure the expression by using the process described in Configure advanced policy expression. A message in the status bar indicates that the policy expression is configured successfully.

Configure advanced policy expressions outside the context of a policy

February 26, 2020

A number of functions, including the following, can require an advanced policy expression that is not part of a policy:

- Integrated Caching selectors:
  You define multiple non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND relationship with the others.

- Load Balancing:
  You configure an expression for the TOKEN method of load balancing for a load balancing virtual server.

- Rewrite actions:
Expressions define the location of the rewrite action and the type of rewriting to be performed, depending on the type of rewrite action that you are configuring. For example, a DELETE action only uses a target expression. A REPLACE action uses a target expression and an expression to configure the replacement text.

- Rate-based policies:

You use advanced policy expressions to configure Limit Selectors. You can use these selectors when configuring policies to throttle the rate of traffic to various servers. You define up to five non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND with the others.

**Configure an advanced policy expression outside a policy by using the CLI (cache selector example)**

At the command prompt, type the following commands to configure an advanced policy expression outside a policy and verify the configuration:

```
1 - add cache selector <selectorName> <rule>
2 - show cache selector <selectorName>
```

**Example:**

```
1 > add cache selector mainpageSelector "http.req.cookie.value("ABC_def")"
2        "http.req.url.query.value("ghi")" selector "mainpageSelector" added
3 Done
4 > show cache selector mainpageSelector
5       Name: mainpageSelector
6       Expressions:
7           1) http.req.cookie.value("ABC_def")
8           2) http.req.url.query.value("ghi")
9 Done
```

Following is an equivalent command that uses the more readable q delimiter, as described in Configure advanced policy expressions in a policy:

```
1 > add cache selector mainpageSelector2 q~http.req.cookie.value("ABC_def")~
2        q~http.req.url.query.value("ghi")~selector "mainpageSelector2" added
3 Done
4 > show cache selector mainpageSelector2
5       Name: mainpageSelector2
```
Expressions:
1) http.req.cookie.value("ABC_def")
2) http.req.url.query.value("_ghi")

Advanced policy expressions: evaluating text

February 12, 2020
You can configure a policy with an advanced policy expression that evaluates text in a request or response. Advanced policy text expressions can range from simple expressions that perform string matching in HTTP headers to complex expressions that encode and decode text. You can configure text expressions to be case sensitive or case insensitive and to use or ignore spaces. You can also configure complex text expressions by combining text expressions with Boolean operators.

You can use expression prefixes and operators for evaluating HTTP requests, HTTP responses, and VPN and Clientless VPN data. However, text expression prefixes are not restricted to evaluating these elements of your traffic.

About text expressions

February 21, 2020
You can configure various expressions for working with text that flows through the Citrix ADC appliance. Following are some examples of how you can parse text by using a default syntax expression:

- Determine that a particular HTTP header exists.
  For example, you may want to identify HTTP requests that contains a particular Accept-Language header for the purpose of directing the request to a particular server.

- Determine that a particular HTTP URL contains a particular string.
  For example, you may want to block requests for particular URLs. Note that the string can occur at the beginning, middle, or end of another string.
• Identify a POST request that is directed to a particular application.

For example, you may want to identify all POST requests that are directed to a database application for the purpose of refreshing cached application data.

Note that there are specialized tools for viewing the data stream for HTTP requests and responses. You can use the tools to view the data stream.

**About operations on text**

A text-based expression consists of at least one prefix to identify an element of data and usually (although not always) an operation on that prefix. Text-based operations can apply to any part of a request or a response. Basic operations on text include various types of string matches.

For example, the following expression compares a header value with a string:

```plaintext
http.req.header("myHeader").contains("some-text")
```

Following expressions are examples of matching a file type in a request:

```plaintext
http.req.url.suffix.contains("jpeg")
http.req.url.suffix.eq("jpeg")
```

In the preceding examples, the contains operator permits a partial match and the eq operator looks for an exact match.

Other operations are available to format the string before evaluating it. For example, you can use text operations to strip out quotes and white spaces, to convert the string to all lowercase, or to concatenate strings.

**Note:**

Complex operations are available to perform matching based on patterns or to convert one type of text format to another type.

For more information, see the following topics:

- Pattern sets and data sets.
- Regular expressions.
- Typecasting data.

**Compounding and precedence in text expressions**

You can apply various operators to combine text prefixes or expressions. For example, the following expression concatenates the returned values of each prefix:

```plaintext
http.req.hostname + http.req.url
```
Following is an example of a compound text expression that uses a logical AND. Both components of this expression must be TRUE for a request to match the expression:

```
http.req.method.eq(post) && http.req.body(1024).startswith("destination=")
```

**Note:**
For more information on operators for compounding, see Compound advanced expressions.

### Categories of text expressions

The primary categories of text expressions that you can configure are:

- Information in HTTP headers, HTTP URLs, and the POST body in HTTP requests.
  
  For more information, see Expression prefixes for text in HTTP requests and responses.

- Information regarding a VPN or a clientless VPN.
  
  For more information, see Expression prefixes for VPNs and clientless VPNs.

- TCP payload information.
  
  For more information about TCP payload expressions, see Advanced policy expressions: Parsing HTTP, TCP, and UDP data.

- Text in a Secure Sockets Layer (SSL) certificate.
  
  For information about text expressions for SSL and SSL certificate data, see Advanced policy expressions: Parsing SSL certificates and Expressions for SSL certificate dates.

**Note:**
Parsing a document body, such as the body of a POST request, can affect performance. You may want to test the performance impact of policies that evaluate a document body.

### Guidelines for text expressions

From a performance standpoint, it typically is best to use protocol-aware functions in an expression. For example, the following expression makes use of a protocol-aware function:

```
HTTP.REQ.URL.QUERY
```

The previous expression performs better than the following equivalent expression, which is based on string parsing:

```
HTTP.REQ.URL.AFTER_STR("?")
```

In the first case, the expression looks specifically at the URL query. In the second case, the expression scans the data for the first occurrence of a question mark.
There is also a performance benefit from structured parsing of text, as in the following expression:

```
HTTP.REQ.HEADER("Example").TYPECAST_LIST_T(’,’).GET(1)
```

(For more information on typecasting, see Typecasting data. The typecasting expression, which collects comma-delimited data and structures it into a list, typically would perform better than the following unstructured equivalent:

```
HTTP.REQ.HEADER("Example").AFTER_STR(",").BEFORE_STR(",")
```

Finally, unstructured text expressions typically have better performance than regular expressions. For example, the following is an unstructured text expression:

```
HTTP.REQ.HEADER("Example").AFTER_STR("more")
```

The previous expression would generally provide better performance than the following equivalent, which uses a regular expression:

```
HTTP.REQ.HEADER("Example").AFTER_REGEX(re/more/)
```

For more information on regular expressions, see Regular expressions.

Expression prefixes for text in HTTP requests and responses

July 8, 2020

An HTTP request or response typically contains text, such as in the form of headers, header values, URLs, and POST body text. You can configure expressions to operate on one or more of these text-based items in an HTTP request or response.

Refer to the Expression Prefix table for information on how to configure and extract text from different parts of an HTTP request or response.

Expression prefixes for VPNs and clientless VPNs

July 8, 2020

The Advanced policy engine provides prefixes that are specific to parsing VPN or Clientless VPN data. This data includes the following:
Basic operations on text

August 19, 2020

Basic operations on text include operations for string matching, calculating the length of a string, and controlling case sensitivity. You can include white space in a string that is passed as an argument to an expression, but the string cannot exceed 255 characters.

String comparison functions

The following table lists basic string matching operations in which the functions return a Boolean TRUE or FALSE.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.CONTAINS(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the target contains <code>&lt;string&gt;</code>. Example: <code>http.req.url.contains(&quot;.jpeg&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;.EQ(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the target is an exact match with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.eq(&quot;myhostabc&quot;)</code></td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>&lt;text&gt;</code> .STARTSWITH(&lt;string&gt;)</td>
<td>Returns a Boolean TRUE value if the target begins with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.startswith(&quot;myhost&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;</code> .ENDSWITH(&lt;string&gt;)</td>
<td>Returns a Boolean TRUE value if the target ends with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.endswith(&quot;abc&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;</code> .NE(&lt;string&gt;)</td>
<td>Returns a Boolean TRUE value if the prefix is not equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
<tr>
<td><code>&lt;text&gt;</code> .GT(&lt;string&gt;)</td>
<td>Returns a Boolean TRUE value if the prefix is alphabetically greater than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
</tbody>
</table>
## Function Description

### `<text>.GE(<string>)`

Returns a Boolean TRUE value if the prefix is alphabetically greater than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with

- `SET_TEXT_MODE(IGNORECASE)`
- `SET_TEXT_MODE(NOIGNORECASE)`, and with both ASCII and UTF-8 character sets.

### `<text>.LT(<string>)`

Returns a Boolean TRUE value if the prefix is alphabetically lesser than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with

- `SET_TEXT_MODE(IGNORECASE)`
- `SET_TEXT_MODE(NOIGNORECASE)`, and with both ASCII and UTF-8 character sets.

### `<text>.LE(<string>)`

Returns a Boolean TRUE value if the prefix is alphabetically lesser than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with

- `SET_TEXT_MODE(IGNORECASE)`
- `SET_TEXT_MODE(NOIGNORECASE)`, and with both ASCII and UTF-8 character sets.

---

### Calculate the length of a string

The `<text>.LENGTH` operation returns a numeric value that is equal to the number of characters (not bytes) in a string:

```plaintext
<text>.LENGTH
```

For example, you may want to identify request URLs that exceed a particular length. Following is an expression that implements this example:
After taking a count of the characters or elements in a string, you can apply numeric operations to them. For more information, see Default Syntax Expressions: Working with Dates, Times, and Numbers.

Consider, ignore, and change text case

The following functions operate on the case (upper-case or lower-case) of the characters in the string.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.SET_TEXT_MODE</code></td>
<td>NOIGNORECASE)</td>
</tr>
<tr>
<td>(IGNORECASE</td>
<td>This function turns case sensitivity on or off for all text operations.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.TO_LOWER</code></td>
<td>Converts the target to lowercase for a text block of up to 2 kilobyte (KB). Returns UNDEF if the target exceeds 2 KB. For example, the string “ABCd:” is converted to “abcd:”.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.TO_UPPER</code></td>
<td>Converts the target to uppercase. Returns UNDEF if the target exceeds 2 KB. For example, the string “abcD:” is converted to “ABCD:”.</td>
</tr>
</tbody>
</table>

Strip specific characters from a string

You can use the STRIP_CHARS(<string>) function to remove specific characters from the text that is returned by a default syntax expression prefix (the input string). All instances of the characters that you specify in the argument are stripped from the input string. You can use any text method on the resulting string, including the methods used for matching the string with a pattern set.

For example, in the expression CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS(".-_"), the STRIP_CHARS(<string>) function strips all periods (.), hyphens (-), and underscores (_) from the domain name returned by the prefix CLIENT.UDP.DNS.DOMAIN. If the domain name that is returned is “a.dom_ai_n-name”, the function returns the string “adomainname”.

© 1999-2020 Citrix Systems, Inc. All rights reserved.
In the following example, the resulting string is compared with a pattern set called “listofdomains”:

```plaintext
CLIENT.UDP.DNS.DOMAIN.STRIPE_CHARS(".-_\).CONTAINS_ANY("listofdomains")
```

**Note:** You cannot perform a rewrite on the string that is returned by the `STRIPE_CHARS(<string>)` function.

The following functions strip matching characters from the beginning and end of a given string input.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;</code>.STRIPE_START_CHARS(s)</td>
<td>Strips matching characters from the beginning of the input string until the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and <code>:/en_us:is its value</code>, <code>HTTP.RES.HEADER(&quot;TestLang&quot;).STRIPE_START_CHARS(&quot;:/&quot;)</code> strips the specified characters from the beginning of the value of the header until the first non-matching character <code>e</code> is found and returns <code>en_us:</code> as a string.</td>
</tr>
<tr>
<td><code>&lt;text&gt;</code>.STRIPE_END_CHARS(s)</td>
<td>Strips matching characters from the end of the input string to the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and <code>:/en_us:is its value</code>, <code>HTTP.RES.HEADER(&quot;TestLang&quot;).STRIPE_END_CHARS(&quot;:/&quot;)</code> strips the specified characters from the end of the value of the header until the first non-matching character <code>s</code> is found and returns <code>:/_en_us</code> as a string.</td>
</tr>
</tbody>
</table>

**Append a string to another string**

You can use the `APPEND()` function to append the string representation of the argument to the string representation of the value returned by the preceding function. The preceding function can be one that returns a number, unsigned long, double, time value, IPv4 address, or IPv6 address. The argu-
ment can be a text string, number, unsigned long, double, time value, IPv4 address, or IPv6 address. The resulting string value is the same string value that is obtained by using the + operator.

Complex operations on text

July 8, 2020

In addition to simple string matching, you can configure expressions that examine string length and text block for patterns rather than specific strings.

Be aware of the following for any text-based operation:

- For any operation that takes a string argument, the string cannot exceed 255 characters.
- You can include white space when you specify a string in an expression.

Operations on the length of a string

The following operations extract strings by a character count.

<table>
<thead>
<tr>
<th>Character Count Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.TRUNCATE(&lt;count&gt;)</code></td>
<td>Returns a string after truncating the end of the target by the number of characters in <code>&lt;count&gt;</code>. If the entire string is shorter than <code>&lt;count&gt;</code>, nothing is returned.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.TRUNCATE(&lt;character&gt;,&lt;count&gt;)</code></td>
<td>Returns a string after truncating the text after <code>&lt;character&gt;</code> by the number of characters specified in <code>&lt;count&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.PREFIX(&lt;character&gt;,&lt;count&gt;)</code></td>
<td>Selects the longest prefix in the target that has at most <code>&lt;count&gt;</code> occurrences of <code>&lt;character&gt;</code>.</td>
</tr>
</tbody>
</table>
Character Count Operation | Description
--- | ---
<text>.SUFFIX(<character>,<count>) | Selects the longest suffix in the target that has at most <count> occurrences of <character>. For example, consider the following response body: JLEwx. The following expression returns a value of “JLEwx”: http.res.body(100).suffix('L',1) The following expression returns “LLEwx”: http.res.body(100).suffix('L',2)
<text>.SUBSTR(<starting_offset>, <length>) | Select a string with <length> number of characters from the target object. Begin extracting the string after the <starting_offset>. If the number of characters after the offset are fewer than the value of the <length> argument, select all the remaining characters.
<text>.SKIP(<character>,<count>) | Select a string from the target after skipping over the longest prefix that has at most <count> occurrences of <character>.

**Operations on a portion of a string**

Refer to the String operations table to know how to extract a subset of a larger string by using one of the operations.

**Operations for comparing the alphanumerical order of two strings**

The COMPARE operation examines the first nonmatching character of two different strings. This operation is based on lexicographic order, which is the method used when ordering terms in dictionaries.

This operation returns the arithmetic difference between the ASCII values of the first nonmatching characters in the compared strings. The following differences are examples:

- The difference between “abc” and “and” is -1 (based on the third pair-wise character comparison).
- The difference between “@” and “abc” is -33.
- The difference between “1” and “abc” is -47.

Following is the syntax for the COMPARE operation.
<text>.COMPARE(<string>)

**Extract an integer from a string of bytes that represent text**

Refer to the Integer extraction table to know how to treat a string of bytes that represent text as a sequence of bytes, extract 8 bits, 16 bits, or 32 bits from the sequence, and then convert the extracted bits to an integer.

**Convert text to a hash value**

You can convert a text string to a hash value by using the HASH function. This function returns a 31-bit positive integer as a result of the operation. Following is the format of the expression:

<text>.HASH

This function ignores case and white spaces. For example, after the operation, the two strings Ab c and a bc would produce the same hash value.

**Encode and decode text by applying the Base64 encoding algorithm**

The following two functions encode and decode a text string by applying the Base64 encoding algorithm:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text.B64ENCODE</td>
<td>Encodes the text string (designated by text) by applying the Base64 encoding algorithm.</td>
</tr>
<tr>
<td>text.B64DECODE</td>
<td>Decodes the Base64-encoded string (designated by text) by applying the Base64 decoding algorithm. The operation raises an UNDEF if text is not in B64-encoded format.</td>
</tr>
</tbody>
</table>

**Refine the search in a rewrite action by using the EXTEND function**

The EXTEND function is used in rewrite actions that specify patterns or pattern sets and target the bodies of HTTP packets. When a pattern match is found, the EXTEND function extends the scope of the search by a predefined number of bytes on both sides of the matching string. A regular expression can then be used to perform a rewrite on matches in this extended region. Rewrite actions that are configured with the EXTEND function perform rewrites faster than rewrite actions that evaluate entire
HTTP bodies using only regular expressions.

The format of the EXTEND function is \text{EXTEND}(m,n), where \text{m} and \text{n} are the number of bytes by which the scope of the search is extended before and after the matching pattern, respectively. When a match is found, the new search scope comprises \text{m} bytes that immediately precede the matching string, the string itself, and the \text{n} bytes that follow the string. A regular expression can then be used to perform a rewrite on a portion of this new string.

The EXTEND function can be used only if the rewrite action in which it is used fulfills the following requirements:

• The search is performed by using patterns or patterns sets (not regular expressions)
• The rewrite action evaluates only the bodies of HTTP packets.

Also, the EXTEND function can be used only with the following types of rewrite actions:

• replace\_all
• insert\_after\_all
• delete\_all
• insert\_before\_all

For example, you might want to delete all instances of “\texttt{http://exampleurl.com/}” and “\texttt{http://exampleurl.au/}” in the first 1000 bytes of the body. To do this, you can configure a rewrite action to search for all instances of the string exampleurl, extend the scope of the search on both sides of the string when a match is found, and then use a regular expression to perform the rewrite in the extended region. The following example extends the scope of the search by 20 bytes to the left and 50 bytes to the right of the matching string:

\begin{verbatim}
add rewrite action delurl_example delete_all 'HTTP.REQ.BODY(1000)'-pattern exampleurl -refineSearch 'extend(20,50).regex_select(re##http://exampleurl.(com|au)##)'
\end{verbatim}

Convert text to hexadecimal format

The following function converts text to hexadecimal format and extracts the resulting string:

\begin{verbatim}
<text>.BLOB\_TO\_HEX(<string>)
\end{verbatim}

For example, this function converts the byte string “abc” to “61:62:63”.

Encrypt and decrypt text

In default syntax expressions, you can use the ENCRYPT and DECRYPT functions to encrypt and decrypt text. Data encrypted by the ENCRYPT function on a given Citrix ADC appliance or high availability (HA) pair is intended for decryption by the DECRYPT function on the same Citrix ADC appliance or
HA pair. The appliance supports the RC4, DES3, AES128, AES192, and AES256 encryption methods. The key value that is required for encryption is not user-specifiable. When an encryption method is set, the appliance automatically generates a random key value that is appropriate for the specified method. The default method is AES256 encryption, which is the most secure encryption method and the one that Citrix recommends.

You do not need to configure encryption unless you want to change the encryption method or you want the appliance to generate a new key value for the current encryption method.

**Note:** You can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see Encrypt and decrypt XML payloads.

Configure encryption

During startup, the appliance runs the set ns encryptionParams command with, by default, the AES256 encryption method, and uses a randomly generated key value that is appropriate for AES256 encryption. The appliance also encrypts the key value and saves the command, with the encrypted key value, to the Citrix ADC configuration file. Therefore, the AES256 encryption method is enabled for the ENCRYPT and DECRYPT functions by default. The key value that is saved in the configuration file persists across reboots even though the appliance runs the command each time you restart it.

You can run the set ns encryptionParams command manually, or use the configuration utility, if you want to change the encryption method or if you want the appliance to generate a new key value for the current encryption method. To use the CLI to change the encryption method, set only the method parameter, as shown in "**Example 1: Changing the Encryption Method**." If you want the appliance to generate a new key value for the current encryption method, set the method parameter to the current encryption method and the keyValue parameter to an empty string (""), as shown in "**Example 2: Generating a New Key Value for the Current Encryption Method**." After you generate a new key value, you must save the configuration. If you do not save the configuration, the appliance uses the newly generated key value only until the next restart, after which it reverts to the key value in the saved configuration.

**Configure encryption by using the GUI**

1. Navigate to **System > Settings**.
2. In the **Settings** area, click **Change Encryption** parameters.
3. In the **Change Encryption Parameters** dialog box, do one of the following:
   - To change the encryption method, in the Method list, select the encryption method that you want.
   - To generate a new key value for the current encryption method, click Generate a new key for the selected method.
4. Click **OK**.
Use the ENCRYPT and DECRYPT functions

You can use the ENCRYPT and DECRYPT functions with any expression prefix that returns text. For example, you can use the ENCRYPT and DECRYPT functions in rewrite policies for cookie encryption. In the following example, the rewrite actions encrypt a cookie named MyCookie, which is set by a back-end service, and decrypt the same cookie when it is returned by a client:

```
1  add rewrite action my-cookie-encrypt-action replace "HTTP.RES.
   SET_COOKIE.COOKIE("MyCookie").VALUE(0)" "HTTP.RES.SET_COOKIE.COOKIE(
   "MyCookie").VALUE(0).ENCRYPT" -bypassSafetyCheck YES

2  add rewrite action my-cookie-decrypt-action replace "HTTP.REQ.COOKIE.
   VALUE("MyCookie")" "HTTP.REQ.COOKIE.VALUE("MyCookie").DECRYPT" -
   bypassSafetyCheck YES
```

After you configure policies for encryption and decryption, save the configuration to bring the policies into effect.

Configure encryption key for third-party encryption

In default syntax expressions, you can use ENCRYPT and DECRYPT functions for encrypting and decrypting text in a request or response. The data encrypted by the ENCRYPT function on an appliance (standalone, high availability, or cluster) is intended to be decrypted by the DECRYPT function by the same appliance. The appliance supports RC4, DES, Triple-DES, AES92, and AES256 encryption methods and each of these methods use a secret key for both encryption and decryption of data. You can use any of these methods to encrypt and decrypt data in two ways - self-encryption and third-party encryption.

The self-encryption feature in an appliance (standalone, high availability or cluster) encrypts and then decrypts data by evaluating the header value. One example to understand this is the HTTP Cookie encryption. The expression evaluates the header, encrypts the HTTP cookie value in the Set-Cookie header in the outgoing response and then decrypts the cookie value when it is returned in the cookie header of a subsequent incoming request from the client. The key value is not user configurable, instead when an encryption method is configured in the set ns encryptionParams command, the appliance automatically generates a random key value for the configured method. By default, the command uses the AES256 encryption method, which is the highly secured method and Citrix recommends this method.

The third-party encryption feature encrypts or decrypts data with a third-party application. For example, a client may encrypt data in a request and the appliance decrypts the data before sending it the back-end server or vice versa. To perform this, the appliance and the third party application must share a secret key. On the appliance, you can directly configure the secret key using an encryption function.
key object and key value is automatically generated by the appliance for a stronger encryption. The same key is manually configured on the third-party appliance so that both appliance and third-party application can use the same key for encrypting and decryption data.

Note: Using third-party encryption, you can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see “Encrypting and Decrypting XML Payloads.”

Cipher methods

A cipher method provides two functions: an encryption function that transforms a plaintext byte sequence into a ciphertext byte sequence, and a decryption function that transforms the ciphertext back to the plaintext. Cipher methods use byte sequences called keys to perform encryption and decryption. Cipher methods that use the same key for encryption and decryption are called symmetric. Cipher methods that use different keys for encryption and decryption are asymmetric. The most notable examples of asymmetric ciphers are in public key cryptography, which uses a public key available to anyone for encryption and a private key known only to the decrypter.

A good cipher method makes it infeasible to decrypt (“crack”) ciphertext if you don’t possess the key. “Infeasible” really means that cracking the cyphertext would take more time and computing resources than it is worth. As computers become more powerful and cheaper, ciphers that were formerly infeasible to crack become more feasible. Also, over time, flaws are found in cipher methods (or their implementations), making cracking easier. Newer cipher methods are therefore preferred over older ones. In general, longer length keys provide better security than shorter keys, at the cost of longer encryption and decryption times.

A cipher method can use stream ciphers or block ciphers. RC4 is the mostly secured stream ciphers and it is used only for legacy application. Block ciphers can include padding.

Stream ciphers

A stream cipher method operates on individual bytes. Only one stream cipher is available on Citrix ADC appliances: RC4, which uses a 128 bit (16 bytes) key length. For a given key, RC4 generates a pseudo-random sequence of bytes, call a keystream, which is X-ORED with the plaintext to produce the ciphertext. RC4 is no longer considered secure and should be used only if required by legacy applications.

Block ciphers

A block cipher method operates on a fixed block of bytes. A Citrix ADC appliance provides two block ciphers: Data Encryption Standard (DES) and the Advanced Encryption Standard (AES). DES uses a
block size of 8 bytes and (on a Citrix ADC appliance) two choices for key length: 64 bits (8 bytes), of which 56 bits are data and 8 bits are parity, and Triple-DES, a 192 bit (24 bytes) key length. AES has a block size of 16 bytes and (on Citrix ADC) three choices for key length: 128 bits (16 bytes), 192 bits (24 bytes) and 256 bits (32 bytes).

Padding

If the plaintext for a block cipher is not an integral number of blocks, padding with more bytes might be required. For example, suppose the plaintext is “xyzzy” (hex 78797a7a79). For an 8-byte Triple-DES block, this value would have to be padded to create 8 bytes. The padding scheme must allow the decryption function to determine the length of the original plaintext after decryption. Following are some padding schemes currently in use (n is the number of bytes added):

- **PKCS7**: Adds n bytes of value n each. For example, 78797a7a79000003. This is the padding scheme used by OpenSSL and ENCRYPT() policy function. The PKCS5 padding scheme is the same as PKCS7.
- **ANSI X.923**: Adds n-1 zero bytes and a final byte of value n. For example, 78797a7a79000003.
- **ISO 10126**: Adds n-1 random bytes and a final byte of value n. For example, 78797a7a79xxxx03, where xx can be any byte value. The DECRYPT() policy function accepts this padding scheme, which also allows it to accept the PKCS7 and ANSI X.923 schemes.
- **ISO/IEC 7816-4**: Adds a 0x80 byte and n-1 zero bytes. For example, 78797a7a79800000. This is also call OneAndZeros padding.
- **Zero**: Adds n zero bytes. Example: 78797a7a79000000. This can only be used with plaintext that does not include NUL bytes.

If padding is used and the plaintext is an integral number of blocks, an extra block is typically added so that the decryption function can unambiguously determine the original plaintext length. For PKCS7 and 8 byte block, this would be 0808080808080808.

Modes of operation

There are a number of different modes of operation for block ciphers, which specify how multiple blocks of plaintext are encrypted. Some modes use an initialization vector (IV), a block of data apart from the plaintext that is used to start the encryption process. It is a good practice to use a different IV for each encryption, so that the same plaintext produces different ciphertext. The IV does not need to be secret, and so is prepended to the ciphertext. Modes include:

- **Electronic Codebook (ECB)**: Each block of plaintext is encrypted independently. An IV is not used. Padding is required if the plaintext is not a multiple of the cipher block size. The same plaintext and key always produces the same ciphertext. Because of this, ECB is considered less secure than other modes and should only be used for legacy applications.
• Cipher Block Chaining (CBC): Each block of plaintext is XORed with the previous ciphertext block, or the IV for the first block, before being encrypted. Padding is required if the plaintext is not a multiple of the cipher block size. This is the mode used with the Citrix ADC encryptionParams method.
• Cipher Feedback (CFB): The previous ciphertext block, or the IV for the first block, is encrypted and the output is XORed with the current plaintext block to create the current ciphertext block. The feedback can be 1 bit, 8 bits, or 128 bits. Since the plaintext is XORed with the cipher text, padding is not required.
• Output Feedback (OFB): A keystream is generated by applying the cipher successively to the IV and XORing the keystream blocks with the plaintext. Padding is not required.

Configure encryption keys for third-party encryption

Following are the configuration tasks performed in configuring encryption key.

1. Adding an encryption key. Configures an encryption key for a specified cipher method with a specified key value.
2. Modifying an encryption key. You can edit parameters for a configured encryption key.
3. Unsetting an encryption key. Sets parameters for a configured encryption key to their default values. An encryptionKey value with the name must exist. Sets padding to DEFAULT (determined by the method), Deletes an existing IV, which causes ENCRYPT() to generate a random IV. Deletes an existing comment. The method and key value cannot be reset.
4. Removing an encryption key. Deletes a configured encryption key. The key cannot have any references.
5. Show an encryption key. Displays parameters for the configured encryption key or all configured keys. If the name is omitted, the key value is not displayed.

Add an encryption key by using the CLI

At the command prompt, type:

```
add ns encryptionKey <name> -method <method> [-keyValue <keyvalue>][-padding (OFF | ON)] [-iv <hexstring>] -keyValue <keyvalue> [-comment <string>]
```

Where,

```
1  <method> = ( NONE | RC4 | DES3 | AES128 | AES192 | AES256 | DES | DES-CBC | DES-CFB | DES-0FB | DES-ECB | DES3-CBC | DES3-CFB | DES3-0FB | DES3-ECB | AES128-CBC | AES128-CFB | AES128-0FB | AES128-ECB | AES192-CBC | AES192-CFB | AES192-0FB | AES192-ECB | AES256-CBC | AES256-CFB | AES256-0FB | AES256-ECB ) <hexstring> = hex-encoded byte sequence
```
The above encryption methods specify the operation mode with CBC as the default mode of operation. Therefore, DES, DES2, AES128, AES192, and AES256 methods are equivalent to DES-CBC, DES3-CBC, AES128-CBC, AES192-CBC, and AES256-CBC methods.

Modify an encryption key by using the CLI

At the command prompt, type:

```
set ns encryptionKey <name> [-method <method>] [-keyValue <keyvalue>] [-padding ( OFF | ON )] [-iv <string>] [-comment <string>]
```

Unset an encryption key by using the CLI

At the command prompt, type:

```
unset ns encryptionKey <name> [-padding] [-iv] [-comment]
```

Remove an encryption key by using the CLI

At the command prompt, type:

```
rm ns encryptionKey <name>
```

Show an encryption key by using the CLI

At the command prompt, type:

```
Example:
```

```
1  show ns encryptionKey [ <name> ]
2  add ns encryptionKey my_key -method aes256 -keyValue 26
ea5537b7e0746089476e5658f9327c0b10c3b4778c673a5b38cee182874711
   c2bf0b2e15c15004d6b14bcdc7e5e365
3  set ns encryptionKey my_key -keyValue
   b8742b163abcf62d639837bbee3cef9f5842d82d00dfe6548831d2bd1d93476
4  unset ns encryptionKey my_key -iv
5  rm ns encryptionKey my_key
6  show ns encryptionKey my_key
7  Name: my_key
8  Method: AES256
9  Padding: DEFAULT
10 Key Value: (not disclosed)
```
Add an encryption key by using the GUI

Navigate to System > Encryption Keys and click Add to create an encryption key.

Modify an encryption key by using the GUI

Navigate to System > Encryption Keys and click Edit to modify parameters for a configured encryption key.

Remove an encryption key by using the GUI

Navigate to System > Encryption keys and click Delete.

ENCRYPT and DECRYPT functions for third-party encryption

Following is the ENCRYPT function used for third-party encryption.

ENCRYPT (encryptionKey, out_encoding)

Where,

Input data for the appliance is the text to be encrypted

encryptionKey: An optional string parameter that specifies the configured encryption key object to provide the encryption method, secret key value and other encryption parameters. If omitted, the method uses the automatically generated key value associated with the set ns encryptionParamS command.

out_encoding: This value specifies how the output is encoded. If omitted, BASE64 encoding is used.

Input:

| BASE64: original PEM base64-encoding: 6 bits (0..63) encoded as one ASCII character: |
| 0..23 = 'A'..'Z', 24..51 = 'a'..'z', 52..61 = '0'..'9' |
| 62 = '+', 63 = '/','=' = pad byte. |
| BASE64URL: URL and Filename safe base64-encoding: same as BASE64 except 62 = '-', 63 = '_' |
| HEX_UPPER: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F' |
| HEX_LOWER: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'a'..'f' |
| HEX_COLONS: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F' |
| ';':' between each hex byte. Matches BLOB_TO_HEX() output format |
| HEX: For input, accepts HEX_UPPER, HEX_LOWER, and HEX_COLONS format. For output, produces HEX_LOWER format |
Output: The output is a text encrypted using the specified method and key and encoded using a specified output encoding. It inserts a generated IV before the encrypted text for block methods and modes that require an IV, and either no IV is specified for the encryptionKey or the encryptionKey is omitted.

Following is the DECRYPT function used for third-party decryption.

\[
\text{DECRYPT(encryptionKey, in\_encoding)}
\]

Where,

Input data is an encrypted text using the specified method and key encoded using the specified input encoding. This text is expected to include a generated IV before the encrypted text for block methods and modes that require an IV, and either no IV is specified for the encryptionKey or the encryptionKey is omitted.

- **encryptionKey**—An optional string parameter that specifies the configured encryptionKey object to provide the encryption method, secret key and other encryption parameters. If omitted, the method and automatically generated key associated with the encryptionParams setting will be used.

- **in\_encoding**—An optional enumeration parameter that specifies how the input is expected to be encoded. The values are the same as the out\_encoding of ENCRYPT. If omitted, BASE64 encoding will be expected.

The output data is an unencoded decrypted text.

**Variants and optional parameters**

Following are the variants of these functions with the optional parameters:

<table>
<thead>
<tr>
<th>Variant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENCRYPT</td>
<td>Use encryptionParams command and BASE64 output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(out_encoding)</td>
<td>Use encryptionParams and specified output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(encryptionKey)</td>
<td>Use the specified encryptionKey and BASE64 output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(encryptionKey, out_encoding)</td>
<td>Use the specified encryptionKey and output encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT</td>
<td>Use encryptionParams command and BASE64 input encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT(out_encoding)</td>
<td>Use encryptionParams command and the specified input encoding parameter.</td>
</tr>
</tbody>
</table>
**Variant** | **Description**
---|---
DECRYPT(encryptionKey) | Use the specified encryptionKey and BASE64 input encoding parameter.
DECRYPT(encryptionKey, out_encoding) | Use the specified encryptionKey and input encoding parameter.

**Configure HMAC keys**

Citrix ADC appliances support a Hashed Message Authentication Code (HMAC) function that calculates a digest method or hash of input text by using a secret key shared between a message sender and message receiver. The digest method (derived from an RFC 2104 technique) authenticates the sender and verifies that the message content has not been altered. For example, when a client sends a message with the shared HMAC key to a Citrix ADC appliance, advanced (PI) policy expressions use the HMAC function to compute the hash-based code on the selected text. Then, when the receiver receives the message with the secret key, it recomputes the HMAC by comparing it with the original HMAC to determine whether the message has been altered. The HMAC function is supported by standalone appliances and by appliances in a high availability configuration or in a cluster. Using it is similar to configuring an encryption key.

The add ns hmackey and set ns hmackey commands include a parameter that specifies the digest method and the shared secret key to use for the HMAC computation.

To configure a HMAC key, you must perform the following:

1. Adding an HMAC key. Configures an HMAC key with a specified key value.
2. Modifying an HMAC key. Modifies parameters for a configured HMAC key. The digest method can be changed without changing the key value, since the key value length is not determined by the digest. However, it is advisable to specify a new key when changing the digest.
3. Unsetting an HMAC key. Sets parameters for a configured HMAC key to their default values. An hmacKey object with the name must exist. The only parameter that can be unset is the comment, which is deleted.
4. Removing an HMAC key. Deletes a configured key. The key cannot have any references.
5. Show an HMAC key. Displays parameters for the configured HMAC ac key or all configured keys. If the name is omitted, the key value is not displayed.

**Configure a unique and random HMAC key**

You can automatically generate an unique HMAC key. If you appliance is a cluster configuration, the HMAC key is generated at the start of the process and distributed to all nodes and packet engines. This
ensures the HMAC key is same for all packet engines and all nodes in the cluster.

At the command prompt, type:

```
add ns hmacKey <your_key> -digest <digest> -keyValue <keyvalue>
```

**Example:**

```
add ns hmacKey <name> -digest sha1 -keyValue AUTO
```

Where,

- Name syntax is correct and does not duplicate the name of an existing key.
- The “AUTO” keyValue can be used in the set commands to generate new keys for existing encryptionKey and hmacKey objects.

**Note:**

The automatic key generation is useful if the Citrix ADC appliance is encrypting and decrypting data with the key, or generating and verifying an HMAC key. Since the key value itself is already encrypted when displayed, you cannot retrieve the generated key value for use by any other party.

**Example:**

```
add ns hmacKey my_hmac_key -digest sha1 -keyValue 0c753c6c5ef859189cacdf95b506d02c1797
```

The above encryption methods specify the operation mode with CBC as the default mode of operation. Therefore, DES, DES2, AES128, AES192, and AES256 methods are equivalent to DES-CBC, DES3-CBC, AES128-CBC, AES192-CBC, and AES256-CBC methods.

**Modify an HMAC key by using the CLI**

This command modifies the parameters configured for an HMAC key. You can change the digest without changing the key value, since the key value length is not determined by the digest. However, it is advisable to specify a new key when changing the digest. At the command prompt, type:

```
1 set ns hmacKey <name> [-digest <digest>] [-keyValue <keyvalue>]
2 [-comment <string>]
```

**Unset an HMAC key by using the CLI**

This command sets parameters configured for an HMAC key with their default values. An hmacKey object with the name must exist. The only parameter that you can unset is the comment option, which is deleted. At the command prompt, type:
unset ns hmacKey <name> -comment

**Remove an HMAC key by using the CLI**

This command deletes the configured hmac key. The key cannot have references. At the command prompt, type:

```sh
rm ns hmacKey <name>
```

**Show an HMAC key by using the CLI**

At the command prompt, type:

```sh
1 show ns encryptionKey [...<name>]  
2 3 add ns hmacKey my_hmac_key -digest sha1 -keyValue 0  
c753c6c5ef859189cacdf95b506d02c1797407d  
4 set ns hmacKey my_hmac_key -keyValue  
f348c594341a840a1f641a1cf24aa24c15eb1317  
5 rm ns hmacKey my_hmac_key  
6 show ns hmacKey my_hmac_key  
7 Name: my_hmac_key  
8 Digest: SHA1  
9 Key Value: (not disclosed)
```

Advanced policy expressions: working with dates, times, and numbers

September 25, 2019

Most numeric data that the Citrix ADC appliance processes consists of dates and times. In addition to working with dates and times, the appliance processes other numeric data, such as the lengths of HTTP requests and responses. To process this data, you can configure advanced policy expressions that process numbers.

A numeric expression consists of an expression prefix that returns a number and sometimes, but not always, an operator that can perform an operation on the number. Examples of expression prefixes that return numbers are `SYS.TIME.DAY`, `HTTP.REQ.CONTENT_LENGTH`, and `HTTP.RES.BODY.LENGTH`. Numeric operators can work with any prefix expression that returns data in numeric
Format of dates and times in an expression

May 14, 2019

When configuring an advanced policy expression in a policy that works with dates and times (for example, the Citrix ADC system time or a date in an SSL certificate), you specify a time format as follows:

```
GMT|LOCAL [<yyyy>] [month] [d] [h] [m] [s]
```

Where:

- `<yyyy>` is a four-digit year after GMT or LOCAL.
- `<month>` is a three-character abbreviation for the month, for example, Jan, Dec.
- `<d>` is a day of the week or an integer for the date.

You cannot specify the day as Monday, Tuesday, and so on. You specify either an integer for a specific day of the month, or you specify a date as the first, second, third weekday of the month, and so on. Following are examples of specifying a day of the week:

- Sun_1 is the first Sunday of the month.
- Sun_3 is the third Sunday of the month.
- Wed_3 is the third Wednesday of the month.
- 30 is an example of an exact date in a month.

- `<h>` is the hour, for example, 10h.
- `<s>` is the number of seconds, for example, 30s.

The following example expression is true if the date is between 2008 Jan and 2009 Jan, based on GMT.

```
http.req.date.between(GMT 2008 Jan, GMT 2009 Jan)
```

The following example expression is true for March and all months that follow March in the calendar year, based on GMT:

```
sys.time.ge(GMT 2008 Mar)
```

When you specify a date and time, note that the format is case sensitive and must preserve the exact number of blank spaces between entries.
Expressions for the Citrix ADC system time

May 14, 2019

The SYS.TIME expression prefix extracts the Citrix ADC system time. You can configure expressions that establish whether a particular event occurred at a particular time or within a particular time range according to the Citrix ADC system time.

The following table describes the expressions that you can create by using the SYS.TIME prefix.

- **SYS.TIME.BETWEEN(<time1>, <time2>):**
  Returns a Boolean TRUE if the returned value is later than <time1> and earlier than <time2>.

  You format the <time1>, <time2> arguments as follows:
  - They must both be GMT or both LOCAL.
  - <time2> must be later than <time1>.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:
  - sys.time.between(GMT 2004, GMT 2006)
  - sys.time.between(GMT 2004 Jan, GMT 2006 Nov)
  - sys.time.between(GMT 2004 Jan, GMT 2006)
  - sys.time.between(GMT 2005 May Sun_1, GMT 2005 May Sun_3)
  - sys.time.between(GMT 2005 May 1, GMT May 2005 1)

© 1999-2020 Citrix Systems, Inc. All rights reserved.
- `sys.time.between(LOCAL 2005 May 1, LOCAL May 2005 1)`

**SYS.TIME.DAY:**

Returns the current day of the month as a number from 1 through 31.

**SYS.TIME.EQ(<time>):**

Returns a Boolean TRUE if the current time is equal to the <time> argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.eq(GMT 2005)` (TRUE in this example.)
- `sys.time.eq(GMT 2005 Dec)` (FALSE in this example.)
- `sys.time.eq(LOCAL 2005 May)` (Evaluates to TRUE or FALSE in this example, depending on the current time zone.)
- `sys.time.eq(GMT 10h)` (TRUE in this example.)
- `sys.time.eq(GMT 10h 30s)` (TRUE in this example.)
- `sys.time.eq(GMT May 10h)` (TRUE in this example.)
- `sys.time.eq(GMT Sun)` (TRUE in this example.)
- `sys.time.eq(GMT May Sun_1)` (TRUE in this example.)

**SYS.TIME.NE(<time>):**

Returns a Boolean TRUE if the current time is not equal to the <time> argument.

**SYS.TIME.GE(<time>):**

Returns a Boolean TRUE if the current time is later than or equal to <time>.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.ge(GMT 2004)` (TRUE in this example.)
- `sys.time.ge(GMT 2005 Jan)` (TRUE in this example.)
- `sys.time.ge(LOCAL 2005 May)` (TRUE or FALSE in this example, depending on the current time zone.)
- `sys.time.ge(GMT 8h)` (TRUE in this example.)
- `sys.time.ge(GMT 30m)` (FALSE in this example.)
- `sys.time.ge(GMT May 10h)` (TRUE in this example.)
- `sys.time.ge(GMT May 10h 0m)` (TRUE in this example.)
- `sys.time.ge(GMT Sun)` (TRUE in this example.)
- `sys.time.ge(GMT May Sun_1)` (TRUE in this example.)

**SYS.TIME.GT(<time>):**

Returns a Boolean TRUE if the time value is later than the <time> argument.
For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.gt(GMT 2004)` (TRUE in this example.)
- `sys.time.gt(GMT 2005 Jan)` (TRUE in this example.)
- `sys.time.gt(LOCAL 2005 May)` (TRUE or FALSE, depending on the current time zone.)
- `sys.time.gt(GMT 8h)` (TRUE in this example.)
- `sys.time.gt(GMT 30m)` (FALSE in this example.)
- `sys.time.gt(GMT May 10h)` (FALSE in this example.)
- `sys.time.gt(GMT May 10h 0m)` (TRUE in this example.)
- `sys.time.gt(GMT Sun)` (FALSE in this example.)
- `sys.time.gt(GMT May Sun_1)` (FALSE in this example.)

**SYS.TIME.HOURS:**

Returns the current hour as an integer from 0 to 23.

**SYS.TIME.LE(<time>):**

Returns a Boolean TRUE if the current time value precedes or is equal to the `<time>` argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.le(GMT 2006)` (TRUE in this example.)
- `sys.time.le(GMT 2005 Dec)` (TRUE in this example.)
- `sys.time.le(LOCAL 2005 May)` (TRUE or FALSE depending on the current timezone.)
- `sys.time.le(GMT 8h)` (FALSE in this example.)
- `sys.time.le(GMT 30m)` (TRUE in this example.)
- `sys.time.le(GMT May 10h)` (TRUE in this example.)
- `sys.time.le(GMT Jun 11h)` (TRUE in this example.)
- `sys.time.le(GMT Wed)` (TRUE in this example.)
- `sys.time.le(GMT May Sun_1)` (TRUE in this example.)

**SYS.TIME.LT(<time>):**

Returns a Boolean TRUE if the current time value precedes the `<time>` argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.lt(GMT 2006)` (TRUE in this example.)
- `sys.time.lt(GMT 2005 Dec)` (TRUE in this example.)
- `sys.time.lt(LOCAL 2005 May)` (TRUE or FALSE depending on the current time zone.)
- `sys.time.lt(GMT 8h)` (FALSE in this example.)
- `sys.time.lt(GMT 30m)` (TRUE in this example.)
- `sys.time.lt(GMT May 10h)` (FALSE in this example.)
- sys.time.lt(GMT Jun 11h) (TRUE in this example.)
- sys.time.lt(GMT Wed) (TRUE in this example.)
- sys.time.lt(GMT May Sun_1) (FALSE in this example.)

**SYS.TIME.MINUTES:**

Returns the current minute as an integer from 0 to 59.

**SYS.TIME.MONTH:**

Extracts the current month and returns an integer from 1 (January) to 12 (December).

**SYS.TIME.RELATIVE_BOOT:**

Calculates the number of seconds to the closest previous or scheduled reboot, and returns an integer.

If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.

**SYS.TIME.RELATIVE_NOW:**

Calculates the number of seconds between the current Citrix ADC system time and the specified time, and returns an integer showing the difference.

If the designated time is in the past, the integer is negative; if it is in the future, the integer is positive.

**SYS.TIME.SECONDS:**

Extracts the seconds from the current Citrix ADC system time, and returns that value as an integer from 0 to 59.

**SYS.TIME.WEEKDAY:**

Returns the current weekday as a value from 0 (Sunday) to 6 (Saturday).

**SYS.TIME.WITHIN (<time1>, <time2>):**

If you omit an element of time in <time1>, for example, the day or hour, it is assumed to have the lowest value in its range. If you omit an element in <time2>, it is assumed to have the highest value of its range.

The ranges for the elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. If you specify the year, you must do so in both <time1> and <time2>.

For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are shown in parentheses):

- sys.time.within(GMT 2004, GMT 2006) (TRUE in this example.)
- `sys.time.within(GMT 2004 Jan, GMT 2006 Mar)` (FALSE, May is not in the range of January to March.)
- `sys.time.within(GMT Feb, GMT)` (TRUE, May is in the range of February to December.)
- `sys.time.within(GMT Sun_1, GMT Sun_3)` (TRUE, the second Tuesday is between the first Sunday and the third Sunday.)
- `sys.time.within(GMT 2005 May 1 10h, GMT May 2005 1 17h)` (TRUE in this example.)
- `sys.time.within(LOCAL 2005 May 1, LOCAL May 2005 1)` (TRUE or FALSE, depending on the Citrix ADC system time zone.)

**SYS.TIME.YEAR:**

Extracts the year from the current system time and returns that value as a four-digit integer.

Expressions for SSL certificate dates

May 14, 2019

You can determine the validity period for SSL certificates by configuring an expression that contains the following prefix:

```
CLIENT.SSL.CLIENT_CERT
```

The following example expression matches a particular time for expiration with the information in the certificate:

```
client.ssl.client_cert.valid_not_after.eq(GMT 2009)
```

The following table describes time-based operations on SSL certificates. To obtain the expression you want, replace `certificate` in the expression in the first column with the prefix expression, “CLIENT.SSL.CLIENT_CERT”.

- `<certificate>.VALID_NOT_AFTER`:

  Returns the last day before certificate expiration. The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).

- `<certificate>.VALID_NOT_AFTER.BETWEEN(<time1>, <time2>)`:

  Returns a Boolean TRUE value if the certificate validity is between the `<time1>` and `<time2>` arguments. Both `<time1>` and `<time2>` must be fully specified. Following are examples:

  - GMT 1995 Jan is fully specified.
  - GMT Jan is not fully specified
GMT 1995 20 is not fully specified.

GMT Jan Mon_2 is not fully specified.

The `<time1>` and `<time2>` arguments must be both GMT or both LOCAL, and `<time2>` must be greater than `<time1>`.

For example, if it is GMT 2005 May 1 10h 15m 30s, and the first Sunday of the month, you can specify the following (evaluation results are in parentheses).

- . . . between(GMT 2004, GMT 2006) (TRUE)
- . . . between(GMT 2004 Jan, GMT 2006 Nov) (TRUE)
- . . . between(GMT 2004 Jan, GMT 2006) (TRUE)
- . . . between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE)
- . . . between(GMT 2005 May 1, GMT May 2005 1) (TRUE)
- . . . between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the Citrix ADC system time zone.)

- `<certificate>.VALID_NOT_AFTER.DAY`:

  Extracts the last day of the month that the certificate is valid, and returns a number from 1 through 31, as appropriate for the date.

- `<certificate>.VALID_NOT_AFTER.EQ(<time>)`:

  Returns a Boolean TRUE if the time is equal to the `<time>` argument.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results for this example are in parentheses):

  - . . . eq(GMT 2005) (TRUE)
  - . . . eq(GMT 2005 Dec) (FALSE)
  - . . . eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone)
  - . . . eq(GMT 10h) (TRUE)
  - . . . eq(GMT 10h 30s) (TRUE)
  - . . . eq(GMT May 10h) (TRUE)
  - . . . eq(GMT Sun) (TRUE)
  - . . . eq(GMT May Sun_1) (TRUE)

- `<certificate>.VALID_NOT_AFTER.GE(<time>)`:

  Returns a Boolean TRUE if the time value is greater than or equal to the argument `<time>`.

  For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

  - . . . ge(GMT 2004) (TRUE)
  - . . . ge(GMT 2005 Jan) (TRUE)
- . . .ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .ge(GMT 8h) (TRUE)
- . . .ge(GMT 30m) (FALSE)
- . . .ge(GMT May 10h) (TRUE)
- . . .ge(GMT May 10h 0m) (TRUE)
- . . .ge(GMT Sun) (TRUE)
- . . .ge(GMT May Sun_1) (TRUE)

• <certificate>.VALID_NOT_AFTER.GT(<time>):

Returns a Boolean TRUE if the time value is greater than the argument <time>.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .gt(GMT 2004) (TRUE)
- . . .gt(GMT 2005 Jan) (TRUE)
- . . .gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .gt(GMT 8h) (TRUE)
- . . .gt(GMT 30m) (FALSE)
- . . .gt(GMT May 10h) (FALSE)
- . . .gt(GMT Sun) (FALSE)
- . . .gt(GMT May Sun_1) (FALSE)

• <certificate>.VALID_NOT_AFTER.HOURS:

Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.

• <certificate>.VALID_NOT_AFTER.LE(<time>):

Returns a Boolean TRUE if the time precedes or is equal to the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .le(GMT 2006) (TRUE)
- . . .le(GMT 2005 Dec) (TRUE)
- . . .le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .le(GMT 8h) (FALSE)
- . . .le(GMT 30m) (TRUE)
- . . .le(GMT May 10h) (TRUE)
- . . .le(GMT Jun 11h) (TRUE)
- . . .le(GMT Wed) (TRUE)
- . . .lt(GMT May Sun_1) (TRUE)

• **<certificate>.VALID_NOT_AFTER.LT(<time>):**

  Returns a Boolean TRUE if the time precedes the <time> argument.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:

  - . . .lt(GMT 2006) (TRUE)
  - . . .lt(GMT 2005 Dec) (TRUE)
  - . . .lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
  - . . .lt(GMT 8h) (FALSE)
  - . . .lt(GMT 30m) (TRUE)
  - . . .lt(GMT May 10h) (FALSE)
  - . . .lt(GMT Jun 11h) (TRUE)
  - . . .lt(GMT Wed) (TRUE)
  - . . .lt(GMT May Sun_1) (FALSE)

• **<certificate>.VALID_NOT_AFTER.MINUTES:**

  Extracts the last minute that the certificate is valid and returns that value as an integer from 0 to 59.

• **<certificate>.VALID_NOT_AFTER.MONTH:**

  Extracts the last month that the certificate is valid and returns that value as an integer from 1 (January) to 12 (December).

• **<certificate>.VALID_NOT_AFTER.RELATIVE_BOOT:**

  Calculates the number of seconds to the closest previous or scheduled reboot and returns an integer. If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.

• **<certificate>.VALID_NOT_AFTER.RELATIVE_NOW:**

  Calculates the number of seconds between the current system time and the specified time and returns an integer. If the time is in the past, the integer is negative; if it is in the future, the integer is positive.

• **<certificate>.VALID_NOT_AFTER.SECONDS:**

  Extracts the last second that the certificate is valid and returns that value as an integer from 0 to 59.

• **<certificate>.VALID_NOT_AFTER.WEEKDAY:**

  Extracts the last weekday that the certificate is valid. Returns a number between 0 (Sunday) and 6 (Saturday) to give the weekday in the time value.
• `<certificate>.VALID_NOT_AFTER.WITHIN(<time1>, <time2>):`

Returns a Boolean TRUE if the time lies within all the ranges defined by the elements in `<time1>` and `<time2>`.

If you omit an element of time from `<time1>`, it is assumed to have the lowest value in its range. If you omit an element from `<time2>`, it is assumed to have the highest value of its range. If you specify a year in `<time1>`, you must specify it in `<time2>`.

The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. For the result to be TRUE, each element in the time must exist in the corresponding range that you specify in `<time1>`, `<time2>`.

For example, if time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses):

- . . .within(GMT 2004, GMT 2006) (TRUE)
- . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.)
- . . .within(GMT Feb, GMT) (TRUE, May is in the range for February to December)
- . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday lies within the range of the first Sunday through the third Sunday)
- . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE)
- . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the Citrix ADC system time zone)

• `<certificate>.VALID_NOT_AFTER.YEAR:

Extracts the last year that the certificate is valid and returns a four-digit integer.

• `<certificate>.VALID_NOT_BEFORE:

Returns the date that the client certificate becomes valid.

The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).

• `<certificate>.VALID_NOT_BEFORE.BETWEEN(<time1>, <time2>):`

Returns a Boolean TRUE if the time value is between the two time arguments. Both `<time1>` and `<time2>` arguments must be fully specified.

Following are examples:

GMT 1995 Jan is fully specified.
GMT Jan is not fully specified.
GMT 1995 20 is not fully specified.
GMT Jan Mon_2 is not fully specified.
The time arguments must be both GMT or both LOCAL, and \(<time2>\) must be greater than \(<time1>\).

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- \(\ldots\) between(GMT 2004, GMT 2006) (TRUE)
- \(\ldots\) between(GMT 2004 Jan, GMT 2006 Nov) (TRUE)
- \(\ldots\) between(GMT 2004 Jan, GMT 2006) (TRUE)
- \(\ldots\) between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE)
- \(\ldots\) between(GMT 2005 May 1, GMT May 2005 1) (TRUE)
- \(\ldots\) between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the Citrix ADC system time zone.)

- \(<certificate>.\) VALID NOT BEFORE DAY:

  Extracts the last day of the month that the certificate is valid and returns that value as a number from 1 through 31 representing that day.

- \(<certificate>.\) VALID NOT BEFORE EQ\(<time>\):

  Returns a Boolean TRUE if the time is equal to the \(<time>\) argument.

  For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

  - \(\ldots\) eq(GMT 2005) (TRUE)
  - \(\ldots\) eq(GMT 2005 Dec) (FALSE)
  - \(\ldots\) eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
  - \(\ldots\) eq(GMT 10h) (TRUE)
  - \(\ldots\) eq(GMT 10h 30s) (TRUE)
  - \(\ldots\) eq(GMT May 10h) (TRUE)
  - \(\ldots\) eq(GMT Sun) (TRUE)
  - \(\ldots\) eq(GMT May Sun_1) (TRUE)

- \(<certificate>.\) VALID NOT BEFORE GE\(<time>\):

  Returns a Boolean TRUE if the time is greater than (after) or equal to the \(<time>\) argument.

  For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):

  - \(\ldots\) ge(GMT 2004) (TRUE)
  - \(\ldots\) ge(GMT 2005 Jan) (TRUE)
  - \(\ldots\) ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . . ge(GMT 8h) (TRUE)
- . . . ge(GMT 30m) (FALSE)
- . . . ge(GMT May 10h) (TRUE)
- . . . ge(GMT May 10h 0m) (TRUE)
- . . . ge(GMT Sun) (TRUE)
- . . . ge(GMT May Sun_1) (TRUE)

• <certificate>.VALID_NOT_BEFORE.GT(<time>):

Returns a Boolean TRUE if the time occurs after the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):

- . . . gt(GMT 2004) (TRUE)
- . . . gt(GMT 2005 Jan) (TRUE)
- . . . gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . . gt(GMT 8h) (TRUE)
- . . . gt(GMT 30m) (FALSE)
- . . . gt(GMT May 10h) (FALSE)
- . . . gt(GMT May 10h 0m) (TRUE)
- . . . gt(GMT Sun) (FALSE)
- . . . gt(GMT May Sun_1) (FALSE)

• <certificate>.VALID_NOT_BEFORE.HOURS:

Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.

• **<certificate>.VALID_NOT_BEFORE.LE(<time>)

Returns a Boolean TRUE if the time precedes or is equal to the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . . le(GMT 2006) (TRUE)
- . . . le(GMT 2005 Dec) (TRUE)
- . . . le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . . le(GMT 8h) (FALSE)
- . . . le(GMT 30m) (TRUE)
- . . . le(GMT May 10h) (TRUE)
- . . . le(GMT Jun 11h) (TRUE)
- . . . le(GMT Wed) (TRUE)
- . . . le(GMT May Sun_1) (TRUE)
• `<certificate>.VALID_NOT_BEFORE.LT(<time>):`

  Returns a Boolean TRUE if the time precedes the `<time>` argument.

  For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the
  month of May in 2005, you can specify the following (evaluation results for this example are in
  parentheses):

  - . . .lt(GMT 2006) (TRUE)
  - . . .lt(GMT 2005 Dec) (TRUE)
  - . . .lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
  - . . .lt(GMT 8h) (FALSE)
  - . . .lt(GMT 30m) (TRUE)
  - . . .lt(GMT May 10h) (FALSE)
  - . . .lt(GMT Jun 11h) (TRUE)
  - . . .lt(GMT Wed) (TRUE)
  - . . .lt(GMT May Sun_1) (FALSE)

• `<certificate>.VALID_NOT_BEFORE.MINUTES:`

  Extracts the last minute that the certificate is valid. Returns the current minute as an integer
  from 0 to 59.

• `<certificate>.VALID_NOT_BEFORE.MONTH:`

  Extracts the last month that the certificate is valid. Returns the current month as an integer from
  1 (January) to 12 (December).

• `<certificate>.VALID_NOT_BEFORE.RELATIVE_BOOT:`

  Calculates the number of seconds to the closest previous or scheduled Citrix ADC reboot and
  returns an integer. If the closest boot time is in the past, the integer is negative; if it is in the
  future, the integer is positive.

• `<certificate>.VALID_NOT_BEFORE.RELATIVE_NOW:`

  Returns the number of seconds between the current Citrix ADC system time and the specified
  time as an integer. If the designated time is in the past, the integer is negative. If it is in the
  future, the integer is positive.

• `<certificate>.VALID_NOT_BEFORE.SECONDS:`

  Extracts the last second that the certificate is valid. Returns the current second as an integer
  from 0 to 59.

• `<certificate>.VALID_NOT_BEFORE.WEEKDAY:`

  Extracts the last weekday that the certificate is valid. Returns the weekday as a number between
  0 (Sunday) and 6 (Saturday).
• `<certificate>.VALID_NOT_BEFORE.WITHIN(<time1>, <time2>):`

Returns a Boolean TRUE if each element of time exists within the range defined in the `<time1>`, `<time2>` arguments.

If you omit an element of time from `<time1>`, it is assumed to have the lowest value in its range.
If you omit an element of time from `<time2>`, it is assumed to have the highest value in its range.
If you specify a year in `<time1>`, it must be specified in `<time2>`. The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59.

For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses):

- . . .within(GMT 2004, GMT 2006) (TRUE)
- . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.)
- . . .within(GMT Feb, GMT) (TRUE, May is in the range of February to December.)
- . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.)
- . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE)
- . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the Citrix ADC system time zone)

• `<certificate>.VALID_NOT_BEFORE.YEAR:

Extracts the last year that the certificate is valid. Returns the current year as a four-digit integer.

Expressions for HTTP request and response dates

February 12, 2020

The following expression prefixes return the contents of the HTTP Date header as text or as a date object. These values can be evaluated as follows:

- As a number. The numeric value of an HTTP Date header is returned in the form of the number of seconds since Jan 1, 1970.

For example, the expression http.req.date.mod(86400) returns the number of seconds since the beginning of the day. These values can be evaluated using the same operations as other non-date-related numeric data. For more information, see Expression prefixes for numeric data other than date and time.
• As an HTTP header. Date headers can be evaluated using the same operations as other HTTP headers.

For more information, see Default syntax expressions: Parsing HTTP, TCP, and UDP data.

• As text. Date headers can be evaluated using the same operations as other strings.

For more information, see Advanced Policy Expressions: Evaluating Text.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.DATE</td>
<td>Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT, RFC850. Sunday, 06-Jan-80 09:49:37 GMT, and ASCTIME. Sun Jan 6 08:49:37 1980.</td>
</tr>
<tr>
<td>HTTP.RES.DATE</td>
<td>Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT, RFC850. Sunday, 06-Jan-80 09:49:37 GMT, and ASCTIME. Sun Jan 6 08:49:37 1980.</td>
</tr>
</tbody>
</table>

Generate the day of the week, as a string, in short and long formats

May 31, 2019

The functions, WEEKDAY_STRING_SHORT and WEEKDAY_STRING, generate the day of the week, as a string, in short and long formats, respectively. The strings that are returned are always in English. The prefix used with these functions must return the day of the week in integer format and the acceptable range for the value returned by the prefix is 0-6. Therefore, you can use any prefix that returns an integer in the acceptable range. An UNDEF condition is raised if the returned value is not in this range or if memory allocation fails.

Following are the descriptions of the functions:
**Function**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;prefix&gt;.WEEKDAY_STRING_SHORT</code></td>
<td>Returns the day of the week in short format. The short form is always 3 characters long with an initial capital and the remaining characters in lower case. For example, <code>SYS.TIME.WEEKDAY.WEEKDAY_STRING_SHORT</code> returns Sun if the value returned by the <code>WEEKDAY</code> function is 0 and Sat if the value returned by the prefix is 6.</td>
</tr>
</tbody>
</table>

| `<prefix>.WEEKDAY_STRING` | Returns the day of the week in long format. The long form always has an initial capital, with the remaining characters in lower case. For example, `SYS.TIME.WEEKDAY.WEEKDAY_STRING` returns Sunday if the value returned by the `WEEKDAY` function is 0 and Saturday if the value returned by the prefix is 6. |

---

**Expression prefixes for numeric data other than date and time**

June 18, 2019

In addition to configuring expressions that operate on time, you can configure expressions for the following types of numeric data:

- The length of HTTP requests, the number of HTTP headers in a request, and so on.
  
  For more information, see [Expressions for numeric HTTP payload data other than dates](#).

- IP and MAC addresses.
  
  For more information, see [Expressions for IP addresses and IP subnets](#).

- Client and server data in regard to interface IDs and transaction throughput rate.
  
  For more information, see [Expressions for numeric client and server data](#).
• Numeric data in client certificates other than dates.

For information on these prefixes, including the number of days until certificate expiration and
the encryption key size, see Prefixes for numeric data in SSL certificates.

Converting numbers to text

February 12, 2020

The following functions produce binary strings from a number returned by an expression prefix. These
functions are particularly useful in the TCP rewrite feature as replacement strings for binary data. For
more information about the TCP rewrite feature, see Rewrite.

All the functions return a value of type text. The endianness that some of the functions accept as a
parameter is either LITTLE_ENDIAN or BIG_ENDIAN.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;number&gt;.SIGNED8_STRING</td>
<td>Produces an 8-bit signed binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_SIGNED8(16).SUB(3).SIGNED8_STRING</td>
</tr>
<tr>
<td>&lt;number&gt;.UNSIGNED8_STRING</td>
<td>Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED8(31).ADD(3).UNSIGNED8_STRING</td>
</tr>
<tr>
<td>&lt;number&gt;.SIGNED16_STRING(&lt;endianness&gt;)</td>
<td>Produces a 16-bit signed binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).SKIP(12).GET_SIGNED16(0, BIG_ENDIAN).SUB(4).SIGNED16_STRING(BIG_ENDIAN)</td>
</tr>
<tr>
<td>&lt;number&gt;.UNSIGNED16_STRING(&lt;endianness&gt;)</td>
<td>Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED16(47, LITTLE_ENDIAN).ADD(7).UNSIGNED16_STRING(LITTLE_ENDIAN)</td>
</tr>
</tbody>
</table>
Function | Description
---|---
<number>.SIGNED32_STRING(<endianness>) | Produces a 32-bit signed binary string representing the number. Example: HTTP.REQ.BODY(100).AFTER_STR("delim").GET_SIGNED32(0, BIG_ENDIAN).SUB(1).SIGNED32_STRING(BIG_ENDIAN)
<unsigned_long_number>.UNSIGNED8_STRING | Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED8(24).TYPECAST_UNSIGNED_LONG_AT.ADD(12).UNSIGNED8_STRING
<unsigned_long_number>.UNSIGNED16_STRING(<endianness>) | Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED16(23, LITTLE_ENDIAN).TYPECAST_UNSIGNED_LONG_AT.ADD(10).UNSIGNED16_STRING
<unsigned_long_number>.UNSIGNED32_STRING(<endianness>) | Produces a 32-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).AFTER_STR("delim2").GET_UNSIGNED32(0, BIG_ENDIAN).ADD(2).UNSIGNED32_STRING(BIG_ENDIAN)

Virtual server based expressions

May 31, 2019

The `SYS.VSERVER("<vserver-name>")` expression prefix enables you to identify a virtual server. You can use the following functions with this prefix to retrieve information related to the specified virtual server:

- **THROUGHPUT.** Returns the throughput of the virtual server in Mbps (Megabits per second). The value returned is an unsigned long number.

  **Usage:** `SYS.VSERVER("vserver").THROUGHPUT`
• **CONNECTIONS.** Returns the number of connections being managed by the virtual server. The value returned is an unsigned long number.

  **Usage:** SYS.VSERVER(“vserver”).CONNECTIONS

• **STATE.** Returns the state of the virtual server. The value returned is UP, DOWN, or OUT_OF_SERVICE. One of these values can therefore be passed as an argument to the EQ() operator to perform a comparison that results in a Boolean TRUE or FALSE.

  **Usage:** SYS.VSERVER(“vserver”).STATE

• **HEALTH.** Returns the percentage of services in an UP state for the specified virtual server. The value returned is an integer.

  **Usage:** SYS.VSERVER(“vserver”).HEALTH

• **RESPTIME.** Returns the response time as an integer representing the number of microseconds. Response time is the average TTFB (Time To First Byte) from all the services bound to the virtual server.

  **Usage:** SYS.VSERVER(“vserver”).RESPTIME

• **SURGECOUNT.** Returns the number of requests in the surge queue of the virtual server. The value returned is an integer.

  **Usage:** SYS.VSERVER(“vserver”).SURGECOUNT

**Example 1:**
The following rewrite policy aborts rewrite processing if the number of connections at the load balancing virtual server LBvserver exceeds 10000:

```
add rewrite policy norewrite_pol sys.vserver("LBvserver").connections.gt (10000) norewrite
```

**Example 2:**
The following rewrite action inserts a custom header, TP, whose value is the throughout at the virtual server LBvserver:

```
add rewrite action tp_header insert_http_header TP SYS.VSERVER("LBvserver") .THROUGHPUT
```

**Example 3:**
The following audit log message action writes the average TTFB of the services bound to a virtual server, to the newnslog log file:

```
add audit messageaction log_vserver_resptime_act INFORMATIONAL "\"NS Response Time to Servers:\" + sys.vserver("ssllb").resptime + " millise" -logtoNewnslog YES -bypassSafetyCheck YES
```
Advanced policy expressions: Parsing HTTP, TCP, and UDP data

February 12, 2020

You can configure advanced policy expressions to evaluate payload in a HTTP request or response. The payload associated with an HTTP connection includes HTTP headers (standard or custom headers), body, and connection URL. Additionally, you can evaluate and process payload in a TCP or an UDP packet. For HTTP connections, for example, you can check whether a particular HTTP header is present or if the URL includes a particular query parameter.

You can configure expressions to transform the URL encoding and apply HTML or XML “safe” coding for subsequent evaluation. You can also use XPATH and JSON prefixes to evaluate date in XML and JSON files, respectively.

For more information about authentication expressions such as AAA.USER, AAA.LOGIN, see AAA login and for AAA.AUTHENTICATION expression, see Citrix ADC AAA user authentication topics.

You can also use text-based and numeric Advanced policy expressions to evaluate HTTP request and response data. For more information, see Advanced policy expressions: Evaluating text and Default Syntax Expressions: Working with Dates, Times, and Numbers.

Expressions for identifying the protocol in an incoming IP packet

May 14, 2019

The following table lists the expressions that you can use to identify the protocol in an incoming packet.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IP.PROTOCOL</td>
<td>Identifies the protocol in IPv4 packets sent by clients.</td>
</tr>
<tr>
<td>CLIENT.IPV6.PROTOCOL</td>
<td>Identifies the protocol in IPv6 packets sent by clients.</td>
</tr>
</tbody>
</table>
Expression Description

SERVER.IP.PROTOCOL Identifies the protocol in IPv4 packets sent by servers.

SERVER.IPV6.PROTOCOL Identifies the protocol in IPv6 packets sent by servers.

Arguments to the PROTOCOL function

You can pass the Internet Assigned Numbers Authority (IANA) protocol number to the PROTOCOL function. For example, if you want to determine whether the protocol in an incoming packet is TCP, you can use CLIENT.IP.PROTOCOL.EQ(6), where 6 is the IANA-assigned protocol number for TCP. For some protocols, you can pass an enumeration value instead of the protocol number. For example, instead of CLIENT.IP.PROTOCOL.EQ(6), you can use CLIENT.IP.PROTOCOL.EQ(TCP). The following table lists the protocols for which you can use enumeration values, and the corresponding enumeration values for use with the PROTOCOL function.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Enumeration value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmission Control Protocol (TCP)</td>
<td>TCP</td>
</tr>
<tr>
<td>User Datagram Protocol (UDP)</td>
<td>UDP</td>
</tr>
<tr>
<td>Internet Control Message Protocol (ICMP)</td>
<td>ICMP</td>
</tr>
<tr>
<td>IP Authentication Header (AH), for providing authentication services in IPv4 and IPv6</td>
<td>AH</td>
</tr>
<tr>
<td>Encapsulating Security Payload (ESP) protocol</td>
<td>ESP</td>
</tr>
<tr>
<td>General Routing Encapsulation (GRE)</td>
<td>GRE</td>
</tr>
<tr>
<td>IP-within-IP Encapsulation Protocol</td>
<td>IPIP</td>
</tr>
<tr>
<td>Internet Control Message Protocol for IPv6 (ICMPv6)</td>
<td>ICMPv6</td>
</tr>
<tr>
<td>Fragment Header for IPv6</td>
<td>FRAGMENT</td>
</tr>
</tbody>
</table>

Use case scenarios

The protocol expressions can be used in both request-based and response-based policies. You can use the expressions in various Citrix ADC features, such as load balancing, WAN optimization, content switching, rewrite, and listen policies. You can use the expressions with functions such as EQ() and
NE(), to identify the protocol in a policy and perform an action.

Following are some use cases for the expressions:

• In Branch Repeater load balancing configurations, you can use the expressions in a listen policy for the wildcard virtual server. For example, you can configure the wildcard virtual server with the listen policy CLIENT.IP.PROTOCOL.EQ(TCP) so that the virtual server processes only TCP traffic and simply bridges all non-TCP traffic. Even though you can use an Access Control List instead of the listen policy, the listen policy provides better control over what traffic is processed.

• For content switching virtual servers of type ANY, you can configure content switching policies that switch requests on the basis of the protocol in incoming packets. For example, you can configure content switching policies to direct all TCP traffic to one load balancing virtual server and all non-TCP traffic to another load balancing virtual server.

• You can use the client-based expressions to configure persistence based on the protocol. For example, you can use CLIENT.IP.PROTOCOL to configure persistence on the basis of the protocols in incoming IPv4 packets.

Expressions for HTTP and cache-control headers

July 8, 2020

One common method of evaluating HTTP traffic is to examine the headers in a request or a response. A header can perform a number of functions, including the following:

• Provide cookies that contain data about the sender.

• Identify the type of data that is being transmitted.

• Identify the route that the data has traveled (the Via header).

Note

If an operation is used to evaluate both header and text data, the header-based operation always overrides the text-based operation. For example, the AFTER_STR operation, when applied to a header, overrides text-based AFTER_STR operations for all instances of the current header type.

Prefixes for HTTP headers

The Prefixes for HTTP headers table for expression prefixes that extract HTTP headers.
Operations for HTTP headers

The Operations for HTTP headers table for operations that you can specify with the prefixes for HTTP headers.

Prefixes for cache-control headers

The following prefixes apply specifically to Cache-Control headers.

<table>
<thead>
<tr>
<th>HTTP Header Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.CACHE_CONTROL</td>
<td>Returns a Cache-Control header in an HTTP request.</td>
</tr>
<tr>
<td>HTTP.RES.CACHE_CONTROL</td>
<td>Returns a Cache-Control header in an HTTP response.</td>
</tr>
</tbody>
</table>

Operations for cache-control headers

You can apply any of the operations for HTTP headers to Cache-Control headers.

In addition, the following operations identify specific types of Cache-Control headers. See RFC 2616 for information about these header types.

<table>
<thead>
<tr>
<th>HTTP Header Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache-Control.header.NAME(&lt;integer&gt;)</td>
<td>Returns as a text value the name of the Cache-Control header that corresponds to the nth component in a name-value list, as specified by &lt;integer&gt;. The index of the name-value component is 0-based. If the &lt;integer&gt; that is specified by the integer argument is greater than the number of components in the list, a zero-length text object is returned. Following is an example: http.request.cache_control.name(3).contains(&quot;some_text&quot;)</td>
</tr>
<tr>
<td>Cache-Control.header.IS_INVALID</td>
<td>Returns a Boolean TRUE if the Cache-Control header is not present in the request or response. Following is an example: http.request.cache_control.is_invalid</td>
</tr>
<tr>
<td>HTTP Header Operation</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Cache-Control header.IS_PRIVATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_private</td>
</tr>
<tr>
<td>Cache-Control header.IS_PUBLIC</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_public</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_STORE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Store. Following is an example: http.req.cache_control.is_no_store</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_CACHE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Cache. Following is an example: http.req.cache_control.is_no_cache</td>
</tr>
<tr>
<td>Cache-Control header.IS_MAX_AGE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Max-Age. Following is an example: http.req.cache_control.is_max_age</td>
</tr>
<tr>
<td>Cache-Control header.IS_MIN_FRESH</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Min-Fresh. Following is an example: http.req.cache_control.is_min_fresh</td>
</tr>
<tr>
<td>Cache-Control header.IS_MAX_STALE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Max-Stale. Following is an example: http.req.cache_control.is_max_stale</td>
</tr>
<tr>
<td>Cache-Control header.IS_MUST_REVALIDATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Must-Revalidate. Following is an example: http.req.cache_control.is_must_revalidate</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_TRANSFORM</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Transform. Following is an example: http.req.cache_control.is_no_transform</td>
</tr>
<tr>
<td>Cache-Control header.IS_ONLY_IF_CACHED</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Only-If-Cached. Following is an example: http.req.cache_control.is_only_if_cached</td>
</tr>
</tbody>
</table>
### HTTP Header Operations

<table>
<thead>
<tr>
<th>Header Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache-Control header.IS_PROXY_REVALIDATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Proxy-Revalidate. Following is an example: http.req.cache_control.is_proxy_revalidate</td>
</tr>
<tr>
<td>Cache-Control header.IS_S_MAXAGE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value S-Maxage. Following is an example: http.req.cache_control.is_s_maxage</td>
</tr>
<tr>
<td>Cache-Control header.IS_UNKNOWN</td>
<td>Returns a Boolean TRUE if the Cache-Control header is of an unknown type. Following is an example: http.req.cache_control.is_unknown</td>
</tr>
<tr>
<td>Cache-Control header.MAX_AGE</td>
<td>Returns the value of the Cache-Control header Max-Age. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_age.le(3)</td>
</tr>
<tr>
<td>Cache-Control header.MAX_STALE</td>
<td>Returns the value of the Cache-Control header Max-Stale. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_stale.le(3)</td>
</tr>
<tr>
<td>Cache-Control header.MIN_FRESH</td>
<td>Returns the value of the Cache-Control header Min-Fresh. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.min_fresh.le(3)</td>
</tr>
<tr>
<td>Cache-Control header.S_MAXAGE</td>
<td>Returns the value of the Cache-Control header S-Maxage. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.s_maxage.eq(2)</td>
</tr>
</tbody>
</table>

**Expressions for extracting segments of URLs**

February 12, 2020
You can extract URLs and portions of URLs, such as the host name, or a segment of the URL path. For example, the following expression identifies HTTP requests for image files by extracting image file suffixes from the URL:

```
http.req.url.suffix.eq("jpeg") || http.req.url.suffix.eq("gif")
```

Most expressions for URLs operate on text and are described in Expression Prefixes for Text in HTTP Requests and Responses. This section discusses the GET operation. The GET operation extracts text when used with the following prefixes:

- `HTTP.REQ.URL.PATH`
- `VPN.BASEURL.PATH`
- `VPN.CLIENTLESS_BASEURL.PATH`

The following table describes prefixes for HTTP URLs.

<table>
<thead>
<tr>
<th>URL Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>HTTP.REQ.URL.PATH.GET(&lt;n&gt;)</code></td>
<td>Returns a slash- (“/”) separated list from the URL path. For example, consider the following URL: <code>&lt;http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1&gt;</code>. The following expression returns dir1 from this URL: <code>&lt;http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1&gt;</code>. The following expression returns dir2: http.req.url.path.get(2)</td>
</tr>
<tr>
<td><code>HTTP.REQ.URL.PATH.GET_REVERSE(&lt;n&gt;)</code></td>
<td>Returns a slash- (“/”) separated list from the URL path, starting from the end of the path. For example, consider the following URL: <code>&lt;http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1&gt;</code>. The following expression returns index.html from this URL: <code>&lt;http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1&gt;</code>. The following expression returns dir3: http.req.url.path.get_reverse(1)</td>
</tr>
</tbody>
</table>
Expressions for HTTP status codes and numeric HTTP payload data other than dates

February 12, 2020

The following table describes prefixes for numeric values in HTTP data other than dates.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.CONTENT_LENGTH</td>
<td>Returns the length of an HTTP request as a number. Following is an example:</td>
</tr>
<tr>
<td></td>
<td>http.req.content_length &lt; 500</td>
</tr>
<tr>
<td>HTTP.RES.CONTENT_LENGTH</td>
<td>Returns the length of the HTTP response as a number. Following is an example:</td>
</tr>
<tr>
<td></td>
<td>http.res.content_length &lt;= 1000</td>
</tr>
<tr>
<td>HTTP.RES.STATUS</td>
<td>Returns the response status code</td>
</tr>
<tr>
<td>HTTP.RES.IS_REDIRECT</td>
<td>Returns a Boolean TRUE if the response code is associated with a redirect.</td>
</tr>
<tr>
<td></td>
<td>Following are the redirect response codes: 300 (Multiple Choices), 301</td>
</tr>
<tr>
<td></td>
<td>(Moved Permanently), 302 (Found), 303 (See Other), 305 (Use Proxy), and</td>
</tr>
<tr>
<td></td>
<td>307 (Temporary Redirect). Note: Status code 304 is not considered a redirect</td>
</tr>
<tr>
<td></td>
<td>HTTP response status code. Status code 306 is unused.</td>
</tr>
</tbody>
</table>

SIP expressions

February 27, 2020

The Citrix ADC Advanced policy expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for any supported protocol that operates on a request/response basis. These expressions can be used in content switching, rate limiting, responder, and rewrite policies.
Certain limitations apply to SIP expressions used with responder policies. Only the DROP, NOOP or RESPONDWITH actions are allowed on a SIP load balancing virtual server. Responder policies can be bound to a load balancing virtual server, an override global bind point, a default global bind point, or a sip_udp policy label.

The header format used by the SIP protocol is similar to that used by the HTTP protocol, so many of the new expressions look and function much like their HTTP analogs. Each SIP header consists of a line that includes the SIP method, the URL, and the version, followed by a series of name-value pairs that look like HTTP headers.

Following is a sample SIP header that is referred to in the expressions tables beneath it:

```
1 INVITE sip:16@www.sip.com:5060;transport=udp SIP/2.0
2 Record-Route: <sip:200.200.100.22;lr=on>
3 Via: SIP/2.0/UDP 200.200.100.22;branch=z9hG4bK444b.c8e103d1.0;rport=5060;
4 received=10.102.84.18
5 Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;
6 received=10.102.84.160
7 From: "12" <sip:12@sip_example.com>;tag=00127f4ec85a6d90cc14f45-53cc0185
8 To: "16" <sip:16@sip_example.com>;tag=00127f4ec85a6d90cc14f45-53cc0185
9 Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180
10 Max-Forwards: 69CSeq: 101 INVITE
11 User-Agent: Cisco-CP7940G/8.0
12 Contact: <sip:12@10.102.84.180:5060;transport=udp>
13 Expires: 180
14 Accept: application/sdp
15 Allow: ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE
16 Supported: replaces,join,norefersub
17 Content-Length: 277
18 Content-Type: application/sdp
19 Content-Disposition: session;handling=optional
```

**SIP reference tables**

The following tables contain lists of expressions that operate on SIP headers. The first table contains expressions that apply to request headers. Most response-based expressions are nearly the same as the corresponding request-based expressions. To create a response expression from the corresponding request expression, you change the first two sections of the expression from SIP.REQ to SIP.RES, and make other obvious adjustments. The second table contains those response expressions that are unique to responses and have no request equivalents. You can use any element in the following tables
as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

### SIP request expressions

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.REQ.METHOD</td>
<td>Operates on the method of the SIP request. The supported SIP request methods are ACK, BYE, CANCEL, INFO, INVITE, MESSAGE, NOTIFY, OPTIONS, PRACK, PUBLISH, REFER, REGISTER, SUBSCRIBE, and UPDATE. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns INVITE.</td>
</tr>
<tr>
<td>SIP.REQ.URL</td>
<td>Operates on the SIP request URL. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns sip:16@10.102.84.181:5060;transport=udp.</td>
</tr>
<tr>
<td>SIP.REQ.URL.PROTOCOL</td>
<td>Returns the URL protocol. For example, for a SIP URL ofsip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns sip.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME</td>
<td>Returns the hostname portion of the SIP URL. For example, for a SIP URL ofsip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns <a href="http://www.sip.com:5060">www.sip.com:5060</a>.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.PORT</td>
<td>Returns the port portion of the SIP URL hostname. If no port is specified, this expression returns the default SIP port, 5060. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.DOMAIN</td>
<td>Returns the domain name portion of the SIP URL hostname. If the host is an IP address, then this expression returns an incorrect result. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns sip.com. For a SIP hostname of 192.168.43.15:5060, this expression returns an error.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.SERVER</td>
<td>Returns the server portion of the host. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns www.</td>
</tr>
<tr>
<td>SIP.REQ.URL.USERNAME</td>
<td>Returns the username that precedes the @ character. For example, for a SIP URL of sip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns 16.</td>
</tr>
<tr>
<td>SIP.REQ.VERSION</td>
<td>Returns the SIP version number in the request. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns SIP/2.0.</td>
</tr>
<tr>
<td>SIP.REQ.VERSION.MAJOR</td>
<td>Returns the major version number (the number to the left of the period). For example, for a SIP version number of SIP/2.0, this expression returns 2.</td>
</tr>
<tr>
<td>SIP.REQ.VERSION.MINOR</td>
<td>Returns the minor version number (the number to the right of the period). For example, for a SIP version number of SIP/2.0, this expression returns 0.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.CONTENT_LENGTH</td>
<td>Returns the contents of the Content-Length header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Content-Length header of Content-Length: 277, this expression returns 277.</td>
</tr>
<tr>
<td>SIP.REQ.TO</td>
<td>Returns the contents of the To header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>SIP.REQ.TO.ADDRESS</td>
<td>Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:16@sip_example.com">16@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.TO.DISPLAY_NAME</td>
<td>Returns the display name portion of the To header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 16.</td>
</tr>
<tr>
<td>SIP.REQ.TO.TAG</td>
<td>Returns the “tag” value from the “tag” name value pair in the TO header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.FROM</td>
<td>Returns the contents of the From header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:12@sip_example.com">12@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.ADDRESS</td>
<td>Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:12@sip_example.com">12@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.DISPLAY_NAME</td>
<td>Returns the display name portion of the To header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 12.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.TAG</td>
<td>Returns the “tag” value from the “tag” name/value pair in the TO header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>SIP.REQ.VIA</td>
<td>Returns the complete Via header. If there are multiple Via headers in the request, returns the last Via header. For example, for the two Via headers in the sample SIP header, this expression returns Via: SIP/2.0/UDP10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;re.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.SENTBY_ADDRESS</td>
<td>Returns the address that sent the request. For example, for the Via header Via: SIP/2.0/UDP10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;re this expression returns 10.102.84.180.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.VIA.SENTBY_PORT</td>
<td>Returns the port that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.RPORT</td>
<td>Returns the value from the rport name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.BRANCH</td>
<td>Returns the value from the branch name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns z9hG4bK03e76d0b.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.RECEIVED</td>
<td>Returns the value from the received name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.160.</td>
</tr>
<tr>
<td>SIP.REQ.CALLID</td>
<td>Returns the contents of the Callid header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Callid header of Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180, this expression returns 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180.</td>
</tr>
<tr>
<td>SIP.REQ.CSEQ</td>
<td>Returns the CSEQ number from the CSEQ, as an integer. For example, for a SIP CSEQ header of CSeq: 101 INVITE, this expression returns 101.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;)</td>
<td>Returns the specified SIP header. For &lt;header_name&gt;, substitute the name of the header that you want. For example, to return the SIP From header, you would type SIP.REQ.HEADER(“From”).</td>
</tr>
</tbody>
</table>
### Expression Description

- **SIP.REQ.HEADER(<header_name>).INSTANCE(<line_number>)**: Returns the specified instance of the specified SIP header. Multiple instances of the same SIP header can occur. Where you want a specific instance of such a SIP header (for example, a specific Via header), you can specify that header by typing a number as the `<line_number>`. Header instances are matched from last (0) to first. In other words, `SIP.REQ.HEADER("Via").INSTANCE(0)` returns the last instance of the Via header, while `SIP.REQ.HEADER("Via").INSTANCE(1)` returns the last instance but one of the Via header, and so on. For example, if used on the example SIP header, `SIP.REQ.HEADER("Via").INSTANCE(1)` returns `Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.`

- **SIP.REQ.HEADER(<header_name>).VALUE(<line_number>)**: Returns the contents of the specified instance of the specified SIP header. The usage is nearly the same as the previous expression. For example, if used on the SIP header example in the preceding table entry, `SIP.REQ.HEADER("Via").VALUE(1)` returns `SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.`

- **SIP.REQ.HEADER(<header_name>).COUNT**: Returns the number of instances of a particular header as an integer. For example, if used on the SIP header example above, `SIP.REQ.HEADER("Via").COUNT` returns 2.

- **SIP.REQ.HEADER(<header_name>).EXISTS**: Returns a boolean value of true or false, depending upon whether the specified header exists or not. For example, if used on the SIP header example above, `SIP.REQ.HEADER("Expires").EXISTS` returns true, while `SIP.REQ.HEADER("Caller-ID").EXISTS` returns false.
<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).LIST</td>
<td>Returns the comma-separated parameter list in the specified header. For example, if used on the SIP header example above, SIP.REQ.HEADER(&quot;Allow&quot;).LIST returns ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE. You can append the string .GET(&lt;list_item_number&gt;) to select a specific list item. For example, to get the first item (ACK) from the above list, you would type SIP.REQ.HEADER(&quot;Allow&quot;).LIST.GET(0). To extract the second item (BYE), you would type SIP.REQ.HEADER(&quot;Allow&quot;).LIST.GET(1). Note: If the specified header contains a list of name/value pairs, the entire name/value pair is returned.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).TYPECAST_SIP_HEADER_T(&lt;in_header_name&gt;)</td>
<td>Typecasts &lt;header_name&gt; to &lt;in_header_name&gt;. Any text can be typecasted to the sip_header_t class, after which all header-based operations can be used. After you perform this operation, you can apply all operations that can be used with &lt;in_header_name&gt;. For example, the expression SIP.REQ.CONTENT_LENGTH.TYPECAST_SIP_HEADER_T typecasts all instances of the Content-Length header. After you perform this operation, you can apply all header operations to all instances of the specified header.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS(&lt;string&gt;)</td>
<td>Returns boolean true if the specified text string is present in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).EQUALS_ANY(patset)</td>
<td>Returns boolean true if any pattern associated with &lt;patset&gt; matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS_ANY(patset)</td>
<td>Returns boolean true if any pattern associated with &lt;patset&gt; matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS_INDEX(patset)</td>
<td>Returns the index of the matching pattern associated with &lt;patset&gt; if that pattern matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).EQUALS_INDEX(patset)</td>
<td>Returns the index of the matching pattern associated with &lt;patset&gt; if that pattern matches any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).SUBSTR(&lt;string&gt;)</td>
<td>If the specified string is present in any instance of the specified header, this expression returns that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, SIP.REQ.HEADER(“Via”).SUBSTR(“rport=5060”) returns “rport=5060”. SIP.REQ.HEADER(“Via”).SUBSTR(“rport=5061”) returns an empty string.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).AFTER_STR(&lt;string&gt;)</td>
<td>If the specified string is present in any instance of the specified header, this expression returns the string immediately after that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(“Via”).AFTER_STR(“rport=”') returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).REGEX_MATCH(&lt;regex&gt;)</td>
<td>Returns boolean true if the specified regular expression (regex) matches any instance of the specified header. You must specify the regular expression in the following format: re&lt;delimiter&gt;regular expression&lt;same delimiter&gt;. The regular expression cannot be larger than 1499 characters in length. It must conform to the PCRE regular expression library. See <a href="http://www.pcre.org/pcre.txt">http://www.pcre.org/pcre.txt</a> for documentation on PCRE regular expression syntax. The pcrepattern man page also has useful information on specifying patterns by using PCRE regular expressions. The regular expression syntax supported in this expression has some differences from PCRE. Back references are not allowed. You should avoid recursive regular expressions; although some work, many do not. The dot (.) metacharacter matches newlines. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.</td>
</tr>
</tbody>
</table>
### Expression Description

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).REGEX_SELECT(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(&quot;Via&quot;).REGEX_SELECT(&quot;received=[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}&quot;&quot;) returns received=10.102.84.160.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).AFTER_REGEX(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately after that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(&quot;Via&quot;).AFTER_REGEX(&quot;received=&quot;) returns 10.102.84.160.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).BEFORE_REGEX(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately before that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(&quot;Via&quot;).BEFORE_REGEX(&quot;[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}&quot;&quot;) returns received=.</td>
</tr>
<tr>
<td>SIP.REQ.FULL_HEADER</td>
<td>Returns the entire SIP header, including the terminating CR/LF.</td>
</tr>
<tr>
<td>SIP.REQ.IS_VALID</td>
<td>Returns boolean true if the request format is valid.</td>
</tr>
<tr>
<td>SIP.REQ.BODY(&lt;length&gt;)</td>
<td>Returns the request body, up to the specified length. If the specified length is greater than the length of the request body, this expression returns the entire request body.</td>
</tr>
</tbody>
</table>
Expression Description

**SIP.REQ.LB_VSERVER**
Returns the name of the load balancing virtual server (LB vserver) that is serving the current request.

**SIP.REQ.CS_VSERVER**
Returns the name of the content switching virtual server (CS vserver) that is serving the current request.

**SIP response expressions**

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SIP.RES.STATUS</strong></td>
<td>Returns the SIP response status code. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns 100.</td>
</tr>
<tr>
<td><strong>SIP.RES.STATUS_MSG</strong></td>
<td>Returns the SIP response status message. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns Trying.</td>
</tr>
<tr>
<td><strong>SIP.RES.IS_REDIRECT</strong></td>
<td>Returns boolean true if the response code is a redirect.</td>
</tr>
<tr>
<td><strong>SIP.RES.METHOD</strong></td>
<td>Returns the response method extracted from the request method string in the CSeq header.</td>
</tr>
</tbody>
</table>

Operations for HTTP, HTML, and XML encoding and “safe” characters

February 12, 2020

The following operations work with the encoding of HTML data in a request or response and XML data in a POST body.

- `<text>.HTML_XML_SAFE`:
  Transforms special characters into XML safe format, as in the following examples:
A left-pointing angle bracket (<) is converted to <
A right-pointing angle bracket (>) is converted to >
An ampersand (&) is converted to &
This operation safeguards against cross-site scripting attacks. Maximum length of the transformed text is 2048 bytes. This is a read-only operation.

After applying the transformation, additional operators that you specify in the expression are applied to the selected text. Following is an example:

http.req.url.query.html_xml_safe. contains(“myQueryString”)

- **<text>.HTTP_HEADER_SAFE:**
  Converts all new line (\n) characters in the input text to ‘%0A’ to enable the input to be used safely in HTTP headers.
  This operation safeguards against response-splitting attacks.
  The maximum length of the transformed text is 2048 bytes. This is a read-only operation.

- **<text>.HTTP_URL_SAFE:**
  Converts unsafe URL characters to ‘%xx’ values, where “xx” is a hex-based representation of the input character. For example, the ampersand (&) is represented as %26 in URL-safe encoding.
  The maximum length of the transformed text is 2048 bytes. This is a read-only operation.

Following are URL safe characters. All others are unsafe:

- Alpha-numeric characters: a-z, A-Z, 0-9
- Asterix: “*”
- Ampersand: “&”
- At-sign: “@”
- Colon: “;”
- Comma: “,”
- Dollar: “$”
- Dot: “.”
- Equals: “=”
- Exclamation mark: “!”
- Hyphen: “-“
- Open and close parentheses: “(, “)“
- Percent: “%”
- Plus: “+”
- Semicolon: “;”
- Single quote: “’”
- Slash: “/”
- Question mark: “?”
- Tilde: “~”
- Underscore: “_”

- `<text>.MARK_SAFE:`
  Marks the text as safe without applying any type of data transformation.

**<text>.SET_TEXT_MODE(URLENCODED NOURLENCODED)**

- Transforms all %HH encoding in the byte stream. This operation works with characters (not bytes). By default, a single byte represents a character in ASCII encoding. However, if you specify URLENCODED mode, three bytes can represent a character.

  In the following example, a PREFIX(3) operation selects the first 3 characters in a target.

  http.req.url.hostname.prefix(3)

  In the following example, the Citrix ADC can select up to 9 bytes from the target:

  http.req.url.hostname.set_text_mode(urlencoded).prefix(3)

**<text>.SET_TEXT_MODE(PLUS_AS_SPACE NO_PLUS_AS_SPACE):**

- Specifies how to treat the plus character (+). The PLUS_AS_SPACE option replaces a plus character with white space. For example, the text “hello+world” becomes “hello world.” The NO_PLUS_AS_SPACE option leaves plus characters as they are.

**<text>.SET_TEXT_MODE(BACKSLASH_ENCODED NO_BACKSLASH_ENCODED):**

- Specifies whether or not backslash decoding is performed on the text object represented by `<text>`. If BACKSLASH_ENCODED is specified, the SET_TEXT_MODE operator performs the following operations on the text object:
  - All occurrences of “\XXX” will be replaced with the character “Y” (where XXX represents a number in the octal system and Y represents the ASCII equivalent of XXX). The valid range of octal values for this type of encoding is 0 to 377. For example, the encoded text “http\72/” and http\072//” will both be decoded to `<http://>`, where the colon (:) is the ASCII equivalent of the octal value “72”.
  - All occurrences of “\xHH” will be replaced with the character “Y” (HH represents a number in the hexadecimal system and Y denotes the ASCII equivalent of HH). For example, the encoded text “http\x3a/” will be decoded to `<http://>`, where the colon (:) is the ASCII equivalent of the hexadecimal value “3a”.

Expressions for TCP, UDP, and VLAN data

February 12, 2020

TCP and UDP data take the form of a string or a number. For expression prefixes that return string values for TCP and UDP data, you can apply any text-based operations. For more information, see Advanced policy expressions: Evaluating text.

For expression prefixes that return numeric value, such as a source port, you can apply an arithmetic operation. For more information, see Basic operations on expression prefixes and Compound operations for numbers.

The following table describes prefixes that extract TCP and UDP data.
<table>
<thead>
<tr>
<th>GET Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CLIENT.TCP.PAYLOAD(&lt;integer&gt;)</code></td>
<td>Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the <code>&lt;integer&gt;</code> argument. You can apply any text-based operation to this prefix.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.SRCPORT</code></td>
<td>Returns the ID of the current packet’s source port as a number.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.DSTPORT</code></td>
<td>Returns the ID of the current packet’s destination port as a number.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.OPTIONS</code></td>
<td>Returns the TCP options set by the client. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(&lt;type&gt;), and TYPE_NAME(&lt;m&gt;) operators can be used with this prefix. For the TCP options set by the server, see the SERVER.TCP.OPTIONS prefix.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.OPTIONS.COUNT</code></td>
<td>Returns the number of TCP options that the client has set.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;)</code></td>
<td>Returns the value of the TCP option whose type (or option kind) is specified as the argument. The value is returned as a string of bytes in big endian format (or network byte order). Parameters: type - Type value.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.OPTIONS.TYPE_NAME(&lt;m&gt;)</code></td>
<td>Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). Parameters: m - TCP option enumeration constant.</td>
</tr>
<tr>
<td>GET Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>CLIENT.TCP.REPEATER_OPTION.EXISTS</code></td>
<td>Returns a Boolean TRUE if Repeater TCP options exist.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.REPEATER_OPTION.IP</code></td>
<td>Returns the branch repeater's IPv4 address from the Repeater TCP options.</td>
</tr>
<tr>
<td><code>CLIENT.TCP.REPEATER_OPTION.MAC</code></td>
<td>Returns the branch repeater's MAC address from the Repeater TCP options.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.DOMAIN</code></td>
<td>Returns the DNS domain name.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.DOMAIN.EQ(&quot;&lt;hostname&gt;&quot;)</code></td>
<td>Returns a Boolean TRUE if the domain name matches the <code>&lt;hostname&gt;</code> argument. The comparison is case insensitive. Following is an example: client.udpdns.domain.eq(&quot;www.mycompany.com&quot;)</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_AAAAREC</code></td>
<td>Returns a Boolean TRUE if the record type is AAAA. These types of records indicate an IPv6 address in forward lookups.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_ANYREC</code></td>
<td>Returns a Boolean TRUE if it is of any record type.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_AREC</code></td>
<td>Returns a Boolean TRUE if the record is type A. Type A records provide the host address.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_CNAME</code></td>
<td>Returns a Boolean TRUE if the record is of type CNAME. In systems that use multiple names to identify a resource, there is one canonical name and a number of aliases. The CNAME provides the canonical name.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_MXREC</code></td>
<td>Returns a Boolean TRUE if the record is of type MX (mail exchanger). This DNS record describes a priority and a host name. The MX records for the same domain name specify the email servers in the domain and the priority for each server.</td>
</tr>
<tr>
<td><code>CLIENT.UDP.DNS.IS_NSREC</code></td>
<td>Returns a Boolean TRUE if the record is of type NS. This is a name server record that includes a host name with an associated A record. This enables locating the domain name that is associated with the NS record.</td>
</tr>
<tr>
<td>GET Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_PTRREC</td>
<td>Returns a Boolean TRUE if the record is of type PTR. This is a domain name pointer and is often used to associate a domain name with an IPv4 address.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_SOAREC</td>
<td>Returns a Boolean TRUE if the record is of type SOA. This is a start of authority record.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_SRVREC</td>
<td>Returns a Boolean TRUE if the record is of type SRV. This is a more general version of the MX record.</td>
</tr>
<tr>
<td>CLIENT.UDP.DSTPORT</td>
<td>Returns the numeric ID of the current packet’s UDP destination port.</td>
</tr>
<tr>
<td>CLIENT.UDP.SRCPORT</td>
<td>Returns the numeric ID of the current packet’s UDP source port.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS</td>
<td>Returns RADIUS data for the current packet.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS.ATTR_TYPE(&lt;type&gt;)</td>
<td>Returns the value for the attribute type specified as the argument.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS.USERNAME</td>
<td>Returns the RADIUS user name.</td>
</tr>
<tr>
<td>CLIENT.TCP.MSS</td>
<td>Returns the maximum segment size (MSS) for the current connection as a number.</td>
</tr>
<tr>
<td>CLIENT.VLAN.ID</td>
<td>Returns the numeric ID of the VLAN through which the current packet entered the Citrix ADC.</td>
</tr>
<tr>
<td>SERVER.TCP.DSTPORT</td>
<td>Returns the numeric ID of the current packet’s destination port.</td>
</tr>
<tr>
<td>SERVER.TCP.SRCPORT</td>
<td>Returns the numeric ID of the current packet’s source port.</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS</td>
<td>Returns the TCP options set by the server. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(&lt;type&gt;), and TYPE_NAME(&lt;m&gt;) operators can be used with this prefix. For the TCP options set by the client, see the CLIENT.TCP.OPTIONS prefix.</td>
</tr>
<tr>
<td>GET Operation</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.COUNT</td>
<td>Returns the number of TCP options that the server has set.</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.TYPE(&lt;type&gt;)</td>
<td>Returns the value of the TCP option whose type (or option kind) is specified as the argument. The value is returned as a string of bytes in big endian format (or network byte order). Parameters: type - Type value</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.TYPE_NAME(&lt;m&gt;)</td>
<td>Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). Parameters: m - TCP option enumeration constant</td>
</tr>
<tr>
<td>SERVER.VLAN</td>
<td>Operates on the VLAN through which the current packet entered the Citrix ADC.</td>
</tr>
<tr>
<td>SERVER.VLAN.ID</td>
<td>Returns the numeric ID of the VLAN through which the current packet entered the Citrix ADC.</td>
</tr>
</tbody>
</table>

Expressions for evaluating a DNS message and identifying its carrier protocol

February 12, 2020

You can evaluate DNS requests and responses by using expressions that begin with DNS.REQ and
DNS.RES, respectively. You can also identify the transport layer protocol that is being used to send the DNS messages.

The following functions return the contents of a DNS query.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS.REQ.QUESTION.DOMAIN</td>
<td>Return the domain name (the value of the QNAME field) in the question section of the DNS query. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.</td>
</tr>
<tr>
<td>DNS.REQ.QUESTION.TYPE</td>
<td>Return the query type (the value of the QTYPE field) in the DNS query. The field indicates the type of resource record (for example, A, NS, or CNAME) for which the name server is being queried. The returned value can be compared to one of the following values by using the EQ() and NE() functions: A, AAAA, NS, SRV, PTR, CNAME, SOA, MX, and ANY. Note: You can use only the EQ() and NE() functions with the TYPE function. Example: DNS.REQ.QUESTION.TYPE.EQ(MX)</td>
</tr>
</tbody>
</table>

The following functions return the contents of a DNS response.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS.RES.HEADER.RCODE</td>
<td>Return the response code (the value of the RCODE field) in the header section of the DNS response. You can use only the EQ() and NE() functions with the RCODE function. Following are the possible values: NOERROR, FORMERR, SERVFAIL, NXDOMAIN, NOTIMP, and REFUSED.</td>
</tr>
<tr>
<td>DNS.RES.QUESTION.DOMAIN</td>
<td>Return the domain name (the value of the QNAME field) in the question section of the DNS response. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.</td>
</tr>
</tbody>
</table>
Function Description

**DNS.RES.QUESTION.TYPE**  
Return the query type (the value of the QTYPE field) in the question section of the DNS response. The field indicates the type of resource record (for example, A, NS, or CNAME) that is contained in the response. The returned value can be compared to one of the following values by using the EQ() and NE() functions: A, AAAA, NS, SRV, PTR, CNAME, SOA, MX, and ANY. You can use only the EQ() and NE() functions with the TYPE function. Example: 
DNS.RES.QUESTION.TYPE.EQ(SOA)

The following functions return the transport layer protocol name.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DNS.REQ.TRANSPORT</strong></td>
<td>Return the name of the transport layer protocol that was used to send the DNS query. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. Example: DNS.REQ.TRANSPORT.EQ(TCP)</td>
</tr>
<tr>
<td><strong>DNS.RES.TRANSPORT</strong></td>
<td>Return the name of the transport layer protocol that was used for the DNS response. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. Example: DNS.RES.TRANSPORT.EQ(TCP)</td>
</tr>
</tbody>
</table>

XPath and HTML, XML, or JSON expressions

February 25, 2020

© 1999-2020 Citrix Systems, Inc. All rights reserved. 1753
The Advanced policy infrastructure supports expressions for evaluating and retrieving data from HTML, XML, and JavaScript Object Notation (JSON) files. This enables you to find specific nodes in an HTML, XML, or JSON document, determine if a node exists in the file, locate nodes in XML contexts (for example, nodes that have specific parents or a specific attribute with a given value), and return the contents of such nodes. Additionally, you can use XPath expressions in rewrite expressions.

The Advanced policy expression implementation for XPath comprises an Advanced policy expression prefix (such as “HTTP.REQ.BODY”) that designates HTML or XML text, and the XPATH operator that takes the XPath expression as its argument.

HTML files are a largely free-form collection of tags and text elements. You can use the XPATH_HTML operator, which takes an XPath expression as its argument, to process HTML files. JSON files are either a collection of name/value pairs or an ordered list of values. You can use the XPATH_JSON operator, which takes an XPath expression as its argument, to process JSON files.

- **<text>.XPATH(xpathex):**
  
  Operate on an XML file and return a Boolean value.

  For example, the following expression returns a Boolean TRUE if a node called “creator” exists under the node “Book” within the first 1000 bytes of the XML file.

  ```
  HTTP.REQ.BODY(1000).XPATH(xpathboolean)//Book/creator%)
  ```

  Parameters:

  xpathex - XPath Boolean expression

- **<text>.XPATH(xpathex):**
  
  Operate on an XML file and return a value of data type “double.”

  For example, the following expression converts the string “36" (a price value) to a value of data type “double" if the string is in the first 1000 bytes of the XML file:

  ```
  HTTP.REQ.BODY(1000).XPATH(xp%number//Book/price%)
  ```

  Parameters:

  xpathex - XPath numeric expression

Example:

```xml
1   <Book>
2     <creator>
3        <Person>
4           <name>Milton</name>
5        </Person>
6     </creator>
7     <title>Paradise Lost</title>
8   </Book>
```
• **.XPATH(xpathex):**

Operate on an XML file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.

For example, the following expression selects all the nodes that are enclosed by "/Book/creator" (a node-set) in the first 1000 bytes of the body:

```plaintext
HTTP.REQ.BODY(1000).XPATH(xp%/Book/creator%)
```

Parameters:

xpathex - XPath expression

• **.XPATH_HTML(xpathex)**

Operate on an HTML file and return a text value.

For example, the following expression operates on an HTML file and returns the text enclosed in `<title></title>` tags if the title HTML element is found in the first 1000 bytes:

```plaintext
HTTP.REQ.BODY(1000).XPATH_HTML(xp%/html/head/title%)
```

Parameters:

xpathex - XPath text expression

• **.XPATH_HTML_WITH_MARKUP(xpathex)**

Operate on an HTML file and return a string that contains the entire selected portion of the document, including markup such as including the enclosing element tags.

The following expression operates on the HTML file and selects all content within the `<title>` tag, including markup.

```plaintext
HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%/html/head/title%)
```

Parameters:

xpathex - XPath expression

• **.XPATH_JSON(xpathex)**

Operate on a JSON file and return a Boolean value.

For example, consider the following JSON file:

```json
{ "Book":{ "creator":{ "person":{ "name":"<name>" } }, "title":"<title>" } }
```

The following expression operates on the JSON file and returns a Boolean TRUE if the JSON file contains a node named "creator," whose parent node is "Book," in the first 1000 bytes:

```plaintext
HTTP.REQ.BODY(1000).XPATH_JSON(xp%/boolean(/Book/creator%)
```
Parameters:

xpathex - XPath Boolean expression

- `<text>.XPATH_JSON(xpathex)

Operate on a JSON file and return a value of data type “double.”

For example, consider the following JSON file:

```json
{ "Book": { "creator": { "person": { "name": '<name>' } }, "title": '<title>' }, "price": "36" }
```

The following expression operates on the JSON file and converts the string “36” to a value of data type “double” if the string is present in the first 1000 bytes of the JSON file.

`HTTP.REQ.BODY(1000).XPATH_JSON(xp%number(/Book/price)%)

Parameters:

xpathex - XPath numeric expression

- `<text>.XPATH_JSON(xpathex)

Operate on a JSON file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.

For example, consider the following JSON file:

```json
{ "Book": { "creator": { "person": { "name": '<name>' } }, "title": '<title>' } }
```

The following expression selects all the nodes that are enclosed by “/Book” (a node-set) in the first 1000 bytes of the body of the JSON file and returns the corresponding string value, which is “<name><title>”:

`HTTP.REQ.BODY(1000).XPATH_JSON(xp%/Book%)

Parameters:

xpathex - XPath expression

- `<text>.XPATH_JSON_WITH_MARKUP(xpathex)

Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.

For example, consider the following JSON file:

```json
{ "Book": { "creator": { "person": { "name": '<name>' } }, "title": '<title>' } }
```

The following expression operates on the JSON file and selects all the nodes that are enclosed by “/Book/creator” in the first 1000 bytes of the body, which is “creator:{ person:{ name:'<name>' } }.”

`HTTP.REQ.BODY(1000).XPATH_JSON_WITH_MARKUP(xp%/Book/creator%)`
The portion of the JSON body that is selected by the expression is marked for further processing.

Parameters:
xpathex - XPath expression

• `<text>.XPATH_WITH_MARKUP(xpathex)>:
Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.

For example, the following expression operates on an XML file and selects all the nodes enclosed by “/Book/creator” in the first 1000 bytes of the body.

`HTTP.REQ.BODY(1000).XPATH_WITH_MARKUP(xp%/Book/creator%)`

The portion of the JSON body that is selected by the expression is marked for further processing.

Parameters:
xpathex - XPath expression

---

**Encrypt and decrypt XML payloads**

March 9, 2020

You can use the XML_ENCRYPT() and XML_DECRYPT() functions in Advanced policy expressions to encrypt and decrypt, respectively, XML data. These functions conform to the W3C XML Encryption standard defined at “http://www.w3.org/TR/2001/PR-xmldsig-core-20010820/.” XML_ENCRYPT() and XML_DECRYPT() support a subset of the XML Encryption specification. In the subset, data encryption uses a bulk cipher method (RC4, DES3, AES128, AES192, or AES256), and an RSA public key is used to encrypt the bulk cipher key.

**Note:** If you want to encrypt and decrypt text in a payload, you must use the ENCRYPT and DECRYPT functions. For more information about these functions, see Encrypt and decrypt text.

The XML_ENCRYPT() and XML_DECRYPT() functions are not dependent on the encryption/decryption service that is used by the ENCRYPT and DECRYPT commands for text. The cipher method is specified explicitly as an argument to the XML_ENCRYPT() function. The XML_DECRYPT() function obtains the information about the specified cipher method from the `<xenc:EncryptedData>` element. Following are synopses of the XML encryption and decryption functions:
• **XML_ENCRYPT(〈certKeyName〉, 〈method〉 [, 〈flags〉])**. Returns an 〈xenc:EncryptedData〉 element that contains the encrypted input text and the encryption key, which is itself encrypted by using RSA.

• **XML_DECRYPT(〈certKeyName〉)**. Returns the decrypted text from the input 〈xenc:EncryptedData〉 element, which includes the cipher method and the RSA-encrypted key.

**Note:** The 〈xenc:EncryptedData〉 element is defined in the W3C XML Encryption specification.

Following are descriptions of the arguments:

• **certKeyName**: Selects an X.509 certificate with an RSA public key for XML_ENCRYPT() or an RSA private key for XML_DECRYPT(). The certificate key must have been previously created by an add ssl certKey command.

• **method**: Specifies which cipher method to use for encrypting the XML data. Possible values: RC4, DES3, AES128, AES192, AES256.

• **flags**: A bitmask specifying the following optional key information (〈ds:KeyInfo〉) to be included in the 〈xenc:EncryptedData〉 element that is generated by XML_ENCRYPT():
  - 1 - Include a KeyName element with the certKeyName. The element is 〈ds:KeyName〉.
  - 2 - Include a KeyValue element with the RSA public key from the certificate. The element is 〈ds:KeyValue〉.
  - 4 - Include an X509IssuerSerial element with the certificate serial number and issuer DN. The element is 〈ds:X509IssuerSerial〉.
  - 8 - Include an X509SubjectName element with the certificate subject DN. The element is 〈ds:X509SubjectName〉.
  - 16 - Include an X509Certificate element with the entire certificate. The element is 〈ds:X509Certificate〉.

**Use the XML_ENCRYPT() and XML_DECRYPT() functions in expressions**

The XML encryption feature uses SSL certificate-key pairs to provide X.509 certificates (with RSA public keys) for key encryption and RSA private keys for key decryption. Therefore, before you use the XML_ENCRYPT() function in an expression, you must create an SSL certificate-key pair. The following command creates an SSL certificate-key pair, my-certkey, with the X.509 certificate, my-cert.pem, and the private key file, my-key.pem.

```
add ssl certKey my-certkey -cert my-cert.pem -key my-key.pem -passcrypt kxPeMRYnitY=
```

The following CLI commands create rewrite actions and policies for encrypting and decrypting XML content.
In the above example, the rewrite action my-xml-encrypt-action encrypts the entire XML document (XPATH_WITH_MARKUP(xp%/x)) in the request by using the AES-256 bulk encryption method and the RSA public key from my-certkey to encrypt the bulk encryption key. The action replaces the document with an <xenc:EncryptedData> element containing the encrypted data and an encrypted key. The flags represented by 31 include all of the optional <ds:KeyInfo> elements.

The action my-xml-decrypt-action decrypts the first <xenc:EncryptedData> element in the response (XPATH_WITH_MARKUP(xp%/xenc:EncryptedData%)). This requires the prior addition of the xenc XML namespace by use of the following CLI command:

```
add ns xmlnamespace xenc http://www.w3.org/2001/04/xmlenc#
```

The my-xml-decrypt-action uses the RSA private key in my-certkey to decrypt the encrypted key and then uses the bulk encryption method specified in the element to decrypt the encrypted contents. Finally, the action replaces the encrypted data element with the decrypted content.

The rewrite policy my-xml-encrypt-policy applies my-xml-encrypt-action to requests for URLs containing xml-encrypt. The action encrypts the entire response from a service configured on the Citrix ADC appliance.

The rewrite policy my-xml-decrypt-policy applies my-xml-decrypt-action to requests that contain an <xenc:EncryptedData> element (XPATH(xp%/xenc:EncryptedData%) returns a non-empty string). The action decrypts the encrypted data in requests that are bound for a service configured on the Citrix ADC appliance.
Advanced policy expressions: parsing SSL

July 12, 2020

There are advanced policy expressions to parse SSL certificates and SSL client hello messages.

Parse SSL certificates

You can use advanced policy expressions to evaluate X.509 Secure Sockets Layer (SSL) client certificates. A client certificate is an electronic document that can be used to authenticate a user’s identity. A client certificate contains (at a minimum) version information, a serial number, a signature algorithm ID, an issuer name, a validity period, a subject (user) name, a public key, and signatures.

You can examine both SSL connections and data in client certificates. For example, you may want to send SSL requests that use low-strength ciphers to a particular load balancing virtual server farm. The following command is an example of a Content Switching policy that parses the cipher strength in a request and matches cipher strengths that are less than or equal to 40:

```
1 add cs policy p1 -rule "client.ssl.cipher_bits.le(40)"
```

As another example, you can configure a policy that determines whether a request contains a client certificate:

```
1 add cs policy p2 -rule "client.ssl.client_cert_exists"
```

Or, you can configure a policy that examines particular information in a client certificate. For example, the following policy verifies that the certificate has one or more days before expiration:

```
1 add cs policy p2 -rule "client.ssl.client_cert_exists &amp; client.ssl.client_cert.days_to_expire.ge(1)"
```

Note

For information on parsing dates and times in a certificate, see Format of Dates and Times in an Expression and Expressions for SSL Certificate Dates.

Prefixes for text-based SSL and certificate data

The following table describes expression prefixes that identify text-based items in SSL transactions and client certificates.

Table 1. Prefixes That Return Text or Boolean Values for SSL and Client Certificate Data
## Prefixes for numeric data in SSL certificates

The following table describes prefixes that evaluate numeric data other than dates in SSL certificates. These prefixes can be used with the operations that are described in [Basic Operations on Expression Prefixes](#) and [Compound Operations for Numbers](#).

### Table 2. Prefixes That Evaluate Numeric Data Other Than Dates in SSL Certificates

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.DAYS_TO_EXPIRE</td>
<td>Returns the number of days that the certificate is valid, or returns -1 for expired certificates.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.PK_SIZE</td>
<td>Returns the size of the public key used in the certificate.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.VERSION</td>
<td>Returns the version number of the certificate. If the connection is not SSL-based, returns zero (0).</td>
</tr>
<tr>
<td>CLIENT.SSL.CIPHER_BITS</td>
<td>Returns the number of bits in the cryptographic key. Returns 0 if the connection is not SSL-based.</td>
</tr>
</tbody>
</table>
Prefix Description

CLIENT.SSL.VERSION

Returns a number that represents the SSL protocol version, as follows: 0. The transaction is not SSL-based.; 0x002. The transaction is SSLv2.; 0x300. The transaction is SSLv3.; 0x301. The transaction is TLSv1.; 0x302. The transaction is TLS 1.1.; 0x303. The transaction is TLS 1.2; 0x304. The transaction is TLS 1.3.

Note

For expressions related to expiration dates in a certificate, see Expressions for SSL Certificate Dates.

Expressions for SSL certificates

You can parse SSL certificates by configuring expressions that use the following prefix:

CLIENT.SSL.CLIENT_CERT

This section discusses the expressions that you can configure for certificates, except expressions that examine certificate expiration. Time-based operations are described in Advanced Policy Expressions: Working with Dates, Times, and Numbers.

The following table describes operations that you can specify for the CLIENT.SSL.CLIENT_CERT prefix.

Table 3. Operations That Can Be Specified with the CLIENT.SSL.CLIENT_CERT Prefix

<table>
<thead>
<tr>
<th>SSL Certificate Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;certificate&gt;.EXISTS</td>
<td>Returns a Boolean TRUE if the client has an SSL certificate.</td>
</tr>
<tr>
<td>&lt;certificate&gt;.ISSUER</td>
<td>Returns the Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=””) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs. Following is an example of the returned DN: /C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=<a href="mailto:myuserid@mycompany.com">myuserid@mycompany.com</a></td>
</tr>
</tbody>
</table>
SSL Certificate Operation Description

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;certificate&gt;.ISSUER.IGNORE_EMPTY_ELEMENTS</td>
<td>Returns the Issuer and ignores the empty elements in a name-value list. For example, consider the following: Cert-Issuer: /c=in/st=kar/l=bangalore /o=mycompany/ou=sales /emailAddress=<a href="mailto:muserid@mycompany.com">muserid@mycompany.com</a>. The following Rewrite action returns a count of 6 based on the preceding Issuer definition: escape rewrite action insert_ssl_header Name: insert_sslOperation: insert_http_header Target: Cert-Issuer Value: CLIENT.SSL.CLIENT_CERT.ISSUER.COUNT. However, if you change the value to the following, the returned count is 9: CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT</td>
</tr>
</tbody>
</table>

Parse SSL client hello

You can parse the SSL client hello message by configuring expressions that use the following prefix:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.CIPHERS.HAS_HEX_CODE</td>
<td>Matches the hex code provided in the expression with the hex codes of cipher suites received in the client hello message.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.CLIENT_VERSION</td>
<td>Version received in the client hello message header.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.IS_RENEGOTIATE</td>
<td>Returns true if a client or server initiates session renegotiation.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.IS_REUSE</td>
<td>Returns true if the appliance reuses the SSL session based on the non-zero session-ID received in the client-hello message.</td>
</tr>
<tr>
<td>Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.IS_SCSV</td>
<td>Returns true if Signaling Cipher Suite Value (SCSV) capability is advertised in the client hello message. The hex code for fallback SCSV is 0x5600.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.IS_SESSION_TICKET</td>
<td>Returns true if session ticket extension with non-zero length is advertised in the client-hello message.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.LENGTH</td>
<td>Length received in the client hello message header.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.SNI</td>
<td>Returns the server name received in the Server Name extension of the client hello message.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_HELLO.ALPN.HAS_NEXTPROC</td>
<td>Returns true if the application protocol in the ALPN extension received in the client hello message matches the protocol provided in the expression.</td>
</tr>
</tbody>
</table>

These expressions can be used at CLIENTHELLO_REQ bind point. For more information, see SSL policy binding.

Advanced policy expressions: IP and MAC addresses, throughput, VLAN IDs

July 8, 2020

You can use Advanced policy expression prefixes that return IPv4 and IPv6 addresses, MAC addresses, IP subnets, useful client and server data such as the throughput rates at the interface ports (Rx, Tx, and RxTx), and the IDs of the VLANs through which packets are received. You can then use various operators to evaluate the data that is returned by these expression prefixes.
Expressions for IP addresses and IP subnets

You can use Advanced policy expressions to evaluate addresses and subnets that are in Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) format. Expression prefixes for IPv6 addresses and subnets include IPv6 in the prefix. Expression prefixes for IPv4 addresses and subnets include IP in the prefix. Following is an example of an expression that identifies whether a request has originated from a particular IPv4 subnet.

```
1 client.ip.src.in_subnet(147.1.0.0/16)
```

Following are two examples of Rewrite policies that examine the subnet from which the packet is received and perform a rewrite action on the Host header. With these two policies configured, the rewrite action that is performed depends on the subnet in the request. These two policies evaluate IP addresses that are in the IPv4 address format.

```
1 - add rewrite action URL1-rewrite-action replace "http.req.header("Host")" "www.mycompany1.com"
2 - add rewrite policy URL1-rewrite-policy "http.req.header("Host").contains("www.test1.com") && client.ip.src.in_subnet(147.1.0.0/16)" URL1-rewrite-action
3 - add rewrite action URL2-rewrite-action replace "http.req.header("Host")" "www.mycompany2.com"
4 - add rewrite policy URL2-rewrite-policy "http.req.header("Host").contains("www.test2.com") && client.ip.src.in_subnet(10.202.0.0/16)" URL2-rewrite-action
```

**Note**

The preceding examples are commands that you type at the Citrix ADC command-line interface (CLI) and, therefore, each quotation mark must be preceded by a backslash (\). For more information, see Configuring advanced policy expressions in a policy.”

Prefixes for IPv4 addresses and IP subnets

The following table describes prefixes that return IPv4 addresses and subnets, and segments of IPv4 addresses. You can use numeric operators and operators that are specific to IPv4 addresses with these prefixes. For more information about numeric operations, see “Basic Operations on Expression Prefixes” and “Compound Operations for Numbers.”

Table 1. Prefixes That Evaluate IP and MAC Addresses
### Prefix Descriptions

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IP.SRC</td>
<td>Returns the source IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>CLIENT.IP.DST</td>
<td>Returns the destination IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>SERVER.IP.SRC</td>
<td>Returns the source IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>SERVER.IP.DST</td>
<td>Returns the destination IP of the current packet as an IP address or as a number.</td>
</tr>
</tbody>
</table>

### Operations for IPv4 Addresses

The Prefix for IPV4 operations table describes the operators that can be used with prefixes that return an IPv4 address.

### About IPv6 expressions

The IPv6 address format allows more flexibility than the older IPv4 format. IPv6 addresses are in the hexadecimal format (RFC 2373). In the following examples, Example 1 is an IPv6 address, Example 2 is a URL that includes the IPv6 address, and Example 3 includes the IPv6 address and a port number.

#### Example 1:

```
1 9901:0ab1:22a2:88a3:3333:4a4b:5555:6666
```

#### Example 2:

```
1 http://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]/
```

#### Example 3:

```
1 https://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]:8080/
```

In Example 3, the brackets separate the IP address from the port number (8080).

Note that you can only use the ‘+’ operator to combine IPv6 expressions with other expressions. The output is a concatenation of the string values that are returned from the individual expressions. You cannot use any other arithmetic operator with an IPv6 expression. The following syntax is an example:

```
1 client.ipv6.src + server.ip.dst
```
For example, if the client source IPv6 address is `ABCD::1234::ABCD`, and the server destination IPv4 address is `10.100.10.100`, the preceding expression returns "`ABCD:1234::ABCD10.100.10.100`".

Note that when the Citrix ADC appliance receives an IPv6 packet, it assigns a temporary IPv4 address from an unused IPv4 address range and changes the source address of the packet to this temporary address. At response time, the outgoing packet's source address is replaced with the original IPv6 address.

**Note**

You can combine an IPv6 expression with any other expression except an expression that produces a Boolean result.

**Expression prefixes for IPv6 addresses**

The IPv6 addresses that are returned by the expression prefixes in the following table can be treated as text data. For example, the prefix `client.ipv6.dst` returns the destination IPv6 address as a string that can be evaluated as text.

The following table describes expression prefixes that return an IPv6 address.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IPV6</td>
<td>Operates on the IPv6 address in with the current packet.</td>
</tr>
<tr>
<td>CLIENT.IPV6.DST</td>
<td>Returns the IPv6 address in the destination field of the IP header.</td>
</tr>
<tr>
<td>SERVER.IPV6</td>
<td>Operates on the IPv6 address in with the current packet.</td>
</tr>
<tr>
<td>SERVER.IPV6.DST</td>
<td>Returns the IPv6 address in the destination field of the IP header.</td>
</tr>
<tr>
<td>SERVER.IPV6.SRC</td>
<td>Returns the IPv6 address in the source field of the IP header. Following are examples: <code>server.ipv6.src.in_subnet(2007::2008/64)</code> <code>server.ipv6.src.get1.le(2008)</code></td>
</tr>
</tbody>
</table>
## Operations for IPv6 prefixes

The following table describes the operators that can be used with prefixes that return an IPv6 address:

<table>
<thead>
<tr>
<th>IPv6 Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;ipv6&gt;.EQ(&lt;IPv6_address&gt;)</code></td>
<td>Returns a Boolean TRUE if the IP address value is same as the <code>&lt;IPv6_address&gt;</code> argument. Following is an example: <code>client.ipv6.dst.eq(ABCD:1234::ABCD)</code></td>
</tr>
<tr>
<td><code>&lt;ipv6&gt;.GET1 . . . GET8</code></td>
<td>Returns a segment of an IPv6 address as a number. The following example expressions retrieve segments from the ipv6 address 1000:1001:CD10:0000:0000:89AB:4567:CDEF: <code>client.ipv6.dst.get5 extracts 0000</code>, which is the fifth set of bits in the address. <code>client.ipv6.dst.get6 extracts 89AB. client.ipv6.dst.get7 extracts 4567</code>. You can perform numeric operations on these segments. Note that you cannot perform numeric operations when you retrieve an entire IPv6 address. This is because expressions that return an entire IPv6 address, such as CLIENT.IPV6.SRC, return the address in text format.</td>
</tr>
<tr>
<td><code>&lt;ipv6&gt;.IN_SUBNET(&lt;subnet&gt;)</code></td>
<td>Returns a Boolean TRUE if the IPv6 address value is in the subnet specified by the <code>&lt;subnet&gt;</code> argument. Following is an example: <code>client.ipv6.dst.eq(1000:1001:CD10:0000:0000:89AB:4567:CDEF/60)</code></td>
</tr>
<tr>
<td><code>&lt;ipv6&gt;.IS_IPV4</code></td>
<td>Returns a Boolean TRUE if this is an IPv4 client, and returns a Boolean FALSE if it is not.</td>
</tr>
<tr>
<td><code>&lt;ipv6&gt;.SUBNET(&lt;n&gt;)</code></td>
<td>Returns the IPv6 address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 128. For example: <code>CLIENT.IPV6.SRC.SUBNET(24)</code></td>
</tr>
</tbody>
</table>
Expressions for MAC addresses

A MAC address consists of colon-delimited hexadecimal values in the format ##:##:##:##:##:##, where each “#” represents either a number from 0 through 9 or a letter from A through F. Default syntax expression prefixes and operators are available for evaluating source and destination MAC addresses.

Prefixes for MAC addresses

The following table describes prefixes that return MAC addresses.

Table 5. Prefixes That Evaluate MAC Addresses

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client.ether.dstmac</td>
<td>Returns the MAC address in the destination field of the Ethernet header.</td>
</tr>
<tr>
<td>client.ether.srcmac</td>
<td>Returns the MAC address in the source field of the Ethernet header.</td>
</tr>
</tbody>
</table>

Operations for MAC addresses

The following table describes the operators that can be used with prefixes that return a MAC address.

Table 6. Operations on MAC Addresses

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;mac address&gt;.EQ(&lt;address&gt;)</td>
<td>Returns a Boolean TRUE if the MAC address value is same as the &lt;address&gt; argument.</td>
</tr>
<tr>
<td>&lt;mac address&gt;.GET1 . . .GET4</td>
<td>Returns a numeric value extracted from the segment of the MAC address that is specified in the GET operation. For example, if the MAC address is 12:34:56:78:9a:bc, the following returns 34: client.ether.dstmac.get2</td>
</tr>
</tbody>
</table>

Expressions for numeric client and server data

The following table describes prefixes for working with numeric client and server data, including throughput, port numbers, and VLAN IDs.
### Table 7. Prefixes that evaluate numeric client and server data

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client.interface.rxthroughput</td>
<td>Returns an integer representing the raw received traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>client.interface.txthroughput</td>
<td>Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>client.interface.rtxthroughput</td>
<td>Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.rxthroughput</td>
<td>Returns an integer representing the raw received traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.txthroughput</td>
<td>Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.rtxthroughput</td>
<td>Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.vlan.id</td>
<td>Returns a numeric ID of the VLAN through which the current packet entered the Citrix ADC.</td>
</tr>
<tr>
<td>client.vlan.id</td>
<td>Returns a numeric ID for the VLAN through which the current packet entered the Citrix ADC.</td>
</tr>
</tbody>
</table>
Stream Analytics expressions begin with the ANALYTICS.STREAM(<identifier_name>) prefix. The following list describes the functions that can be used with this prefix.

- **COLLECT_STATS**
  Collect statistical data from the requests that are evaluated against the policy and create a record for each request.

- **REQUESTS**
  Return the number of requests that exist for the specified record grouping. The value returned is of type unsigned long.

- **BANDWIDTH**
  Return the bandwidth statistic for the specified record grouping. The value returned is of type unsigned long.

- **RESPTIME**
  Return the response time statistic for the specified record grouping. The value returned is of type unsigned long.

- **CONNECTIONS**
  Return the number of concurrent connections that exist for the specified record grouping. The value returned is of type unsigned long.

- **IS_TOP(n)**
  Return a Boolean TRUE if the statistical value for the specified record grouping is one among the top n groups. Otherwise, return a Boolean FALSE.

- **CHECK_LIMIT**
  Return a Boolean TRUE if the statistic for the specified record grouping has hit the preconfigured limit. Otherwise, return a Boolean FALSE.

Advanced policy expressions: DataStream

February 12, 2020

The policy infrastructure on the Citrix ADC appliance includes expressions that you can use to evaluate and process database server traffic when the appliance is deployed between a farm of application servers and their associated database servers.
This topic includes the following sections:

- Expressions for the MySQL Protocol
- Expressions for Evaluating Microsoft SQL Server Connections

### Expressions for the MySQL protocol

The following expressions evaluate traffic associated with MySQL database servers. You can use the request-based expressions (expressions that begin with MYSQL.CLIENT and MYSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

- **MYSQL.CLIENT.** Operates on the client properties of a MySQL connection.

- **MYSQL.CLIENT.CAPABILITIES.** Returns the set of flags that the client has set in the capabilities field of the handshake initialization packet during authentication. Examples of the flags that are set are CLIENT_FOUND_ROWS, CLIENT_COMPRESS, and CLIENT_SSL.

- **MYSQL.CLIENT.CHAR_SET.** Returns the enumeration constant assigned to the character set that the client uses. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the character set enumeration constants:
  - LATIN2_CZECH_CS
  - DEC8_SWEDISH_CI
  - CP850_GENERAL_CI
  - GREEK_GENERAL_CI
  - LATIN1_GERMAN1_CI
  - HP8_ENGLISH_CI
  - KOI8R_GENERAL_CI
  - LATIN1_SWEDISH_CI
  - LATIN2_GENERAL_CI
  - SWE7_SWEDISH_CI
  - ASCII_GENERAL_CI
  - CP1251_BULGARIAN_CI
  - LATIN1 DANISH_CI
  - HEBREW_GENERAL_CI
  - LATIN7_ESTONIAN_CS
  - LATIN2_HUNGARIAN_CI
  - KOI8U_GENERAL_CI
  - CP1251_UKRAINIAN_CI
  - CP1250_GENERAL_CI
- LATIN2_CROATIAN_CI
- CP1257_LITHUANIAN_CI
- LATIN5_TURKISH_CI
- LATIN1_GERMAN2_CI
- ARMSCII8GENERAL_CI
- UTF8GENERAL_CI
- CP1250_CZECH_CS
- CP866GENERAL_CI
- KEYBCS2GENERAL_CI
- MACCEGENERAL_CI
- MACROMANGENERAL_CI
- CP852GENERAL_CI
- LATIN7GENERAL_CI
- LATIN7GENERAL_CS
- MACCE_BIN
- CP1250_CROATIAN_CI
- LATIN1_BIN
- LATIN1GENERAL_CI
- LATIN1GENERAL_CS
- CP1251_BIN
- CP1251GENERAL_CI
- CP1251GENERAL_CS
- MACROMAN_BIN
- CP1256GENERAL_CI
- CP1257_BIN
- CP1257GENERAL_CI
- ARMSCII8_BIN
- ASCII_BIN
- CP1250_BIN
- CP1256_BIN
- CP866_BIN
- DEC8_BIN
- GREEK_BIN
- HEBREW_BIN
- HP8_BIN
- KEYBCS2_BIN
- KOI8R_BIN
- KOI8U_BIN
- LATIN2_BIN
- LATIN5_BIN
- LATIN7_BIN
- CP850_BIN
- CP852_BIN
- SWE7_BIN
- UTF8_BIN
- GEOSTD8_GENERAL_CI
- GEOSTD8_BIN
- LATIN1_SPANISH_CI
- UTF8_UNICODE_CI
- UTF8_ICELANDIC_CI
- UTF8_LATVIAN_CI
- UTF8_ROMANIAN_CI
- UTF8_SLOVENIAN_CI
- UTF8_POLISH_CI
- UTF8_ESTONIAN_CI
- UTF8_SPANISH_CI
- UTF8_SWEDISH_CI
- UTF8_TURKISH_CI
- UTF8_CZECH_CI
- UTF8_DANISH_CI
- UTF8_LITHUANIAN_CI
- UTF8_SLOVAK_CI
- UTF8_SPANISH2_CI
- UTF8_ROMAN_CI
- UTF8_PERSIAN_CI
- UTF8_ESPERANTO_CI
- UTF8_HUNGARIAN_CI
- INVAL_CHARSET

- MYSQL.CLIENT.DATABASE. Returns the name of the database specified in the authentication packet that the client sends to the database server. This is the databasename attribute.

- MYSQL.CLIENT.USER. Returns the user name (in the authentication packet) with which the client is attempting to connect to the database. This is the user attribute.

- MYSQL.REQ. Operates on a MySQL request.

- MYSQL.REQ.COMMAND. Identifies the enumeration constant assigned to the type of command in the request. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the enumeration constant values:
- SLEEP
- QUIT
- INIT_DB
- QUERY
- FIELD_LIST
- CREATE_DB
- DROP_DB
- REFRESH
- SHUTDOWN
- STATISTICS
- PROCESS_INFO

- **MYSQL.REQ.QUERY.** Identifies the query in the MySQL request.

- **MYSQL.REQ.QUERY.COMMAND.** Returns the first keyword in the MySQL query.

- **MYSQL.REQ.QUERY.SIZE.** Returns the size of the request query in integer format. The SIZE method is similar to the CONTENT_LENGTH method that returns the length of an HTTP request or response.

- **MYSQL.REQ.QUERY.TEXT.** Returns a string covering the entire query.

- **MYSQL.REQ.QUERY.TEXT(<n>).** Returns the first n bytes of the MySQL query as a string. This is similar to HTTP.BODY(<n>).

**Parameters:**
n - Number of bytes to be returned

- **MYSQL.RES.** Operates on a MySQL response.

- **MYSQL.RES.ATLEAST_ROWS_COUNT(<i>).** Checks whether the response has at least i number of rows and returns a Boolean TRUE or FALSE to indicate the result.

  **Parameters:**
  
i - Number of rows

- **MYSQL.RES.ERROR.** Identifies the MySQL error object. The error object includes the error number and the error message.

- **MYSQL.RES.ERROR.MESSAGE.** Returns the error message that is retrieved from the server’s error response.

- **MYSQL.RES.ERROR.NUM.** Returns the error number that is retrieved from the server’s error response.

- **MYSQL.RES.ERROR.SQLSTATE.** Returns the value of the SQLSTATE field in the server’s error response. The MySQL server translates error number values to SQLSTATE values.

- **MYSQL.RES.FIELD(<i>).** Identifies the packet that corresponds to the i<sup>th</sup> individual field in the server’s response. Each field packet describes the properties of the associated column. The packet count (i) begins at 0.

  **Parameters:**
  
i - Packet number

- **MYSQL.RES.FIELD(<i>).CATALOG.** Returns the catalog property of the field packet.

- **MYSQL.RES.FIELD(<i>).CHAR_SET.** Returns the character set of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

- **MYSQL.RES.FIELD(<i>).DATATYPE.** Returns an enumeration constant that represents the data type of the column. This is the type (also called enum_field_type) attribute of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. The possible values for the various data types are:

  - DECIMAL
  - TINY
  - SHORT
  - LONG
  - FLOAT
  - DOUBLE
  - NULL
- TIMESTAMP
- LONGLONG
- INT24
- DATE
- TIME
- DATETIME
- YEAR
- NEWDATE
- VARCHAR (new in MySQL 5.0)
- BIT (new in MySQL 5.0)
- NEWDECIMAL (new in MySQL 5.0)
- ENUM
- SET
- TINY_BLOB
- MEDIUM_BLOB
- LONG_BLOB
- BLOB
- VAR_STRING
- STRING
- GEOMETRY

- MYSQL.RES.FIELD(<i>).DB. Returns the database identifier (db) attribute of the field packet.
- MYSQL.RES.FIELD(<i>).DECIMALS. Returns the number of positions after the decimal point if the type is DECIMAL or NUMERIC. This is the decimals attribute of the field packet.
- MYSQL.RES.FIELD(<i>).FLAGS. Returns the flags property of the field packet. Following are the possible hexadecimal flag values:
  - 0001: NOT_NULL_FLAG
  - 0002: PRI_KEY_FLAG
  - 0004: UNIQUE_KEY_FLAG
  - 0008: MULTIPLE_KEY_FLAG
  - 0010: BLOB_FLAG
  - 0020: UNSIGNED_FLAG
  - 0040: ZEROFILL_FLAG
  - 0080: BINARY_FLAG
  - 0100: ENUM_FLAG
  - 0200: AUTO_INCREMENT_FLAG
  - 0400: TIMESTAMP_FLAG
  - 0800: SET_FLAG
- MYSQL.RES.FIELD(<i>).LENGTH. Returns the length of the column. This is the value of the
length attribute of the field packet. The value that is returned might be larger than the actual value. For example, an instance of a VARCHAR(2) column might return a value of 2 even when it contains only one character.

- **MYSQL.RES.FIELD(<i>).NAME.** Returns the column identifier (the name after the AS clause, if any). This is the name attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).ORIGINAL_NAME.** Returns the original column identifier (before the AS clause, if any). This is the org_name attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).ORIGINAL_TABLE.** Returns the original table identifier of the column (before the AS clause, if any). This is the org_table attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).TABLE.** Returns the table identifier of the column (after the AS clause, if any). This is the table attribute of the field packet.

- **MYSQL.RES.FIELDS_COUNT.** Returns the number of field packets in the response (the field_count attribute of the OK packet).

- **MYSQL.RES.OK.** Identifies the OK packet sent by the database server.

- **MYSQL.RES.OK.AFFECTED_ROWS.** Returns the number of rows affected by an INSERT, UPDATE, or DELETE query. This is the value of the affected_rows attribute of the OK packet.

- **MYSQL.RES.OK.INSERT_ID.** Identifies the unique_id attribute of the OK packet. If an auto-increment identity is not generated by the current MySQL statement or query, the value of unique_id, and hence the value returned by the expression, is 0.

- **MYSQL.RES.OK.MESSAGE.** Returns the message property of the OK packet.

- **MYSQL.RES.OK.STATUS.** Identifies the bit string in the server_status attribute of the OK packet. Clients can use the server status to check whether the current command is a part of a running transaction. The bits in the server_status bit string correspond to the following fields (in the given order):
  - IN TRANSACTION
  - AUTO_COMMIT
  - MORE RESULTS
  - MULTI QUERY
  - BAD INDEX USED
  - NO INDEX USED
  - CURSOR EXISTS
  - LAST ROW SEEN
  - DATABASE DROPPED
  - NO BACKSLASH ESCAPES

- **MYSQL.RES.OK.WARNING_COUNT.** Returns the warning_count attribute of the OK packet.
- **MYSQL.RES.ROW(<i>).** Identifies the packet that corresponds to the i<sup>th</sup> individual row in the database server's response.

  **Parameters:**
  
i - Row number

- **MYSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>).** Checks whether the j<sup>th</sup> column of the i<sup>th</sup> row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the (i+1)<sup>th</sup> row and the (j+1)<sup>th</sup> column, respectively.

  **Parameters:**
  
i - Row number
  j - Column number

- **MYSQL.RES.ROW(<i>).IS_NULL_ELEM(j).** Checks whether the j<sup>th</sup> column of the i<sup>th</sup> row of the table is NULL. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the (i+1)<sup>th</sup> row and the (j+1)<sup>th</sup> column, respectively.

  **Parameters:**
  
i - Row number
  j - Column number

- **MYSQL.RES.ROW(<i>).NUM_ELEM(<j>).** Returns an integer value from the j<sup>th</sup> column of the i<sup>th</sup> row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the (i+1)<sup>th</sup> row and the (j+1)<sup>th</sup> column, respectively.

  **Parameters:**
  
i - Row number
  j - Column number

- **MYSQL.RES.ROW(<i>).TEXT_ELEM(j).** Returns a string from the j<sup>th</sup> column of the i<sup>th</sup> row of the table. Following C conventions, both indexes i and j start from 0. Therefore, row i and column j are actually the (i+1)<sup>th</sup> row and the (j+1)<sup>th</sup> column, respectively.

  **Parameters:**
  
i - Row number
  j - Column number
- **MYSQL.RES.TYPE.** Returns an enumeration constant for the response type. Its values can be ERROR, OK, and RESULT_SET. The \( \text{EQ}(<m>) \) and \( \text{NE}(<m>) \) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

**Expressions for evaluating Microsoft SQL server connections**

The following expressions evaluate traffic associated with Microsoft SQL Server database servers. You can use the request-based expressions (expressions that begin with MSSQL.CLIENT and MSSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MSSQL.RES) to evaluate server responses to user-configured health monitors.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSSQL.CLIENT.CAPABILITIES</td>
<td>Returns the OptionFlags1, OptionFlags2, OptionFlags3, and TypeFlags fields of the LOGIN7 authentication packet, in that order, as a 4-byte integer. Each field is 1 byte long and specifies a set of client capabilities.</td>
</tr>
<tr>
<td>MSSQL.CLIENT.DATABASE</td>
<td>Returns the name of the client database. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.CLIENT.USER</td>
<td>Returns the user name with which the client authenticated. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.REQ.COMMAND</td>
<td>Returns an enumeration constant that identifies the type of command in the request sent to a Microsoft SQL Server database server. The value returned is of type text. Examples of the values of the enumeration constant are QUERY, RESPONSE, RPC, and ATTENTION. The ( \text{EQ}(&lt;m&gt;) ) and ( \text{NE}(&lt;m&gt;) ) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.COMMAND</td>
<td>Returns the first keyword in the SQL query. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.SIZE</td>
<td>Returns the size of the SQL query in the request. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.TEXT</td>
<td>Returns the entire SQL query as a string. The value returned is of type text.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.TEXT(&lt;n&gt;)</td>
<td>Returns the first n bytes of the SQL query. The value returned is of type text. Parameters: n - Number of bytes</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.NAME</td>
<td>Returns the name of the procedure that is being called in a remote procedure call (RPC) request. The name is returned as a string.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.IS_PROCID</td>
<td>Returns a Boolean value that indicates whether the remote procedure call (RPC) request contains a procedure ID or an RPC name. A return value of TRUE indicates that the request contains a procedure ID and a return value of FALSE indicates that the request contains an RPC name.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.PROCID</td>
<td>Returns the procedure ID of the remote procedure call (RPC) request as an integer.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.BODY Note: Not available for releases before 10.1.</td>
<td>Returns the body of the SQL request as a string in the form of parameters represented as “a=b” clauses separated by commas, where “a” is the RPC parameter name and “b” is its value.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.BODY(n) Note: Not available for releases before 10.1.</td>
<td>Returns part of the body of the SQL request as a string in the form of parameters represented as “a=b” clauses separated by commas, where “a” is the RPC parameter name and “b” is its value. Parameters are returned from only the first “n” bytes of the request, skipping the SQL header. Only complete name-value pairs are returned.</td>
</tr>
<tr>
<td>MSSQL.RES.ATLEAST_ROWS_COUNT(i)</td>
<td>Checks whether the response has at least i number of rows. The value returned is a Boolean TRUE or FALSE value. Parameters: i - Number of rows</td>
</tr>
<tr>
<td>MSSQL.RES.DONE.ROWCOUNT</td>
<td>Returns a count of the number of rows affected by an INSERT, UPDATE, or DELETE query. The value returned is of type unsigned long.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MSSQL.RES.DONE.STATUS</td>
<td>Returns the status field from the DONE token sent by a Microsoft SQL Server database server. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.MESSAGE</td>
<td>Returns the error message from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the MsgText field in the ERROR token. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.NUM</td>
<td>Returns the error number from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the Number field in the ERROR token. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.STATE</td>
<td>Returns the error state from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the State field in the ERROR token. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).DATATYPE</td>
<td>Returns the data type of the ith field in the server response. The EQ(&lt;m&gt;) and NE(&lt;m&gt;) functions, which return Boolean values to indicate the result of a comparison, are used with this prefix. For example, the following expression returns a Boolean TRUE if the DATATYPE function returns a value of datetime for the third field in the response: MSSQL.RES.FIELD(&lt;2&gt;).DATATYPE.EQ(datetime) Parameters: i - Row number</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).LENGTH</td>
<td>Returns the maximum possible length of the ith field in the server response. The value returned is a number. Parameters: i - Row number</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).NAME</td>
<td>Returns the name of the ith field in the server response. The value returned is of type text. Parameters: i - Row number</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).DOUBLE_ELEM(&lt;j&gt;)</td>
<td>Returns a value of type double from the jth column of the ith row of the table. If the value is not a double value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).NUM_ELEM(j)</td>
<td>Returns an integer value from the jth column of ith row of the table. If the value is not an integer value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).IS_NULL_ELEM(j)</td>
<td>Checks whether the jth column of the ith row of the table is NULL and returns a Boolean TRUE or FALSE to indicate the result. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).TEXT_ELEM(j)</td>
<td>Returns a text string from the jth column of ith row of the table. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
</tbody>
</table>
Expression Description

MSSQL.RES.TYPE  Returns an enumeration constant that identifies the response type. Following are the possible return values: ERROR, OK, and RESULT_SET. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.

Typecasting data

July 8, 2020
You can extract data of one type (for example, text or an integer) from requests and responses and transform it to data of another type. For example, you can extract a string and transform the string to time format. You can also extract a string from an HTTP request body and treat it like an HTTP header or extract a value from one type of request header and insert it in a response header of a different type.

After typecasting the data, you can apply any operation that is appropriate for the new data type. For example, if you typecast text to an HTTP header, you can apply any operation that is applicable to HTTP headers to the returned value.

For more information about typecasting data, see the Typecasting Operations pdf.

Regular Expressions

February 12, 2020
When you want to perform string matching operations that are more complex than the operations that you perform with the CONTAINS("<string>") or EQ("<string>") operators, you use regular expressions. The policy infrastructure on the Citrix® Citrix ADC® appliance includes operators to which you
can pass regular expressions as arguments for text matching. The names of the operators that work with regular expressions include the string REGEX. The regular expressions that you pass as arguments must conform to the regular expression syntax that is described in "<http://www.pcre.org/pcre.txt>". You can learn more about regular expressions at "<http://www.regular-expressions.info/quickstart.html>" and at "<http://www.silverstones.com/thebat/Regex.html>".

The target text for an operator that works with regular expressions can be either text or the value of an HTTP header. Following is the format of a default syntax expression that uses a regular expression operator to operate on text:

```xml
<text>.<regex_operator>(re<delimiter><regex_pattern><delimiter>)
```

The string `<text>` represents the default syntax expression prefix that identifies a text string in a packet (for example, HTTP.REQ.URL). The string `<regex_operator>` represents the regular expression operator. The regular expression always begins with the string re. A pair of matching delimiters, represented by `<delimiter>`, enclose the string `<regex_pattern>`, which represents the regular expression.

The following example expression checks whether the URL in an HTTP packet contains the string *.*.jpeg (where * is a wildcard) and returns a Boolean TRUE or FALSE to indicate the result. The regular expression is enclosed within a pair of slash marks (/), which act as delimiters.

```xml
http.req.url.regex_match(re/.*jpeg/)
```

Regular expression operators can be combined to define or refine the scope of a search. For example, `<text>.AFTER_REGEX(re/regex_pattern1).BEFORE_REGEX(re/regex_pattern2)` specifies that the target for string matching is the text between the patterns `regex_pattern1` and `regex_pattern2`. You can use a text operator on the scope that is defined by the regular expression operators. For example, you can use the CONTAINS("<string>") operator to check whether the defined scope contains the string abc:

```xml
<text>.AFTER_REGEX(re/regex_pattern1).BEFORE_REGEX(re/regex_pattern2/).CONTAINS("abc")
```

**Note**

The process of evaluating a regular expression inherently takes more time than that for an operator such as CONTAINS("<string>") or EQ("<string>"), which work with simple string arguments. You should use regular expressions only if your requirement is beyond the scope of other operators.

*Copied!*

*Failed!*
Basic characteristics of regular expressions

May 31, 2019

Following are notable characteristics of regular expressions as defined on the Citrix ADC appliance:

• A regular expression always begins with the string “re” followed by a pair of delimiting characters (called delimiters) that enclose the regular expression that you want to use.

For example, re#<regex_pattern># uses the number sign (#) as a delimiter.

• A regular expression cannot exceed 1499 characters.

• Digit matching can be done by using the string \d (a backslash followed by d).

• White space can be represented by using \s (a backslash followed by s).

• A regular expression can contain white spaces.

Following are the differences between the Citrix ADC syntax and the PCRE syntax:

• The Citrix ADC does not allow back references in regular expressions.

• You should not use recursive regular expressions.

• The dot meta-character also matches the newline character.

• Unicode is not supported.

• The operation SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option in the regular expression.

Operations for regular expressions

February 12, 2020

The following table describes the operators that work with regular expressions. The operation performed by a regular expression operator in a given default syntax expression depends on whether the expression prefix identifies text or HTTP headers. Operations that evaluate headers override any text-based operations for all instances of the specified header type. When you use an operator, replace <text> with the default syntax expression prefix that you want to configure for identifying text.
<table>
<thead>
<tr>
<th>Regular Expression Operation</th>
<th>Description</th>
</tr>
</thead>
</table>
| `<text>.BEFORE_REGEX(<regular expression>)` | Selects the text that precedes the string that matches the `<regular expression>` argument. If the regular expression does not match any data in the target, the expression returns a text object of length 0. The following expression selects the string “text” from “text/plain”:
```html
http.res.header("content-type").before_regex(re/#/#)
``` |
| `<text>.AFTER_REGEX(<regular expression>)` | Selects the text that follows the string that matches the `<regular expression>` argument. If the regular expression does not match any text in the target, the expression returns a text object of length 0. The following expression extracts “Example” from “myExample”:
```html
http.req.header("etag").after_regex(re/my/)
``` |
| `<text>.REGEX_SELECT(<regular expression>)` | Selects a string that matches the `<regular expression>` argument. If the regular expression does not match the target, a text object of length 0 is returned. The following example extracts the string “NS-CACHE-9.0: 90” from a Via header:
```html
http.req.header("via").regex_select(re!NS-CACHE-\d\d\.\d\d:s\*d\{1,3}\))
``` |
<table>
<thead>
<tr>
<th>Regular Expression Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.REGEX_MATCH(&lt;regular expression&gt;)</code></td>
<td>Returns TRUE if the target matches a <code>&lt;regular expression&gt;</code> argument of up to 1499 characters. The regular expression must be of the following format: <code>re&lt;delimiter&gt;regular expression&lt; delimiter&gt;</code> Both delimiters must be the same. Additionally, the regular expression must conform to the Perl-compatible (PCRE) regular expression library syntax. For more information, go to <a href="http://www.pcre.org/pcre.txt">http://www.pcre.org/pcre.txt</a>. In particular, see the pcrepattern man page. However, note the following: Back-references are not allowed. Recursive regular expressions are not recommended. The dot metacharacter also matches the newline character. The Unicode character set is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression. The following are examples: http.req.hostname.regex_match(re[([:alpha:]+)(abc){2,3}]) and http.req.url.set_text_mode(urlencoded).regex_match(re#(a\b+c)#) The following example matches ab and aB: http.req.url.regex_match(re/a(?i)b/) The following example matches ab, aB, Ab and AB: http.req.url.set_text_mode(ignorecase).regex_match(re/ab/) The following example performs a case-insensitive, multiline match in which the dot meta-character also matches a newline character: http.req.body.regex_match(re/(?ixm) (ˆab (. *) cd$) /)</td>
</tr>
</tbody>

Configuring classic policies and expressions

July 8, 2020

Some Citrix ADC features use classic policies and classic expressions. As with default syntax policies, classic policies can be either global or specific to a virtual server. However, to a certain extent, the configuration method and bind points for classic policies are different from those of default syntax policies. As with default syntax expressions, you can configure named expressions and use a named expression in multiple classic policies.

The following table summarizes Citrix ADC features that can be configured by using classic policies.

Click here to view the table.

Configure a classic policy

May 31, 2019

You can configure classic policies and classic expressions by using either the configuration utility or the command-line interface. A policy rule cannot exceed 1,499 characters. When configuring the policy rule, you can use named classic expressions. For more information about named expressions, see Create named classic expressions. After configuring the policy, you bind it either globally or to a virtual server.

Note that there are small variations in the policy configuration methods for various Citrix ADC features.

Note: You can embed a classic expression in a default syntax expression by using the syntax SYS.EVAL_CLASSIC_EXPR(classic_expression), specifying the classic_expression as the argument.

Create a classic policy by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1  - add cmp policy <name> -rule <expression> -action <action>
2
3  - show cmp policy [<policyName>]
```
Example

The following commands first create a compression action and then create a compression policy that applies the action:

```
1 > add cmp action cmp-act-compress compress
2 Done
3 > show cmp action cmp-act-compress
4 1) Name: cmp-act-compress  Compression Type: compress
5 Done
6 > add cmp pol cmp-pol-compress -rule ExpCheckIp -resAction cmp-act-compress
7 Done
8 > show cmp pol cmp-pol-compress
9 1) Name: cmp-pol-compress  Rule: ExpCheckIp
10 Response action: cmp-act-compress  Hits: 0
11 Done
12 >
```

Create a policy with classic expressions by using the GUI

1. In the navigation pane, expand the feature for which you want to configure a policy and, depending on the feature, do the following:
   - For Content Switching, Cache Redirection, and the application firewall, click Policies.
   - For SSL, click Policies, and then in the details pane, click the Policies tab.
   - For System Authentication, click Authentication, and then in the details pane, click the Policies tab.
   - For Filter, SureConnect, and Priority Queuing, expand Protection Features, select the desired function, and then in the details pane, click the Policies tab.
   - For the Citrix Gateway, expand Citrix Gateway, expand Policies, select the desired function, and then in the details pane, click the Policies tab.

2. For most features, click the Add button.

3. In the Create <feature name> Policy dialog box, in the Name* text box, enter a name for the policy.

   Note: You must begin a policy name with a letter or underscore. A policy name can consist of 1 to 31 characters, including letters, numbers, hyphen (-), period (.), pound sign (#), space ( ), and underscore (_).

4. For most features, you associate an action or a profile. For example, you may be required to select an action, or, in the case of an Citrix Gateway or application firewall policy, you select a
profile to associate with the policy. A profile is a set of configuration options that operate as a set of actions that are applied when the data being analyzed matches the policy rule.

5. Create an expression that describes the type of data that you want this policy to match.

Depending on the type of policy you want to create, you can choose a predefined expression, or you can create a new expression.

Named expressions are predefined expressions that you can reference by name in a policy rule.

6. Click Create to create your new policy.

7. Click Close to return to the Policies screen for the type of policy you were creating.

Configure a classic expression

July 27, 2020

Classic expressions consist of the following expression elements, listed in hierarchical order:

- **Flow Type.** Specifies whether the connection is incoming or outgoing. The flow type is REQ for incoming connections and RES for outgoing connections.
- **Protocol.** Specifies the protocol, the choices for which are HTTP, SSL, TCP, and IP.
- **Qualifier.** The protocol attribute, which depends on the selected protocol.
- **Operator.** The type of test you want to perform on the connection data. Your choice of operator depends upon the connection information you are testing. If the connection information you are testing is text, you use text operators. If it is a number, you use standard numeric operators.
- **Value.** The string or number against which the connection data element—defined by the flow type, protocol, and qualifier—is tested. The value can be either a literal or an expression. The literal or expression must match the data type of the connection data element.

In a policy, classic expressions can be combined to create more complex expressions using Boolean and comparative operators.

Expression elements are parsed from left to right. The leftmost element is either REQ or RES and designates a request or a response, respectively. Successive terms define a specific connection type and a specific attribute for that connection type. Each term is separated from any preceding or following term by a period. Arguments appear in parentheses and follow the expression element to which they are passed.

The following classic expression fragment returns the client source IP for an incoming connection.

$$REQ.IP\cdot SOURCEIP$$
The example identifies an IP address in a request. The expression element `SOURCEIP` designates the source IP address. This expression fragment may not be useful by itself. You can use an additional expression element, an operator, to determine whether the returned value meets specific criteria. The following expression tests whether the client IP is in the subnet 200.0.0.0/8 and returns a Boolean TRUE or FALSE:

\[ \text{REQ.IP.SOURCEIP} == 200.0.0.0 - \text{netmask} 255.0.0.0 \]

**Create a classic policy expression by using the CLI**

At the command prompt, type the following commands to set the parameters and verify the configuration:

1. `set appfw policy \<name\> -rule \<expression\> -action \<action\>`
2. `show appfw policy \<name\>`

**Example**

1. > set appfw policy GenericApplicationSSL_ 'HTTP.REQ.METHOD.EQ("get")' APPFW_DROP
2. Done
3. > show appfw policy GenericApplicationSSL_
4. Name: GenericApplicationSSL_   Rule: HTTP.REQ.METHOD.EQ("get")
5. Profile: APPFW_DROP   Hits: 0

7. Policy is bound to following entities
8. 1) REQ VSERVER app_u_GenericApplicationSSLPortalPages
   PRIORITY : 100
9. Done

**Add an expression for a classic policy by using the GUI**

This procedure documents the Add Expression dialog box. Depending on the feature for which you are configuring a policy, the route by which you arrive at this dialog box may be different.

1. Perform steps 1-4 in “To create a policy with classic expressions by using the GUI”.
2. In the **Add Expression** dialog box, in Expression Type, click the type of expression you want to create.
3. Under **Flow Type**, click the down arrow and choose a flow type.
The flow type is typically REQ or RES. The REQ option specifies that the policy applies to all incoming connections or requests. The RES option applies the policy to all outgoing connections or responses.

For Application Firewall policies, you should leave the expression type set to General Expression, and the flow type set to REQ. The Application Firewall treats each request and response as a single paired entity, so all Application Firewall policies begin with REQ.

1. Under Protocol, click the down arrow and choose the protocol you want for your policy expression. Your choices are:
   - HTTP. Evaluates HTTP requests that are sent to a Web server. For classic expressions, HTTP includes HTTPS requests.
   - SSL. Evaluates SSL data associated with the current connection.
   - TCP. Evaluates the TCP data associated with the current connection.
   - IP. Evaluates the IP addresses associated with the current connection.

2. Under Qualifier, click the down arrow and choose a qualifier for your policy. The qualifier defines the type of data to be evaluated. The list of qualifiers that appears depends on which protocol you selected in step 4.
   The following choices appear for the HTTP protocol:
   - METHOD. Filters HTTP requests that use a particular HTTP method.
   - URL. Filters HTTP requests for a specific Web page.
   - URLQUERY. Filters HTTP requests that contain a particular query string.
   - VERSION. Filters HTTP requests on the basis of the specified HTTP protocol version.
   - HEADER. Filters on the basis of a particular HTTP header.
   - URLEN. Filters on the basis of the length of the URL.
   - URLQUERY. Filters on the basis of the query portion of the URL.
   - URLQUERYLEN. Filters on the basis of the length of the query portion of the URL only.

3. Under Operator, click the down arrow and choose the operator for your policy expression. Some common operators are:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>==</code></td>
<td>Matches the specified value exactly or is exactly equal to the specified value.</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>Does not match the specified value.</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>Is greater than the specified value.</td>
</tr>
<tr>
<td><code>&lt;</code></td>
<td>Is less than the specified value.</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>Is greater than or equal to the specified value.</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>Is less than or equal to the specified value.</td>
</tr>
</tbody>
</table>
1. If a Value text box appears, type a string or numeric value, as appropriate. For example, chose REQ as the Flow Type, HTTP as the Protocol, and HEADER as the qualifier, and then type the value of the header string in the Value field and the header type for which you want to match the string in the Header Name text box.

2. Click OK.

3. To create a compound expression, click Add. Note that the type of compounding that is done depends on the following choices in the Create Policy dialog box:

   • **Match Any Expression.** The expressions are in a logical OR relationship.
   • **Match All Expressions.** The expressions are in a logical AND relationship.
   • **Tabular Expressions.** Click the AND, OR, and parentheses buttons to control evaluation.
   • **Advanced Free-Form.** Enter the expressions components directly into the Expression field, and click the AND, OR, and parentheses buttons to control evaluation.

# Bind a classic policy

May 31, 2019

Depending on the policy type, you can bind a classic policy either globally or to a virtual server. Policy bind points are described in the table, “Policy Type and Bind Points for Policies in Features That Use Classic Policies.”

**Note:** You can bind a classic policy to multiple bind points.
Bind a classic policy globally by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - bind cmp global <policyName> [-priority <positive_integer>]
2
3 - show cmp global
```

Example

```
1 > bind cmp global cmp-pol-compress -priority 2
2   Done
3 > show cmp global
4  1) Policy Name: cmp-pol-compress   Priority: 2
  5  2) Policy Name: ns_nocmp_xml_ie   Priority: 8700
  6  3) Policy Name: ns_nocmp_mozilla_47 Priority: 8800
  7  4) Policy Name: ns_cmp_mscss      Priority: 8900
  8  5) Policy Name: ns_cmp_msapp      Priority: 9000
  9  6) Policy Name: ns_cmp_content_type Priority: 10000
10 Done
11 >
```

Bind a classic policy to a virtual server by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - bind lb vserver <name> [<targetVserver>] [-policyName <string> [-priority <positive_integer>]]
2
3 - show lb vserver <name>
```

Example

```
1 > bind lb vserver lbtemp -policyName cmp-pol-compress -priority 1
2   Done
3 > show lb vserver lbtemp
4   lbtemp (10.102.29.101:80) - HTTP    Type: ADDRESS
  5   State: UP
```
Bind a classic policy globally by using the GUI

Note: This procedure documents the Global Bindings dialog box. Depending on the feature for which you want to globally bind a policy, the route by which you arrive at this dialog box may be different.

1. In the navigation pane, expand the feature for which you want to globally bind a classic policy, and then locate the policy that you want to bind globally.

   Note: You cannot globally bind policies for Content Switching, Cache Redirection, SureConnect, Priority Queuing, or Citrix Gateway Authorization.

2. In the details pane, click Global Bindings.

3. In the Bind/Unbind <feature name> Policy(s) to Global dialog box, click Insert Policy.
4. In the **Policy Name** column, click the name of an existing policy that you want to globally bind, or click New Policy to open the Create <feature name> Policy dialog box.

5. After you have selected the policy or created a new policy, in the Priority column, type the priority value.

   The lower the number, the sooner this policy is applied relative to other policies. For example, a policy assigned a priority of 10 is applied before a policy with a priority of 100. You can use the same priority for different policies. All features that use classic policies implement only the first policy that a connection matches, so policy priority is important for getting the results you intend.

   As a best practice, leave room to add policies by setting priorities with intervals of 50 (or 100) between each policy.

6. Click **OK**.

**Bind a classic policy to a virtual server by using the GUI**

1. In the navigation pane, expand the feature that contains the virtual server to which you want to bind a classic policy (for example, if you want to bind a classic policy to a content switching virtual server, expand Traffic Management > Content Switching), and then click Virtual Servers.

2. In the details pane, select the virtual server, and then click Open.

3. In the Configure <Feature> Virtual Server dialog box, on the Policies tab, click the feature icon for the type policy that you want, and then click Insert Policy.

4. In the Policy Name column, click the name of an existing policy that you want to bind to a virtual server, or click A to open the Create <feature name> Policy dialog box.

5. After you have selected the policy or created a new policy, in the Priority column, set the priority.

   If you are binding a policy to a content switching virtual server, in the Target column, select a load balancing virtual server to which traffic that matches the policy should be sent.

6. Click **OK**.

**View classic policies**

May 14, 2019
You can view classic policies by using either the configuration utility or the command line. You can view details such as the policy's name, expression, and bindings.

**View a classic policy and its binding information by using the CLI**

At the command prompt, type the following commands to view a classic policy and its binding information:

```
show <featureName> policy [policyName]
```

**Example**

```
1 > show appfw policy GenericApplicationSSL_
2     Name: GenericApplicationSSL_   Rule: ns_only_get_adv
3     Profile: GenericApplicationSSL_Prof1   Hits: 0
4     Undef Hits: 0
5     Policy is bound to following entities
6       1) REQ VSERVER app_u_GenericApplicationSSLPortalPages
8          PRIORITY : 100
7     Done
```

**Note:** If you omit the policy name, all policies are listed without the binding details.

**View classic policies and policy bindings by using the GUI**

1. In the navigation pane, expand the feature whose policies you want to view, (for example, if you want to view application firewall policies, expand Application Firewall), and then click Policies.
2. In the details pane, do one or more of the following:
   - To view details for a specific policy, click the policy. Details appear in the Details area of the configuration pane.
   - To view bindings for a specific policy, click the policy, and then click Show Bindings.
   - To view global bindings, click the policy, and then click Global Bindings. Note that you cannot bind a Content Switching, Cache Redirection, SureConnect, Priority Queuing, or Citrix Gateway Authorization policy globally.

Create named classic expressions

June 18, 2019

A named classic expression is a classic expression that can be referenced through an assigned name. Often, you need to configure classic expressions that are large or complex and form a part of a larger compound expression. You might also configure classic expressions that you need to use frequently and in multiple compound expressions or classic policies. In these scenarios, you can create the classic expression you want, save it with a name of your choice, and then reference the expression from compound expressions or policies through its name. This saves configuration time and improves the readability of complex compound expressions. Additionally, any modifications to a named classic expression need to be made only once.

Some named expressions are built-in, and a subset of these are read-only. Built-in named expressions are divided into four categories: General, Anti-Virus, Personal Firewall, and Internet Security. General named expressions have a wide variety of uses. For example, from the General category, you can use the expressions ns_true and ns_false to specify a value of TRUE or FALSE, respectively, to be returned for all traffic. You can also identify data of a particular type (for example, HTM, DOC, or GIF files), determine whether caching headers are present, or determine whether the round trip time for packets between a client and the Citrix ADC is high (over 80 milliseconds).

Anti-Virus, Personal Firewall, and Internet Security named expressions test clients for the presence of a particular program and version and are used primarily in Citrix Gateway policies.

**Note:** You cannot modify or delete built-in named expressions.

Create a named classic expression by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - add expression <name> <value> [-comment <string>] [-clientSecurityMessage <string>]
2 - show expression [<name> | -type CLASSIC]
```

**Example**

```
1 > add expression classic_ne "REQ.HTTP.URL CONTAINS www.example1.com" -comment "Checking the URL for www.example1.com"
2 Done
3 > show expression classic_ne
```
Create a named classic expression by using the GUI

1. In the navigation pane, expand AppExpert, expand Expressions, and then click Classic Expressions.

2. In the details pane, click Add.

   Note: Some of the built-in expressions in the Expressions list are read-only.

3. In the Create Policy Expression dialog box, specify values for the following parameters:
   - Expression Name*—name
   - Client Security Message—clientSecurityMessage
   - Comments—comment

   *A required parameter

4. To create the expression, do one of the following:
   - You can choose inputs to this expression from the Named Expressions drop-down list.
   - You can create a new expression, as described in Add an expression for a classic policy by using the GUI.

5. When you are done, click Close. Verify that your new expression was created by scrolling to the bottom of the Classic Expressions list to view it.

Expressions reference-advanced policy expressions

July 8, 2020

Warning

Q and S prefixes are deprecated from Citrix ADC 12.0 build 56.20 onwards and are no longer supported in Advanced policy expressions.
The following table is a listing of default syntax expression prefixes, with cross-references to descriptions of these prefixes and the operators that you can specify for them. Note that some prefixes can work with multiple types of operators. For example, a cookie can be parsed by using operators for text or operators for HTTP headers.

You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

**Note:** The Description column in the following table contains cross-references to additional information about prefix usage and applicable operators for the prefix.

For more information, refer [Expression PDF](#) to view the table.

Expressions reference-classic expressions

July 8, 2020

**Warning**

Classic policy expressions are no longer supported from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see [Advanced Policies](#).

The subtopics listed in the table of contents on the left side of your screen contain tables listing the Citrix ADC classic expressions.

In the table of operators, the result type of each operator is shown at the beginning of the description. In the other tables, the level of each expression is shown at the beginning of the description. For named expressions, each expression is shown as a whole.

**Operators**
<table>
<thead>
<tr>
<th>Expression Element</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>Boolean. Returns TRUE if the current expression equals the argument. For text operations, the items being compared must exactly match one another. For numeric operations, the items must evaluate to the same number.</td>
</tr>
<tr>
<td>!=</td>
<td>Boolean. Returns TRUE if the current expression does not equal the argument. For text operations, the items being compared must not exactly match one another. For numeric operations, the items must not evaluate to the same number.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Boolean. Returns TRUE if the current expression contains the string that is designated in the argument.</td>
</tr>
<tr>
<td>NOTCONTAINS</td>
<td>Boolean. Returns TRUE if the current expression does not contain the string that is designated in the argument.</td>
</tr>
<tr>
<td>CONTENTS</td>
<td>Text. Returns the contents of the current expression.</td>
</tr>
<tr>
<td>EXISTS</td>
<td>Boolean. Returns TRUE if the item designated by the current expression exists.</td>
</tr>
<tr>
<td>NOTEXISTS</td>
<td>Boolean. Returns TRUE if the item designated by the current expression does not exist.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is greater than the argument.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is less than the argument.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is greater than or equal to the argument.</td>
</tr>
</tbody>
</table>
Expression Element | Definition
--- | ---
<= | Boolean. Returns TRUE if the current expression evaluates to a number that is less than or equal to the argument.

**General expressions**

Expression Element | Definition
--- | ---
REQ | Flow Type. Operates on incoming (or request) packets.
REQ.HTTP | Protocol. Operates on HTTP requests.
REQ.HTTP.METHOD | Qualifier. Designates the HTTP method.
REQ.HTTP.URL | Qualifier. Designates the URL.
REQ.HTTP.URLTOKENS | Qualifier. Designates the URL token.
REQ.HTTP.VERSION | Qualifier. Designates the HTTP version.
REQ.HTTP.HEADER | Qualifier. Designates the HTTP header.
REQ.HTTP.URllen | Qualifier. Designates the number of characters in the URL.
REQ.HTTP.URLquery | Qualifier. Designates the query portion of the URL.
REQ.HTTP.URLquerylen | Qualifier. Designates the length of the query portion of the URL.
REQ.SSL | Protocol. Operates on SSL requests.
REQ.SSL.CLIENT.CERT | Qualifier. Designates the entire client certificate.
REQ.SSL.CLIENT.CERT.SUBJECT | Qualifier. Designates the client certificate subject.
REQ.SSL.CLIENT.CERT.ISSUER | Qualifier. Designates the issuer of the client certificate.
REQ.SSL.CLIENT.CERT.SIGALGO | Qualifier. Designates the validation algorithm used by the client certificate.
REQ.SSL.CLIENT.CERT.VERSION | Qualifier. Designates the client certificate version.
<table>
<thead>
<tr>
<th>Expression Element</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQ.SSL.CLIENT.CERT.VALIDFROM</td>
<td>Qualifier. Designates the date before which the client certificate is not valid.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CERT.VALIDTO</td>
<td>Qualifier. Designates the date after which the client certificate is not valid.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CERT.SERIALNUMBER</td>
<td>Qualifier. Designates the serial number of the client certificate.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CIPHER.TYPE</td>
<td>Qualifier. Designates the encryption protocol used by the client.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CIPHER.BITS</td>
<td>Qualifier. Designates the number of bits used by the client’s SSL key.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.SSL.VERSION</td>
<td>Qualifier. Designates the SSL version that the client is using.</td>
</tr>
<tr>
<td>REQ.TCP</td>
<td>Protocol. Operates on incoming TCP packets.</td>
</tr>
<tr>
<td>REQ.TCP.SOURCEPORT</td>
<td>Qualifier. Designates the source port of the incoming packet.</td>
</tr>
<tr>
<td>REQ.TCP.DESTPORT</td>
<td>Qualifier. Designates the destination port of the incoming packet.</td>
</tr>
<tr>
<td>REQ.IP</td>
<td>Protocol. Operates on incoming IP packets.</td>
</tr>
<tr>
<td>REQ.IP.SOURCEIP</td>
<td>Qualifier. Designates the source IP of the incoming packet.</td>
</tr>
<tr>
<td>REQ.IP.DESTIP</td>
<td>Qualifier. Designates the destination IP of the incoming packet.</td>
</tr>
<tr>
<td>RES</td>
<td>Flow Type. Operates on outgoing (or response) packets.</td>
</tr>
<tr>
<td>RES.HTTP</td>
<td>Protocol. Operates on HTTP responses.</td>
</tr>
<tr>
<td>RES.HTTP.VERSION</td>
<td>Qualifier. Designates the HTTP version.</td>
</tr>
<tr>
<td>RES.HTTP.HEADER</td>
<td>Qualifier. Designates the HTTP header.</td>
</tr>
<tr>
<td>RES.HTTP.STATUSCODE</td>
<td>Qualifier. Designates the status code of the HTTP response.</td>
</tr>
<tr>
<td>RES.TCP</td>
<td>Protocol. Operates on incoming TCP packets.</td>
</tr>
<tr>
<td>RES.TCP.SOURCEPORT</td>
<td>Qualifier. Designates the source port of the outgoing packet.</td>
</tr>
</tbody>
</table>
Expression Element | Definition
--- | ---
RES.TCP.DESTPORT | Qualifier. Designates the destination port of the outgoing packet.
RES.IP | Protocol. Operates on outgoing IP packets.
RES.IP.SOURCEIP | Qualifier. Designates the source IP of the outgoing packet. This can be in IPv4 or IPv6 format. For example: add expr exp3 “sourceip == 10.102.32.123 –netmask 255.255.255.0 && destip == 2001::23/120”.
RES.IP.DESTIP | Qualifier. Designates the destination IP of the outgoing packet.

Client security expressions

The expressions to configure client settings on the Access Gateway with the following software:

- Antivirus
- Personal firewall
- Antispam
- Internet Security

For example usage, see [http://support.citrix.com/article/CTX112599](http://support.citrix.com/article/CTX112599).

Actual Expression | Definition
--- | ---
CLIENT.APPLICATION.AV(<NAME>.VERSION == <VERSION>) | Checks whether the client is running the designated anti-virus program and version.
CLIENT.APPLICATION.AV(<NAME>.VERSION != <VERSION>) | Checks whether the client is not running the designated anti-virus program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION == <VERSION>) | Checks whether the client is running the designated personal firewall program and version.
CLIENT.APPLICATION.PF(<NAME>.VERSION != <VERSION>) | Checks whether the client is not running the designated personal firewall program and version.
CLIENT.APPLICATION.IS(<NAME>.VERSION == <VERSION>) | Checks whether the client is running the designated internet security program and version.
## Actual Expression Definition

<table>
<thead>
<tr>
<th>Expression</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.APPLICATION.IS(&lt;NAME&gt;.VERSION != &lt;VERSION&gt;)</td>
<td>Checks whether the client is not running the designated internet security program and version.</td>
</tr>
<tr>
<td>CLIENT.APPLICATION.AS(&lt;NAME&gt;.VERSION == &lt;VERSION&gt;)</td>
<td>Checks whether the client is running the designated anti-spam program and version.</td>
</tr>
<tr>
<td>CLIENT.APPLICATION.AS(&lt;NAME&gt;.VERSION != &lt;VERSION&gt;)</td>
<td>Checks whether the client is not running the designated anti-spam program and version.</td>
</tr>
</tbody>
</table>

### Network-based expressions

</thead>
<tbody>
<tr>
<td>TIME</td>
<td>Qualifier. Operates on the date and time of day, GMT.</td>
</tr>
<tr>
<td>DATE</td>
<td>Qualifier. Operates on the date, GMT.</td>
</tr>
<tr>
<td>DAYOFWEEK</td>
<td>Operates on the specified day in the week, GMT.</td>
</tr>
</tbody>
</table>

### File system expressions

You can specify file system expressions in authorization policies for users and groups who access file sharing through the Citrix Gateway file transfer utility (the VPN portal). These expressions work with the Citrix Gateway file transfer authorization feature to control user access to file servers, folders, and files. For example, you can use these expressions in authorization policies to control access based on file type and size.

For more information, refer to the [File Name Expression pdf](#).

**Note:** File system expressions do not support regular expressions.
## Built-in named expressions (General)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns_all_apps_ncomp</td>
<td>Tests for connections with destination ports between 0 and 65535. In other words, tests for all applications.</td>
</tr>
<tr>
<td>ns_cachecontrol_nocache</td>
<td>Tests for connections with an HTTP Cache-Control header that contains the value “no-cache”.</td>
</tr>
<tr>
<td>ns_cachecontrol_nostore</td>
<td>Tests for connections with an HTTP Cache-Control header that contains the value “no-store”.</td>
</tr>
<tr>
<td>ns_cmpclient</td>
<td>Tests the client to determine if it accepts compressed content.</td>
</tr>
<tr>
<td>ns_content_type</td>
<td>Tests for connections with an HTTP Content-Type header that contains “text”.</td>
</tr>
<tr>
<td>ns_css</td>
<td>Tests for connections with an HTTP Content-Type header that contains “text/css”.</td>
</tr>
<tr>
<td>ns_ext_asp</td>
<td>Tests for HTTP connections to any URL that contains the string .asp—in other words, any connection to an active server page (ASP).</td>
</tr>
<tr>
<td>ns_ext_cfm</td>
<td>Tests for HTTP connections to any URL that contains the string .cfm</td>
</tr>
<tr>
<td>ns_ext cgi</td>
<td>Tests for HTTP connections to any URL that contains the string .cgi—in other words, any connection to a common gateway interface (CGI) script.</td>
</tr>
<tr>
<td>ns_ext ex</td>
<td>Tests for HTTP connections to any URL that contains the string .ex</td>
</tr>
<tr>
<td>ns_ext exe</td>
<td>Tests for HTTP connections to any URL that contains the string .exe—in other words, any connection to a executable file.</td>

</tr>
<tr>
<td>ns_ext_not_jpeg</td>
<td>Tests for HTTP connections to any URL that does not contain the string .jpeg—in other words, any connection to a URL that is not a JPEG image.</td>
</tr>
<tr>
<td>ns_ext_shtml</td>
<td>Tests for HTTP connections to any URL that contains the string .shtml—in other words, any connection to a server-parsed HTML page.</td>
</tr>
<tr>
<td>ns_false</td>
<td>Always returns a value of FALSE.</td>
</tr>
<tr>
<td>ns_farclient</td>
<td>Client is in a different geographical region from the Citrix ADC, as determined by the geographical region in the client’s IP address. The following regions are predefined: 192.0.0.0 – 193.255.255.255: Multi-regional, 194.0.0.0 – 195.255.255.255: European Union, 196.0.0.0 – 197.255.255.255: Other1, 198.0.0.0 – 199.255.255.255: North America, 200.0.0.0 – 201.255.255.255: Central and South America, 202.0.0.0 – 203.255.255.255: Pacific Rim, 204.0.0.0 – 205.255.255.255: Other2, and 206.0.0.0 – 207.255.255.255: Other3</td>
</tr>
<tr>
<td>ns_header_cookie</td>
<td>Tests for HTTP connections that contain a Cookie header.</td>
</tr>
<tr>
<td>ns_headerPragma</td>
<td>Tests for HTTP connections that contain a Pragma: no-cache header.</td>
</tr>
<tr>
<td>ns_mozilla_47</td>
<td>Tests for HTTP connections whose User-Agent header contains the string Mozilla/4.7—in other words, any connection from a client using the Mozilla 4.7 Web browser.</td>
</tr>
<tr>
<td>Expression</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ns_msexcel</td>
<td>Tests for HTTP connections whose Content-Type header contains the string application/vnd.msexcel—in other words, any connection transmitting a Microsoft Excel spreadsheet.</td>
</tr>
<tr>
<td>ns_msie</td>
<td>Tests for HTTP connections whose User-Agent header contains the string MSIE—in other words, any connection from a client using any version of the Internet Explorer Web browser.</td>
</tr>
<tr>
<td>ns_msppt</td>
<td>Tests for HTTP connections whose Content-Type header contains the string application/vnd.ms-powerpoint—in other words, any connection transmitting a Microsoft PowerPoint file.</td>
</tr>
<tr>
<td>ns_msword</td>
<td>Tests for HTTP connections whose Content-Type header contains the string application/vnd.msword—in other words, any connection transmitting a Microsoft Word file.</td>
</tr>
<tr>
<td>ns_non_get</td>
<td>Tests for HTTP connections that use any HTTP method except for GET.</td>
</tr>
<tr>
<td>ns_slowclient</td>
<td>Returns TRUE if the average round trip time between the client and the Citrix ADC is more than 80 milliseconds.</td>
</tr>
<tr>
<td>ns_true</td>
<td>Returns TRUE for all traffic.</td>
</tr>

check_client_ip_policy 200 300 bind rewrite global
insert_ns_client_policy 300 END set rewrite action
insert_ns_client_header -stringBuilderExpr 'HTTP.REQ.HEADER("x-forwarded-for").VALUE(0)+ " " + HTTP.REQ.HEADER("client-ip").VALUE(0)+ " " + CLIENT.IP.SRC'
-bypassSafetyCheck YES``` |
Tutorial examples of default syntax policies for rewrite

February 20, 2020

With the rewrite feature, you can modify any part of an HTTP header, and, for responses, you can modify the HTTP body. You can use this feature to accomplish a number of useful tasks, such as removing unnecessary HTTP headers, masking internal URLs, redirecting Web pages, and redirecting queries or keywords.

In the following examples, you first create a rewrite action and a rewrite policy. Then you bind the policy globally.

This document includes the following details:

- Redirecting an External URL to an Internal URL
- Redirecting a Query
- Rewriting HTTP to HTTPS
- Removing Unwanted Headers
- Reducing Web Server Redirects
- Masking the Server Header
- Converting plain text to URL encoded string and vice-versa

For more information about the commands and syntax descriptions, see Rewrite Command Reference page.

Redirecting an external URL to an internal URL

This example describes how to create a rewrite action and rewrite policy that redirects an external URL to an internal URL. You create an action, called act_external_to_internal, that performs the rewrite. Then you create a policy called pol_external_to_internal.

To redirect an external URL to an internal URL by using the command line interface

- To create the rewrite action, at the command prompt, type:

  \[\text{add rewrite action act\_external\_to\_internal REPLACE "http.}\text{req.}\text{hostname.}\text{server"} \text{"host_name_of_internal_Web_server"}\]

- To create the rewrite policy, at the Citrix ADC command prompt, type:

  \[\text{add rewrite policy pol\_external\_to\_internal } "\text{http.}\text{req.}\text{hostname.}\text{server.eq("host_name_of_external_Web_server")act\_external\_to\_internal"}\]

- Bind the policy globally.
To redirect an external URL to an internal URL by using the configuration utility

1. Navigate to **AppExpert > Rewrite > Actions.**
2. In the details pane, click **Add**.
3. In the **Create Rewrite Action** dialog box, enter the name act_external_to_internal.
4. To replace the HTTP server host name with the internal server name, choose **Replace** from the Type list box.
5. In the header name field, type **Host**.
6. In the string expression for replacement text field, type the internal host name of your Web server.
7. Click **Create** and then click **Close**.
8. In the navigation pane, click **Policies**.
9. In the details pane, click **Add**.
10. In the Name field, type pol_external_to_internal. This policy will detect connections to the Web server.
11. In the **Action** drop-down menu, choose the action act_external_to_internal.
12. In the Expression editor, construct the following expression:

   ```
   HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
   ```

1. Bind your new policy globally.

Redirecting a query

This example describes how to create a rewrite action and rewrite policy that redirects a query to the proper URL. The example assumes that the request contains a Host header set to `www.example.com` and a GET method with the `string/query.cgi?server=5`. The redirect extracts the domain name from the host header and the number from the query string, and redirects the user’s query to the server `Web5.example.com`, where the rest of the user’s query is processed.

**Note:**

Although the following commands appears on multiple lines, you should enter them on a single line without line breaks.

To redirect a query to the appropriate URL using the command line

- To create a rewrite action named act_redirect_query that replaces the HTTP server host name with the internal server name, type:

  ```
  add rewrite action act_redirect_query REPLACE q##http.req.header("Host").
  before_str(\".example.com\")\"Web\"##http.req.url.query.value("server")##
  ```
To create a rewrite policy named pol_redirect_query, type the following commands at the Citrix ADC command prompt. This policy detects connections to the Web server that contain a query string. Do not apply this policy to connections that do not contain a query string:

```
add rewrite policy pol_redirect_query q##http.req.header("Host").eq("www.example.com")&& http.req.url.contains("?")'act_redirect_query##
```

- Bind your new policy globally.

Because this rewrite policy is highly specific and should be run before any other rewrite policies, it is advisable to assign it a high priority. If you assign it a priority of 1, it will be evaluated first.

**Rewriting HTTP to HTTPS**

This example describes how to rewrite Web server responses to find all URLs that begin with the string “http” and replace that string with “https.” You can use this to avoid having to update Web pages after moving a server from HTTP to HTTPS.

**To redirect HTTP URLs to HTTPS by using the command line interface**

- To create a rewrite action named act_replace_http_with_https that replaces all instances of the string “http” with the string “https,” enter the following command:

  ```
  add rewrite action act_replace_http_with_https replace_all 'http.res.body(100)''"https"'-pattern http
  ```

- To create a rewrite policy named pol_replace_http_with_https that detects connections to the Web server, enter the following command:

  ```
  add rewrite policy pol_replace_http_with_https TRUE act_replace_http_with_https NOREWRITE
  ```

- Bind your new policy globally.

To troubleshoot this rewrite operation, see “Case Study: Rewrite Policy for Converting HTTP Links to HTTPS not Working.”

**Removing Unwanted Headers**

This example explains how to use a Rewrite policy to remove unwanted headers. Specifically, the example shows how to remove the following headers:

- **Accept Encoding header.** Removing the Accept Encoding header from HTTP responses prevents compression of the response.
• **Content Location header.** Removing the Content Location header from HTTP responses prevents your server from providing a hacker with information that might allow a security breach.

To delete headers from HTTP responses, you create a rewrite action and a rewrite policy, and you bind the policy globally.

**To create the appropriate Rewrite action by using the command line interface**

At the command prompt, type one of the following commands to either remove the Accept Encoding header and prevent response compression or remove the Content Location header:

- `add rewrite action "act_remove-ae" delete_http_header "Accept-Encoding"
- `add rewrite action "act_remove-cl" delete_http_header "Content-Location"

**To create the appropriate Rewrite policy by using the command line interface**

At the command prompt, type one of the following commands to remove either the Accept Encoding header or the Content Location header:

- `add rewrite policy "pol_remove-ae" true "act_remove-ae"
- `add rewrite policy "pol_remove-cl" true "act_remove-cl"

**To bind the policy globally by using the command line interface**

At the command prompt, type one of the following commands, as appropriate, to globally bind the policy that you have created:

- `bind rewrite global pol_remove_ae 100
- `bind rewrite global pol_remove_cl 200

**Reducing Web Server Redirects**

This example explains how to use a Rewrite policy to modify connections to your home page and other URLs that end with a forward slash (/) to the default index page for your server, preventing redirects and reducing load on your server.

**To modify directory-level HTTP requests to include the default home page by using the command line**

- To create a Rewrite action named action-default-homepage that modifies URLs that end in a forward slash to include the default home page index.html, type:
add rewrite action "action-default-homepage"replace q\#http.req.url.path " /"\#/index.html"

- To create a Rewrite policy named policy-default-homepage that detects connections to your home page and applies your new action, type:

add rewrite policy "policy-default-homepage"q\#http.req.url.path.EQ("/") action-default-homepage"

- Globally bind your new policy to put it into effect.

**Masking the Server Header**

This example explains how to use a Rewrite policy to mask the information in the Server header in HTTP responses from your Web server. That header contains information that hackers can use to compromise your Web site. While masking the header will not prevent a skilled hacker from finding out information about your server, it will make hacking your Web server more difficult and encourage hackers to choose less well protected targets.

**To mask the Server header in responses from the command line**

1. To create a Rewrite action named act_mask-server that replaces the contents of the Server header with an uninformative string, type:

add rewrite action "act_mask-server"replace "http.RES.HEADER(\\"Server\\")" "\\"Web Server 1.0\\"

1. To create a Rewrite policy named pol_mask-server that detects all connections, type:

add rewrite policy "pol_mask-server"true "act_mask-server"

1. Globally bind your new policy to put it into effect.

**How to convert plain text to URL encoded string and vice-versa**

The following expressions convert plain text to URL encoded string and vice-versa:

1. URL_RESERVED_CHARS_SAFE (string to URL ENCODED).

**Example:**

```
1 ("abc def&123").URL_RESERVED_CHARS_SAFE
2 Output will be
3 "abc%20def%26123" which is url encoded.
```
1. SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE. (URL ENCODED to string)

Example:

```
1  ("abc%20def%26123").SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE
2  Output will be
3  "abc def&123"
```

Tutorial examples of classic policies

May 14, 2019

The following examples describe useful examples of classic policy configuration for certain Citrix ADC features, such as Citrix Gateway, application firewall, and SSL.

This document includes the following details:

- Citrix Gateway Policy to Check for a Valid Client Certificate
- Application Firewall Policy to Protect a Shopping Cart Application
- Application Firewall Policy to Protect Scripted Web Pages
- DNS Policy to Drop Packets from Specific IPs
- SSL Policy to Require Valid Client Certificates

Citrix Gateway policy to check for a valid client certificate

The following policies enable the Citrix ADC to ensure that a client presents a valid certificate before establishing a connection to a company’s SSL VPN.

To check for a valid client certificate by using the command line interface

- Add an action to perform client certificate authentication.
  
  `add ssl action act1 -client Auth DOCLIENTAUTH`

- Create an SSL policy to evaluate the client requests.
  
  `add ssl policy pol1 -rule "REQ.HTTP.METHOD == GET"-action act1`

- Add a rewrite action to insert the certificate issuer details into the HTTP header of the requests being sent to web server.
add rewrite action act2 insert_http_header "CertDN"CLIENT.SSL.CLIENT_CERT.SUBJECT

- Create a rewrite policy to insert the certificate issuer details, if the client certificate exists.
add rewrite policy pol2 "CLIENT.SSL.CLIENT_CERT.EXISTS"act2

Bind these new policies to the Citrix ADC VIP to put them into effect.

Application firewall policy to protect a shopping cart application

Shopping cart applications handle sensitive customer information, for example, credit card numbers and expiration dates, and they access back-end database servers. Many shopping cart applications also use legacy CGI scripts, which can contain security flaws that were unknown at the time they were written, but are now known to hackers and identity thieves.

A shopping cart application is particularly vulnerable to the following attacks:

- **Cookie tampering.** If a shopping cart application uses cookies, and does not perform the appropriate checks on the cookies that users return to the application, an attacker could modify a cookie and gain access to the shopping cart application under another user’s credentials. Once logged on as that user, the attacker could obtain sensitive private information about the legitimate user or place orders using the legitimate user’s account.

- **SQL injection.** A shopping cart application normally accesses a back-end database server. Unless the application performs the appropriate safety checks on the data users return in the form fields of its Web forms before it passes that information on to the SQL database, an attacker can use a Web form to inject unauthorized SQL commands into the database server. Attackers normally use this type of attack to obtain sensitive private information from the database or modify information in the database.

The following configuration will protect a shopping cart application against these and other attacks.

**To protect a shopping cart application by using the configuration utility**

1. Navigate to Security > Application Firewall > Profiles, and then click Add.

2. In the Create Application Firewall Profile dialog box, in the Profile Name field, enter shopping_cart.

3. In the Profile Type drop-down list, select Web Application.

4. In the Configure Select Advanced defaults.

5. Click Create and then click Close.

6. In the details view, double-click the new profile.
7. In the Configure Web Application Profile dialog box, configure your new profile as described below:

- Click the Checks tab, double-click the Start URL check, and in the Modify Start URL Check dialog box, click the General tab and disable blocking, and enable learning, logging, statistics, and URL closure. Click OK and then click Close.

Note that if you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

```plaintext
set appfw profile shopping_cart -startURLAction LEARN LOG STATS -startURLClosure ON
```

- For the Cookie Consistency check and Form Field Consistency checks, disable blocking, and enable learning, logging, statistics, using a similar method to the Modify Start URL Check configuration.

If you are using the command line, you configure these settings by typing the following commands:

```plaintext
set appfw profile shopping_cart -cookieConsistencyAction LEARN LOG STATS
set appfw profile shopping_cart -fieldConsistencyAction LEARN LOG STATS
```

- For the SQL Injection check, disable blocking, and enable learning, logging, statistics, and transformation of special characters in the Modify SQL Injection Check dialog box, General tab, Check Actions section.

If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

```plaintext
set appfw profile shopping_cart -SQLInjectionAction LEARN LOG STATS
```

- For the Credit Card check, disable blocking; enable logging, statistics, and masking of credit card numbers; and enable protection for those credit cards you accept as forms of payment.

  - If you are using the configuration utility, you configure blocking, logging, statistics, and masking (or x-out) in the Modify Credit Card Check dialog box, General tab, Check Actions section. You configure protection for specific credit cards in the Settings tab of the same dialog box.
  - If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:
set appfw profile shopping_cart -creditCardAction LOG STATS -
creditCardXOut ON -creditCard <name> [<name>...]

For <name> you substitute the name of the credit card you want to protect. For Visa, you
substitute VISA. For Master Card, you substitute MasterCard. For American Express, you
substitute Amex. For Discover, you substitute Discover. For Diners Club, you substitute
DinersClub. For JCB, you substitute JCB.

8. Create a policy named shopping_cart that detects connections to your shopping cart applica-
tion and applies the shopping_cart profile to those connections.

To detect connections to the shopping cart, you examine the URL of incoming connections. If
you host your shopping cart application on a separate host (a wise measure for security and
other reasons), you can simply look for the presence of that host in the URL. If you host your
shopping cart in a directory on a host that handles other traffic, as well, you must determine
that the connection is going to the appropriate directory and/or HTML page.

The process for detecting either of these is the same; you create a policy based on the following
expression, and substitute the proper host or URL for <string>.

```plaintext
1  REQ.HTTP.HEADER URL CONTAINS <string>
```

- If you are using the configuration utility, you navigate to the application firewall Policies
  page, click the Add... button to add a new policy, and follow the policy creation process
described in “To create a policy with classic expressions using the configuration utility”
beginning on page 201 and following.

- If you are using the command line, you type the following command at the prompt and
  press Enter:

  ```plaintext
  add appfw policy shopping_cart "REQ.HTTP.HEADER URL CONTAINS <
  string>"shopping_cart"
  ```

2. Globally bind your new policy to put it into effect.

Because you want to ensure that this policy will match all connections to the shopping cart, and not
be preempted by another more general policy, you should assign a high priority to it. If you assign one
(1) as the priority, no other policy can preempt this one.

**Application firewall policy to protect scripted web pages**

Web pages with embedded scripts, especially legacy JavaScripts, often violate the “same origin rule,”
which does not allow scripts to access or modify content on any server but the server where they are
located. This security vulnerability is called cross-site scripting. The application firewall Cross-Site
Scripting rule normally filters out requests that contain cross-site scripting.
Unfortunately, this can cause Web pages with older JavaScripts to stop functioning, even when your system administrator has checked those scripts and knows that they are safe. The example below explains how to configure the application firewall to allow cross-site scripting in Web pages from trusted sources without disabling this important filter for the rest of your Web sites.

To protect Web pages with cross-site scripting by using the command line interface

• At the command line, to create an advanced profile, type:
  add appfw profile pr_xssokay -defaults advanced

• To configure the profile, type:
  set appfw profile pr_xssokay -startURLAction NONE -startURLClosure OFF -cookieConsistencyAction LEARN LOG STATS -fieldConsistencyAction LEARN LOG STATS -crossSiteScriptingAction LEARN LOG STATS$

• Create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile, type:
  add appfw policy pol_xssokay "REQ.HTTP.HEADER URL CONTAINS ^\.pl\?\$ || REQ.HTTP.HEADER URL CONTAINS ^\.js$" pr_xssokay

• Globally bind the policy.

To protect Web pages with cross-site scripting by using the configuration utility

1. Navigate to Security > Application Firewall > Profiles.
2. In the details view, click Add.
3. In the Create Application Firewall Profile dialog box, create a Web Application profile with advanced defaults and name it pr_xssokay. Click Create and then click Close.
4. In the details view, click the profile, click Open, and in the Configure Web Application Profile dialog box, configure the pr_xssokay profile as shown below.

   Start URL Check: Clear all actions.
   - Cookie Consistency Check: Disable blocking.
   - Form Field Consistency Check: Disable blocking.
   - Cross-Site Scripting Check: Disable blocking.

   This should prevent blocking of legitimate requests involving Web pages with cross-site scripting that you know are nonetheless safe.
5. Click Policies, and then click Add.
6. In the Create Application Firewall Policy dialog box, create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile:

- Policy name: pol_xssokay
- Associated profile: pr_xssokay

   Policy expression:
   
   "REQ.HTTP.HEADER URL CONTAINS "\.pl\?\$"

   "REQ.HTTP.HEADER URL CONTAINS "\.js$"

7. Globally bind your new policy to put it into effect.

**DNS Policy to drop packets from specific IPs**

The following example describes how to create a DNS action and DNS policy that detects connections from unwanted IPs or networks, such as those used in a DDOS attack, and drops all packets from those locations. The example shows networks within the IANA reserved IP block 192.168.0.0/16. A hostile network will normally be on publicly routable IPs.

**To drop packets from specific IPs by using the command line interface**

- To create a DNS policy named pol_ddos_drop that detects connections from hostile networks and drops those packets, type:

  ```plaintext
  add dns policy pol_ddos_drop 'client.ip.src.in_subnet(192.168.253.128/25) || client.ip.src.in_subnet(192.168.254.32/27)'-drop YES'
  ```

  For the example networks in the 192.168.0.0/16 range, you substitute the IP and netmask in "####.####.####.####/##" format of each network you want to block. You can include as many networks as you want, separating each CLIENT.IP.SRC.IN_SUBNET("####.####.####.####/##") command with the OR operator.

- Globally bind your new policy to put it into effect.

**SSL policy to require valid client certificates**

The following example shows an SSL policy that checks the user's client certificate validity before initiating an SSL connection with a client.
To block connections from users with expired client certificates

- Log on to the command line interface.
  If you are using the GUI, navigate to the SSL Policies page, then in the Data area, click the Actions tab.
- Create an SSL action named act_current_client_cert that requires that users have a current client certificate to establish an SSL connection with the Citrix ADC.
  ```
  add ssl action act_current_client_cert-clientAuth DOCLIENTAUTH -clientCert ENABLED -certHeader "clientCertificateHeader"-clientCertNotBefore ENABLED -certNotBeforeHeader "Mon, 01 Jan 2007 00:00:00 GMT"
  ```
- Create an SSL policy named pol_current_client_cert that detects connections to the Web server that contain a query string.
  ```
  add ssl policy pol_current_client_cert 'REQ.SSL.CLIENT.CERT.VALIDFROM \
  >= "Mon, 01 Jan 2007 00:00:00 GMT"' act_block_ssl
  ```
- Bind your new policy globally.
  Because this SSL policy should apply to any user’s SSL connection unless a more specific SSL policy applies, you may want to assign it a low priority. If you assign it a priority of one thousand (1000), that should ensure that other SSL policies are evaluated first, meaning that this policy will apply only to connections that do not match more specific policy criteria.

Migration of Apache mod_rewrite rules to the default syntax

The Apache HTTP Server provides an engine known as mod_rewrite for rewriting HTTP request URLs. If you migrate the mod_rewrite rules from Apache to the Citrix ADC, you boost back-end server performance. In addition, because the Citrix ADC typically load balances multiple (sometimes thousands of) Web servers, after migrating the rules to the Citrix ADC you will have a single point of control for these rules.

Following are examples of mod_rewrite functions, and translations of these functions into Rewrite and Responder policies on the Citrix ADC.

Converting URL variations into canonical URLs

On some Web servers you can have multiple URLs for a resource. Although the canonical URLs should be used and distributed, other URLs can exist as shortcuts or internal URLs. You can make sure that
users see the canonical URL regardless of the URL used to make an initial request.
In the following examples, the URL /~user is converted to /u/user.

**Apache mod_rewrite solution for converting a URL**

```
1    RewriteRule ^/~([^/]+)/(.*) /u/$1/$2[R]
```

**Citrix ADC solution for converting a URL**

```
1    add responder action act1 redirect '/u/'+HTTP.REQ.URL.AFTER_STR('/~')' -bypassSafetyCheck yes
2    add responder policy poll 'HTTP.REQ.URL.STARTS_WITH('/~') && HTTP.REQ.URL.LENGTH.GT(2)' act1
3    bind responder global poll 100
```

**Converting Host Name Variations to Canonical Host Names**

You can enforce the use of a particular host name for reaching a site. For example, you can enforce the use of www.example.com instead of example.com.

**Apache mod_rewrite solution for enforcing a particular host name for sites running on a port other than 80**

```
1    RewriteCond %{HTTP_HOST} !^www.example.com
2    RewriteCond %{HTTP_HOST} !^$
3    RewriteCond %{SERVER_PORT} !^80$
4    RewriteRule ^/(.*) http://www.example.com:%{SERVER_PORT} /$1 [L,R]
```
Citrix ADC 13.0

Apache mod_rewrite solution for enforcing a particular host name for sites running on port 80

1. RewriteCond %{HTTP_HOST} !^www.example.com
2. RewriteCond %{HTTP_HOST} !^$
3. RewriteRule ^/(.*) http://www.example.com/$1 [L,R]

Citrix ADC solution for enforcing a particular host name for sites running on a port other than 80

1. add responder action act1 redirect "http://www.example.com:"+CLIENT.TCP.DSTPORT+HTTP.REQ.URL’ -bypassSafetyCheck yes
2. add responder policy pol1 '!'HTTP.REQ.HOSTNAME.CONTAINS("www.example.com")&!'HTTP.REQ.HOSTNAME.EQ("")&!'HTTP.REQ.HOSTNAME.PORT.EQ(80)&!'HTTP.REQ.HOSTNAME.CONTAINS("example.com")' act1
3. bind responder global pol1 100 END

Citrix ADC solution for enforcing a particular host name for sites running on port 80

1. add responder action act1 redirect "http://www.example.com”+HTTP.REQ.URL’ -bypassSafetyCheck yes
2. add responder policy pol1 '!'HTTP.REQ.HOSTNAME.CONTAINS("www.example.com")&!'HTTP.REQ.HOSTNAME.EQ("")&!'HTTP.REQ.HOSTNAME.PORT.EQ(80)&!'HTTP.REQ.HOSTNAME.CONTAINS("example.com")’ act1
3. bind responder global pol1 100 END

Moving a document root

Usually the document root of a Web server is based on the URL “/”. However, the document root can be any directory. You can redirect traffic to the document root if it changes from the top-level “/” directory to another directory.

In the following examples, you change the document root from / to /e/www. The first two examples simply replace one string with another. The third example is more universal because, along with replacing the root directory, it preserves the rest of the URL (the path and query string), for example, redirecting /example/file.html to /e/www/example/file.html.
Citrix ADC 13.0

Apache mod_rewrite solution for moving the document root

1  RewriteEngine on
2  RewriteRule  ^/$  /e/www/  [R]

Citrix ADC solution for moving the document root

1  add responder action act1 redirect "'/e/www/'" -bypassSafetyCheck yes
2  add responder policy poll 'HTTP.REQ.URL.EQ("/")' act1
3  bind responder global poll 100

Citrix ADC solution for moving the document root and appending path information to the request

1  add responder action act1 redirect "'/e/www"+HTTP.REQ.URL' -bypassSafetyCheck yes
2  add responder policy poll '!HTTP.REQ.URL.STARTSWITH("/e/www")' act1
3  bind responder global poll 100  END

Moving home directories to a new web server

You may want to redirect requests that are sent to home directories on a Web server to a different Web server. For example, if a new Web server is replacing an old one over time, as you migrate home directories to the new location you need to redirect requests for the migrated home directories to the new Web server.

In the following examples, the host name for the new Web server is newserver.

Apache mod_rewrite solution for redirecting to another Web server

1  RewriteRule  ^/(.+)$  http://newserver/$1  [R,L]

Citrix ADC solution for redirecting to another Web server (method 1)

1  add responder  action act1 redirect '"http://newserver"+HTTP.REQ.URL' -bypassSafetyCheck yes
2  add responder policy poll 'HTTP.REQ.URL.REGEX_MATCH(re"^/(.+)#")' act1
Working with structured home directories

Typically, a site with thousands of users has a structured home directory layout. For example, each home directory may reside under a subdirectory that is named using the first character of the user name. For example, the home directory for jsmith (~jsmith/anypath) might be /home/j/jsmith/.www/anypath, and the home directory for rvalveti (~rvalveti/anypath) might be /home/r/rvalveti/.www/anypath.

The following examples redirect requests to the home directory.

Apache mod_rewrite solution for structured home directories

```bash
RewriteRule ^/((a-z)*a-z0-9)+(.*) /home/$2/$1/.www$3
```

Citrix ADC solution for structured home directories

```bash
add rewrite action act1 replace "HTTP.REQ.URL" ""/home/"+ HTTP.REQ.URL .AFTER_STR("-").PREFIX(1)+"+ HTTP.REQ.URL.AFTER_STR("-"). BEFORE_STR("/")+"/.www"+HTTP.REQ.URL.SKIP('\'/\',1)" - bypassSafetyCheck yes
add rewrite policy pol1 'HTTP.REQ.URL.PATH.STARTSWITH("/-")' act1
bind rewrite global pol1 100
```

Redirecting invalid URLs to other web servers

If a URL is not valid, it should be redirected to another Web server. For example, you should redirect to another Web server if a file that is named in a URL does not exist on the server that is named in the URL.
On Apache, you can perform this check using mod_rewrite. On the Citrix ADC, an HTTP callout can check for a file on a server by running a script on the server. In the following Citrix ADC examples, a script named file_check.cgi processes the URL and uses this information to check for the presence of the target file on the server. The script returns TRUE or FALSE, and the Citrix ADC uses the value that the script returns to validate the policy.

In addition to performing the redirection, the Citrix ADC can add custom headers or, as in the second Citrix ADC example, it can add text in the response body.

**Apache mod_rewrite solution for redirection if a URL is wrong**

```plaintext
1 RewriteCond /your/docroot/%{REQUEST_FILENAME} !-f
2 RewriteRule ^(.+) http://webserverB.com/$1 [R]
```

**Citrix ADC solution for redirection if a URL is wrong (method 1)**

```plaintext
1 add HTTPCallout Call
2 set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr '/cgi-bin/file_check.cgi' -parameters query=http.req.url.path -headers Name("ddd")
3 add responder action act1 redirect "http://webserverB.com"+HTTP.REQ.URL -bypassSafetyCheck yes
4 add responder policy pol1 '!'HTTP.REQ.HEADER("Name").EXISTS && !SYS.HTTP_CALLOUT(call)' act1
5 bind responder global pol1 100
```

**Citrix ADC solution for redirection if a URL is wrong (method 2)**

```plaintext
1 add HTTPCallout Call
2 set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr '/cgi-bin/file_check.cgi' -parameters query=http.req.url.path -headers Name("ddd")
3 add responder action act1 respondwith "HTTP/1.1 302 Moved Temporarily\r\n\nLocation: http://webserverB.com"+HTTP.REQ.URL+"\r\n\nHTTPCallout Used" -bypassSafetyCheck yes
```
Rewriting a URL based on time

You can rewrite a URL based on the time. The following examples change a request for example.html to example.day.html or example.night.html, depending on the time of day.

Apache mod_rewrite solution for rewriting a URL based on the time

```
1 RewriteCond %{TIME_HOUR} >0700
2 RewriteCond %{TIME_MIN} >0700
3 RewriteRule ^example\.html$ example.day.html [L]
4 RewriteRule ^example\.html$ example.night.html
```

Citrix ADC solution for rewriting a URL based on the time

```
1 add rewrite action act1 insert_before 'HTTP.REQ.URL.PATH.SUFFIX (\'.\',0)' "day."
2 add rewrite action act2 insert_before 'HTTP.REQ.URL.PATH.SUFFIX (\'.\',0)' "night."
3 add rewrite policy poll 'SYS.TIME.WITHIN(LOCAL 07h 00m,LOCAL 18h 59m)' act1
4 add rewrite policy pol2 'true' act2
5 bind rewrite global pol1 101
6 bind rewrite global pol2 102
```

Redirecting to a new file name (Invisible to the User)

If you rename a Web page, you can continue to support the old URL for backward compatibility while preventing users from recognizing that the page was renamed.
In the first two of the following examples, the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

**Apache mod_rewrite solution for managing a file name change in a fixed location**

```plaintext
1 RewriteEngine on
2 RewriteBase /~quux/
3 RewriteRule ^foo\.html$ bar.html
```

**Citrix ADC solution for managing a file name change in a fixed location**

```plaintext
1 add rewrite action act1 replace 'HTTP.REQ.URL.AFTER_STR("/~quux").SUBSTR("foo.html")' '"bar.html"
2 add rewrite policy poll 'HTTP.REQ.URL.ENDSWITH("/~quux/foo.html")' act1
3 bind rewrite global poll 100
```

**Citrix ADC solution for managing a file name change regardless of the base directory or query strings in the URL**

```plaintext
1 add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX(\'\'/\',0)' '" bar.html"
2 Add rewrite policy poll 'HTTP.REQ.URL.PATH.CONTAINS("foo.html")' act1
3 Bind rewrite global poll 100
```

**Redirecting to new file name (user-visible URL)**

If you rename a Web page, you may want to continue to support the old URL for backward compatibility and allow users to see that the page was renamed by changing the URL that is displayed in the browser.

In the first two of the following examples, redirection occurs when the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

**Apache mod_rewrite solution for changing the file name and the URL displayed in the browser**
Citrix ADC 13.0

Citrix ADC solution for changing the file name and the URL displayed in the browser

```
1 RewriteEngine on
2 RewriteBase ~/quux/
3 RewriteRule ^old\.html$ new\.html [R]
```

Citrix ADC solution for changing the file name and the URL displayed in the browser regardless of the base directory or query strings in the URL

```
1 add responder action act1 redirect 'HTTP.REQ.URL.BEFORE_STR("foo.html") +"new.html"' -bypassSafetyCheck yes
2 add responder policy pol1 'HTTP.REQ.URL.ENDSWITH("/\~quux/old.html")' act1
3 bind responder global pol1 100
```

Accommodating browser dependent content

To accommodate browser-specific limitations—at least for important top-level pages—it is sometimes necessary to set restrictions on the browser type and version. For example, you might want to set a maximum version for the latest Netscape variants, a minimum version for Lynx browsers, and an average feature version for all others.

The following examples act on the HTTP header “User-Agent”, such that if this header begins with “Mozilla/3”, the page MyPage.html is rewritten to MyPage.NS.html. If the browser is “Lynx” or “Mozilla” version 1 or 2, the URL becomes MyPage.20.html. All other browsers receive page MyPage.32.html.

Apache mod_rewrite solution for browser-specific settings

```
1 RewriteCond %{HTTP_USER_AGENT} ^Mozilla/3.*
2 RewriteRule ^MyPage\..html$ MyPage.NS.html [L]
```
Blocking access by robots

You can block a robot from retrieving pages from a specific directory or a set of directories to ease up the traffic to and from these directories. You can restrict access based on the specific location or you can block requests based on information in User-Agent HTTP headers.

In the following examples, the Web location to be blocked is /~quux/foo/arc/, the IP addresses to be blocked are 123.45.67.8 and 123.45.67.9, and the robot’s name is NameOfBadRobot.

Apache mod_rewrite solution for blocking a path and a User-Agent header

```apache
RewriteCond %{HTTP_USER_AGENT} ^Lynx/.* [OR]
RewriteRule ^MyPage\..html$ MyPage.20.html [L]
RewriteRule ^fMyPage\..html$ MyPage.32.html [L]
Citrix ADC solution for browser-specific settings
add patset pat1
bind patset pat1 Mozilla/1
bind Patset pat1 Mozilla/2
bind patset pat1 Lynx
bind patset pat1 Mozilla/3
add rewrite action act1 insert_before 'HTTP.REQ.URL.SUFFIX' '"NS."
add rewrite action act2 insert_before 'HTTP.REQ.URL.SUFFIX' '"20."
add rewrite action act3 insert_before 'HTTP.REQ.URL.SUFFIX' '"32."
add rewrite policy pol1 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX ("pat1").EQ(4)' act1
add rewrite policy pol2 'HTTP.REQ.HEADER("User-Agent").STARTSWITH_INDEX ("pat1").BETWEEN(1,3)' act2
add rewrite policy pol3 '!HTTP.REQ.HEADER("User-Agent").STARTSWITH_ANY ("pat1")' act3
bind rewrite global pol1 101 END
bind rewrite global pol2 102 END
bind rewrite global pol3 103 END
```
Citrix ADC solution for blocking a path and a User-Agent header

```
1 add responder action act1 respondwith '"HTTP/1.1 403 Forbidden\r\n\n"
2 add responder policy pol1 'HTTP.REQ.HEADER("User_Agent").STARTSWITH("NameOfBadRobot")&&CLIENT.IP.SRC.EQ(123.45.67.8)\n&& HTTP.REQ.URL.STARTSWITH('/~quux/foo/arc')' act1
3 bind responder global pol1 100
```

Blocking access to inline images

If you find people frequently going to your server to copy inline graphics for their own use (and generating unnecessary traffic), you may want to restrict the browser’s ability to send an HTTP Referer header.

In the following example, the graphics are located in Example.

Apache mod_rewrite solution for blocking access to an inline image

```
1 RewriteCond %{HTTP_REFERER} !^http://www.quux-corp.de/~quux/.*$
2 RewriteRule .*\.png$ - [F]
```

Citrix ADC solution for blocking access to an inline image

```
1 add patset pat1
2 bind patset pat1 .png
3 bind patset pat1 .jpeg
4 add responder action act1 respondwith '"HTTP/1.1 403 Forbidden\r\n\n"
```
Creating extensionless links

To prevent users from knowing application or script details on the server side, you can hide file extensions from users. To do this, you may want to support extensionless links. You can achieve this behavior by using rewrite rules to add an extension to all requests, or to selectively add extensions to requests.

The first two of the following examples show adding an extension to all request URLs. In the last example, one of two file extensions is added. Note that in the last example, the mod_rewrite module can easily find the file extension because this module resides on the Web server. In contrast, the Citrix ADC must invoke an HTTP callout to check the extension of the requested file on the Web server. Based on the callout response, the Citrix ADC adds the .html or .php extension to the request URL.

**Note**

In the second Citrix ADC example, an HTTP callout is used to query a script named file_check.cgi hosted on the server. This script checks whether the argument that is provided in the callout is a valid file name.

**Apache mod_rewrite solution for adding a .php extension to all requests**

```plaintext
1 RewriteRule ^/?([a-z]+)$ $1.php [L]
```

**Citrix ADC policy for adding a .php extension to all requests**

```plaintext
1 add rewrite action act1 insert_after 'HTTP.REQ.URL' "'.php"'
2 add rewrite policy pol1 'HTTP.REQ.URL.PATH.REGEX_MATCH(re#^/([a-z]+)$#)'	act1
3 bind rewrite global pol1 100
```

**Apache mod_rewrite solution for adding either .html or .php extensions to requests**

```plaintext
1 RewriteCond %{REQUEST_FILENAME} 
2 REQUEST_FILENAME }
```
Redirecting a Working URI to a New Format

Suppose that you have a set of working URLs that resemble the following:

```
/index.php?id=nnnn
```

To change these URLs to /nnnn and make sure that search engines update their indexes to the new URI format, you need to do the following:
- Redirect the old URIs to the new ones so that search engines update their indexes.
- Rewrite the new URI back to the old one so that the index.php script runs correctly.

To accomplish this, you can insert marker code into the query string (making sure that the marker code is not seen by visitors), and then removing the marker code for the index.php script.

The following examples redirect from an old link to a new format only if a marker is not present in the query string. The link that uses the new format is re-written back to the old format, and a marker is added to the query string.

**Apache mod_rewrite solution**

```apache
1  RewriteCond %{QUERY_STRING} !marker
2  RewriteCond %{QUERY_STRING} id=[-a-zA-Z0-9_]+)
3  RewriteRule ^/index.php$ %1? [R,L]
4  RewriteRule ^/([-a-zA-Z0-9_]+)$ index.php?marker&id=$1 [L]
5  Citrix ADC solution
6  add responder action act_redirect redirect 'HTTP.REQ.URL.PATH.
7     'BEFORE_STR("index.php")+HTTP.REQ.URL.QUERY.VALUE("id")' -
8     bypassSafetyCheck yes
9  add responder policy pol_redirect '!HTTP.REQ.URL.QUERY.CONTAINS("marker
10     ")&& HTTP.REQ.URL.QUERY.VALUE("id").REGEX_MATCH(re/[-a-zA-Z0-9_]+/)
11     && HTTP.REQ.URL.PARAMS.CONTAINS("index.php")' act_redirect
12  bind responder global pol_redirect 100 END
13  add rewrite action act1 replace 'HTTP.REQ.URL.QUERY.SUFFIX(\'/\',0)' ''
14     index.php?marker&id"+HTTP.REQ.URL.QUERY.SUFFIX(\'/\',0)' -
15     bypassSafetyCheck yes
16  add rewrite policy poll '!HTTP.REQ.URL.QUERY.CONTAINS("marker")' act1
17  bind rewrite global poll 100 END
```

**Ensuring That a Secure Server Is Used for Selected Pages**

To make sure that only secure servers are used for selected Web pages, you can use the following Apache mod_rewrite code or Citrix ADC Responder policies.

**Apache mod_rewrite solution**
Citrix ADC 13.0

**Citrix ADC solution using regular expressions**

```plaintext
1 add responder action res_redirect redirect "https://www.example.com"+ HTTP.REQ.URL -bypassSafetyCheck yes
2 add responder policy pol_redirect '!CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.REGEX_MATCH(re/page[1-5]/)’ res_redirect
3 bind responder global pol_redirect 100 END
```

**Citrix ADC solution using pattern sets**

```plaintext
1 add patset pat1
2 bind patset pat1 page1
3 bind patset pat1 page2
4 bind patset pat1 page3
5 bind patset pat1 page4
6 bind patset pat1 page5
7 add responder action res_redirect redirect "https://www.example.com"+ HTTP.REQ.URL -bypassSafetyCheck yes
8 add responder policy pol_redirect '!CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.CONTAINS_ANY("pat1")’ res_redirect
9 bind responder global pol_redirect 100 END
```

**Rate limiting**

February 12, 2020

The rate limiting feature enables you to define the maximum load for a given network entity or virtual entity on the Citrix ADC appliance. The feature enables you to configure the appliance to monitor the rate of traffic associated with the entity and take preventive action, in real time, based on the traffic...
rate. This feature is particularly useful when the network is under attack from a hostile client that is sending the appliance a flood of requests. You can mitigate the risks that affect the availability of resources to clients, and you can improve the reliability of the network and the resources that the appliance manages.

You can monitor and control the rate of traffic that is associated with virtual and user-defined entities, including virtual servers, URLs, domains, and combinations of URLs and domains. You can throttle the rate of traffic if it is too high, base information caching on the traffic rate, and redirect traffic to a given load balancing virtual server if the traffic rate exceeds a predefined limit. You can apply rate-based monitoring to HTTP, TCP, and DNS requests.

To monitor the rate of traffic for a given scenario, you configure a rate limit identifier. A rate limit identifier specifies numeric thresholds such as the maximum number of requests or connections (of a particular type) that are permitted in a specified time period called a time slice.

Optionally, you can configure filters, known as stream selectors, and associate them with rate limit identifiers when you configure the identifiers. After you configure the optional stream selector and the limit identifier, you must invoke the limit identifier from a default syntax policy. You can invoke identifiers from any feature in which the identifier may be useful, including rewrite, responder, DNS, and integrated caching.

You can globally enable and disable SNMP traps for rate limit identifiers. Each trap contains cumulative data for the rate limit identifier’s configured data collection interval (time slice), unless you specified multiple traps to be generated per time slice. For more information about configuring SNMP traps and managers, see SNMP.

Copied!

Failed!

**Configuring a Stream Selector**

February 12, 2020

A traffic stream selector is an optional filter for identifying an entity for which you want to throttle access. The selector is applied to a request or a response and selects data points (keys) that can be analyzed by a rate stream identifier. These data points can be based on almost any characteristic of the traffic, including IP addresses, subnets, domain names, TCP or UDP identifiers, and particular strings or extensions in URLs.

A stream selector consists of individual default syntax expressions called selectlets. Each selectlet is a non-compound default syntax expression. A traffic stream selector can contain up to five non-compound expressions called selectlets. Each selectlet is considered to be in an AND relationship with the other expressions. Following are some examples of selectlets:
The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the Citrix ADC considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the Citrix ADC, again, can count the same transaction more than once.

Note: If you modify an expression in a stream selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a stream selector named myStreamSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myStreamSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

To configure a traffic stream selector by using the command line interface

At the command prompt, type:

```
add stream selector <name> <rule> ...
```

Example:

```
add stream selector myStreamSel HTTP.REQ.URL CLIENT.IP.SRC
```

To configure a stream selector by using the configuration utility

Navigate to AppExpert > Rate Limiting > Selectors, click Add and specify the relevant details.

Configuring a Traffic Rate Limit Identifier

April 2, 2020
A rate limit identifier checks if the amount of traffic exceeds a specified value, within a particular time interval. The identifier returns a “Boolean TRUE” if the amount of traffic exceeds a limit within a particular time interval. When you include a limit identifier in the compound default syntax expression in a policy rule, you must include a stream selector. If you do not specify, the limit identifier is applied to all requests or responses identified by the compound expressions.

Note:
The maximum length for storing string results (for example, HTTP.REQ.URL) is 60 characters. If the string (for example, URL) is 1000 characters long, out of which 50 characters are long enough to uniquely identify a string, you can use an expression to extract required 50 characters.

**To configure a traffic limit identifier from the command line interface**

At the command prompt, type:

```
add ns limitIdentifier <limitIdentifier> -threshold <positive_integer> -timeSlice <positive_integer> -mode <mode> -limitType ( BURSTY | SMOOTH ) -selectorName <string> -maxBandwidth <positive_integer> -trapsInTimeSlice <positive_integer>
```

**Argument description**

**limitIdentifier.** Name for a rate limit identifier. Must begin with an ASCII letter or underscore (_) character, and must consist only of ASCII alphanumeric or underscore characters. Reserved words must not be used. This is a mandatory argument. Maximum Length: 31

**threshold.** A maximum number of requests that are allowed in the given timeslice when requests (mode is set as REQUEST_RATE) are tracked per timeslice. When connections (mode is set as CONNECTION) are tracked, it is the total number of connections that would be let through. Default value: 1 Minimum value: 1 Maximum Value: 4294967295

**timeSlice.** Time interval, in milliseconds, specified in multiples of 10, during which requests are tracked to check if they cross the threshold. This argument is needed only when the mode is set to REQUEST_RATE. Default value: 1000 Minimum value: 10 Maximum Value: 4294967295

**mode.** Defines the type of traffic to be tracked.

1. REQUEST_RATE. Tracks requests/timeslice.
2. CONNECTION. Tracks active transactions.

**limitType.** Smooth or bursty request type.
**selectorName.** Name of the rate limit selector. If this argument is NULL, rate limiting will be applied on all traffic received by the virtual server or the Citrix ADC (depending on whether the limit identifier is bound to a virtual server or globally) without any filtering. **Maximum Length:** 31

**maxBandwidth.** Maximum bandwidth permitted, in kbps. Minimum value: 0 Maximum value: 4294967287

**Example:**

Configuring traffic rate limit identifier in BURSTY mode:

```
1 add ns limitIdentifier 100_request_limit -threshold 100 -timeSlice 1000
   -mode REQUEST_RATE -limitType BURSTY -selectorName
   limit_100_requests_selector -trapsInTimeSlice 30
```

Configuring traffic rate limit identifier in SMOOTH mode:

```
1 add ns limitIdentifier limit_req -mode request_rate -limitType smooth -
   timeslice 1000 -Threshold 2000 -trapsInTimeSlice 200
```

**To configure a traffic limit identifier by using the configuration utility**

Navigate to AppExpert > Rate Limiting > Limit Identifiers, click Add and specify the relevant details.

**Configuring and Binding a Traffic Rate Policy**

April 23, 2019

You implement rate-based application behavior by configuring a policy in an appropriate Citrix ADC feature. The feature must support default syntax policies. The policy expression must contain the following expression prefix to enable the feature to analyze the traffic rate:

```
1 sys.check_limit(<limit_identifier>)
```

Where limit_identifier is the name of a limit identifier.

The policy expression must be a compound expression that contains at least two components:

- An expression that identifies traffic to which the rate limit identifier is applied. For example:

```
1 http.req.url.contains("my_aspx.aspx")
```
• An expression that identifies a rate limit identifier, for example, sys.check_limit("my_limit_identifier"). This must be the last expression in the policy expression.

To configure a rate-based policy by using the command line interface

At the command prompt, type the following command to configure a rate-based policy and verify the configuration:

```
add cache|dns|rewrite|responder policy <policy_name> -rule expression && sys.check_limit("<LimitIdentifierName>") [feature-specific information]
```

Following is a complete example of a rate-based policy rule. Note that this example assumes that you have configured the responder action, send_direct_url, that is associated with the policy. Note that the sys.check_limit parameter must be the last element of the policy expression:

```
add responder policy responder_threshold_policy "http.req.url.contains("myindex.html") && sys.check_limit("my_limit_identifier")"

send_direct_url
```

For information about binding a policy globally or to a virtual server, see "Binding Default Syntax Policies."

To configure a rate-based policy by using the configuration utility

1. In the navigation pane, expand the feature in which you want to configure a policy (for example, Integrated Caching, Rewrite, or Responder), and then click Policies.
2. In the details pane, click Add. In Name, enter a unique name for the policy.
3. Under Expression, enter the policy rule, and make sure that you include the sys.check_limit parameter as the final component of the expression. For example:

```
http.req.url.contains("my_aspx.aspx") && sys.check_limit("my_limit_identifier")
```

4. Enter feature-specific information about the policy.
   For example, you may be required to associate the policy with an action or a profile. For more information, see the feature-specific documentation.
5. Click Create, and then click Close.
6. Click Save.
Viewing the Traffic Rate

April 23, 2019

If traffic through one or more virtual servers matches a rate-based policy, you can view the rate of this traffic. The rate statistics are maintained in the limit identifier that you named in the rule for the rate-based policy. If more than one policy uses the same limit identifier, you can view the traffic rate as defined by hits to all of the policies that use the particular limit identifier.

To view the traffic rate by using the command line interface

At the command prompt, type the following command to view the traffic rate:

```
show ns limitSessions <limitIdentifier>
```

Example:

```
sh limitsession myLimitSession
```

To view the traffic rate by using the configuration utility

1. Navigate to AppExpert > Rate Limiting > Limit Identifiers.
2. Select a limit identifier whose traffic rate you want to view.
3. Click the Show Sessions button. If traffic through one or more virtual servers has matched a rate limiting policy that uses this limit identifier (and the hits are within the configured time slice for this identifier), the Session Details dialog box appears. Otherwise, you receive a “No session exists” message.

Testing a Rate-Based Policy

April 23, 2019
To test a rate-based policy, you can send traffic to any virtual server to which a rate-based policy is bound.

**Task overview: Testing a rate-based policy**

1. Configure a stream selector (optional) and a rate limit identifier (required). For example:

   ```
   1 add stream selector sel_subnet Q.URL "CLIENT.IP.SRC.SUBNET(24)"
   2 add ns limitIdentifier k_subnet -Threshold 4 -timeSlice 3600 -mode REQUEST_RATE -limittype smooth -selectorName sel_subnet -trapsInTimeSlice 8
   ```

2. Configure the action that you want to associate with the policy that uses the rate limit identifier. For example:

   ```
   1 add responder action resp_redirect redirect "http://response_site.com/"
   ```

3. Configure a policy that uses the sys.check_limit expression prefix to call the rate limit identifier. For example, the policy can apply a rate limit identifier to all requests arriving from a particular subnet, as follows:

   ```
   1 add responder policy resp_subnet "SYS.CHECK_LIMIT("k_subnet")"
   resp_redirect
   ```

4. Bind the policy globally or to a virtual server. For example:

   ```
   1 bind responder global resp_subnet 6 END -type DEFAULT
   ```

5. In a browser address bar, send a test HTTP query to a virtual server. For example:

   ```
   1 http://<IP of a vserver>/testsuite/test.txt
   ```

6. At the Citrix ADC command prompt, type:

   ```
   1 show ns limitSessions \<limitIdentifier>\>
   ```

**Example**

```
1 > sh limitsession k_subnet
2 1) Time Remaining: 98 secs Hits: 2 Action Taken: 0
3 Total Hash: 1718618 Hash String: /test.txt
4 IPs gathered:
```
5  1) 10.217.253.0
6  Active Transactions: 0
7  Done
8  >

7. Repeat the query and check the limit identifier statistics again to verify that the statistics are being updated correctly.

Examples of Rate-Based Policies

April 23, 2019

The following table shows examples of rate-based policies.
<table>
<thead>
<tr>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit the number of requests per second from a URL</td>
<td>add stream selector ipStreamSelector http.req.url &quot;client.ip.src&quot; add ns limitIdentifier ipLimitIdentifier -threshold 4 -timeSlice 1000 -mode request_rate -limitType smooth -selectorName ipStreamSelector add responder action myWebsiteRedirectAction redirect &quot;\<a href="http://www.mycompany.com/">http://www.mycompany.com/</a>&quot; add responder policy ipLimitResponderPolicy 'http.req.url.contains(&quot;myasp.asp&quot;) &amp;&amp; sys.check_limit(&quot;ipLimitIdentifier&quot;)' myWebsiteRedirectAction bind responder global ipLimitResponderPolicy 100 END -type default</td>
</tr>
<tr>
<td>Cache a response if the request URL rate exceeds 5 per 20000 milliseconds</td>
<td>add stream selector cacheStreamSelector http.req.url add ns limitIdentifier cacheRateLimitIdentifier -threshold 5 -timeSlice 2000 -selectorName cacheStreamSelector add cache policy cacheRateLimitPolicy -rule 'http.req.method.eq(get) &amp;&amp; sys.check_limit(&quot;cacheRateLimitIdentifier&quot;)' -action cache bind cache global cacheRateLimitPolicy -priority 10</td>
</tr>
<tr>
<td>Drop a connection on the basis of cookies received in requests from <a href="http://www.yourcompany.com">www.yourcompany.com</a> if the requests exceed the rate limit</td>
<td>add stream selector reqCookieStreamSelector 'http.req.cookie .value(&quot;mycookie&quot;)' &quot;client.ip.src.subnet(24)&quot; add ns limitIdentifier myLimitIdentifier -Threshold 2 -timeSlice 3000 -selectorName reqCookieStreamSelector add responder action sendRedirectUrl redirect &quot;\<a href="http://www.mycompany.com/">http://www.mycompany.com/</a>&quot; + http.req.url&quot; -bypassSafetyCheck YES add responder policy rateLimitCookiePolicy 'http.req.url.contains(&quot;www.yourcompany.com&quot;) &amp;&amp; sys.check_limit(&quot;myLimitIdentifier&quot;)' sendRedirectUrl</td>
</tr>
<tr>
<td>Drop a DNS packet if the requests from a particular client IP address and DNS domain exceed the rate limit</td>
<td>add stream selector dropDNSStreamSelector client.udp.dns.domain client.ip.src add ns limitIdentifier dropDNSRateIdentifier -timeSlice 20000 -mode request_rate -selectorName dropDNSStreamSelector -maxBandwidth 1 -transintimeslice 20 add dns policy dnsDropOnClientRatePolicy &quot;sys.check_limit (!&quot;dropDNSRateIdentifier&quot;)&quot; -drop yes</td>
</tr>
<tr>
<td>Limit the number of HTTP requests that arrive from the same host (with a subnet mask of 32) and that have the same destination IP address</td>
<td>add stream selector ipv6_sel &quot;CLIENT.IPv6.src.subnet(32)&quot; CLIENT.IPv6.dst Q.URL add ns limitIdentifier ipv6_id -timeSlice 20000 -selectorName ipv6_sel add lb vserver ipv6_vip HTTP 3ffe:209 80 -persistenceType NONE -ctlTimeout 180 add responder action redirect_page redirect &quot;\<a href="http://redirectpage.com/">http://redirectpage.com/</a>&quot; add responder policy ipv6_resp_pol1 &quot;SYS.CHECK_LIMIT(!&quot;ipv6_id&quot;)&quot; redirect_page bind responder global ipv6_resp_pol 5 END -type DEFAULT</td>
</tr>
</tbody>
</table>
Sample Use Cases for Rate-Based Policies

February 13, 2020

The following scenarios describe two uses of rate-based policies in global server load balancing (GSLB):

- The first scenario describes the use of a rate-based policy that sends traffic to a new data center if the rate of DNS requests exceed 1000 per second.
- In the second scenario, if more than five DNS requests arrive for a local DNS (LDNS) client within a particular period, the additional requests are dropped.

Redirecting Traffic on the Basis of Traffic Rate

In this scenario, you configure a proximity-based load balancing method, and a rate-limiting policy that identifies DNS requests for a particular region. In the rate-limiting policy, you specify a threshold of 1000 DNS requests per second. A DNS policy applies the rate limiting policy to DNS requests for the region “Europe.GB.17.London.UK-East.ISP-UK.” In the DNS policy, DNS requests that exceed the rate limiting threshold, starting with request 1001 and continuing to the end of the one-second interval, are to be forwarded to the IP addresses that are associated with the region “North America.US.TX.Dallas.US-East.ISP-US.”

The following configuration demonstrates this scenario:

```
1  add stream selector DNSSelector1 client.udp.dns.domain
2 3  add ns limitIdentifier DNSLimitIdentifier1 -threshold 5 -timeSlice 1000
   -selectorName DNSSelector1
4 5  add dns policy DNSLimitPolicy1 "client.ip.src.matches_location("Europe
   .GB.17.London.*.*") &&
   6  sys.check_limit("DNSLimitIdentifier1")" -preferredLocation "North
   America.US.TX.Dallas.*.*"
7 8  bind dns global DNSLimitPolicy1 5
```

Dropping DNS Requests on the Basis of Traffic Rate

In the following example of global server load balancing, you configure a rate limiting policy that permits a maximum of five DNS requests in a particular interval, per domain, to be directed to an LDNS
client for resolution. Any requests that exceed this rate are dropped. This type of policy can help pro-
tect the Citrix ADC from resource exploitation. For example, in this scenario, if the time to live (TTL) for a connection is five seconds, this policy prevents the LDNS from requerying a domain. Instead, it uses data that is cached on the Citrix ADC.

```
1. add stream selector LDNSSelector1 client.udp.dns.domain client.ip.src
2. add ns limitIdentifier LDNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName LDNSSelector1
3. add dns policy LDNSPolicy1 "client.udp.dns.domain.contains(".") && sys.check_limit("LDNSLimitIdentifier1")" -drop YES
4. bind dns global LDNSPolicy1 6
5. show gslb vserver gvip
6. gvip - HTTP State: UP
7. Last state change was at Mon Sep 8 11:50:48 2008 (+711 ms)
8. Time since last state change: 1 days, 02:55:08.830
9. Configured Method: STATICPROXIMITY
10. BackupMethod: ROUNDROBIN
11. No. of Bound Services : 3 (Total) 3 (Active)
12. Persistence: NONE Persistence ID: 100
13. Disable Primary Vserver on Down: DISABLED Site Persistence: NONE

```
Rate Limiting for Traffic Domains

April 23, 2019

You can configure rate limiting for traffic domains. The following expression in the Citrix ADC expressions language for identifies traffic associated with traffic domains.

- client.traffic_domain.id

You can configure rate limiting for traffic associated with a particular traffic domain, a set of traffic domains, or all traffic domains.

For configuring rate limiting for traffic domains, you perform the following steps on a Citrix ADC appliance by using the configuration utility or the Citrix ADC command line:

1. Configure a stream selector that uses the client.traffic_domain.id expression for identifying the traffic, associated with traffic domains, to be rate limited.
2. Configure a rate limit identifier that specifies parameters such as maximum threshold for traffic to be rate limited. You also associate a stream selector to the rate limiter in this step.
3. Configure an action that you want to associate with the policy that uses the rate limit identifier.
4. Configure a policy that uses the sys.check_limit expression prefix to call the rate limit identifier, and associate the action with this policy.
5. Bind the policy globally.

Consider an example in which two traffic domains, with IDs 10 and 20, are configured on Citrix ADC NS1. On traffic domain 10, LB1-TD-1 is configured to load balance servers S1 and S2; LB2-TD1 is configured to load balance servers S3 and S4.

On traffic domain 20, LB1-TD-2 is configured to load balance servers S5 and S6; LB2-TD2 is configured to load balance servers S7 and S8.

The following table lists some examples of rate limiting policies for traffic domains in the example setup.
<table>
<thead>
<tr>
<th>Purpose</th>
<th>CLI commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit the number of requests to 10 per second for each of the traffic domains.</td>
<td>add stream selector tdratelimit-1 CLIENT.TRAFFIC.DOMAIN.ID add ns limitIdentifier limitidf-1 -threshold 10 -selectorName tdratelimit-1 -trapsInTimeSlice 0 add responder policy ratelimit-pol “sys.check_limit(&quot;limitidf-1&quot;)” DROP bind responder global ratelimit-pol 1</td>
</tr>
<tr>
<td>Limit the number of requests to 5 per client per second for each of the traffic domains.</td>
<td>add stream selector tdandclientip CLIENT.IP.SRC,CLIENT.TRAFFIC.DOMAIN.ID add ns limitIdentifier td_limitidf -threshold 5 -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy tdratelimit-pol “sys.check_limit(&quot;td_limitidf&quot;)” DROP bind responder global tdratelimit-pol 2</td>
</tr>
<tr>
<td>Limit the number of requests sent for a particular traffic domain (for example traffic domain 10) to 30 requests every 3 seconds.</td>
<td>add stream selector tdratelimit CLIENT.TRAFFIC.DOMAIN.ID add ns limitIdentifier td10_limitidf -threshold 30 -timeSlice 3000 -selectorName tdratelimit -trapsInTimeSlice 5 add responder policy td10ratelimit “client.traffic_domain.id==10 &amp;&amp; sys.check_limit(&quot;td10_limitidf&quot;)” DROP bind responder global td10ratelimit 3</td>
</tr>
<tr>
<td>Limit the number of connections to 5 per client per second for a particular traffic domain (for example traffic domain 20).</td>
<td>add stream selector tdandclientip CLIENT.IP.SRC CLIENT.TRAFFIC.DOMAIN.ID add ns limitIdentifier td20_limitidf -threshold 5 -mode CONNECTION -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy td20_ratelimit “client.traffic_domain.id==20 &amp;&amp; sys.check_limit(&quot;td20_limitidf&quot;)” DROP bind responder global td20_ratelimit 4</td>
</tr>
</tbody>
</table>
Configure rate limit at packet level

February 12, 2020

You can configure a stream selector and a responder policy to collect statistics at the packet level flowing through all the connections identified by the selector. If the number of packets per second exceed the configured threshold, the policy applies the configured action (RESET or DROP). You can configure these policies for all types of virtual servers. Packets of all sizes are considered.

To configure rate limiting at packet level, perform the following tasks

1. Enable load balancing
2. Add stream selector
3. Add stream identifier
4. Add responder policy
5. Add load balancing virtual server
6. Bind responder policy

To enable load balancing feature

At the command prompt, type:

```
1 enable ns feature lb
```

To add a stream selector

At the command prompt, type:

```
1 add stream selector packetlimitselector client.ip.src client.tcp.srcport client.ip.dst client.tcp.dstport
```

To add a stream identifier

At the command prompt, type:

```
1 add stream identifier packetlimitidentifier packetlimitselector -interval 1
```
To enable tracking of ACK only packets

At the command prompt, type:

```
set stream identifier packetlimitidentifier -trackAckOnlyPackets ENABLED
```

To add a responder policy

At the command prompt, type:

```
add responder policy packet_rate_sessionpolicy "ANALYTICS.STREAM(\"packetlimitidentifier\")\).COLLECT_STATS("PACKET_LIMIT\", \<max_threshold_PPS\>, ACTION, 0/1)" NOOP
```

Where,

- `<max_threshold_PPS>` is the maximum number of packets allowed through the connection per second.
- ACTION can be DROP or RESET.
- 0 or 1 represents the limit type; 0 represents the BURSTY limit type and 1 represents the SMOOTH limit type.

Example:

```
add responder policy packet_rate_sessionpolicy "ANALYTICS.STREAM(\"packetlimitidentifier\")\).COLLECT_STATS("PACKET_LIMIT\", 40, RESET, 0)" NOOP
```

To add a load balancing virtual server

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
ad lb vserver Vserver-lb-1 HTTP 10.102.20.200 80
```

To bind a responder policy

After the selector and the responder policy are configured, the policy can be bound globally or to the specific virtual server.

At the command prompt, type either of the following commands:
Responder

July 10, 2020

Warning

Filter features using classic policies are deprecated and as an alternative Citrix recommends you to use the rewrite and responder features with advanced policy infrastructure.

Today’s complex Web configurations often require different responses to HTTP requests that appear, on the surface, to be similar. When users request a webpage, you may want to provide a different page depending on the user geographical location, browser specification, or languages the browser accepts and the order of preference. You might want to drop the connection if the request is coming from an IP range that has been generating DDoS attacks or initiating hacking attempts.

Responder supports protocols such as TCP, DNS (UDP), and HTTP. With responder enabled on your appliance, server responses can be based on who sends the request, where it is sent from, and other criteria with security and system management implications. The feature is simple and quick to use. By avoiding the invocation of more complex features, it reduces CPU cycles and time spent in handling requests that do not require complex processing.
For handling sensitive data such as financial information, if you want to ensure that the client uses a secure connection to browse a site, you can redirect the request to a secure connection by using https: instead of http://.

To use a responder, do the following:

- Enable a responder feature on the appliance.
- Configure a responder action. The action can be to generate a custom response, redirect a request to a different webpage, or reset a connection.
- Configure a responder policy. The policy determines the requests (traffic) on which an action has to be taken.
- Bind each policy to a bind point put it into effect. A bind point refers to an entity at which the Citrix ADC appliance examines the traffic to see if it matches a policy. For example, a bind point can be a load balancing virtual server.

You can specify a default action for requests that do not match any policy, and you can bypass the safety check for actions that would otherwise generate error messages.

The Rewrite feature of Citrix ADC helps in rewriting some information in the requests or responses handled by Citrix ADC. The following section shows some differences between the two features.

**Comparison between Rewrite and Responder options**

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting an HTTP request to new websites or webpages
- Responding with some custom response
- Dropping or resetting a connection at request level

If there is a responder policy, the Citrix ADC examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

If there is a rewrite policy, the Citrix ADC examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use a responder if you want the appliance to reset or drop a connection based on a request-based parameter. Use a responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.
Enabling the Responder Feature

To use the Responder feature, you must first enable it.

To enable the responder feature by using the Citrix ADC command line:

At the command prompt, type the following commands to enable the responder feature and verify the configuration:

- `enable ns feature <feature>`
- `show ns feature`

**Example:**

```
1   enable ns feature Responder
2     Done
3     > show ns feature
```

### Feature | Acronym | Status
---|---|---
1) Web Logging | WL | ON
2) Surge Protection | SP | ON
1) Responder | RESPONDER | ON
2) HTML Injection | HTMLInjection | ON
3) Citrix ADC Push | push | OFF
```

To enable the responder feature by using the GUI:

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes** and **Features**, click **Change advanced features**.
3. In the **Configure Advanced Features** dialog box, select the **Responder** check box, and then click **OK**.
4. In the **Enable/Disable Feature(s)?** dialog box, click **YES**. A message appears in the status bar, stating that the feature has been enabled.
Configurer responder action

July 29, 2020

After enabling the responder feature, you must configure one or more actions for handling requests. The responder supports the following types of actions:

- **Respond with.** Sends the response defined by the Target expression without forwarding the request to a web server. (The Citrix ADC appliance substitutes for and acts as a web server.) Use this type of action to manually define a simple HTML-based response. Normally the text for a Respond with action consists of a web server error code and brief HTML page.

- **Respond with SQL OK.** Sends the designated SQL OK response defined by the Target expression. Use this type of action to send an SQL OK response to an SQL query.

- **Respond with SQL Error.** Sends the designated SQL Error response defined by the Target expression. Use this type of action to send an SQL Error response to an SQL query.

- **Respond with HTML page.** Sends the designated HTML page as the response. You can choose from a drop-down list of HTML pages that were previously uploaded, or upload a new HTML page. Use this type of action to send an imported HTML page as the response. The appliance responds with a custom header in the respondwithhtmlpage responder action. You can configure up to eight custom headers.

- **Redirect.** Redirects the request to a different webpage or web server. A Redirect action can redirect requests originally sent to a “dummy” website that exists in DNS, but for which there is no actual web server, to an actual website. It can also redirect search requests to an appropriate URL. Normally, the redirection target for a Redirect action consists of a complete URL.

To configure a responder action by using the Citrix ADC command line:

Displays the current settings for the specified responder action. If no action name is provided, display a list of all responder actions currently configured on the Citrix ADC appliance, with abbreviated settings.

At the command prompt, type the following commands to configure a responder action and verify the configuration:

- add responder action <name> <type> <target> [-bypassSafetyCheck (YES | NO)]
- show responder action

**Parameters:**

- **Name.** Name of the responder action. Maximum Length: 127
- **type.** Type of responder action. It can be: (respondwith).
• **target.** An expression specifying what to respond with

• **htmlpage.** Option specifying to respond with htmlpage

• **bypassSafetyCheck.** The safety check to allow unsafe expressions. **Note:** This attribute is deprecated.

• **hits.** The number of times the action has been taken.

• **referenceCount.** The number of references to the action.

• **undefHits.** The number of times the action resulted in UNDEF.

• **comment.** Any type of information about this responder action.

• **builtin.** Flag to determine whether responder action is built in or not

**Example:**

```
1 To create a responder action that displays a “Not Found” error page for URLs that do not exist:
2
3 > add responder action act404Error respondWith ’”HTTP/1.1 404 Not Found
4 \r\n\r\n"+ HTTP.REQ.URL.HTTP_URL_SAFE + ” does not exist on the web server.”
5 Done
6
7 > show responder action
8 1) Name: act404Error
9 Operation: respondwith
10 Target: ”HTTP/1.1 404 Not Found” + HTTP.REQ.URL.HTTP_URL_SAFE + ” does not exist on the web server.”
11 BypassSafetyCheck : NO
12 Hits: 0
13 Undef Hits: 0
14 Action Reference Count: 0
15 Done
16
17 To create a responder action that displays a “Not Found” error page for URLs that do not exist:
18
19 add responder action act404Error respondWith ’”HTTP/1.1 404 Not Found\r
20 \n\r\n"+ HTTP.REQ.URL.HTTP_URL_SAFE + ” does not exist on the web server.”
21 Done
22 > show responder action
23 1) Name: act404Error
```
To modify an existing responder action by using the Citrix ADC command line:

At the command prompt, type the following command to modify an existing responder action and verify the configuration:

- set responder action <name> -target <string> [-bypassSafetyCheck ( YES | NO )]
  - show responder action

**Example:**

```
set responder action act404Error -target "HTTP/1.1 404 Not Found\r\n\r\n"+ HTTP.REQ.URL.HTTP_URL_SAFE + " does not exist on the web server."
```

To remove a responder action by using the Citrix ADC command line:

At the command prompt, type the following command to remove a responder action and verify the configuration:

- rm responder action <name>
  - show responder action

**Example:**

```
rm responder action act404Error
```
To add custom headers in responsewithhtmlpage responder action by using the Citrix ADC command line:

A Citrix ADC appliance can now respond with custom headers in the responsewithhtmlpage responder action. You can configure up to eight custom headers. Previously, the appliance responded only with Content-type:text/html and Content-Length:<value> static headers.

Note:
In the custom header configuration, you can also over-write the “Content-Type” header value.

At the command prompt, type the following command:

```
add responder action <name> <type> (<target> | <htmlpage>)[-comment <string>] [-responseStatusCode <positive_integer>] [-reasonPhrase <expression>] [-headers <name(value)> ...]
```

Where,

name. Name for the responder action. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.), hash (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the responder policy is added.

Type. Type of responder action. Available settings function as follows:

1. respondwith <target> - Respond to the request with the expression specified as the target.
2. responsewithhtmlpage - Respond to the request with the uploaded HTML page object specified as the target.
3. redirect - Redirect the request to the URL specified as the target.
4. sqlresponse_ok - Send an SQL OK response.
5. sqlresponse_error - Send an SQL ERROR response. This is a mandatory argument. Possible values: noop, respondwith, redirect, responsewithhtmlpage, sqlresponse_ok, sqlresponse_error

Target. Expression specifying what to respond with. Typically a URL for redirect policies or a default-syntax expression. In addition to Citrix ADC default-syntax expressions that refer to information in the request, a stringbuilder expression can contain text and HTML, and simple escape codes that define new lines and paragraphs. Enclose each stringbuilder expression element (either a Citrix ADC default-syntax expression or a string) in double quotation marks. Use the plus (+) character to join the elements.

htmlpage. For responsewithhtmlpage policies, name of the HTML page object to use as the response. You must first import the page object. Maximum Length: 31
Comment. Any type of information about this responder action. Maximum Length: 255

responseStatusCode. HTTP response status code, for example 200, 302, 404, and so forth. The default value for the redirect action type is 302 and for respondwithhtmlpage is 200 Minimum value: 100 Maximum value: 599

reasonPhrase. Expression specifying the reason phrase of the HTTP response. The reason phrase may be a string literal with quotes or a PI expression. For example: “Invalid URL: “ + HTTP.REQ.URL Maximum Length: 8191

Headers. One or more headers to insert into the HTTP response. Each header is specified as “name(expr),” where expr is an expression that is evaluated at runtime to provide the value for the named header. You can configure a maximum of eight headers for a responder action.

To configure a responder action by using the GUI:

2. In the details pane, do one of the following:
   - To create an action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. Click Create or OK, depending on whether you are creating an action or modifying an existing action.
4. Click Close. A message appears in the status bar, stating that the feature has been enabled.
5. To delete a responder action, select the action, and then click Remove. A message appears in the status bar, stating that the feature has been disabled.

To add an expression by using the Add Expression dialog box

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   - HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SYS. One or more protected websites. Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - ANALYTICS. The analytics data associated with the request. Choose this if you want to examine request metadata.
   - SIP. A SIP request. Choose this if you want to examine some aspect of a SIP request. When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.
3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you
make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Configuring the Global HTTP Action

You can configure the global HTTP action to invoke a responder action when an HTTP request times out. To configure this feature, you must first create the responder action that you want to invoke. Then, you configure the global HTTP timeout action to respond to a timeout with that responder action.

To configure the global HTTP action by using the Citrix ADC command line:

At the command prompt, type the following command:

- set ns httpProfile -reqTimeoutAction <responder action name>
- save ns config

For <responder action name>, substitute the name of the responder action.

Configure HTML page import

When a Citrix ADC appliance responds with a custom message, we can respond with an HTML file. You can import the file using the `import responder htmlpage` command and then use this file in `add responder action <act name> respondwithhtmlpage <file name>` command. You can also import the file through the Citrix ADC GUI. You can import a desired HTML page into the appliance folder and upload the page during responder run time.

Import HTML page by using the CLI

At the command prompt, type:

```
import responder htmlpage [<src>] <name> [-comment <string>] [-overwrite][-CAcertFile <string>]
```

Example:

```
import responder htmlpage http://www.example.com/page.html my-responder-page -CAcertFile my_root_ca_cert
```
Where,
CA certificate is used for verifying the client certificate. The certificate should be imported using “import ssl certfile” CLI command or equivalent through API or GUI. If certificate name is not configured, then default root CA certificates are used for the certificate verification.

Import HTML page by using the Citrix ADC GUI

1. Navigate to **AppExpert > Responder > HTML Page Imports.**
2. In the **Responder HTML Imports** details pane, click **Add.**
3. In the **HTML Page Import Object** page, set the following parameters:
   a) Name. Name of the HTML page.
   b) Import From. Imported from file, text, or text.
   c) URL. Select to enter the URL location of the HTML file.
   d) File. Select the HTML file from the appliance directory.
   e) Text. Select the HTML file as a text.
4. Click **Continue.**
5. Verify responder HTML page details.
6. Click **Done.**

To edit an HTML page, you can select a file and click **Edit Responder HTML Page File** from the **Select Action** drop-down list.
After you configure a responder action, you must next configure a responder policy to select the requests to which the Citrix ADC appliance should respond. A responder policy is based on a rule, which consists of one or more expressions. The rule is associated with an action, which is performed if a request matches the rule.

**Note:** For creating and managing responder policies, the GUI provides assistance that is not available at the Citrix ADC command prompt.

To configure a responder policy by using the Citrix ADC command line:

At the command prompt, type:

- `add responder policy <name> <expression> <action> [undefaction]`-appFlowaction <actionName>
- `show responder policy <name>`

**Example:**

```
1 > add responder policy policyThree "CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)" RESET
2 Done
3 > show responder policy policyThree
```
To modify an existing responder policy by using the Citrix ADC command line:

At the command prompt, type:

• `set responder policy <name> [-rule <expression>] [-action <string>] [-undefAction <string>]`
  • `show responder policy <name>

To remove a responder policy by using the Citrix ADC command line:

At the command prompt, type:

• `rm responder policy <name>`
  • `show responder policy`

Example:

```
1 >rm responder policy pol404Error
2 Done
3
4 > show responder policy
5 Done
```

To configure a responder policy by using the GUI:

1. Navigate to **AppExpert > Responder > Policies**.
2. In the details pane, do one of the following:
   • To create a new policy, click **Add**.
   • To modify an existing policy, select the policy, and then click **Open**.
3. Click **Create** or **OK**, depending on whether you are creating a new policy or modifying an existing policy.
4. Click **Close**. A message appears in the status bar, stating that the feature has been configured.
Binding a Responder Policy

July 29, 2020

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to requests whose destination IP address is the VIP of that virtual server.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the Citrix ADC operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The responder feature implements only the first policy that a request matches, not any additional policies that it might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the Citrix ADC, see Policies and Expressions.

Note:

Responder policies are bound to TCP-based virtual servers.

To globally bind a responder policy by using the Citrix ADC command line:

At the command prompt, type the following command to globally bind a responder policy and verify the configuration:

```
bind responder global <policyName> <priority> [ <gotoPriorityExpression> ] [-type <type>] [-invoke ( <labelType> <labelName> )]
```

```
> bind responder global poliError 100

Done
```

```
> show responder global

1) Global bindpoint: REQ_DEFAULT
   Number of bound policies: 1

Done
```
To bind responder policy to a specific virtual server by using the Citrix ADC command line:

At the command prompt, type:

- `bind lb vserver <name> -policyname <policy_name> -priority <priority>`
- `sh lb vserver <name>`

**Example:**

```
1 > bind lb vserver vs-loadbal -policyname policyTwo -priority 100
Done
3 > show lb vserver
```

1) `vs-loadbal (10.102.29.20:80) - HTTP`  `Type: ADDRESS`
   `State: OUT OF SERVICE`
   `Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)`
   `Time since last state change: 2 days, 00:58:03.260`
   `Effective State: DOWN`
   `Client Idle Timeout: 180 sec`
   `Down state flush: ENABLED`
   `Disable Primary Vserver On Down : DISABLED`
   `Port Rewrite : DISABLED`
   `No. of Bound Services : 0 (Total) 0 (Active)`
   `Configured Method: LEASTCONNECTION`
   `Mode: IP`
   `Persistence: NONE`
   `Vserver IP and Port insertion: OFF`
   `Push: DISABLED`  `Push VServer: none`
   `Push Multi Clients: NO`
   `Push Label Rule: none`

2) `vs-cont-sw (0.0.0.0:0) - TCP`  `Type: ADDRESS`
   `State: DOWN`
   `Last state change was at Wed Aug 19 10:03:46 2009 (+213 ms)`
   `Time since last state change: 2 days, 00:00:04.260`
   `Effective State: DOWN`
   `Client Idle Timeout: 9000 sec`
   `Down state flush: ENABLED`
   `Disable Primary Vserver On Down : DISABLED`
   `No. of Bound Services : 0 (Total) 0 (Active)`
   `Configured Method: LEASTCONNECTION`
   `Mode: IP`
   `Persistence: NONE`
   `Connection Failover: DISABLED`

30 Done

To globally bind a responder policy by using the GUI:

1. Navigate to **AppExpert > Responder > Policies**.
2. On the **Responder Policies** page, select a responder policy, and then click **Policy Manager**.
3. In the **Responder Policy Manager** dialog box Bind Points menu, select Default Global.
4. Click **Insert Policy** to insert a new row and display a drop-down list of all unbound responder policies.
5. Click one of the policies on the list. That policy is inserted into the list of globally bound responder policies.
6. Click **Apply Changes**.
7. Click **Close**. A message appears in the status bar, stating that the configuration has been successfully completed.

To bind a responder policy to a specific virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. On the **Load Balancing Virtual Servers** page, select the virtual server to which you want to bind the responder policy, and then click **Open**.
3. In the **Configure Virtual Server** (Load Balancing) dialog box, select the **Policies** tab, which displays a list of all policies configured on your Citrix ADC appliance.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click **OK**. A message appears in the status bar, stating that the configuration has been successfully completed.

---

**Setting the Default Action for a Responder Policy**

August 12, 2020

The Citrix ADC appliance generates an undefined event (UNDEF event) when a request does not match a responder policy. The appliance then performs the default action assigned to undefined events. By default, the action forwards the request to the next feature such as load balancing, content filtering and so forth. This default behavior ensures the requests do not require any specific responder action to be sent to your Web servers. Also, the clients receive access to the content that they have requested.

If one or more websites your Citrix ADC appliance protects receive a significant number of invalid or malicious requests, however, you might want to change the default action to either reset the client connection or drop the request. In this type of configuration, you would write one or more responder policies that would match any legitimate requests, and simply redirect those requests to their original destinations. Your Citrix ADC appliance would then block any other requests as specified by the default action you configured.

You can assign any one of the following actions to an undefined event:
• **NOOP.** The NOOP action aborts responder processing but does not alter the packet flow. So that the appliance continues to process requests that do not match any responder policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers and is the default setting.

• **RESET.** If the undefined action is set to RESET, the appliance resets the client connection, informing the client that it must re-establish its session with the Web server. The action is appropriate for repeat requests for webpages that do not exist, or for connections that might be attempts to hack or probe your protected websites.

• **DROP.** If the undefined action is set to DROP, the appliance silently drops the request without responding to the client in any way. This action is appropriate for requests that appear to be part of a DDoS attack or other sustained attack on your servers.

**Note:** UNDEF events are triggered only for client requests. No UNDEF events are triggered for responses.

To set the undefined action by using the Citrix ADC command line:

At the command prompt, type the following command to set the undefined action and verify the configuration:

```
set responder param -undefAction (RESET|DROP|NOOP)[-timeout <msecs>]
```

Where,

- **timeout** - Maximum time in milliseconds to allow for processing all the policies and their selected actions without interruption. If the timeout is reached then the evaluation causes an UNDEF to be raised and no further processing is performed.

Minimum value: 1

Maximum value: 5000

**Example:**

```
1 > set responder param -undefAction RESET -timeout 3900
2     Done
3 > show responder param
4     Action Name: RESET
5     Timeout: 3900
6     Done
7 >
```
Set the undefined action by using the GUI

1. Navigate to AppExpert > Responder, and then under Settings, click the Change Responder Settings link.

2. In the Set Responder Params page, set the following parameters:
   a) Global Undefined-Result Action. Undefined-result action is preferred in an unhandled processing exception in the responder policies and actions. Select NOOP, RESET, or DROP.
   b) Timeout. Maximum time in milliseconds to allow for processing all the policies and their selected actions without interruption. If the timeout is reached then the evaluation causes an UNDEF to be raised and no further processing is performed.

3. Click OK.

Configure Responder Params

Global Undefined-Result Action*

- NOOP

Note: Undefined-result action is used in case of an unhandled processing exception.

Timeout

- 3900

OK Close

Responder Action and Policy Examples

April 23, 2019

Responder actions and policies are powerful and complex, but you can get started with relatively simple applications.
Example: Blocking Access from Specified IPs

The following procedures block access to your protected Web site(s) by clients originating from the CIDR 222.222.0.0/16. The responder sends an error message stating that the client is not authorized to access the URL requested.

To block access by using the Citrix ADC command line:

At the command prompt, type the following commands to block access:

- add responder action act_unauthorized respond with “HTTP/1.1 403 Forbidden\r\n\r\n“Client: “ + CLIENT.IP.SRC + “ is not authorized to access URL:” + “HTTP.REQ.URL.HTTP_URL_SAFE”
- add responder policy pol_un “CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)” act_unauthorized
- bind responder global pol_un 10

To block access by using the GUI:

1. In the navigation pane, expand Responder, and then click Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
   a) In the Name text box, type act_unauthorized.
   b) Under Type, select Respond with.
   c) In the Target text area, type the following string: “HTTP/1.1 200 OK\r\n\r\n“Client: “ + CLIENT.IP.SRC + “ is not authorized to access URL:” + HTTP.REQ.URL.HTTP_URL_SAFE
   d) Click Create, and then click Close.

   The responder action you configured, named act_unauthorized, now appears in the Responder Actions page.
4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
   a) In the Name text box, type pol_unauthorized.
   b) Under Action, select act_unauthorized.
   c) In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
   d) Click Create, then click Close.

   The responder policy you configured, named pol_unauthorized, now appears in the Responder Policies page.
7. Globally bind your new policy, pol_unauthorized, as described in Binding a Responder Policy.

Example: Redirecting a client to a new URL

The following procedures redirect clients who access your protected Web site(s) from within the CIDR 222.222.0.0/16 to a specified URL.
To redirect clients by using the Citrix ADC command line:

At the command prompt, type the following commands to redirect clients and verify the configuration:

- add responder action act_redirect redirect "http://www.example.com/404.html"
- show responder action act_redirect
- add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
- show responder policy pol_redirect
- bind responder global pol_redirect 10

**Example:**

1. `> add responder action act_redirect redirect "http://www.example.com/404.html"`
2. `Done`
3. `Add`
4. `> add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect`
5. `Done`

To redirect clients by using the GUI:

1. Navigate to **AppExpert > Responder > Actions**.
2. In the details pane, click **Add**.
3. In the **Create Responder Action** dialog box, do the following:
   a) In the **Name** text box, type act_redirect.
   b) Under **Type**, select **Redirect**.
   c) In the **Target** text area, type the following string: "http://www.example.com/404.html"
   d) Click **Create**, then click **Close**.

   The responder action you configured, named act_redirect, now appears in the **Responder Actions** page.

4. In the navigation pane, click **Policies**.
5. In the details pane, click **Add**.
6. In the **Create Responder Policy** dialog box, do the following:
   a) In the **Name** text box, type pol_redirect.
   c) In the **Expression** window, type the following rule: "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)"
   d) Click **Create**, then click **Close**.

   The responder policy you configured, named pol_redirect, now appears in the **Responder Policies** page.

7. Globally bind your new policy, pol_redirect, as described in **Binding a Responder Policy**.
Diameter Support for Responder

October 1, 2019

The Responder feature now supports the Diameter protocol. You can configure Responder to respond to Diameter requests as it does HTTP and TCP requests. For example, you could configure Responder to respond to requests from a specific Diameter origin with a redirect to a web page enhanced for mobile devices. A number of Citrix ADC expressions have been added that support examination of the Diameter header and the attribute-value pairs (AVPs). These expressions support lookup of specific AVPs by index, ID or name, examine the information in each AVP, and send an appropriate response.

To configure Responder to respond to a Diameter request:

At the command prompt, type the following commands:

- add responder action <actname> RESPONDWITH "DIAMETER.NEW_REDIRECT("aaa://host.example.com")"
  
  For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For aaa://host.example.com, substitute the URL of the diameter host to which you want to redirect connections.

- add responder policy <polname> “diameter.req.avp(264).value.eq("host1.example.net")”<actname>
  
  For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host1.example.net, substitute the name of the originating host of the requests that you want to redirect. For <actname>, substitute the name of the action that you just created.

- bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST
  
  For <vservername>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

Example:

To create a Responder action and policy to respond to Diameter requests that originate from “host1.example.net” with a redirect to “host.example.com”, you could add the following action and
policy, and bind the policy as shown.

```
> add responder action act_resp-dm-redirect RESPONDWITH "DIA.slider.
NE glert("aaa://host.example.com")"
1
Done

> add responder pol_resp-dm-redirect "diameter.req.avp(264).value.eq("".
host1.example.net")" act_resp-dm-redirect
2
Done

> bind lb vserver vs1 -policyName pol_resp-dm-redirect -priority 10 -
type REQUEST
3
Done
```

**RADIUS Support for Responder**

October 1, 2019

The Citrix ADC expressions language contains expressions that can extract information from and manipulate RADIUS requests. These expressions enable you to use the Responder feature to respond to RADIUS requests. Your responder policies and actions can use any expression that is appropriate or relevant to a RADIUS request. The available expressions enable you to identify the RADIUS message type, extract any attribute-value pair (AVP) from the connection, and send different responses on the basis of that information. You can also create policy labels that invoke all responder policies for RADIUS connections.

You can use RADIUS expressions to construct simple responses that do not require communication with the RADIUS server to which the request was sent. When a responder policy matches a connection, the Citrix ADC constructs and sends the appropriate RADIUS response without contacting the RADIUS authentication server. For example, if the source IP address of a RADIUS request is from a subnet that is specified in the responder policy, the Citrix ADC can reply to that request with an access-reject message, or can simply drop the request.

You can also create policy labels to route specific types of RADIUS requests through a series of policies that are appropriate to those requests.

**Note:** The current RADIUS expressions do not work with RADIUS IPv6 attributes.

The Citrix ADC documentation for expressions that support RADIUS assumes familiarity with the basic structure and purpose of RADIUS communications. If you need more information about RADIUS, see
your RADIUS server documentation or search online for an introduction to the RADIUS protocol.

**Configuring Responder Policies for RADIUS**

The following procedure uses the Citrix ADC command line to configure a responder action and policy, and bind the policy to a RADIUS-specific global bind point.

To configure a Responder action and policy, and bind the policy:

At the command prompt, type the following commands:

- `add responder action <actName> <actType>
- add responder policy <polName> <rule> <actName>
- bind responder policy <polName> <priority> <nextExpr> -type <bindPoint>

where `<bindPoint>` represents one of the RADIUS-specific global bind points.

**RADIUS Expressions for Responder**

In a responder configuration, you can use the following Citrix ADC expressions to refer to various portions of a RADIUS request.

**Identifying the Type of Connection:**

- `RADIUS.IS_CLIENT`. Returns TRUE if the connection is a RADIUS client (request) message.
- `RADIUS.IS_SERVER`. Returns TRUE if the connection is a RADIUS server (response) message.

**Request Expressions:**

- `RADIUS.REQ.CODE`. Returns the number that corresponds to the RADIUS request type. A derivative of the num_at class. For example, a RADIUS access request would return 1 (one). A RADIUS accounting request would return 4.
- `RADIUS.REQ.LENGTH`. Returns the length of the RADIUS request, including the header. A derivative of the num_at class.
- `RADIUS.REQ.IDENTIFIER`. Returns the RADIUS request identifier, a number assigned to each request that allows the request to be matched to the corresponding response. A derivative of the num_at class.
- `RADIUS.REQ.AVP(<AVP Code No>).VALUE`. Returns the value of first occurrence of this AVP as a string of type text_t.
- `RADIUS.REQ.AVP(<AVP code no>).INSTANCE(instance number)`. Returns the specified instance of the AVP as a string of type RAVP_t. A specific RADIUS AVP can occur multiple times in a RADIUS message. INSTANCE (0) returns the first instance, INSTANCE (1) returns second instance, and so on, up to sixteen instances.
• **RADIUS.REQ.AVP**(<AVP code no>).**VALUE**(instance number). Returns the value of specified instance of the AVP as a string of type text_t.

• **RADIUS.REQ.AVP**(<AVP code no>).**COUNT**. Returns the number of instances of a specific AVP in a RADIUS connection, as an integer.

• **RADIUS.REQ.AVP**(<AVP code no>).**EXISTS**. Returns TRUE if the specified type of AVP exists in the message, or FALSE if it does not.

**Response Expressions:**

RADIUS response expressions are identical to RADIUS request expressions, except that RES replaces REQ.

**Typecasts of AVP Values:**

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other Citrix ADC typecast expressions.

**Example:**

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other Citrix ADC typecast expressions.

```
1  RADIUS.REQ.AVP(8).VALUE(0).typecast_ip_address_at
```

**AVP Type Expressions:**

The Citrix ADC supports expressions to extract RADIUS AVP values by using the assigned integer codes described in RFC2865 and RFC2866. You can also use text aliases to accomplish the same task. Some examples follow.

• **RADIUS.REQ.AVP** (1).**VALUE** or **RADIUS.REQ.USERNAME.value**. Extracts the RADIUS user-name value.

• **RADIUS.REQ.AVP** (4). **VALUE** or **RADIUS.REQ.ACCT_SESSION_ID.value**. Extracts the Acct-Session-ID AVP (code 44) from the message.

• **RADIUS.REQ.AVP** (26). **VALUE** or **RADIUS.REQ.VENDOR_SPECIFIC.VALUE**. Extracts the vendor-specific value.

The values of most commonly-used RADIUS AVPs can be extracted in the same manner.

**RADIUS Bind Points:**

Four global bind points are available for policies that contain RADIUS expressions.

• **RADIUS_REQ_OVERRIDE**. Priority/override request policy queue.

• **RADIUS_REQ_DEFAULT**. Standard request policy queue.

• **RADIUS_RES_OVERRIDE**. Priority/override response policy queue.
• RADIUS_RES_DEFAULT. Standard response policy queue.

**RADIUS Responder-Specific Expressions:**

• RADIUS_RESPONDWITH. Respond with the specified RADIUS response. The response is created with Citrix ADC expressions, both RADIUS expressions and any others that are applicable.
• RADIUS.NEW_ANSWER. Sends a new RADIUS answer to the user.
• RADIUS.NEW_ACCESSREJECT. Rejects the RADIUS request.
• RADIUS.NEW_AVP. Adds the specified new AVP to the response.

**Use Cases**

Following are use cases for RADIUS with responder.

**Blocking RADIUS Requests from a Specific Network**

To configure the responder feature to block authentication requests from a specific network, begin by creating a responder action that rejects requests. Use the action in a policy that selects requests from the networks that you want to block. Bind the responder policy to a RADIUS-specific global bind point, specifying:

• The priority
• END as the nextExpr value, to ensure that policy evaluation stops when this policy is matched
• RADIUS_REQ_OVERRIDE as the queue to which you assign the policy, so that it is evaluated before policies assigned to the default queue

To configure Responder to block logons from a specific network**

• add responder action <actName> <actType>
• add responder policy <polName> <rule> <actName>
• bind responder global <polName> <priority> <nextExpr> -type <bindPoint>

**Example:**

```
1 > add responder action rspActRadiusReject respondwith radius.
   new_accessreject
2 Done
3
4 > add responder policy rspPolRadiusReject client.ip.src.in_subnet
   (10.224.85.0/24) rspActRadiusReject
5 Done
6
7 > bind responder global rspPolRadiusReject 1 END -type
   RADIUS_REQ_OVERRIDE
```
DNS Support for the Responder Feature

October 1, 2019

You can configure the responder feature to respond to DNS requests as it does to HTTP and TCP requests. For example, you could configure it to send DNS responses over UDP and ensure that the DNS requests from the client are sent over TCP. A number of Citrix ADC expressions support examination of the DNS header in the request. These expressions examine specific header fields and send an appropriate response.

- **DNS Expressions.** In a responder configuration, you can use the following Citrix ADC expressions to refer to various portions of a DNS request:

<table>
<thead>
<tr>
<th>Expressions</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS.NEW_RESPONSE</td>
<td>Creates a new empty DNS response based on the request.</td>
</tr>
<tr>
<td>DNS.NEW_RESPONSE &lt;AA, TC, rcode&gt;</td>
<td>Creates a new DNS response based on the specified parameters.</td>
</tr>
</tbody>
</table>

- **DNS Bind Points.** The following global bind points are available for policies that contain DNS expressions.

<table>
<thead>
<tr>
<th>Bind Points</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS_REQ_OVERRIDE</td>
<td>Priority/override request policy queue.</td>
</tr>
<tr>
<td>DNS_REQ_DEFAULT</td>
<td>Standard request policy queue.</td>
</tr>
</tbody>
</table>

In addition to the default bind points, you can create policy labels of type DNS and bind DNS policies to them.

**Configuring Responder Policies for DNS**

The following procedure uses the Citrix ADC command line to configure a responder action and policy and bind the policy to a responder-specific global bind point.
To configure Responder to respond to a DNS request:

At the command prompt, type the following commands:

1. add responder action <actName> <actType>

   For <actname>, substitute a name for your new action. The name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For <actType>, substitute a responder action type, respondWith.

2. add responder policy <polName> <rule> <actName>

   For <polname>, substitute a name for your new policy. For <actname>, the name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For <actname>, substitute the name of the action that you just created.

3. bind responder policy <polName> <priority> <nextExpr> -type <bindPoint>

   For <bindPoint>, specify one of the responder-specific global bind points. For <polName>, substitute the name of the policy that you just created. For <priority>, specify the priority of the policy.

Sample configuration - Enforce all DNS request over TCP:

To enforce all the DNS requests over TCP, create a responder action that will set the TC bit and rcode as NOERROR.

```
> add responder action resp_act_set_tc_bit respondwith DNS.NEW_RESPONSE
   (true, true, NOERROR)
  Done

> add responder policy enforce_tcp dns.REQ.TRANSPORT.EQ(udp) resp_act_set_tc_bit
  Done

> bind lb vserver dns_udp -policyName enforce_tcp -type request -priority 100
  Done
```

How to redirect HTTP request to HTTPS using responder

October 1, 2019
This article explains how to configure the responder feature with a load balancing virtual server IP addresses and redirect client requests from HTTP to HTTPS.

Consider a scenario, where a user might attempt to access a secure web site by sending an HTTP request. Instead of dropping the request, you might want to redirect the request to a secure web site. You can use the responder feature to redirect the request to the secure web site without changing the path and the URL query which the user attempts to access.

**How Citrix ADC responder redirects a request from HTTP to HTTPS**

The following illustration shows a step by step flow of how the appliance redirects a request.

![Illustration of responder feature configuration](https://via.placeholder.com/150)

**Note:** The navigation paths and screen shots are derived from NetScaler 11.0.

To configure the Responder feature along with the Load Balancing VIP addresses of a NetScaler appliance to redirect client requests from HTTP to HTTPS, complete the following procedure.

1. Enable the responder feature on the appliance. Navigate to **System > Settings > Configure Advanced Features > Responder**.
2. Create a responder action and specify an appropriate name, such as, `http_to_https_actn`, in the Name field.

3. To create a responder action, in the navigation pane, expand **AppExpert > Responder**, click **Actions** and then click **Add**.

4. Select Redirect as Type.

5. In the **Expression** field, type the following expression:

   "https://" + HTTP.REQ.HOSTNAME.HTTP_URL_SAFE + HTTP.REQ.URL.PATH_AND_QUERY.HTTP_URL_SAFE.

6. In NetScaler version 9.0 and 10.0 ensure that the **Bypass Safety Check** option is cleared.

   **Note:** This option is not present from NetScaler 11.0 onwards.

7. Create **Responder Policy** and specify an appropriate name, such as `http_to_https_pol`, in the Name field.

8. To create a Responder Policy, in the navigation pane, expand **AppExpert > Responder**, click **Policies** and then click **Add**.

9. From the Action list, select the action name that you have created.

10. From the Undefined Action list, select **RESET**.

11. Type the `HTTP.REQ.IS_VALID` expression in the **Expression** field as shown in the following screen shot.
1. Create a monitor for which the status is always marked as UP and specify an appropriate name, such as localhost_ping, in the Name field.

2. To create a monitor, in the navigation pane expand Load Balancing, click Monitors and then click Add.

3. In the Destination IP field, specify the 127.0.0.1 IP address, as shown in the following screen shot.
4. Create a service and specify an appropriate name, such as Always_UP_service, in the Name field.

5. To create a service, in the navigation pane, expand Load Balancing, click Services and then click Add.

6. Specify a non-existent IP address in the Server field.
7. Specify 80 in the **Port** field.

8. Add the created monitor from the **Available Monitors** list.

9. Create a Load Balancing Virtual Server and specify an appropriate name in the **Name** field.

10. To create a Load Balancing Virtual Server, in the navigation pane, expand **Load Balancing**, click **Services** and then click **Add**.

11. Specify the IP address of the web site in **IP Address** field.

12. Select HTTP from the **Protocol** list.

13. Type 80 in the **Port** field.

14. On NetScaler version 9.0 and 10.0, select the Active option for the service you have created in the **Services** tab as shown in the following screen shot. This option is deprecated in NetScaler version 11.0.
15. Click the **Policies** tab.

16. Bind the Responder policy you created to the HTTP Load Balancing VIP address of the web site.

17. Create a secure Load Balancing virtual server that has the IP address of the web site and port as 443.

To create a configuration similar to the preceding procedure from the command line interface of the appliance, run following commands:

```bash
1. enable ns feature responder
2. add responder action http_to_https_actn redirect "\"https://\"" + http.req.hostname.HTTP_URL_SAFE + http.REQ.URL.HTTPS + http.REQ.URL_PATH_AND_QUERY.HTTP_URL_SAFE"
3. add responder policy http_to_https_pol HTTP.REQUEST.IS_VALID http_to_https_actn RESET
4. add lb monitor localhost_ping PING -LRTM ENABLED -destIP 127.0.0.1
5. add service Always_UP_service 1.2.3.4 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0 -cip ENABLED dummy -usip NO -sp OFF -cltTimeout 180 -svrTimeout 360 -CKA NO -TCPB NO -CMP YES
6. bind lb monitor localhost_ping Always_UP_service
7. add lb vserver http_site.com HTTP 10.217.96.238 80 -persistenceType COOKIEINSERT -timeout 0 -cltTimeout 180
8. bind lb vserver http_site.com Always_UP_service
9. bind lb vserver http_site.com -policyName http_to_https_pol -priority 1 -gotoPriorityExpression END
```
Notes:

- The status of the port 80 Load Balancing Redirect virtual server must be UP for the redirect to work.
- Web browsers might not redirect correctly if the HTTPS virtual server is not active.
- This redirect setup allows for situations where multiple domains are bound to the same IP address.
- If the client sends an invalid HTTP request to the redirect virtual server, then the appliance sends a RESET message code.

Troubleshooting

February 13, 2020

If the responder feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for Troubleshooting

For best results, use the following resources to troubleshoot an integrated cache issue on a Citrix ADC appliance:

- The ns.conf file
- The relevant trace files from the client and the Citrix ADC appliance

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the Citrix ADC trace files

Troubleshooting Responder Issues

- Issue
  
  The Responder feature is configured, but the responder action is not working.

  Resolution
  
  - Verify that the feature is enabled.
  - Check the hit counters of any of the policies to see if the counters are getting incremented.
Verify that the policies and actions are configured correctly.
Verify that the actions and policies are bound appropriately.
Record the packet traces on the client and the Citrix ADC appliance, and analyze the them to get some pointer to the issue.
Record the iehttpHeaters packet traces on the client and verify the HTTP requests and responses to get some pointer to the issue.

**Issue**

You need to create a maintenance page.

**Resolution**

1. Configure the services and virtual Server.
2. Configure a backup virtual server with a service bound to it. This ensures that the status of the Web site is always displayed as UP.
3. Configure the primary virtual server to use the backup virtual server as a backup.
4. Create a responder action with an appropriate target. Following is an example for your reference:

   ```
   add responder action sorry_page respondwith q{ "HTTP/1.0 200 OK"+"\r\n\r\n"+ "<html><body>Sorry, this page is not available</body></html>"+ "\r\n\r\n"}
   ```
5. Create a responder policy and bind the action to it.
6. Bind the responder policy to the backup virtual Server.

---

**Rewrite**

July 10, 2020

**Warning**

Filter features using classic policies are deprecated and as an alternative Citrix recommends you to use the rewrite and responder features with advanced policy infrastructure.

Rewrite refers to the rewriting of some information in the requests or responses handled by the Citrix ADC appliance. Rewriting can help in providing access to the requested content without exposing unnecessary details about the Web site’s actual configuration. A few situations in which the rewrite feature is useful are described below:
• To improve security, the Citrix ADC can rewrite all the http://links to https:// in the response body.
• In the SSL offload deployment, the insecure links in the response have to be converted into secure links. Using the rewrite option, you can rewrite all the http://links to https:// for making sure that the outgoing responses from Citrix ADC to the client have the secured links.
• If a Web site has to show an error page, you can show a custom error page instead of the default 404 Error page. For example, if you show the home page or site map of the Web site instead of an error page, the visitor remains on the site instead of moving away from the Web site.
• If you want to launch a new Web site, but use the old URL, you can use the Rewrite option.
• When a topic in a site has a complicated URL, you can rewrite it with a simple, easy-to-remember URL (also referred to as ‘cool URL’).
• You can append the default page name to the URL of a Web site. For example, if the default page of a company’s Web site is http://www.abc.com/index.php, when the user types ‘abc.com’ in the address bar of the browser, you can rewrite the URL to ‘abc.com/index.php’.

When you enable the rewrite feature, Citrix ADC can modify the headers and body of HTTP requests and responses.

To rewrite HTTP requests and responses, you can use protocol-aware Citrix ADC policy expressions in the rewrite policies you configure. The virtual servers that manage the HTTP requests and responses must be of type HTTP or SSL. In HTTP traffic, you can take the following actions:

- Modify the URL of a request
- Add, modify or delete headers
- Add, replace, or delete any specific string within the body or headers.

To rewrite TCP payloads, consider the payload as a raw stream of bytes. Each of the virtual servers that managing the TCP connections must be of type TCP or SSL_TCP. The term TCP rewrite is used to refer to the rewrite of TCP payloads that are not HTTP data. In TCP traffic, you can add, modify, or delete any part of the TCP payload.

For examples to use the rewrite feature, see Rewrite Action and Policy Examples.

Comparison between Rewrite and Responder options

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
• Dropping or resetting a connection at request level

In case of a responder policy, the Citrix ADC examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the Citrix ADC examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the Citrix ADC to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

**How rewrite works**

February 12, 2020

A rewrite policy consists of a rule and action. The rule determines the traffic on which rewrite is applied and the action determines the action to be taken by the Citrix ADC. You can define multiple rewrite policies. For each policy, specify the bind point and priority.

A bind point refers to a point in the traffic flow at which the Citrix ADC examines the traffic to verify whether any rewrite policy can be applied to it. You can bind a policy to a specific load balancing or content switching virtual server, or make the policy global if you want the policy to be applied to the entire traffic handled by the Citrix ADC. These policies are referred to as global policies.

In addition to the user-defined policies, the Citrix ADC has some default policies. You cannot modify or delete a default policy.

For evaluating the policies, Citrix ADC follows the order mentioned below:

- Global policies
- Policies bound to specific virtual servers
- Default policies

Note: Citrix ADC can apply a rewrite policy only when it is bound to a point.

Citrix ADC implements the rewrite feature in the following steps:

- The Citrix ADC appliance checks for global policies and then checks for policies at individual bind points.
If multiple policies are bound to a bind point, the Citrix ADC evaluates the policies in the order of their priority. The policy with the highest priority is evaluated first. After evaluating each policy, if the policy is evaluated to TRUE (the traffic matches the rule), it adds the action associated with the policy to a list of actions to be performed. A match occurs when the characteristics specified in the policy rule match the characteristics of the request or response being evaluated.

For any policy, in addition to the action, you can specify the policy that should be evaluated after the current policy is evaluated. This policy is referred to as the ‘Go to Expression’. For any policy, if a Go to Expression (gotoPriorityExpr) is specified, the Citrix ADC evaluates the Go to Expression policy; it ignores policy with the next highest priority.

You can specify the priority of the policy to indicate the Go to Expression policy; you cannot use the name of the policy. If you want the Citrix ADC to stop evaluating other policies after evaluating a particular policy, you can set the Go to Expression to ‘END’.

After all the policies are evaluated or when a policy has the Go to Expression set as END, the Citrix ADC starts performing the actions according to the list of actions.

For more information about configuring rewrite policies, see Configuring a Rewrite Policy and about binding rewrite policies, see Binding a Rewrite Policy.

The following figure illustrates how Citrix ADC processes a request or response when the rewrite feature is used.

Figure 1. The Rewrite Process
Policy Evaluation

The policy with the highest priority is evaluated first. Citrix ADC does not stop the evaluation of rewrite policies when it finds a match; it evaluates all the rewrite policies configured on the Citrix ADC.

- If a policy evaluates to TRUE, the Citrix ADC follows the procedure below:
  - If the policy has the Go to Expression set to END, the Citrix ADC stops evaluating all the other policies and starts performing the rewrite.
  - The gotoPriorityExpression can be set to ‘NEXT’, ‘END’, some integer or ‘INVOCATION_LIST’. The value determines the policy with the next priority. The following table shows the action taken by Citrix ADC for each value of the expression.

<table>
<thead>
<tr>
<th>Value of the expression</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEXT</td>
<td>Policy with the next priority gets evaluated.</td>
</tr>
<tr>
<td>END</td>
<td>Evaluation of policies stops.</td>
</tr>
<tr>
<td>&lt;an integer&gt;</td>
<td>Policy with specified priority gets evaluated.</td>
</tr>
</tbody>
</table>
Value of the expression | Action
---|---
INVOCATION_LIST | Goto NEXT or END is applied based on the result of the invocation list.

- If a policy evaluates to FALSE, the Citrix ADC continues the evaluation in the order of priority.
- If a policy evaluates to UNDEFINED (cannot be evaluated on the received traffic due to an error), the Citrix ADC performs the action assigned to the UNDEFINED condition (referred to as undefAction) and stops further evaluation of policies.

The Citrix ADC starts the actual rewriting only after the evaluation is complete. It refers to the list of actions identified by policies that are evaluated to TRUE, and starts the rewriting. After implementing all the actions in the list, the Citrix ADC forwards the traffic as required.

**Note:**
Ensure that the policies do not specify conflicting or overlapping actions on the same part of the HTTP header or body, or TCP payload. When such a conflict occurs, the Citrix ADC encounters an undefined situation and aborts the rewrite.

### Rewrite Actions

On the Citrix ADC appliance, specify the actions to be taken such as adding, replacing, or deleting text within the body, or adding, modifying or deleting headers, or any changes in the TCP payload as rewrite actions. For more information about rewrite actions, see [Configuring a Rewrite Action](#).

The following table describes the steps the Citrix ADC can take when a policy evaluates to TRUE.

<table>
<thead>
<tr>
<th>Action</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>The rewrite action specified for the policy is carried out.</td>
</tr>
<tr>
<td>NOREWRITE</td>
<td>The request or response is not rewritten. Citrix ADC forwards the traffic without rewriting any part of the message.</td>
</tr>
<tr>
<td>RESET</td>
<td>The connection is aborted at the TCP level.</td>
</tr>
<tr>
<td>DROP</td>
<td>The message is dropped.</td>
</tr>
</tbody>
</table>

**Note:**
For any policy, you can configure the undefaction (action to be taken when the policy evaluates to UNDEFINED) as NOREWRITE, RESET, or DROP.

To use the Rewrite feature, take the following steps:

- Enable the feature on the Citrix ADC.
- Define rewrite actions.
- Define rewrite policies.
- Bind the policies to a bind point to bring a policy into effect.

Enabling the rewrite feature

February 21, 2020

Enable the rewrite feature on the Citrix ADC appliance if you want to rewrite the HTTP or TCP requests or responses. If the feature is enabled, Citrix ADC takes rewrite action according to the specified policies. For more information, see How rewrite works.

To enable the rewrite feature by using the command line interface

At the command prompt, type the following commands to enable the rewrite feature and verify the configuration:

- `enable ns feature REWRITE`
- `show ns feature`

Example:

```
> enable ns feature REWRITE
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
</tbody>
</table>
```
To enable the rewrite feature by using the configuration utility

1. In the navigation pane, click **System**, and then click **Settings**.
2. In the details pane, under Modes and Features, click **Configure basic features**.
3. In the **Configure Basic Features** dialog box, select the Rewrite check box, and then click **OK**.
4. In the **Enable/Disable Feature(s)** dialog box, click **Yes**. A message appears in the status bar, stating that the selected feature was enabled.

**Configuring a Rewrite Action**

July 8, 2020

**Warning**

The Pattern function in a rewrite action is deprecated from Citrix ADC 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the Search rewrite action parameter.

After enabling the rewrite feature, you need to configure one or more actions unless a built-in rewrite action is sufficient. All of the built-in actions have names beginning with the string ns_cvpn, followed by a string of letters and underscore characters. Built-in actions perform useful and complex tasks such as decoding parts of a clientless VPN request or response or modifying JavaScript or XML data. The built-in actions can be viewed, enabled, and disabled, but cannot be modified or deleted.

Target expressions in actions for TCP rewrite must begin with one of the following expression prefixes:

- **CLIENT.TCP.PAYLOAD**. For rewriting TCP payloads in client requests. For example, `CLIENT.TCP.PAYLOAD(10000).AFTER_STR("string1")`.
- **SERVER.TCP.PAYLOAD**. For rewriting TCP payloads in server responses. For example, `SERVER.TCP.PAYLOAD(1000).B64DECODE.BETWEEN("string1","string2")`.

You can use all types of existing string manipulation functions with these prefixes to identify the strings that you want to rewrite. To configure a rewrite action, you assign it a name, specify an action type,
and add one or more arguments specifying additional data. The following table describes the action types and the arguments you use with them.

| Note: Action types that can be used only for HTTP rewrite are identified in the Rewrite Action Type column. |

See Rewrite action type pdf for more information.

**To create a new rewrite action by using the command line interface**

At the command prompt, type the following commands to create a new rewrite action and verify the configuration:

- `add rewrite action <name> <type> <target> [stringBuilderExpr] [(-pattern expression) [~patset string]] [-bypassSafetyCheck (YES|NO)]`
- `show rewrite action <name>`

**Example 1. Inserting an HTTP Header With the Client IP:**

```
1  > add rewrite action insertact INSERT_HTTP_HEADER "client-IP" CLIENT.IP .SRC
2       Done
3
4  > show rewrite action insertact
5       Name: insertact
6       Operation: insert_http_header Target:Client-IP
7       Value:CLIENT.IP.SRC
8       BypassSafetyCheck : NO
9       Hits: 0
10      Undef Hits: 0
11      Action Reference Count: 0
12       Done
```

**Example 2. Replacing Strings in a TCP Payload (TCP Rewrite):**

```
1  > add rewrite action client_tcp_payload_replace_all REPLACE_ALL 'client.tcp.payload(1000)' "new-string" -search text("old-string")
2       Done
3
4  > show rewrite action client_tcp_payload_replace_all
5       Name: client_tcp_payload_replace_all
6       Operation: replace_all
7       Target:client.tcp.payload(1000)
```
To modify an existing rewrite action by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite action and verify the configuration:

- `set rewrite action <name> [-target <string>] [-stringBuilderExpr <string>] [(-pattern <expression> | -patset <string>)] [-bypassSafetyCheck (YES|NO)]`
- `show rewrite action <name>

Example:

```
> set rewrite action insertact -target "Client-IP"
Done
> show rewrite action insertact

Name: insertact
Operation: insert_http_header   Target:Client-IP
Value:CLIENT.IP.SRC
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Done
```

To remove a rewrite action by using the command line interface

At the command prompt, type the following commands to remove a rewrite action:

```
rm rewrite action <name>
```

Example:

```
> rm rewrite action insertact
Done
```
To configure a rewrite action by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, do one of the following:
   • To create a new action, click Add.
   • To modify an existing action, select the action, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Action has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close.

To add an expression by using the Add Expression dialog box

1. In the Create Rewrite Action or Configure Rewrite Action dialog box, under the text area for the type argument you want to enter, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   • HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   • SYS. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   • CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.
1. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.
2. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.
   For more information about the PI expressions language and creating expressions for responder policies, see “Policies and Expressions.”

If you want to test the effect of a rewrite action when used on sample HTTP data, you can use the Rewrite Expression Evaluator.
Note:
The Rewrite Expression Evaluator is only available in the configuration utility. There is no Citrix ADC command line version.

To evaluate a rewrite action by using the Rewrite Action Evaluator dialog box

1. In the Rewrite Actions details pane, select the rewrite action that you want to evaluate, and then click Evaluate.

2. In the Rewrite Expression Evaluator dialog box, specify values for the following parameters. (An asterisk indicates a required parameter.)
   - **Rewrite Action**—If the rewrite action you want to evaluate is not already selected, select it from the drop-down list. After you select a Rewrite action, the Details section displays the details of the selected Rewrite action.
   - **New**—Select New to open the Create Rewrite Action dialog box and create a new rewrite action.
   - **Modify**—Select Modify to open the Configure Rewrite Action dialog box and modify the selected rewrite action.
   - **Flow Type**—Specifies whether to test the selected rewrite action with HTTP Request data or HTTP Response data. The default is Request. If you want to test with Response data, select Response.
   - **HTTP Request/Response Data**—Provides a space for you to provide the HTTP data that the Rewrite Action Evaluator will use for testing. You can paste the data directly into the window, or click Sample to insert some sample HTTP headers.
   - **Show end-of-line**—Specifies whether to show UNIX-style end-of-line characters (\n) at the end of each line of sample HTTP data.
   - **Sample**—Inserts sample HTTP data into the HTTP Request/Response Data window. You can choose either GET or POST data.
   - **Browse**—Opens a local browse window so that you can choose a file containing sample HTTP data from a local or network location.
   - **Clear**—Clears the current sample HTTP data from the HTTP Request/Response Data window.

3. Click Evaluate. The Rewrite Action Evaluator evaluates the effect of the Rewrite action on the sample data that you chose, and displays the results as modified by the selected Rewrite action in the Results window. Additions and deletions are highlighted as indicated in the legend in the lower left-hand corner of the dialog box.

4. Continue evaluating Rewrite actions until you have determined that all of your actions have the effect that you wanted.
   - You can modify the selected rewrite action and test the modified version by clicking Modify to open the Configure Rewrite Action dialog box, making and saving your changes,
and then clicking Evaluate again.

- You can evaluate a different rewrite action using the same request or response data by selecting it from the **Rewrite Action** drop-down list, and then clicking **Evaluate** again.

5. Click **Close** to close the **Rewrite Expression Evaluator** and return to the **Rewrite Actions** pane.

6. To delete a rewrite action, select the rewrite action you want to delete, then click **Remove** and, when prompted, confirm your choice by clicking **OK**.

---

**Configuring a Rewrite Policy**

February 13, 2020

After you create any needed rewrite action(s), you must create at least one rewrite policy to select the requests that you want the Citrix ADC appliance to rewrite.

A rewrite policy consists of a rule, which itself consists of one or more expressions, and an associated action that is performed if a request or response matches the rule. Policy rules for evaluating HTTP requests and responses can be based on almost any part of a request or response.

Even though you cannot use TCP rewrite actions to rewrite data other than the TCP payload, you can base the policy rules for TCP rewrite policies on the information in the transport layer and the layers below the transport layer.

If a configured rule matches a request or response, the corresponding policy is triggered and the action associated with it is carried out.

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policies. Users who are not thoroughly familiar with the command line interface and the Citrix ADC Policy expression language will usually find using the configuration utility much easier.

**To add a new rewrite policy by using the command line interface**

At the command prompt, type the following commands to add a new rewrite policy and verify the configuration:

- `<add rewrite policy <name> <expression> <action> [<undefaction>]`
- `<show rewrite policy <name>`

**Example 1. Rewriting HTTP Content:**
Example 2. Rewriting a TCP Payload (TCP Rewrite):

```
> add rewrite policy client_tcp_payload_policy CLIENT.IP.SRC.EQ (172.168.12.232) client_tcp_payload_replace_all
Done
> show rewrite policy client_tcp_payload_policy
Name: client_tcp_payload_policy
Rule: CLIENT.IP.SRC.EQ(172.168.12.232)
RewriteAction: client_tcp_payload_replace_all
UndefAction: Use Global
LogAction: Use Global
Hits: 0
Undef Hits: 0
```

To modify an existing rewrite policy by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite policy and verify the configuration:

- `<set rewrite policy <name> -rule <expression> -action <action> [undefaction]>`
- `<show rewrite policy <name>`
To remove a rewrite policy by using the command line interface

At the command prompt, type the following command to remove a rewrite policy:

```
rm rewrite policy <name>
```

**Example:**

```
> rm rewrite policy policyNew
Done
```

To configure a rewrite policy by using the configuration utility

2. In the details pane, do one of the following:
   • To create a new policy, click Add.
   • To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Policy has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close. To delete a rewrite policy, select the rewrite policy you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

Binding a Rewrite Policy

March 13, 2020
After creating a rewrite policy, you must bind it to put it into effect. You can bind your policy to Global if you want to apply it to all traffic that passes through your Citrix ADC, or you can bind your policy to a specific virtual server or bind point to direct only that virtual server or bind point’s incoming traffic to that policy. If an incoming request matches a rewrite policy, the action associated with that policy is carried out.

Rewrite policies for evaluating HTTP requests and responses can be bound to virtual servers of type HTTP or SSL, or they can be bound to the REQ_OVERRIDE, REQ_DEFAULT, RES_OVERRIDE, and RES_DEFAULT bind points. Rewrite policies for TCP rewrite can be bound only to virtual servers of type TCP or SSL_TCP, or to the OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, OTHERTCP_RES_OVERRIDE, and OTHERTCP_RES_DEFAULT bind points.

Note: The term OTHERTCP is used in the context of the Citrix ADC appliance to refer to all TCP or SSL_TCP requests and responses that you want to treat as a raw stream of bytes regardless of the protocols that the TCP packets encapsulate.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the Citrix ADC operating system, policy priorities work in reverse order - the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is applied first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

Unlike most other features in the Citrix ADC operating system, the rewrite feature continues to evaluate and implement policies after a request matches a policy. However, the effect of a particular action policy on a request or response will often be different depending on whether it is performed before or after another action. Priority is important to get the results you intended.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind it. If you do this, you can add additional policies at any time without having to reassign the priority of an existing policy.

When binding a rewrite policy, you also have the option of assigning a goto expression (gotoPriorityExpression) to the policy. A goto expression can be any positive integer that matches the priority assigned to a different policy that has a higher priority than the policy that contains the goto expression. If you assign a goto expression to a policy, and a request or response matches the policy, the Citrix ADC will immediately go to the policy whose priority matches the goto expression. It will skip over any policies with priority numbers that are lower than that of the current policy, but higher than the priority number of the goto expression, and not evaluate those policies.
To globally bind a rewrite policy by using the command line interface

At the command prompt, type the following commands to globally bind a rewrite policy and verify the configuration:

- \texttt{bind rewrite global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]}
- \texttt{show rewrite global}

\textbf{Example:}

\begin{verbatim}
 1  > bind rewrite global policyNew 10
 2    Done

 4  > show rewrite global
 5    1)  Global bindpoint: RES_DEFAULT
 6        Number of bound policies: 1
 7
 8    2)  Global bindpoint: REQ_OVERRIDE
 9        Number of bound policies: 1
10
11    Done
\end{verbatim}

To bind rewrite policy to a specific virtual server by using the command line interface

At the command prompt, type the following commands to bind rewrite policy to a specific virtual server and verify the configuration:

- \texttt{bind lb vserver <name>@ (<serviceName>@ [-weight <positive_integer>] | <serviceGroupName>@ | (-policyName <string>@[ -priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )] [-invoke (<labelType> <labelName>)])}
- \texttt{show lb vserver <name>}

\textbf{Example:}

\begin{verbatim}
 1  > bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
 2    Done

 4  > show lb vserver lbvip
 5    lbvip (8.7.6.6:80) - HTTP Type: ADDRESS
 6    State: DOWN
 7    Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)
 8    Time since last state change: 28 days, 01:57:26.350
 9    Effective State: DOWN
\end{verbatim}
**Citrix ADC 13.0**

---

**To bind a rewrite policy to a bind point by using the configuration utility**

1. Navigate to **AppExpert > Rewrite > Policies**.
2. In the details pane, select the rewrite policy you want to globally bind, and then click **Policy Manager**.
3. In the **Rewrite Policy Manager** dialog box, in the **Bind Points** menu, do one of the following:
   a) If you want to configure bindings for HTTP rewrite policies, click **HTTP**, and then click either **Request** or **Response**, depending on whether you want to configure request-based rewrite policies or response-based rewrite policies.
   b) If you want to configure bindings for TCP rewrite policies, click **TCP**, and then click either **Client** or **Server**, depending on whether you want to configure client-side TCP rewrite policies or server-side TCP rewrite policies.
4. Click the bind point to which you want to bind the rewrite policy. The **Rewrite Policy Manager** dialog box displays all the rewrite policies that are bound to the selected bind point.
5. Click **Insert Policy** to insert a new row and display a drop-down list with all available, unbound rewrite policies.
6. Click the policy you want to bind to the bind point. The policy is inserted into the list of rewrite policies bound to the bind point.
7. In the **Priority** column, you can change the priority to any positive integer. For more information about this parameter, see priority in “Parameters for binding a rewrite policy.”
8. If you want to skip over policies and go directly to a specific policy in the event that the current policy is matched, change the value in the **Goto Expression** column to equal the priority of the next policy to be applied. For more information about this parameter, see gotoPriorityExpression in “Parameters for binding a rewrite policy.”

© 1999-2020 Citrix Systems, Inc. All rights reserved. 1911
9. To modify a policy, click the policy, and then click **Modify Policy**.
10. To unbind a policy, click the policy, and then click **Unbind Policy**.
11. To modify an action, in the Action column, click the action you want to modify, and then click **Modify Action**.
12. To modify an invoke label, in the **Invoke** column, click the invoke label you want to modify, and then click **Modify Invoke Label**.
13. To regenerate the priorities of all the policies that are bound to the bind point you are currently configuring, click **Regenerate Priorities**. The policies retain their existing priorities relative to the other policies, but the priorities are renumbered in multiples of ten.
14. Click **Apply Changes**.
15. Click **Close**. A message appears in the status bar, stating that the Policy has been configured successfully.

**To bind a rewrite policy to a specific virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane list of virtual servers, select the virtual server to which you want to bind the rewrite policy, and then click **Open**.
3. In the **Configure Virtual Server (Load Balancing)** dialog box, select the **Policies** tab. All policies configured on your Citrix ADC appear on the list.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click **OK**. A message appears in the status bar, stating that the Policy has been configured successfully.

**Configuring Rewrite Policy Labels**

February 12, 2020

If you want to build a more complex policy structure than is supported by single policies, you can create policy labels and then bind them as you would policies. A policy label is a user-defined point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority you configured. A policy label can include one or multiple policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and the return of control to the policy that invoked the policy label.
A rewrite policy label consists of a name, a transform name that describes the type of policy included in the policy label, and a list of policies bound to the policy label. Each policy that is bound to the policy label contains all of the elements described in Configuring a Rewrite Policy.

Note: You can use either the command line interface or the configuration utility to create and configure rewrite policy labels. Users who are not thoroughly familiar with the command line interface and the Citrix ADC Policy Infrastructure (PI) language will usually find using the configuration utility much easier.

To configure a rewrite policy label by using the command line interface

To add a new rewrite policy label, at the command prompt, type the following command:

```
add rewrite policylabel <labelName> <transform>
```

For example, to add a rewrite policy label named polLabelHTTPResponses to group all policies that work on HTTP responses, you would type the following:

```
add rewrite policylabel polLabelHTTPResponses http_res
```

To modify an existing rewrite policy label, at the Citrix ADC command prompt, type the following command:

```
set rewrite policy <name> <transform>
```

Note: The set rewrite policy command takes the same options as the add rewrite policy command.

To remove a rewrite policy label, at the Citrix ADC command prompt, type the following command:

```
rm rewrite policy <name>
```

For example, to remove a rewrite policy label named polLabelHTTPResponses, you would type the following:

```
rm rewrite policy polLabelHTTPResponses
```

To configure a rewrite policy label by using the configuration utility

2. In the details pane, do one of the following:
   - To create a new policy label, click **Add**.
   - To modify an existing policy label, select the policy, and then click **Open**.

3. Add or remove policies from the list that is bound to the policy label.
To add a policy to the list, click Insert Policy, and choose a policy from the drop-down list. You can create a new policy and add it to the list by choosing New Policy in the list, and following the instructions in Configuring a Rewrite Policy.

To remove a policy from the list, select that policy, and then click Unbind Policy.

4. Modify the priority of each policy by editing the number in the Priority column. You can also automatically renumber policies by clicking Regenerate Priorities.

5. Click Create or OK, and then click Close.

To remove a policy label, select it, and then click Remove. To rename a policy label, select it and then click Rename. Edit the name of the policy, and then click OK to save your changes.

Configuring the Default Rewrite Action

February 12, 2020

An undefined event is triggered when the Citrix ADC cannot evaluate a policy, usually because it detects a logical or other error in the policy or an error condition on the Citrix ADC. When the rewrite policy evaluation results in an error, the specified undefined action is carried out. Undefined actions configured at the rewrite policy level are carried out before a globally configured undefined action.

The Citrix ADC supports following three types of undefined actions:

- undefAction NOREWRITE
  Aborts rewrite processing, but does not alter the packet flow. This means that the Citrix ADC continues to process requests and responses that do not match any rewrite policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers, and is the default setting.

- undefAction RESET
  Resets the client connection. This means that the Citrix ADC tells the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

- undefAction DROP
Silently drops the request without responding to the client in any way. This means that the Citrix ADC simply discards the connection without responding to the client. This action is appropriate for requests that appear to be part of a DDoS attack or another sustained attack on your servers.

Note: Undefined events can be triggered for both request and response flow specific policies.

To configure the default action by using the command line interface

At the command prompt, type the following commands to configure the default action and verify the configuration:

```
<set rewrite param -undefAction ( NOREWRITE RESET DROP )
```

```
•
• <show rewrite param
```

Example:

```
1 > set rewrite param -undefAction NOREWRITE
2   Done
3 > show rewrite param
4       Action Name: NOREWRITE
5   Done
```

To configure the default action by using the configuration utility

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Rewrite Overview, click the Change Rewrite Settings link. The Set Rewrite Params dialog box appears.
3. Under Global Undefined-Result Action, select an option as follows:
   • NoRewrite—NOREWRITE
   • Reset—RESET
   • Drop—DROP
4. Click OK. The global undefined action is set to the value you chose.
Bypassing the Safety Check

February 13, 2020

When you create a rewrite action, the Citrix ADC verifies that the expression you used to create the action is safe. Expressions created by the Citrix ADC from run-time data, such as URLs contained in HTTP requests, can cause unexpected errors. The Citrix ADC reports expressions that cause such errors as unsafe expressions.

In some cases, the expressions may be safe. For example, the Citrix ADC cannot validate an expression that contains a URL that does not resolve, even if the URL does not resolve because the Web server is temporarily unavailable. You can manually bypass the Safety Check to allow these expressions.

To bypass the safety check by using the command line interface

At the command prompt, type the following commands to bypass the safety check and verify the configuration:

- `<set rewrite action <name> -bypassSafetyCheck YES`
- `<show rewrite action <name>`

Example:

```
1 > set rewrite action insertact -bypassSafetyCheck YES
2   Done
3 > show rewrite action insertact
4   Name: insertact
5   Operation: insert_http_header   Target: Client-IP
6   Value: CLIENT.IP.SRC
7   BypassSafetyCheck : YES
8   Hits: 0
9   Undef Hits: 0
10  Action Reference Count: 2
11 Done
```

To bypass safety check by using the configuration utility

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, select the rewrite action to be exempted from the safety check, and then click Open.
3. In the Configure Rewrite Action dialog box, select the Bypass Safety Check check box.
Rewrite Action and Policy Examples

April 23, 2019

The examples in this section demonstrate how to configure rewrite to perform various useful tasks. The examples occur in the server room of Example Manufacturing Inc., a mid-sized manufacturing company that uses its Web site to manage a considerable portion of its sales, deliveries, and customer support.

Example Manufacturing has two domains: example.com for its Web site and email to customers, and example.net for its intranet. Customers use the Example Web site to place orders, request quotes, research products, and contact customer service and technical support.

As an important part of Example’s revenue stream, the Web site must respond quickly and keep customer data confidential. Example therefore has several Web servers and uses Citrix ADC appliances to balance the Web site load and manage traffic to and from its Web servers.

The Example system administrators use the rewrite features to perform the following tasks:

**Example 1: Delete old X-Forwarded-For and Client-IP Headers**
Example Inc. removes old X-Forwarded-For and Client-IP HTTP headers from incoming requests.

**Example 2: Adding a Local Client-IP Header**
Example Inc. adds a new, local Client-IP header to incoming requests.

**Example 3: Tagging Secure and Insecure Connections**
Example Inc. tags incoming requests with a header that indicates whether the connection is a secure connection.

**Example 4: Mask the HTTP Server Type**
Example Inc. modifies the HTTP Server: header so that unauthorized users and malicious code cannot use that header to determine the HTTP server software it uses.

**Example 5: Redirect an External URL to an Internal URL**
Example Inc. hides information about the actual names of its Web servers and the configuration of its server room from users, to make URLs on its Web site shorter and easier to remember and to improve security on its site.
Example 6: Migrating Apache Rewrite Module Rules

Example Inc. moved its Apache rewrite rules to a Citrix ADC appliance, translating the Apache PERL-based script syntax to the Citrix ADC rewrite rule syntax.

Example 7: Marketing Keyword Redirection

The marketing department at Example Inc. sets up simplified URLs for certain predefined keyword searches on the company's Web site.

Example 8: Redirect Queries to the Queried Server

Example Inc. redirects certain query requests to the appropriate server.

Example 9: Home Page Redirection

Example Inc. recently acquired a smaller competitor, and it now redirects requests to the acquired company's home page to a page on its own Web site.

Example 10: Policy-based RSA Encryption

Example Inc. encrypt HTTP predefined and user-defined header or body content by using PEM RSA public key.

Each of these tasks requires that the system administrators create rewrite actions and policies and bind them to a valid bind point on the Citrix ADC.

Example 1: Delete Old X-Forwarded-For and Client-IP Headers

October 1, 2019

Example Inc. wants to remove old X-Forwarded-For and Client-IP HTTP headers from incoming requests, so that the only X-Forwarded-For headers that appear are the ones added by the local server. This configuration can be done through the Citrix ADC command line or the configuration utility. The Example Inc. system administrator is an old-school networking engineer and prefers to use a CLI where possible, but wants to be sure he understands the configuration utility interface so that he can show new system administrators on the team how to use it.

The examples below demonstrate how to perform each configuration with both the CLI and the configuration utility. The procedures are abbreviated on the assumption that users will already know the basics of creating rewrite actions, creating rewrite policies, and binding policies.

- For more detailed information about creating rewrite actions, see Configuring a Rewrite Action.
- For more detailed information about creating rewrite policies, see Configuring a Rewrite Policy.
• For more detailed information about binding rewrite policies, see Binding a Rewrite Policy.

To delete old X-Forwarded and Client-IP headers from a request by using the command line interface

At the command prompt, type the following commands in the order shown:

1. add rewrite action act_del_xfor delete_http_header x-forwarded-for
2. add rewrite action act_del_cip delete_http_header client-ip
3. add rewrite policy pol_check_xfor 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' act_del_xfor
4. add rewrite policy pol_check_cip 'HTTP.REQ.HEADER("client-ip").EXISTS' act_del_cip
5. bind rewrite global pol_check_xfor 100 200
6. bind rewrite global pol_check_cip 200 300

To delete old X-Forwarded and Client-IP headers from a request by using the configuration utility

In the Create Rewrite Action dialog box, create two rewrite actions with the following descriptions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Argument(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>act_del_xfor</td>
<td>delete_http_header</td>
<td>x-forwarded-for</td>
</tr>
<tr>
<td>act_del_cip</td>
<td>delete_http_header</td>
<td>client-ip</td>
</tr>
</tbody>
</table>

In the Create Rewrite Policy dialog box, create two rewrite policies with the following descriptions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Expression</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pol_check_xfor</td>
<td>‘HTTP.REQ.HEADER(&quot;x-forwarded-for&quot;).EXISTS’</td>
<td>act_del_xfor</td>
</tr>
<tr>
<td>pol_check_cip</td>
<td>‘HTTP.REQ.HEADER(&quot;client-ip&quot;).EXISTS’</td>
<td>act_del_cip</td>
</tr>
</tbody>
</table>

Bind both policies to global, assigning the priorities and goto expression values shown below.
All old X-Forwarded-For and Client-IP HTTP headers are now deleted from incoming requests.

**Example 2: Adding a Local Client-IP Header**

February 12, 2020

Example Inc. wants to add a local Client-IP HTTP header to incoming requests. This example contains two slightly different versions of the same basic task.

**To add a local Client-IP header by using the command line interface**

At the command prompt, type the following commands in the order shown:

1. add rewrite action act_ins_client insert_http_header NS-Client 'CLIENT.IP.SRC'
2. add rewrite policy pol_ins_client 'HTTP.REQ.HEADER("x-forwarded-for") EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' act_ins_client
3. bind rewrite global pol_ins_client 300 END

**To add a local Client-IP header by using the configuration utility**

In the Create Rewrite Action dialog box, create a rewrite action with the following description.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Argument(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>act_ins_client</td>
<td>insert_http_header</td>
<td>NS-Client ‘CLIENT.IP.SRC’</td>
</tr>
</tbody>
</table>

In the Create Rewrite Policy dialog box, create a rewrite policy with the following description.
Bind policy to global, assigning the priorities and goto expression values shown below.
<table>
<thead>
<tr>
<th>Name</th>
<th>Priority</th>
<th>Goto Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>–</td>
<td>–</td>
<td>–</td>
</tr>
<tr>
<td>pol_ins_client</td>
<td>100</td>
<td>Next</td>
</tr>
</tbody>
</table>

A local Client-IP HTTP header is now added to incoming requests. You can also modify the configuration above to append all IPs from X-Forwarded-For headers to the new Client-IP header, as shown below.

Example 3: Tagging Secure and Insecure Connections

April 23, 2019

Example Inc. wants to tag incoming requests with a header that indicates whether or not the connection is a secure connection. This helps the server keep track of secure connections after the Citrix ADC has decrypted the connections.

To implement this configuration, you would begin by creating rewrite actions with the values shown in the following tables. These actions label connections to port 80 as insecure connections, and connections to port 443 as secure connections.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite</th>
<th>Header Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-SSL_YES</td>
<td>INSERT_HTTP_HEADER</td>
<td>SSL</td>
<td>YES</td>
</tr>
</tbody>
</table>
You would then create a rewrite policy with the values shown in the following tables. These policies check incoming requests to determine which requests are directed to port 80 and which are directed to port 443. The policies then add the correct SSL header.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-SSL_YES</td>
<td>Action-Rewrite-SSL_YES</td>
<td>NOREWRITE</td>
<td>CLIENT.TCP.DSTPORT.EQ(443)</td>
</tr>
<tr>
<td>Policy-Rewrite-SSL_NO</td>
<td>Action-Rewrite-SSL_NO</td>
<td>NOREWRITE</td>
<td>CLIENT.TCP.DSTPORT.EQ(80)</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policies to Citrix ADC, assigning the first policy a priority of 200, and the second a priority of 300, and setting the goto expression of both policies to END.

Each incoming connection to port 80 now has an SSL: NO HTTP header added to it and each incoming connection to port 443 has an SSL: YES HTTP header added to it.

Example 4: Mask the HTTP Server Type

October 1, 2019

Example Inc. wants to modify the HTTP Server: header so that unauthorized users and malicious code cannot use the header to identify the software that the HTTP server uses.

To modify the HTTP Server: header, you would create a rewrite action and a rewrite policy with the values in the following tables.
Example commands:

> add rewrite action Action-Rewrite-Server_Mask REPLACE HTTP.RES.HEADER("Server") "Web Server 1.0"

> add rewrite policy Policy-Rewrite-Server_Mask HTTP.RES.IS_VALID Action-Rewrite-Server_Mask NOREWRITE

You would then globally bind the rewrite policy, assigning a priority of 100 and setting the Goto Priority Expression of the policy to END.

The HTTP Server: header is now modified to read “Web Server 1.0,” masking the actual HTTP server software used by the Example Inc. Web site.

Copied!
Failed!

Example 5: Redirect an external URL to an internal URL

October 14, 2019

Example Inc. wants to hide its actual server room configuration from users to improve security on its Web servers.

To do this, you would create a rewrite action with the values as shown in the following tables. For request headers, the action in the table modifies www.example.com to web.hq.example.net. For response headers, the action does the opposite, translating web.hq.example.net to www.example.com.
The first policy checks incoming requests to see if they are valid, and if they are, it performs the Action-Rewrite-Request_Server_Replace action. The second policy checks responses to see if they originate at the server web.hq.example.net. If they do, it performs the Action-Rewrite-Response_Server_Replace action.

Examples of rewrite action and policy for redirecting an external URL.

```plaintext
add rewrite action Action-Rewrite-Request_Server_Replace REPLACE HTTP.REQ.HOSTNAME.SERVER 'Web.hq.example.net'
add rewrite action Action-Rewrite-Response_Server_Replace REPLACE HTTP.RES.HEADER("Server") 'www.example.com'
add rewrite policy Policy-Rewrite-Request_Server_Replace HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com") Action-Rewrite-Request_Server_Replace NOREWRITE
add rewrite policy Policy-Rewrite-Response_Server_Replace HTTP.REQ.HEADER("Server").EQ("Web.hq.example.net") Action-Rewrite-Response_Server_Replace
```

Finally, you would bind the rewrite policies, assigning each a priority of 500 because they are in different policy banks and therefore will not conflict. You should set the goto expression to NEXT for both bindings.

```plaintext
bind rewrite global Policy-Rewrite-Request_Server_Replace 500 END -type REQ_DEFAULT
bind rewrite global Policy-Rewrite-Response_Server_Replace 500 END -type RES_DEFAULT
```

All instances of www.example.com in the request headers are now changed to web.hq.example.net, and all instances of web.hq.example.net in response headers are now changed to www.example.com.
Example 6: Migrating Apache Rewrite Module Rules

February 12, 2020

Example Inc., is currently using the Apache rewrite module to process search requests sent to its Web servers and redirect those requests to the appropriate server on the basis of information in the request URL. Example Inc. wants to simplify its setup by migrating these rules onto the Citrix ADC platform.

Several Apache rewrite rules that Example currently uses are shown below. These rules redirect search requests to a special results page if they do not have a SiteID string or if they have a SiteID string equal to zero (0), or to the standard results page if these conditions do not apply.

The following are the current Apache rewrite rules:

- RewriteCond %{REQUEST_FILENAME} ˆ/search$ [NC]
- RewriteCond %{QUERY_STRING} !SiteId= [OR]
- RewriteCond %{QUERY_STRING} SiteId=0
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ˆ. *$ results2.html [P,L]
- RewriteCond %{REQUEST_FILENAME} ˆ/search$ [NC]
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ˆ. *$ /results.html [P,L]

To implement these Apache rewrite rules on the Citrix ADC, you would create rewrite actions with the values in the following tables.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Display_Results_NulSit</td>
<td>REPLACE</td>
<td>HTTP.REQ.URL</td>
<td>“/results2.html”</td>
</tr>
<tr>
<td>Action-Rewrite-Display_Results</td>
<td>REPLACE</td>
<td>HTTP.REQ.URL</td>
<td>“/results2.html”</td>
</tr>
</tbody>
</table>

You would then create rewrite policies with the values as shown in the tables below.
Finally, you would bind the rewrite policies, assigning the first a priority of 600 and the second a priority of 700, and then set the goto expression to NEXT for both bindings.

The Citrix ADC now handles these search requests exactly as the Web server did before the Apache rewrite module rules were migrated.

Copied!
Failed!

### Example 7: Marketing Keyword Redirection

October 1, 2019

The marketing department at Example Inc. wants to set up simplified URLs for certain predefined keyword searches on the company’s Web site. For these keywords, it wants to redefine the URL as shown below.

- **External URL:**
  
  \[http://www.example.com/\<marketingkeyword\>\]

- **Internal URL:**
  
  \[http://www.example.com/go/kwsearch.asp?keyword=\<marketingkeyword\>\]

To set up redirection for marketing keywords, you would create a rewrite action with the values in the following table.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
</table>
| Policy-Rewrite-Display_Results_NulSite | Action-Rewrite-Display_Results_NulSite | NOREWRITE         | HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") &&
|                            |                            |                  | (!HTTP.REQ.URL.QUERY.CONTAINS("SiteId=") || HTTP.REQ.URL.QUERY.CONTAINS("SiteId=0") || HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults")) |
| Policy-Rewrite-Display_Results | Action-Rewrite-Display_Results | NOREWRITE         | HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ("/search") || HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS("CallName=DisplayResults") |
You would then create a rewrite policy with the values in the following table.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Modify_URL</td>
<td>Action-Rewrite-Modify_URL</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.example.com&quot;)</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policy, assigning it a priority of 800. Unlike the previous rewrite policies, this policy should be the last to be applied to a request that matches its criteria. For this reason, Citrix ADC administrator sets its Goto Priority Expression to END.

Any request using a marketing keyword is redirected to the keyword search CGI page, whereupon a search is performed and all remaining policies are skipped.

Copied!
Failed!

**Example 8: Redirect Queries to the Queried Server**

October 1, 2019

Example Inc. wants to redirect query requests to the appropriate server, as shown here.

- **Request**: GET /query.cgi?server=5
  
  **HOST**: www.example.com

- **Redirect URL**: <http://web-5.example.com/>

To implement this redirection, you would first create a rewrite action with the values in the following table.
You would then create a rewrite policy with the values in the following table.

<table>
<thead>
<tr>
<th><strong>Policy Name</strong></th>
<th><strong>Action Name</strong></th>
<th><strong>Undefined Action</strong></th>
<th><strong>Expression</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Replace_Hostheader</td>
<td>Action-Rewrite-Replace_Hostheader</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.HEADER(&quot;Host&quot;).EQ(&quot;www.example.com&quot;)</td>
</tr>
</tbody>
</table>

**Example commands:**

```plaintext
> add rewrite action Action-Rewrite-Server_Mask REPLACE HTTP.RES.HEADER("Server") "Web Server 1.0"
Done
> add rewrite policy Policy-Rewrite-Server_Mask HTTP.RES.IS_VALID Action-Rewrite-Server_Mask NOREWRITE
Done
```

Finally, you would bind the rewrite policy, assigning it a priority of 900. Because this policy should be the last policy applied to a request that matches its criteria, you set the goto expression to END.

Incoming requests to any URL that begins with http://www.example.com/ query.cgi?server >= are redirected to the server number in the query.

**Example 9: Home Page Redirection**

October 1, 2019

New Company, Inc. recently acquired a smaller competitor, Purchased Company, and wants to redirect the home page for Purchased Company to a new page on its own Web site, as shown here.

- Old URL: http://www.purchasedcompany.com/*
To redirect requests to the Purchased Company home page, you would create rewrite actions with the values in the following table.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Replace_URLr</td>
<td>REPLACE</td>
<td>HTTP.REQ.URL_PATH_A</td>
<td>/products/page.htm</td>
</tr>
<tr>
<td>Action-Rewrite-Replace_Host</td>
<td>REPLACE</td>
<td>HTTP.REQ.HOSTNAME</td>
<td><a href="http://www.newcompany.com">www.newcompany.com</a></td>
</tr>
</tbody>
</table>

You would then create rewrite policies with the values in the following table.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Replace-None</td>
<td>Action-Rewrite-Replace-None</td>
<td>NOREWRITE</td>
<td>!HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.purchasedcompany.com&quot;)</td>
</tr>
<tr>
<td>Policy-Rewrite-Replace-Host</td>
<td>Action-Rewrite-Replace_Host</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.purchasedcompany.com&quot;)</td>
</tr>
<tr>
<td>Policy-Rewrite-Replace-URL</td>
<td>Action-Rewrite-Replace_URL</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.IS_VALID</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policies globally, assigning the first a priority of 100, the second a priority of 200, and the third a priority of 300. These policies should be the last policies applied to a request that matches the criteria. For this reason, set the goto expression to END for the first and third policies, and to 300 for the second policy. This ensures that all remaining requests are processed correctly.

Requests to the acquired company’s old Web site are now redirected to the correct page on the New Company home page.
Example 10: Policy-based RSA Encryption

February 12, 2020

The RSA algorithm uses the `PKEY_ENCRYPT_PEM()` function to encrypt HTTP predefined and user-defined header or body content. The function accepts only RSA public keys (not private keys) and the encrypted data cannot be longer than the length of the public key. When the data being encrypted is shorter than the key length, the algorithm uses RSA_PKCS1 padding method.

In a sample scenario, the function can be used with `B64ENCODE()` function in a rewrite action to replace an HTTP header value with a value encrypted by an RSA public key. The data being encrypted is then decrypted by the recipient using the RSA private key.

You can implement the feature by using a rewrite policy. To do this, you must complete the following tasks:

1. Add RSA public key as a policy expression.
2. Create rewrite action.
3. Create rewrite policy.
4. Bind rewrite policy as global.
5. Verify RSA encryption

Policy-based RSA encryption by using Citrix ADC command interface

Complete the following tasks to configure policy-based RSA encryption by using the Citrix ADC command interface.

To add RSA public key as a policy expression by using the Citrix ADC command interface:

```
1 add policy expression pubkey "-----BEGIN RSA PUBLIC KEY-----
MIIGAoGBAKl5vgQEj73Kxp+9
yn1v5gPR1pnc4oLM2a0kaWBoS76rzCIy6znwvwyC1xRvQhRlJSAYJbloL7wZFIj2FOR8Cz
+8QWXU2syG+udI4EnWqLgFYowF9zK+o79az597eNPAjsHZ/C2oL/+6qY5a/
f1z8bQPPrHC4GpFfAEJhh/+NnAgMBAAE=-----END RSA PUBLIC KEY-----"
```

To add rewrite an action to encrypt an HTTP header request by using the Citrix ADC command interface:

```
add rewrite action encrypt_act insert_http_header encrypted_data HTTP.REQ.HEADER("data_to_encrypt").PKEY_ENCRYPT_PEM(pubkey).B64ENCODE
```

To add rewrite policy by using the Citrix ADC command interface:
To bind rewrite policy global by using the Citrix ADC command interface:

```plaintext
bind rewrite global encrypt_pol 10 -type RES_DEFAULT
```

To verify RSA encryption by using the Citrix ADC command interface:

```plaintext
> curl -v -H "data_to_encrypt: Now is the time that tries men’s souls"
   http://10.217.24.7/

* About to connect() to 10.217.24.7 port 80 (#0)
* Trying 10.217.24.7...
* connected
* Connected to 10.217.24.7 (10.217.24.7) port 80 (#0)
> GET / HTTP/1.1
> User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4) libcurl/7.24.0
   OpenSSL/0.9.8y zlib/1.2.3
> Host: 10.217.24.7
> Accept: */*
> data_to_encrypt: Now is the time that tries men’s souls
> < HTTP/1.1 200 OK
< Date: Mon, 09 Oct 2017 05:22:37 GMT
< Server: Apache/2.2.24 (FreeBSD) mod_ssl/2.2.24 OpenSSL/0.9.8y DAV/2
< Last-Modified: Thu, 20 Feb 2014 20:29:06 GMT
< ETag: "6bd9f2-2c-4f2dc5b570880"
< Accept-Ranges: bytes
< Content-Length: 44
< Content-Type: text/html
< encrypted_data: UliegKBJqZd7JdaC9XMLEK1+eQN2rEfevypW9igKvBVlaKM9N9/C2BKuztS995E0xQaisidzNSIgeIcpQMn+CiKYVllzPG1RhGaqHYyZt6C8A842da7xE40lV5SHwScqkJ5aVrXc3EwtUksna7j0Lr40aLeXnnB/DB11pUAE=
<
< Connection #0 to host 10.217.24.7 left intact
< 
```

Subsequent execution of this curl command with the same data to encrypt shows that the encrypted data is different each execution. This is because the padding inserts random bytes at the beginning.
of the data to encrypt, causing the encrypted data to be different each time.

```bash
1 > curl -v -H "data_to_encrypt: Now is the time that tries men's souls" http://10.217.24.7/
2 < encrypted_data:
   DaOjtl1Pl4DlQKf58MMeL4cFwFvZwhjMqv5aUYMSIyzk4UpwYhpRvgTNu2lXEVc1H0tcR1EGC

```

### Policy-based RSA encryption by using the GUI

The GUI enables you to complete the following tasks:

**To add RSA public key as a policy expression by using the GUI:**

1. Sign into the Citrix ADC appliance and navigate to **Configurations** > **AppExpert** > **Advanced Expressions**.
2. In the details pane, click **Add** to define an RSA public key as an advanced policy expression.
3. In Create Expression page, set the following parameters:
   a) **Expression name.** Name of the advanced expression.
   b) **Expression.** Define RSA public key as an advanced expression using the Expression Editor.
   c) **Comments.** A brief description of the expression.
4. Click **Create**.

**To add rewrite an action to encrypt an HTTP header request by using the GUI:**

1. Sign into the Citrix ADC appliance and navigate to **Configurations** > **AppExpert** > **Rewrite** > **Actions**.
2. In the details pane, click **Add** to add a rewrite action.
3. In the **Create Rewrite Action** screen, set the following parameters:
   a) **Name.** Name of the rewrite action.
   b) **Type.** Select action type as INSERT_HTTP_HEADER.
c) Use the action type to insert a header. Enter the name of the HTTP header that needs to be rewritten.

d) Expression. Name of the advanced policy expression associated to the action.

e) Comments. A brief description of the rewrite action.

4. Click **Create**.

**To add rewrite advanced policy by using the GUI:**

1. Sign into the Citrix ADC appliance and navigate to **Configurations > AppExpert > Rewrite > Policies**.

2. In the **Rewrite Policies** page, click **Add** to add a rewrite policy.

3. In the **Create Rewrite Policy** page, set the following parameters:
   
a) Name. Name of the rewrite policy.

   b) Action. Name of the rewrite action to perform if the request or response matches this rewrite policy.

   c) Log Action. Name of message log action to use when a request matches this policy.

   d) Undefined-Result Action. Action to perform if the result of policy evaluation is undefined.

   e) Expression. Name of the advanced policy expression that triggers the action.

   f) Comments. A brief description of the rewrite action.

4. Click **Create**.

**To bind rewrite policy global by using the GUI:**

1. Sign into the Citrix ADC appliance and navigate to **Configurations > AppExpert > Rewrite > Policies**.

2. In the **Rewrite Policies** screen, select a rewrite policy that you want to bind and click **Policy Manager**.

3. In the Rewrite Policy Manager page, in the Bind Points section, set the following parameters:
   
a) Bind Point. Select the binding point as Default Global.

   b) Protocol. Select the protocol type as HTTP.

   c) Connection Type. Select the connection type as Request.

   d) Click **Continue** to view the **Policy Binding** section.

   e) In the **Policy Binding** section, select the rewrite policy and set the bind parameters.

4. Click **Bind**.

*Copied!*

*Failed!*
Example 12: Configure rewrite to change the host name and URL in client request on Citrix ADC appliance

February 27, 2020

Rewrite feature on a Citrix ADC appliance is used to convert the URL available in the client request to another URL that the back end server can understand. You can achieve the following benefits by using the rewrite feature:

- Enhances the security by hiding the actual URL to the resource, which is requested by the client.
- Prevents the unauthorized user access from gaining access to the network resources.

Consider an example where your current organization is acquired by another organization. It becomes a difficult job for admins to inform about the new web address to every user of the acquired organization. In this scenario, using rewrite feature becomes convenient to change the host name and URL in the client requests for the website of the acquired organization. You can use rewrite to change the URLs in the client request temporarily when the website is under maintenance.

The following section describes the procedure to change the host name and URL in a client request using rewrite feature.

Consider an example where the user enters a http://www.example.com URL in the web browser. The website administrator wants the Citrix ADC appliance to convert the preceding URL in the client request as http://myexample.example.net.in/resource/inventory/s?t=112.

In the preceding example, the website administrator wants the Citrix ADC appliance to replace the “example.com” domain name with “myexample.example.net.in” and the URL with “resource/inventory/s?t=112”.

Perform the following by using the CLI

1. Log on to the Citrix ADC appliance using SSH.
2. Add rewrite actions.
   - add rewrite action rewrite_host_hdr_act replace "HTTP.REQ.HEADER(""Host")""""""myexample.example.net.in"
   - add rewrite action rewrite_url_act replace HTTP.REQ.URL.PATH_AND_QUERY ""/resource/inventory/s?t=112"
3. Add rewrite policies for the rewrite actions.
   - add rewrite policy rewrite_host_hdr_pol "HTTP.REQ.HEADER(""Host")".CONTAINS(""www.example.com\")" rewrite_host_hdr_act
URL Transformation

February 12, 2020

The URL transformation feature provides a method for modifying all URLs in designated requests from an external version seen by outside users to an internal URL seen only by your Web servers and IT staff. You can redirect user requests seamlessly, without exposing your network structure to users. You can also modify complex internal URLs that users may find difficult to remember into simpler, more easily remembered external URLs.

Note

Before you can use the URL transformation feature, you must enable the Rewrite feature. To enable the Rewrite feature, see Enabling the Rewrite Feature.

URL transform feature rewrites URLs in HTML response body and is not applied to JavaScript and other variables.

To begin configuring URL transformation, you create profiles, each describing a specific transformation. Within each profile, you create one or more actions that describe the transformation in detail. Next, you create policies, each of which identifies a type of HTTP request to transform, and you associate each policy with an appropriate profile. Finally, you globally bind each policy to put it into effect.
Configuring URL Transformation Profiles

February 19, 2020

A profile describes a specific URL transformation as a series of actions. The profile functions primarily as a container for the actions, determining the order in which the actions are performed. Most transformations transform an external hostname and optional path into a different, internal hostname and path. Most useful transformations are simple and require only a single action, but you can use multiple actions to perform complex transformations.

You cannot create actions and then add them to a profile. You must create the profile first, and then add actions to it. In the CLI, creating an action and configuring the action are separate steps. Creating a profile and configuring the profile are separate steps in both the CLI and the configuration utility.

To create a URL transformation profile by using the Citrix ADC command line

At the Citrix ADC command prompt, type the following commands, in the order shown, to create a URL transformation profile and verify the configuration. You can then repeat the second and third commands to configure additional actions:

1. `add transform profile <profileName> -type URL` [onlyTransformAbsURLinBody (ON|OFF)] [-comment <comment>]
2. `add transform action <name> <profileName> <priority>`
4. `show transform profile <name>`

Example:

```
1 > add transform profile shoppingcart -type URL
Done
2 > add transform action actshopping shoppingcart 1000
Done
3 > set transform action actshopping -priority 1000 -reqUrlFrom 'shopping.example.com' -reqUrlInto 'www.example.net/shopping' -resUrlFrom 'www.example.net/shopping' -resUrlInto 'shopping.example.com' -cookieDomainFrom 'example.com' -cookieDomainInto 'example.net' -state ENABLED -comment 'URL transformation for shopping cart.'
Done
4 > show transform profile shoppingcart
Name: shoppingcart
```
To modify an existing URL transformation profile or action by using the Citrix ADC command line

At the Citrix ADC command prompt, type the following commands to modify an existing URL transformation profile or action and verify the configuration:

Note: Use a set transform profile or set transform action command, respectively. The set transform profile command takes the same arguments as does the add transform profile command, and set transform action is the same command that was used for initial configuration.

- show transform profile <name>

Example:

```
1   > set transform action actshopping -priority 1000 -reqUrlFrom 'searching.example.net' -reqUrlInto 'www.example.net/searching' -resUrlFrom 'www.example.net/searching' -resUrlInto 'searching.example.com' -cookieDomainInto 'example.net' -state ENABLED -comment 'URL transformation for searching cart.'
2   Done
3   > show transform profile shoppingcart
4    Name: shoppingcart
5    Type: URL onlyTransformAbsURLInBody: OFF
6    Comment:
7    Actions:
8
9  1) Priority 1000 Name: actshopping ENABLED
10  Done
```
To remove a URL transformation profile and actions by using the Citrix ADC command line

First remove all actions associated with that profile by typing the following command once for each action:

- `rm transform action <name>` After you have removed all actions associated with a profile, remove the profile as shown below.
- `rm transform profile <name>`

To create a URL transformation profile by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, click Add.
3. In the Create URL Transformation Profile dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation profiles” as follows (asterisk indicates a required parameter):
   - Name*—name
   - Comment—comment
   - Only transform absolute URLs in response body—onlyTransformAbsURLinBody
4. Click Create, and then click Close. A message appears in the status bar, stating that the Profile has been configured successfully.

To configure a URL transformation profile and actions by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, select the profile you want to configure, and then click Open.
3. In the Configure URL Transformation Profile dialog box, do one of the following.
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
4. Fill in the Create URL Transformation Action or Modify URL Transformation Action dialog box by typing or selecting values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation profiles” as follows (asterisk indicates a required parameter):
   - Action Name*—name
   - Comments—comment
   - Priority*—priority
   - Request URL from—reqUrlFrom
   - Request URL into—reqUrlInto
   - Response URL from—resUrlFrom
After you create a URL transformation profile, you next create a URL transformation policy to select the requests and responses that the Citrix ADC should transform by using the profile. URL transformation considers each request and the response to it as a single unit, so URL transformation policies are evaluated only when a request is received. If a policy matches, the Citrix ADC transforms both the request and the response.

Note: The URL transformation and rewrite features cannot both operate on the same HTTP header during request processing. Because of this, if you want to apply a URL transformation to a request, you must make sure that none of the HTTP headers it will modify are manipulated by any rewrite action.

To configure a URL transformation policy by using the Citrix ADC command line

You must create a new policy. On the command line, an existing policy can only be removed. At the Citrix ADC command prompt, type the following commands to configure a URL transformation policy and verify the configuration:
To remove a URL transformation policy by using the Citrix ADC command line

At the Citrix ADC command prompt, type the following command to remove a URL transformation policy:

```
rm transform policy <name>
```

Example:

```
1 > rm transform policy polsearch
2  Done
```

To configure a URL transformation policy by using the configuration utility

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Policies.

2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.

3. In the Create URL Transformation Policy or Configure URL Transformation Policy dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation policies” as follows (asterisk indicates a required parameter):
   - Name*—name (Cannot be changed for a previously configured policy.)
   - Profile*—profileName
• Expression—rule

If you want help with creating an expression for a new policy, you can either hold down the Control key and press the space bar while your cursor is in the Expression text box. To create the expression, you can type it directly as described below, or you can use the Add Expression dialog box.

4. Click **Prefix**, and choose the prefix for your expression.

Your choices are:

- HTTP—The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
- SYS—The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
- CLIENT—The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
- SERVER—The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
- URL—The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.
- TEXT—Any text string in the request. Choose this if you want to examine a text string in the request.
- TARGET—The target of the request. Choose this if you want to examine some aspect of the request target.

After you choose a prefix, the Citrix ADC displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom. The choices depend on which prefix you chose.

5. Select your next term.

If you chose HTTP as your prefix, your choices are REQ, which specifies HTTP requests, and RES, which specifies HTTP responses. If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you are certain which choice you want, double-click it to insert it into the Expression window.

1. Type a period, and then continue selecting terms from the list boxes that appear to the right of the previous list box. You type the appropriate text strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

2. Click **Create** or **OK**, depending on whether you are creating a new policy or modifying an existing policy.
3. Click **Close**. A message appears in the status bar, stating that the Policy has been configured successfully.

**To add an expression by using the Add Expression dialog box**

1. In the **Create Responder Action** or **Configure Responder Action** dialog box, click **Add**.
2. In the **Add Expression** dialog box, in the first list box choose the first term for your expression.
   - HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SYS. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - SERVER. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
   - URL. The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.
   - TEXT. Any text string in the request. Choose this if you want to examine a text string in the request.
   - TARGET. The target of the request. Choose this if you want to examine some aspect of the request target.

   When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

---

**Globally Binding URL Transformation Policies**

February 13, 2020
After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the Citrix ADC OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the Citrix ADC to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the Citrix ADC to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

To bind a URL transformation policy by using the Citrix ADC command line

At the Citrix ADC command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- `bind transform global <policyName> <priority>`
- `show transform global`

**Example:**

```
1 > bind transform global polisearching 100
2   Done
3 > show transform global
4   1) Policy Name: polisearching
5     Priority: 100
6   
7   Done
```

To bind a URL transformation policy by using the configuration utility

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click **Policies**.
2. In the details pane, click **Policy Manager**.
3. In the **Transform Policy Manager** dialog box, choose the bind point to which you want to bind the policy. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance, and are applied before any other policies.
   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
   - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
   - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance.
   - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.

4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound URL transformation policies.

5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound URL transformation policies.

6. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the Configure Transform Policy dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

7. Repeat steps 3 through 6 to add any additional URL transformation policies you want to globally bind.

8. Click **OK** to save your changes. A message appears in the status bar, stating that the Policy has been configured successfully.
Globally Binding URL Transformation Policies

February 13, 2020

After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the Citrix ADC OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the Citrix ADC to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the Citrix ADC to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

To bind a URL transformation policy by using the Citrix ADC command line

At the Citrix ADC command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- `bind transform global <policyName> <priority>`
- `show transform global`

Example:

```plaintext
1 > bind transform global polisearching 100
2 Done
3 > show transform global
4 1) Policy Name: polisearching
5     Priority: 100
6
7 Done
```
To bind a URL transformation policy by using the configuration utility

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click **Policies**.
2. In the details pane, click **Policy Manager**.
3. In the Transform Policy Manager dialog box, choose the bind point to which you want to bind the policy**. The choices are:
   - **Override Global**. Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance, and are applied before any other policies.
   - **LB Virtual Server**. Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
   - **CS Virtual Server**. Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
   - **Default Global**. Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance.
   - **Policy Label**. Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound URL transformation policies.
5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound URL transformation policies.
6. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the Configure Transform Policy dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.
7. Repeat steps 3 through 6 to add any additional URL transformation policies you want to globally bind.
8. Click **OK** to save your changes. A message appears in the status bar, stating that the Policy has been configured successfully.
Diameter Support for Rewrite

February 12, 2020

The Rewrite feature now supports the Diameter protocol. You can configure Rewrite to modify Diameter requests and response as you would HTTP or TCP requests and responses, allowing you to use Rewrite to manage the flow of Diameter requests and make necessary modifications. For example, if the “Origin-Host” value in a Diameter request is inappropriate, you can use Rewrite to replace it with a value that is acceptable to the Diameter server.

To configure Rewrite to modify a Diameter request

To configure the Rewrite feature to replace the Origin-Host in a diameter request with a different value, at the command prompt, type the following commands:

- `<add rewrite action <actname> replace "DIAMETER.REQ.AVP(264,"Citrix ADC.example.net\")"`
  For `<actname>`, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For Citrix ADC.example.net, substitute the Host-Origin that you want to use instead of the original Host-Name.

- `<add rewrite policy <polname> "diameter.req.avp(264).value.eq("host.example.com\")" <actname>`
  For `<polname>`, substitute a name for your new policy. As with `<actname>`, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host.example.com, substitute the name of the Host-Origin that you want to change. For `<actname>`, substitute the name of the action that you just created.

- `<bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST`
  For `<vservername>`, substitute the name of the load balancing virtual server to which you want to bind the policy. For `<polname>`, substitute the name of the policy you just created. For `<priority>`, substitute a priority for the policy.

**Example:**

To create a Rewrite action and policy to modify all Diameter Host-Origins of “host.example.com” to “Citrix ADC.example.net”, you could add the following action and policy, and bind the policy as shown.
You can configure the rewrite feature to modify DNS requests and responses, as you would for HTTP or TCP requests and responses. You can use rewrite to manage the flow of DNS requests, and make necessary modifications in the header, or in the answer section. For example, if the DNS response does not have the AA bit set in the header flag, you can use rewrite to set the AA bit in the DNS response and send it to the client.

DNS Expressions

In a rewrite configuration, you can use the following Citrix ADC expressions to refer to various portions of a DNS request or response:

See Expressions and Descriptions

DNS Bind Points

The following global bind points are available for policies that contain DNS expressions.

<table>
<thead>
<tr>
<th>Bind Points</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS_REQ_OVERRIDE</td>
<td>Override request policy queue.</td>
</tr>
<tr>
<td>DNS_REQ_DEFAULT</td>
<td>Standard request policy queue.</td>
</tr>
<tr>
<td>DNS_RES_OVERRIDE</td>
<td>Override response policy queue.</td>
</tr>
</tbody>
</table>
Bind Points | Description
--- | ---
DNS_RES_DEFAULT | Standard response policy queue.

In addition to the default bind points, you can create policy labels of type DNS_REQ or DNS_RES and bind DNS policies to them.

**Rewrite Action Types for DNS**

- **replace_dns_answer_section**—This action replaces the DNS answers section with the defined expression in the DNS policy.
- **replace_dns_header_field**—Checks the opcode type in the DNS request. Returns True or False, indicating whether the opcode type in the DNS request matches the specified opcode type. This action replaces the DNS header section with the defined expression in the DNS policy.

**Configuring Rewrite Policies for DNS**

The following procedure uses the Citrix ADC command line to configure a rewrite action and policy and bind the policy to a rewrite-specific global bind point.

**Configure Rewrite action and policy, and bind the policy for DNS**

At the command prompt, type the following commands:

1. `add rewrite action <actName> <actType>`
   
   For `<actName>`, substitute a name for your new action. The name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For `<actType>`, specify the rewrite action types provided for DNS expressions.

2. `add rewrite policy <polName> <rule> <actName>`
   
   For `<polName>`, substitute a name for your new policy. For `<actName>`, the name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For `<actName>`, substitute the name of the action that you just created.

3. `bind rewrite global <polName> <priority> <gotoPriorityExpression> -type <bindPoint>`
   
   For `<polName>`, substitute the name of the policy that you just created. For `<priority>`, specify the priority of the policy. For `<bindPoint>`, substitute one of the rewrite-specific global bind points.
Example:

Set the AA bit of DNS request to load balance virtual server.

The following commands configure the Citrix ADC appliance to act as an authoritative DNS server for all the queries that it serves.

```
1  add rewrite action set_aa replace_dns_header_field dns.req.header.flags.set(aa)
2  add rewrite policy pol !dns.req.header.flags.is_set(aa) set_aa
3  bind rewrite global pol 100 -type dns_res_override
```

Modify the response answer and header section.

If the server responds with an NX domain, you can set the rewrite action to replace the response with specified IP address. A NOPOLICY-REWRITE enables you to invoke an external bank without processing an expression (a rule). This entry is a dummy policy that does not contain a rule but directs the entry to a policy label or virtual server specific policy banks.

```
1  add rewrite action set_aa_res replace_dns_header_field "dns.res.header.flags.set(aa)"
2  add rewrite action modify_nxdomain_res replace_dns_answer_section "dns.new_rrset_a("10.102.218.160",300)"
3  add rewrite policy set_res_aa true set_aa_res
4  add add rewrite policy modify_answer "dns.RES.HEADER.RCODE.EQ(nxdomain) && dns.RES.QUESTION.TYPE.EQ(A)"
5  modify_nxdomain_res
6  add rewrite policylabel MODIFY_NODATA dns_res
7  bind rewrite policylabel MODIFY_NODATA modify_answer 10 END
8  bind rewrite policylabel MODIFY_NODATA set_res_aa 11 END
9  bind lb vserver v1 -policyName NOPOLICY-REWRITE -priority 11 -gotoPriorityExpression END -type
10 RESPONSE -invoke policylabel MODIFY_NODATA
```

Limitations:

- Rewrite policies are evaluated only if the Citrix ADC appliance is configured as a DNS proxy server and there is a cache miss.
- If the Recursion Available (RA) flag in the header is set to YES, the RA flag will not be modified in the rewrites.
- If the RA flag in the header is set to YES, the CD flag in the header is modified regardless of any rewrite action.
String maps

You can use string maps to perform pattern matching in all Citrix ADC features that use the default policy syntax. A string map is a Citrix ADC entity that consists of key-value pairs. The keys and values are strings in either ASCII or UTF-8 format. String comparison uses two new functions, `MAP_STRING(<string_map_name>)` and `IS_STRINGMAP_KEY(<string_map_name>)`.

A policy configuration that uses string maps performs better than one that does string matching through policy expressions, and you need fewer policies to perform string matching with a large number of key-value pairs. String maps are also intuitive, simple to configure, and result in a smaller configuration.

How String Maps Work

String maps are similar in structure to pattern sets (a pattern set defines a mapping of index values to strings; a string map defines a mapping of strings to strings) and the configuration commands for string maps (commands such as add, bind, unbind, remove, and show) are syntactically similar to configuration commands for pattern sets. Also, as with index values in a pattern set, each key in a string map must be unique across the map. The following table illustrates a string map called `url_string_map`, which contains URLs as keys and values.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>/url_1.html</td>
<td><code>http://www.redirect_url_1.com/url_1.html</code></td>
</tr>
<tr>
<td>/url_2.html</td>
<td><code>http://www.redirect_url_2.com/url_2.html</code></td>
</tr>
</tbody>
</table>

Table 1. String Map “url_string_map”

The following table describes the two functions that have been introduced to enable string matching with keys in a string map. String matching is always performed with the keys. Additionally, the following functions perform a comparison between the keys in the string map and the complete string that is returned by the expression prefix. The examples in the descriptions refer to the preceding example.

For completed information about the two functions introduced for enabling string matching with keys
in a string map, see String Map Function table pdf.

Configuring a String Map

You first create a string map and then bind key-value pairs to it. You can create a string map from the command line interface (CLI) or the configuration utility.

To configure a string map by using the command line interface

At the command prompt, do the following:

1. Create a string map.

```
add policy stringmap <name> -comment <string>
```

1. Bind a key-value pair to the string map.

```
bind policy stringmap <name> <key> <value> [-comment <string>]
```

Example:

```
bind policy stringmap url_string_map1 "/url_1.html" "http://www.redirect_url_1.com/url_1.html"
```

To configure a string map by using the Citrix ADC GUI

Navigate to AppExpert > String Maps, click Add and specify the relevant details.

Example: responder policy with a redirect action

The following use case involves a responder policy with a redirect action. In the example below, the first four commands create the string map url_string_map and bind the three key-value pairs used in the earlier example. After creating the map and binding the key-value pairs, you create a responder action (act_url_redirects) that redirects the client to the corresponding URL in the string map or to www.default.com. You also configure a responder policy (pol_url_redirects) that checks whether requested URLs match any of the keys in url_string_map and then performs the configured action. Finally, you bind the responder policy to the content switching virtual server that receives the client requests that are to be evaluated.

```
add stringmap url_string_map
bind stringmap url_string_map /url_1.html http://www.redirect_url_1.com/url_1.html
bind stringmap url_string_map /url_2.html http://www.redirect_url_2.com/url_2.html
```
bind stringmap url_string_map /url_3.html http://www.redirect_url_1.com/url_1.html
add responder action act_url_redirects redirect 'HTTP.REQ.URL.MAP_STRING("url_string_map")'ALT "www.default.com"'-bypassSafetyCheck yes
add responder policy pol_url_redirects TRUE act_url_redirects
bind cs vserver csxRedirect -policyname pol_url_redirects -priority 1 -type request

To configure a string map by using the Citrix ADC GUI

Follow the procedure given below to configure a string map.

2. On the details pane, click Add.
3. In the Create String Map page, set the following parameters:
   - Name. Name of the string map.
   - Configure key value. ASCII based key value entry bound to the string map
   - Comments. A short description about the key values bound to the string map.
4. Click Create and Close.

URL Sets

June 18, 2019

This feature enables you to blacklist one million URLs. The section includes the following topics:

- Getting Started
- Using Advanced Policy Expressions for URL Evaluation
- Configuring a URL Set
- URL Pattern Semantics
- Blacklisted URL Categories

Getting Started

August 10, 2020

To prevent access to restricted websites, a Citrix ADC appliance uses a specialized URL matching algorithm. The algorithm uses a URL set that can contain a list of URLs up to 1 million (1,000,000) blacklisted entries. Each entry can include metadata that defines URL categories and category groups as indexed patterns. The appliance can also periodically download URLs of highly sensitive URL sets managed by internet enforcement agencies (with government websites) or internet organizations. Once the URL set is downloaded from a website and imported into the appliance, the appliance encrypts the URL sets (as required by these agencies) and they are kept confidential and the entries are not tampered.

The Citrix ADC appliance uses advanced policies to determine whether an incoming URL must be blocked, allowed, or redirected. These policies use advanced expressions to evaluate incoming URLs against blacklisted entries. An entry can include metadata. For entries that have no metadata, you might want to use an expression that evaluates the URL based on an exact string match. For other URLs, you might want to use an expression that evaluates the URL’s metadata, in addition to an expression that checks for an exact string match.

Use Case for Safe Internet Access Policies for ISPs/Telcos

A URL set enables an ISP (ISP) or a Telco customer to enforce government mandated safe internet access policies such as:
1. Block access to illegal internet sites (child abuse, drugs, and so on)
2. Safe browsing for children

A Citrix ADC appliance enables you to periodically download URL sets managed by internet enforcement agencies or independent internet organizations. The appliance periodically downloads the list and updates it securely. The list is stored as confidential URL sets so that it is not tampered or human readable. The periodically downloaded URL set functions as a blacklisted set for URL evaluation purposes.

If you have a private URL set and the contents of the list are kept confidential and the network administrator does not know about the blacklisted URLs present in the list. To make sure the policy is configured correctly and the correct list is referenced, you must configure the Canary URL and add it to the URL set. Using the Canary URL, the administrator can request through the appliance uses the private URL set to ensure it is looked up for every URL request.

**Advanced Policy Expressions for URL Evaluation**

February 12, 2020

The following table describes the expressions you can use to evaluate incoming URLs with entries in an URL set.

**Note:** HTTP.REQ.URL is generalized to be used as <URL expression>

<table>
<thead>
<tr>
<th>Expression</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;URL expression&gt;.URLSET_MATCHES_ANY</td>
<td>Evaluates to TRUE if the URL exactly matches any entry in the URL set.</td>
</tr>
<tr>
<td>&lt;URL expression&gt;.GET_URLSET_METADATA(&lt;URLSET&gt;)</td>
<td>The GET_URLSET_METADATA() expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there was no match.</td>
</tr>
<tr>
<td>&lt;URL expression&gt;.GET_URLSET_METADATA(&lt;URLSET&gt;).EQ(&lt;METADATA&gt;)</td>
<td>Evaluates to TRUE if the matched metadata is equal to &lt;METADATA&gt;.</td>
</tr>
</tbody>
</table>
Expression | Operation
---|---
`<URL expression> .GET_URLSET_METADATA(<URLSET>).TYPECAST_LIST_T(‘;’).GET(0).EQ(<CATEGORY>)` | Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata, but match only the 1st field.

HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL) | Joins the host and URL parameters, which can then be used as a `<URL expression>` for matching.

---

**Configuring URL Set**

August 19, 2020

You can perform the following tasks to configure a URL set and restrict URLs on a Citrix ADC platform:

1. Import a URL set (download and encrypt it). Importing a URL set in a Citrix ADC appliance allows you to download the URL file, adding the file to the appliance, and then encrypting the file. Until you add the URL set to the system, it is not visible to the user.

You can download a set in the following ways:

- Download a URL set once from a remote server and specify it as `http://myserver.com/file_with_urlset.csv`
- add a file under the `/var/tmp/` path inside ADC and use the command, as in the example:

```shell
1 > shell cat /var/tmp/test_urlset.csv
2 example.com
3 google.com
4 > import policy urlset top10
5 k -url local:test_urlset.csv -delimiter "," -rowSeparator "n" -interval 10 -privateSet -canaryUrl http://www.in.gr
6 Done
```

The imported URL set is further categorized into different categories and category groups in the database. This is valid only if categories exist in the metadata of the URL set file.

**Note:** There can be a chance that you might have URL patterns without metadata.
Once you have imported the file, you can update, delete, or display file properties. After the file is pushed into the appliance, you can modify the entries by more adding rows.

The imported set is then stored in an encrypted file format on the Citrix ADC directory. The imported list contains millions of URL entries. To the following ‘The imported list can contain up to 1 million URL entries. Otherwise, the appliance returns an error message saying that the value exceeds the limit. If the imported URL set has blacklisted entries with metadata, the metadata it is detected by the appliance when it is imported.

Once you import a URL set and add it into the appliance, the URL set is available for advanced policies to identify the correct URL set during incoming URL evaluation. **HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY(<URL set name>)**

1. Updating a URL set on the Citrix ADC appliance. Once you have pushed the file into the appliance, at this interval you can manually update a URL file by using command line interface.

2. Exporting a URL set. If you prefer a backup of the URL set, you can export the list of URL patterns and save a copy of it to a destination URL. Before you export, check whether the URL set is marked as private. If is marked private, the URL set cannot be exported. Export functionality does not work with private set. So a new url set `myurl` would be imported without private set defined, and then it would be exported to another file in a local path, as below:

```
> shell touch /var/tmp/test_urlset_export.csv
Done
> shell cat /var/tmp/test_urlset_export.csv
Done
> shell cat /var/tmp/test_urlset.csv
example.com
google.com
Done
> export urlset myurl -url local:test_urlset_export.csv
> import urlset myurl -url local:test_urlset.csv
Done
(a non-private urlset is imported)
```

1. Removing a URL set. If you want to delete a URL set of blacklisted entries, you can use the remove command to delete the URL set from the Citrix ADC appliance.

2. Displaying a URL set. You can display the properties of a URL set by using the show command.

**Example:**

```
show urlset
```
Import a URL set with meta by using the command line interface

At command prompt, type:

```
```

Where,

delimiter is a CSV file record with default value set as 44.

rowSeparator is a CSV file row separator with default value set as 10.

Interval is the time interval in secs, rounded to the nearest 15 minutes at which the update of the url set occurs.

CanaryURL is a URL used for testing when the contents of the url set is kept confidential.

Example

```
import policy urlset -url local:test_urlset.csv -delimiter "," -rowSeparator "n" -interval 10 -privateSet -canaryUrl http://www.in.gr
```

Perform explicit subdomain match for an imported URL set

You can now perform an explicit subdomain match for an imported URL set. To do this, a new parameter, “subdomainExactMatch” is added to the “import policy URLset” command. When you enable the parameter, the URL Filtering algorithm performs an explicit subdomain match. For example, if the incoming URL is “news.example.com” and if the entry in the URL set is “example.com,” the algorithm does not match the URLs.

At the command prompt, type:

```
```

Example:

```
import policy urlset forth_urlset -url local:test_urlset.csv -interval 3600
```
To show the URL set by using the command line interface

At the command prompt, type:

```
show urlset <name>
```

**Example:**

At the command prompt, type:

```
  URLset   Count
  ------   -----   
  1) top1k   100
  Done

> show urlset top1k
  Count       Delimiter   Interval   RowSeparator
  ------       ----------   ---------   ------------
  100          0           0           0x0a
  Done

> 
```

To show the URL set imported by using the command line interface

At the command prompt, type:

```
show urlset imported
```

**Example:**

At the command prompt, type:

```
  URLset
  ------
  1) top1k
  Done

> 
```

To show URL set by using the command line interface

At the command prompt, type:

```
show urlset <name>
```
To export a URL set by using the command line interface

At the command prompt, type:

```
export urlset <name> <url>
```

To add a URL set by using the command line interface

At the command prompt, type:

```
add urlset <urlset_name>
```

To update a URL set by using the command line interface

At the command prompt, type:

```
update urlset <name>
```

To remove a URL set command by using the command line interface

At the command prompt, type:

```
remove urlset <name>
```

Example:

```
Note:
Before you import or export a URL set, you must make sure the test_urlset_export.csv and test_urlset.csv files are created and available under the /var/tmp directory.

1  import policy urlset -url local: test_urlset.csv -delimiter "," -rowSeparator "n" -interval 10 -privateSet -overwrite -canaryUrl http://www.in.gr
2  3  add policy urlset top10k
4  5  update policy urlset top10k
6  7  sh policy urlset
8  9  sh policy urlset top10k
10 11  export policy urlset urlset1 -url local: test_urlset_export.csv
12
```
**Display imported URL sets**

You can now display imported URL sets in addition to added URL sets. To do this, a new parameter “imported” is added to the “show url set” command. If you enable this option, the appliance displays all imported URL sets and distinguishes the imported URL sets from the added URL sets.

At the command prompt, type:

```bash
show policy urlset [<name>] [-imported]
```

**Example:**

```bash
show policy urlset -imported
```

**To import a URL set by using the GUI**

Navigate to **AppExpert > URL Sets**, click **Import** to download the URL set.

**To add a URL set by using the GUI**

Navigate to **AppExpert > URL Sets**, click **Add** to create a URL set file for the downloaded URL set.

**To edit a URL set by using the GUI**

Navigate to **AppExpert > URL Sets**, select a URL set and click **Edit** to modify.

**To Update a URL set by using the GUI**

Navigate to **AppExpert > URL Sets**, select a URL set and click **Update URL Set** to update the URL set with the latest modifications made to the file.
To Export a URL set by using the GUI

Navigate to **AppExpert > URL Sets**, select a URL set and click **Export URL Set** to export the URL patterns in a set to a destination URL and save it in that location.

**URL Pattern Semantics**

April 23, 2019

The following table shows the URL patterns used for specifying the list of pages you want to filter. For example, the pattern, `www.example.com/bar` will only match the single page `www.example.com/bar`. To cover all the pages where the URL starts with `www.example.com/bar`, you must explicitly add a `*` at the end.

For more information, see [Following is the semantics for a URL pattern to match the metadata mapping](#)

**URL Categories**

April 23, 2019

Following is a list of blacklisted categories.

### AppFlow

June 30, 2020

The Citrix ADC appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. It also collects webpage performance data and database information. AppFlow transmits the information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco’s NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information, webpage performance data, and database information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called flow records, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, SSL_TCP flows, and HDX Insight flows. You can sample and filter the flow types that you want to monitor.

**Note**

For more information on HDX Insight, see [HDX Insight](#).

AppFlow use actions and policies to send records for a selected flow to specific set of collectors. An AppFlow action specifies which set of collectors receive the AppFlow records. Policies, which are
based on Advanced expressions can be configured to select flows for which flow records are sent to the collectors specified by the associated AppFlow action.

To limit the types of flows, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

Note: This feature is supported only on Citrix ADC nCore builds.

**How AppFlow Works**

In the most common deployment scenario, inbound traffic flows to a Virtual IP address (VIP) on the Citrix ADC appliance and is load balanced to a server. Outbound traffic flows from the server to a mapped or subnet IP address on the Citrix ADC and from the VIP to the client. A flow is a unidirectional collection of IP packets identified by the following five tuples: sourceIP, sourcePort, destIP, destPort, and protocol.

The following figure describes how the AppFlow feature works.

**Figure 1. Citrix ADC Flow Sequence**

As shown in the figure, the network flow identifiers for each leg of a transaction depend on the direction of the traffic.

The different flows that form a flow record are:

**Flow1:** `<Client-IP, Client-Port, VIP-IP, VIP-port, Protocol>`

**Flow2:** `<NS-MIP/SNIP, NS-port, Server-IP, Server-Port, Protocol>`

**Flow3:** `<Server-IP, Server-Port, NS-MIP/SNIP, NS-Port, Protocol>`

**Flow4:** `<VIP-IP, VIP-port, Client-IP, Client-Port, Protocol>`

To help the collector link all four flows in a transaction, AppFlow adds a custom transactionID element to each flow. For application-level content switching, such as HTTP, it is possible for a single client TCP connection to be load balanced to different back end TCP connections for each request. AppFlow provides a set of records for each transaction.
Flow Records

AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response status codes, server response time, and latency). Webpage performance data (such as page load time, page render time, and time spent on the page). And database information (such as database protocol, database response status, and database response size). IPFIX flow records are based on templates that need to be sent before sending flow records.

Templates

AppFlow defines a set of templates, one for each type of flow. Each template contains a set of standard Information Elements (IEs) and Enterprise-specific Information Elements (EIEs). IPFIX templates define the order and sizes of the Information Elements (Internet Explorer) in the flow record. The templates are sent to the collectors at regular intervals, as described in RFC 5101.

A template can include the following EIEs:

- transactionID

  An unsigned 32-bit number identifying an application-level transaction. For HTTP, it corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. In the most common case, there are four uniflow records that correspond to this transaction. If the Citrix ADC generates the response by itself (served from the integrated cache or by a security policy), there might be only two flow records for this transaction.

- connectionID

  An unsigned 32-bit number identifying a layer-4 connection (TCP or UDP). The Citrix ADC flows are bidirectional, with two separate flow records for each direction of the flow. This information element can be used to link the two flows.

  For the Citrix ADC, a connectionID is an identifier for the connection data structure to track the progress of a connection. In an HTTP transaction, for instance, a given connectionID might have multiple transactionID elements corresponding to multiple requests that were made on that connection.

- tcpRTT

  The round trip time, in milliseconds, as measured on the TCP connection. It can be used as a metric to determine the client or server latency on the network.

- httpRequestMethod
An 8-bit number indicating the HTTP method used in the transaction. An options template with the number-to-method mapping is sent along with the template.

- httpRequestSize
  An unsigned 32-bit number indicating the request payload size.

- httpRequestURL
  The HTTP URL requested by the client.

- httpUserAgent
  The source of incoming requests to the Web server.

- httpResponseStatus
  An unsigned 32-bit number indicating the response status code.

- httpResponseSize
  An unsigned 32-bit number indicating the response size.

- httpResponseTimeToFirstByte
  An unsigned 32-bit number indicating the time taken to receive the first byte of the response.

- httpResponseTimeToLastByte
  An unsigned 32-bit number indicating the time taken to receive the last byte of the response.

- flowFlags
  An unsigned 64-bit flag used to indicate different flow conditions.

**EIEs for webpage performance data**

- clientInteractionStartTime
  Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and style sheets.

- clientInteractionEndTime
  Time at which the browser received the last byte of response to load all the objects of the page such as images, scripts, and style sheets.

- clientRenderStart_Time
  Time at which the browser starts to render the page.

- clientRenderEndTime
  Time at which a browser finished rendering the entire page, including the embedded objects.
**EI Es for database information**

- dbProtocolName
  
  An unsigned 8-bit number indicating the database protocol. Valid values are 1 for MS SQL and 2 for MySQL.

- dbReqType
  
  An unsigned 8-bit number indicating the database request method used in the transaction. For MS SQL, valid values are 1 is for QUERY, 2 is for TRANSACTION, and 3 is for RPC. For valid values for MySQL, see the MySQL documentation.

- dbReqString
  
  Indicates the database request string without the header.

- dbRespStatus
  
  An unsigned 64-bit number indicating the status of the database response received from the web server.

- dbRespLength
  
  An unsigned 64-bit number indicating the response size.

- dbRespStatString
  
  The response status string received from the web server.

**Configuring the AppFlow Feature**

**June 17, 2020**

You configure AppFlow in the same manner as most other policy-based features. First, you enable the AppFlow feature. Then you specify the collectors to which the flow records are sent. After that, you define actions, which are sets of configured collectors. Then you configure one or more policies and associate an action to each policy. The policy tells the Citrix ADC appliance to select requests the flow records of which are sent to the associated action. Finally, you bind each policy either globally or to the specific virtual server to put it into effect.

You can further set AppFlow parameters to specify the template refresh interval and to enable the exporting of httpURL, httpCookie, and httpReferer information. On each collector, you must specify the Citrix ADC IP address as the address of the exporter.
Enabling AppFlow

To be able to use the AppFlow feature, you must first enable it.

**Note**
AppFlow can be enabled only on nCore Citrix ADC appliances.

To enable the AppFlow feature by using the command line interface

At the command prompt, type one of the following commands:

```
enable ns feature AppFlow
```

To enable the AppFlow feature by using the configuration utility

Navigate to **System > Settings**, click **Configure Advanced Features**, and select the **AppFlow** option.

Specifying a Collector

A collector receives AppFlow records generated by the Citrix ADC appliance. To send the AppFlow records, you must specify at least one collector. By default, the collector listens to IPFIX messages on UDP port 4739. You can change the default port, when configuring the collector. Similarly, by default, NSIP is used as the source IP for AppFlow traffic. You can change this default source IP to a SNIP address when configuring a collector. You can also remove unused collectors.

To specify a collector by using the command line interface

**Important**
Starting from Citrix ADC release 12.1–55.13, you can specify the type of collector that you want
A new parameter “Transport” is introduced in the “add appflow collector” command. By default, the collector listens to IPFIX messages. You can change the type of collector to either logstream or ipfix or rest by using “Transport” parameter. For more information on configuration, see the example.

At the command prompt, type the following commands to add a collector and verify the configuration:

```
1 - add appflow collector <name> -IPAddress <ipaddress> -port <port_number> -netprofile <netprofile_name> -Transport <Transport>
2 - show appflow collector <name>
```

Example

```
1 add appflow collector col1 -IPAddress 10.102.29.251 -port 8000 -netprofile n2 -Transport ipfix
```

To specify multiple collectors by using the command line interface

At the command prompt, type the following commands to add and send same data to multiple collectors:

```
1 add appflow collector <collector1> -IPAddress <IP>
2 add appflow collector <collector2> -IPAddress <IP>
3 add appflow action <action> -collectors <collector1> <collector2>
4 add appflow policy <policy> true <action>
5 bind lbvserver <lbvserver> -policy <policy> -priority <priority>
```

To specify one or more collectors by using the configuration utility

Navigate to System > AppFlow > Collectors, and create the AppFlow collector.

Configuring an AppFlow Action

An AppFlow action is a set collector, to which the flow records are sent if the associated AppFlow policy matches.
To configure an AppFlow action by using the command line interface

At the command prompt, type the following commands to configure an AppFlow action and verify the configuration:

```
1  add appflow action <name> --collectors <string> ... [-clientSideMeasurements (Enabled|Disabled) ] [-comment <string>]
2
3  show appflow action
```

Example

```
1  add appflow action apfl-act-collector-1-and-3 -collectors collector-1-collecter-3
```

To configure an AppFlow action by using the configuration utility

Navigate to System > AppFlow > Actions, and create the AppFlow action.

Configuring an AppFlow Policy

After you configure an AppFlow action, you must next configure an AppFlow policy. An AppFlow policy is based on a rule, which consists of one or more expressions.

**Note**

For creating and managing AppFlow policies, the configuration utility provides assistance that is not available at the command line interface.

To configure an AppFlow policy by using the command line interface

At the command prompt, type the following command to add an AppFlow policy and verify the configuration:

```
1  add appflow policy <name> <rule> <action>
2
3  show appflow policy <name>
```
Example

```
1 add appflow policy apfl-pol-tcp-dsprt client.TCP.DSTPORT.EQ(22) apfl-
act-collector-1-and-3
```

To configure an AppFlow policy by using the configuration utility

Navigate to System > AppFlow > Policies, and create the AppFlow policy.

To add an expression by using the Add Expression dialog box

1. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   - HTTP
     The HTTP protocol. Choose the option if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SSL
     The protected websites. Choose the option if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT
     The computer that sent the request. Choose the option if you want to examine some aspect of the sender of the request.
     When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

2. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

3. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

Binding an AppFlow Policy

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to the traffic related to that virtual server.
When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the Citrix ADC operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first. Later, the policy assigned with a priority of 100, and finally the policy assigned an order of 1000.

You can leave yourself plenty of a room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add more policies at any time without having to change the priority of an existing policy.

To globally bind an AppFlow policy by using the command line interface

At the command prompt, type the following command to globally bind an AppFlow policy and verify the configuration:

```
bind appflow global <policyName> <priority> [<gotoPriorityExpression [-type <type>]] [-invoke (<labelType> <labelName>)]
```

**Example**

```
bind appflow global af_policy_lb1_10.102.71.190 NEXT -type REQ_OVERRIDE -invoke vserver google
```

To bind an AppFlow policy to a specific virtual server by using the command line interface

At the command prompt, type the following command to bind an AppFlow policy to a specific virtual server and verify the configuration:

```
bind lb vserver <name> -policyname <policy_name> -priority <priority>
```

**Example**

```
bind lb vserver google -policyname af_policy_google_10.102.19.179 -priority 251
```
To globally bind an AppFlow policy by using the configuration utility

Navigate to System > AppFlow, click AppFlow policy Manager, and select the relevant Bind Point (Default Global) and Connection Type, and then bind the AppFlow policy.

To bind an AppFlow policy to a specific virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, select the virtual server, and click Policies, and bind the AppFlow policy.

Enabling AppFlow for Virtual Servers

If you want to monitor only the traffic through certain virtual servers, enable AppFlow specifically for those virtual servers. You can enable AppFlow for load balancing, content switching, cache redirection, SSL VPN, GSLB, and authentication virtual servers.

To enable AppFlow for a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> <protocol> <IPAddress> <port> -appflowLog ENABLED
```

Example

```
set cs vserver Vserver-CS-1 HTTP 10.102.29.161 80 -appflowLog ENABLED
```

To enable AppFlow for a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select the virtual server, and enable AppFlow Logging option.

Enabling AppFlow for a Service

You can enable AppFlow for services that are to be bound to the load balancing virtual servers.
To enable AppFlow for a service by using the command line interface

At the command prompt, type:

```
set service <name> -appflowLog ENABLED
```

Example

```
set service ser -appflowLog ENABLED
```

To enable AppFlow for a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, select the service, and enable AppFlow Logging option.

Setting the AppFlow Parameters

You can set AppFlow parameters to customize the exporting of data to the collectors.

To set the AppFlow Parameters by using the command line interface

**Important**

- Starting from Citrix ADC release 12.1–55.13, you can use the NSIP to send Logstream records instead of the SNIP. A new parameter “logstreamOverNSIP” is introduced in the “set appflow param” command. By default, the “logstreamOverNSIP” parameter is DISABLED, you must “ENABLE” it. For more information on configuration, see the example.

- Starting from Citrix ADC release 13.0-58.x release, you can enable the Web SaaS application option in AppFlow feature. It can be enabled to receive the data usage of Web or SaaS applications from the Citrix Gateway service. For more information on configuration, see the example.

At the command prompt, type the following commands to set the AppFlow parameters and verify the settings:

```
set appflow param [-templateRefresh <secs>] [-appnameRefresh <secs>] [-flowRecordInterval <secs>] [-udpPmtu <positive_integer>] [-httpUrl (**ENABLED** | **DISABLED**)] [-httpCookie (**ENABLED** | **DISABLED**)] [-httpReferer (**ENABLED** | **DISABLED**)] [-httpMethod (**ENABLED** | **DISABLED**)] [-httpHost (**ENABLED** | **DISABLED**)] [-httpUserAgent (**ENABLED** | **DISABLED**)]
```

To set the AppFlow parameters by using the configuration utility

Example: Configuring AppFlow for DataStream

The following example illustrates the procedure for configuring AppFlow for DataStream using the command line interface.

```
1 enable feature appflow
2 add db user sa password freebsd
3 add lbvserver lb0 MSSQL 10.102.147.97 1433 -appflowLog ENABLED
4 add service sv0 10.103.24.132 MSSQL 1433 -appflowLog ENABLED
5 bind lbvserver lb0 sv0
6 add appflow collector col0 -IPAddress 10.102.147.90
7 add appflow action act0 -collectors col0
8 add appflow policy pol0 "mssql.req.query.text.contains("select")" act0
9 bind lbvserver lb0 -policyName pol0 -priority 10
```

When the Citrix ADC appliance receives a database request, the appliance evaluates the request against a configured policy. If a match is found, the details are sent to the AppFlow collector configured in the policy.
Exporting Performance Data of Web Pages to AppFlow Collector

April 23, 2019

The EdgeSight Monitoring application provides web page monitoring data with which you can monitor the performance of various Web applications served in a Citrix ADC environment. You can now export this data to AppFlow collectors to get an in-depth analysis of the web page applications. AppFlow, which is based on IPFIX standard, provides more specific information about web application performance than does EdgeSight monitoring alone.

You can configure both load balancing and content switching virtual servers to export EdgeSight Monitoring data to AppFlow collectors. Before configuring a virtual server for AppFlow export, associate an Appflow action with the EdgeSight Monitoring responder policy.

The following web page performance data is exported to AppFlow:

- **Page Load Time.** Elapsed time, in milliseconds, from when the browser starts to receive the first byte of a response until the user starts to interact with the page. At this stage, all the page content might not be loaded.
- **Page Render Time.** Elapsed time, in milliseconds, from when the browser receives the first byte of response until either all page content has been rendered or the page load action has timed out.
- **Time Spent on the Page.** Time spent by users on a page. Represents the period of time from one page request to the next one.

AppFlow transmits the performance data by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. The AppFlow templates use the following enterprise-specific Information Elements (EIEs) to export the information:

- **Client Load End Time.** Time at which the browser received the last byte of a response to load all the objects of the page such as images, scripts, and stylesheets.
- **Client Load Start Time.** Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.
- **Client Render End Time.** Time at which browser finished rendering the entire page, including the embedded objects.
- **Client Render Start Time.** Time at which the browser started rendering the page.
Prerequisites for Exporting Performance Data of Web Pages to AppFlow Collectors

Before associating the AppFlow action with the AppFlow policy, verify that the following prerequisites have been met:

- The AppFlow feature has been enabled and configured.
- The Responder feature has been enabled.
- The EdgeSight Monitoring feature has been enabled.
- EdgeSight Monitoring has been enabled on the load balancing or content switching virtual servers bound to the services of applications for which you want to collect the performance data.

Associating an AppFlow Action with the EdgeSight Monitoring Responder Policy

To export the web page performance data to the AppFlow collector, you must associate an AppFlow action with the EdgeSight Monitoring responder policy. An AppFlow action specifies which set of collectors receive the traffic.

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the command line interface

At the command prompt, type:

```
set responder policy <name> -appflowAction <action_Name>
```

Example

```
set responder policy pol -appflowAction actn
```

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the configuration utility

1. Navigate to **AppExpert > Responder > Policies**.
2. In the details pane, select an EdgeSight Monitoring responder policy, and then click **Open**.
3. In the **Configure Responder Policy** dialog box, in the **AppFlow Action** drop-down list, select the AppFlow action associated with the collectors to which you want to send the web-page performance data.
4. Click **OK**.
Configuring a Virtual Server to Export EdgeSight Statistics to Appflow Collectors

To export EdgeSight statistics information from a virtual server to the AppFlow collector, you must associate an AppFlow action with the virtual server.

To associate an AppFlow action with a Load Balancing or Content Switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers. You can also navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select a virtual server, or multiple virtual servers, and then click Enable EdgeSight Monitoring.
3. In the Enable EdgeSight Monitoring dialog box, select the Export EdgeSight statistics to Appflow check box.
4. From the Appflow Action drop-down list, select the AppFlow action. The AppFlow action defines the list of AppFlow collectors to which it exports EdgeSight Monitoring statistics. If you have selected multiple load balancing virtual servers, the same AppFlow Action will be associated with the responder policies bound to them. You can later change the AppFlow Action configured for each of the selected Load Balancing virtual server individually, if required.
5. Click OK.

Session Reliability on Citrix ADC High Availability Pair

February 18, 2020

When a network disruption or a device failover occurs during an ICA session, session reconnection can use one of two mechanisms: Session Reliability or Auto Client Reconnect.

Session Reliability. The preferred mode, is a seamless experience for the user. The disruption is barely noticeable for brief network interruptions.

Auto Client Reconnect. The fallback option, involves restarting the client. This mechanism is disruptive for the user and is not always supported.

 Receivers can now reconnect their ICA sessions seamlessly using the ICA Session Reliability feature, when HDX Insight is enabled.

This feature works both in standalone and in a Citrix ADC HA pair configuration, and even when a Citrix ADC failover happens.
Note

- Citrix ADC appliances should be running on software version 11.1 build 49.16 or later.
- You should not enable or disable Session Reliability mode when the Citrix ADC appliances have active connections.
- Enabling or disabling the feature when connections are still active causes HDX Insight to stop parsing those sessions after a failover occurs and result in loss of information about the sessions.
- Session Reliability on a high availability setup is disabled by default for Citrix ADC software version 11.1 49.16 or later. Session Reliability is supported on a high availability setup only if both the nodes of the setup run the same build (for example, release 11.1 build 53). In other words, session reliability is not supported on a high availability setup if both the nodes run different builds (for example, one node has release 11.1 build 53 whereas the other has release 11.1 build 56).

To configure Session reliability from Citrix ADC CLI:

1. At the command line, use the default system administrator credentials to log on to the system.
2. To enable Session Reliability on HA failover, at the prompt, type: `set ica parameter EnableSRonHAFailover YES`
3. To disable Session Reliability on HA failover, at the prompt, type: `set ica parameter EnableSRonHAFailover NO`

To Enable Session reliability on HA failover from Citrix ADC GUI:

1. In a web browser, type the IP address of the primary Citrix ADC instance in the HA pair (for example, `http://192.168.100.1`).
2. In User Name and Password, enter the administrator credentials.
3. On the Configuration tab, navigate to System > Settings, and click Change ICA Parameters.
4. In the Change ICA Parameters section, select Session Reliability on HA Failover.
5. Click OK.

Limitations

- Enabling this feature will result in increased bandwidth consumption which is due to ICA compression being turned off by the feature, and the extra traffic between the primary and secondary nodes to keep them in sync.
- This feature is supported in Active-Passive mode only. Active-Active mode is not currently supported.
- When HDX Insight is enabled, and Session Reliability on HA knob is set to NO, only ACR reconnect mode is supported in Citrix ADC high availability failover scenario. The HA knob does not disable Session Reliability if HDX Insight is disabled.
The **Session Reconnect Semantics** table is as follows:

### Session Reconnect Semantics

<table>
<thead>
<tr>
<th>Status</th>
<th>EnableSRonHAFailover</th>
<th>EnableSRonHAFailover No (Default)</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDX Insight enabled</td>
<td>Session reconnect for ICA Session works</td>
<td>Session reconnect for ICA Sessions does not work</td>
</tr>
<tr>
<td>HDX Insight disabled</td>
<td>Session reconnect for ICA Session works</td>
<td>Session reconnect for ICA Sessions works</td>
</tr>
</tbody>
</table>

#### Points to note

- Session Reliability for ICA sessions works out of the box with Citrix Gateway.
- Session Reliability for ICA sessions does not work ONLY when both the following conditions are met:
  - HDX Insight is enabled
  - EnableSRonHAFailover is set to NO
- Setting EnableSRonHAFailover knob to either YES or NO does not make any difference, when HDX Insight is disabled.

### Citrix Web App Firewall

February 4, 2020

The following topics cover installation and configuration of the Citrix Web App Firewall feature.

<table>
<thead>
<tr>
<th>Introduction</th>
<th>An overview of web security and how the Web App Firewall works.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>How to configure the Web App Firewall to protect a web site, a web service, or a Web 2.0 site.</td>
</tr>
</tbody>
</table>
The Citrix Web App Firewall offers easy to configure options to meet a wide range of application security requirements. Web App Firewall profiles, which consist of sets of security checks, can be used to protect both the requests and the responses by providing deep packet-level inspections. Each profile includes an option to select basic protections or advanced protections. Some protections might require use of other files. For example, xml validation checks might require WSDL or schema files. The profiles can also use other files, such as signatures or error objects. These files can be added locally, or they can be imported ahead of time and saved on the appliance for future use. They can be shared by multiple profiles.
Profiles work in conjunction with the Web App Firewall policies. Each policy identifies a type of traffic, and that traffic is inspected for the security check violations specified in the profile that is associated with the policy. The policies can have different bind points, which determine the scope of the policy. For example, a policy that is bound to a specific virtual server is invoked and evaluated for only the traffic flowing through that virtual server. The policies are evaluated in the order of their designated priorities, and the first one that matches the request or response is applied.

- Quick Deployment of Web App Firewall Protection

You can use the following procedure for quick deployment of Web App Firewall security:

1. Add an appfw profile and select the appropriate type (html, xml, JSON) for the security requirements of the application.
2. Select the required level of security (basic or advanced).
3. Add or import the required files, such as signatures or WSDL.
4. Configure the profile to use the files, and make any other necessary changes to the default settings.
5. Add an appfw policy for this profile.
6. Bind the policy to the target bind point and specify the priority.

- Web App Firewall entities

Profile—An Web App Firewall profile specifies what to look for and what to do. It inspects both the request and the response to determine which potential security violations should be checked and what actions should be taken when processing a transaction. A profile can protect an HTML, XML or HTML and XML payload. Depending on the security requirements of the application, you can create either a basic or an advanced profile. A basic profile can protect against known attacks. If higher security is required, you can deploy an advanced profile to allow controlled access to the application resources, blocking zero day attacks. However, a basic profile can be modified to offer advanced protections, and vice versa. Multiple action choices (for example, block, log, learn, and transform) are available. Advanced security checks might use session cookies and hidden form tags for controlling and monitoring the client connections. Web App Firewall profiles can learn the triggered violations and suggest the relaxation rules.

Basic Protections—A basic profile includes a preconfigured set of Start URL and Deny URL relaxation rules. These relaxation rules determine which requests should be allowed and which should be denied. Incoming requests are matched against these lists and the configured actions are applied. This allows the user to be able to secure applications with minimal configuration for relaxation rules. The Start URL rules protect against forceful browsing. Known web server vulnerabilities that are exploited by hackers can be detected and blocked by enabling a set of default Deny URL rules. Commonly launched attacks, such as Buffer Overflow, SQL, or Cross-site scripting can also be easily detected.

Advanced Protections—As the name indicates, advanced protections are used for applications
that have higher security requirements. Relaxation rules are configured to allow access to only specific data and block the rest. This positive security model mitigates unknown attacks, which might not be detected by basic security checks. In addition to all the basic protections, an advanced profile keeps track of a user session by controlling the browsing, checking for cookies, specifying input requirements for various form fields, and protecting against tampering of forms or cross-site request forgery attacks. Learning, which observes the traffic and deploys the appropriate relaxations, is enabled by default for many security checks. Although easy to use, advanced protections require due consideration, because they offer tighter security but also require more processing and do not allow use of caching, which can affect performance.

**Import**—Import functionality is useful when Web App Firewall profiles need to use external files, that is, files hosted on an external or internal web server, or that have to be copied from a local machine. Importing a file and storing it on the appliance is very useful, especially in situations where you have to control access to external websites, or where compilation takes a long time, large files have to be synced across HA deployments, or you can reuse a file by copying it across multiple devices. For example:

- WSDLs hosted on external web servers can be imported locally before blocking access to external websites.
- Large signature files generated by an external scan tool such as Cenzic can be imported and precompiled, using schema on the Citrix appliance.
- A customized HTML or XML error page can be imported from an external web server or copied from a local file.

**Signatures**—Signatures are very powerful, because they use pattern matching to detect malicious attacks and can be configured to check both the request and the response of a transaction. They are a preferred option when a customizable security solution is needed. Multiple choices (for example, block, log, learn, and transform) are available for the action to take when a signature match is detected. The Web App Firewall has a built-in default signature object consisting of more than 1,300 signature rules, with an option to get the latest rules by using the auto-update feature. Rules created by other scan tools can also be imported. The signature object can be customized by adding new rules, which can work in conjunction with the other security checks specified in the Web App Firewall profile. A signature rule can have multiple patterns and can flag a violation only when all the patterns are matched, thereby avoiding false positives. Careful selection of a literal fastmatch pattern for a rule can significantly optimize processing time.

**Policies**—Web App Firewall Policies are used to filter and separate the traffic into different types. This provides the flexibility to implement different levels of security protections for the application data. Access to highly sensitive data can be directed to advanced security-check inspections, while less sensitive data is protected by basic-level security inspections. Policies can also be configured to bypass security-check inspection for harmless traffic. Higher security requires more processing, so careful design of the policies can provide desired security along with opti-
mized performance. The priority of the policy determines the order in which it is evaluated, and its bind point determines the scope of its application.

**Highlights**

1. Ability to secure a wide range of applications by protecting different types of data, implementing the right level of security for different resources, and still getting maximum performance.
2. Flexibility to add or modify a security configuration. You can tighten or relax security checks by enabling or disabling basic and advanced protections.
3. Option to convert an HTML profile to an XML or Web2.0 (HTML+XML) profile and vice-versa, providing the flexibility to add security for different types of payload.
4. Easily deployed actions to block attacks, monitor them in logs, collect statistics, or even transform some attack strings to render them harmless.
5. Ability to detect attacks by inspecting incoming requests, and to prevent leakage of sensitive data by inspecting the responses sent by the servers.
6. Capability to learn from the traffic pattern to get recommendations for easily editable relaxation rules that can be deployed to allow exceptions.
7. Hybrid security model that applies the power of customizable signatures to block attacks that match specified patterns, and provides the flexibility to use the positive-security-model checks for basic or advanced security protections.
8. Availability of comprehensive configuration reports, including information about PCI-DSS compliance.

**FAQs and Deployment Guide**

February 12, 2020

**Q: Why is Citrix Web App Firewall the preferred choice for securing applications?**

With the following features, the Citrix Web Web App Firewall offers a comprehensive security solution:

- **Hybrid security model**: Citrix ADC hybrid security model allows you to take advantage of both a positive security model and a negative security model to come up with a configuration ideally suited for your applications.
- **Positive security model** protects against Buffer Overflow, CGI-BIN Parameter Manipulation, Form/Hidden Field Manipulation, Forceful Browsing, Cookie or Session Poisoning, Broken ACLs, Cross-Site Scripting (XSS), Command Injection, SQL Injection, Error Triggering Sensitive Information Leak, Insecure Use of Cryptography, Server Misconfiguration, Back Doors and Debug Options, Rate-Based Policy Enforcement, Well Known Platform Vulnerabilities, Zero-Day Exploits, Cross Site Request Forgery (CSRF), and leakage of Credit Card and other sensitive data.

- **Negative security model** uses a rich set signatures to protect against L7 and HTTP application vulnerabilities. The Web App Firewall is integrated with several third party scanning tools, such as those offered by Cenzic, Qualys, Whitehat, and IBM. The built-in XSLT files allow easy importation of rules, which can be used in conjunction with the native-format Snort based rules. An auto-update feature gets the latest updates for new vulnerabilities.

The positive security model might be the preferred choice for protecting applications that have a high need for security, because it gives you the option to fully control who can access what data. You allow only what you want and block the rest. This model includes a built-in security check configuration, which is deployable with few clicks. However, keep in mind that the tighter the security, the greater the processing overhead.

The negative security model might be preferable for customized applications. The signatures allow you to combine multiple conditions, and a match and the specified action are triggered only when all the conditions are satisfied. You block only what you don’t want and allow the rest. A specific fast-match pattern in a specified location can significantly reduce processing overhead to optimize performance. The option to add your own signature rules, based on the specific security needs of your applications, gives you the flexibility to design your own customized security solutions.

- **Request as well as response side detection and protection:** You can inspect the incoming requests to detect any suspicious behavior and take appropriate actions, and you can check the responses to detect and protect against leakage of sensitive data.

- **Rich set of built-in protections for HTML, XML and JSON payloads:** The Web App Firewall offers 19 different security checks. Six of them (such as Start URL and Deny URL) apply to both HTML and XML data. Five checks (such as Field Consistency and Field Format) are specific to HTML, and eight (such as XML Format and Web Service Interoperability) are specific to XML payloads. This feature includes a rich set of actions and options. For example, URL Closure enables you to control and optimize the navigation through your website, to safeguard against forceful browsing without having to configure relaxation rules to allow each and every legitimate URL. You have the option to remove or x-out the sensitive data, such as credit-card numbers, in the response. Be it SOAP Array attack protection, XML denial of Service (XDoS), WSDL scan prevention, Attachment check, or any number of other XML attacks, you have the comfort of knowing that you have an ironclad shield protecting your data when your applications are protected by the Web App Firewall. The signatures allow you to configure rules using XPATH-Expressions to...
detect violations in the body as well as the header of a JSON payload.

- **GWT**: Support for protecting Google Web Toolkit applications to safeguard against SQL, XSS and Form Field Consistency check violations.

- **Java-free, user friendly graphical user interface (GUI)**: An intuitive GUI and preconfigured security checks make it easy to deploy security by clicking a few buttons. A wizard prompts and guides you to create the required elements, such as profiles, policies, signatures, and bindings. The HTML5 based GUI is free of any Java dependency. It’s performance is significantly better than that of the older, Java based versions.

- **Easy to Use and automatable CLI**: Most of the configuration options that are available in GUI are also available in the command line interface (CLI). The CLI commands can be executed by a batch file and are easy to automate.

- **Support for REST API**: The Citrix ADC NITRO protocol supports a rich set of REST API’s to automate Web App Firewall configuration and collect pertinent statistics for ongoing monitoring of security violations.

- **Learning**: The Web App Firewall’s ability to learn by monitoring traffic to fine tune security is very user friendly. The learning engine recommends rules, which makes it easy to deploy relaxations without proficiency in regular expressions.

- **RegEx editor support**: Regular expression offer an elegant solution to the dilemma of wanting to consolidate rules and yet optimize search. You can capitalize on the power of regular expressions to configure URLs, field names, signature patterns, and so on. The rich built-in GUI RegEx editor offers you a quick reference for the expressions and provides a convenient way to validate and test your RegEx for accuracy.

- **Customized error page**: Blocked requests can be redirected to an error URL. You also have the option to display a customized error object that uses supported variables and Citrix default syntax (advanced PI expressions) to embed troubleshooting information for the client.

- **PCI-DSS, stats, and other violation reports**: The rich set of reports makes it easy to meet the PCI-DSS compliance requirement, gather stats about traffic counters, and view violation reports for all profiles or just one profile.

- **Logging and click-to-rule from log**: Detailed logging is supported for native as well as CEF format. The Web App Firewall offers you the ability to filter targeted log messages in the syslog viewer. You can select a log message and deploy a corresponding relaxation rule by a simple click of a button. You have the flexibility to customize log messages and also have support for generating web logs. For additional details, see Web App Firewall Log topic.

- **Include violation logs in trace records**: The ability to include log messages in the trace records makes it very easy to debug unexpected behavior such as reset and block.
Cloning: The useful Import/Export profile option allows you to clone the security configuration from one Citrix ADC appliance to others. Export learned data options make it easy to export the learned rules to an Excel file. You can then get them reviewed and approved by application owner before applying them.

An AppExpert template (a set of configuration settings) can be designed to provide appropriate protection for your websites. You can simplify and expedite the process of deploying similar protection on other appliances by exporting these cookie-cutter templates to a template.

For additional details, see AppExpert template topic.

- Sessionless security checks: Deploying sessionless security checks can help you reduce the memory footprint and expedite the processing.
- Interoperability with other Citrix ADC features: The Web App Firewall works seamlessly with other Citrix ADC features, such as rewrite, URL transformation, integrated caching, CVPN, and rate limiting.
- Support of PI expressions in policies: You can leverage the power of advanced PI expressions to design policies to implement different levels of security for different parts of your application.
- Support for IPv6: The Web App Firewall supports both IPv4 and IPv6 protocols.
- Geolocation based security protection: You have the flexibility of using Citrix default syntax (PI Expressions) for configuring location based policies, which can be used in conjunction with a built-in location database to customize firewall protection. You can identify the locations from which malicious requests originate, and enforce the desired level of security-check inspections for requests that originate from a specific geographical location.
- Performance: Request-side streaming significantly improves performance. As soon as a field is processed, the resulting data is forwarded to the back end while evaluation continues for the remaining fields. The improvement in processing time is especially significant when handling large posts.
- Other security features: The Web App Firewall has several other security knobs that can help ensure the security of your data. For example, the Confidential Field lets you block leakage of sensitive information in the log messages, and Strip HTML Comment allows you to remove the HTML comments from the response before forwarding it to the client. Field Types can be used to specify what inputs are allowed in the forms submitted to your application.

Q: What do I need to do to configure Web App Firewall?

Do the following:

- Add an Web App Firewall profile and select the appropriate type (html, xml, web2.0) for the security requirements of the application.
- Select the required level of security (basic or advanced).
- Add or import the required files, such as signatures or WSDL.
• Configure the profile to use the files, and make any other necessary changes to the default settings.
• Add an Web App Firewall policy for this profile.
• Bind the policy to the target bind point and specify the priority.

Q: How do I know what profile type to choose?

The Web App Firewall profile offers protection for both HTML and XML payloads. Depending on the need of your application, you can choose either a HTML profile or XML profile. If your application supports both HTML and XML data, you can choose a Web2.0 profile.

Q: What is the difference between basic and advanced profiles? How do I decide which one I need?

The decision to use a basic or an advance profile depends on the security need of your application. A basic profile includes a preconfigured set of Start URL and Deny URL relaxation rules. These relaxation rules determine which requests are allowed and which are denied. Incoming requests are matched with the preconfigured rules, and the configured actions are applied. The user can secure applications with minimal configuration of relaxation rules. The Start URL rules protect against forceful browsing. Known web server vulnerabilities that are exploited by hackers can be detected and blocked by enabling a set of default Deny URL rules. Commonly launched attacks, such as Buffer Overflow, SQL, or Cross-Site Scripting can also be easily detected.

As the name indicates, advanced protections are for applications that have higher security requirements. Relaxation rules are configured to allow access to only specific data and block the rest. This positive security model mitigates unknown attacks, which might not be detected by basic security checks. In addition to all the basic protections, an advanced profile keeps track of a user session by controlling the browsing, checking for cookies, specifying input requirements for various form fields, and protecting against tampering of forms or Cross-Site Request Forgery attacks. Learning, which observes the traffic and recommends the appropriate relaxations, is enabled by default for many security checks. Although easy to use, advanced protections require due consideration, because they offer tighter security but also require more processing. Some advance security checks do not allow use of caching, which can affect performance.

Keep the following points in mind when deciding whether to use basic or advanced profiles:

• Basic and advanced profiles are just starting templates. You can always modify the basic profile to deploy advanced security features, and vice versa.
• Advanced security checks require more processing and can affect performance. Unless your application needs advanced security, you might want to start with a basic profile and tighten the security as required for your application.
You do not want to enable all security checks unless your application needs it.

**Q: What is a policy? How do I select the bind point and set the priority?**

Web App Firewall policies can help you sort your traffic into logical groups for configuring different levels of security implementation. Carefully select the bind points for the policies to determine which traffic is matched against which policy. For example, if you want every incoming request to be checked for SQL/XSS attacks, you can create a generic policy and bind it globally. Or, if you want to apply more stringent security checks to the traffic of a virtual server hosting applications that contain sensitive data, you can bind a policy to that virtual server.

Careful assignment of priorities can enhance the traffic processing. You want to assign higher priorities to more specific policies and lower priorities to generic policies. Note that the higher the number, the lower the priority. A policy with a priority of 10 is evaluated before a policy that has a priority of 15.

You can apply different levels of security for different kinds of contents, e.g. requests for static objects like images and text can be by-passed by using one policy and requests for other sensitive contents can be subjected to a much stringent check by using a second policy.

**Q: How do I go about configuring the rules to secure my application?**

The Web App Firewall makes it very easy to design the right level of security for your web-site. You can have multiple Web App Firewall policies, bound to different Web App Firewall profiles, to implement different levels of security-check inspections for your applications. You can initially monitor the logs to observe what security threats are being detected and which violations are being triggered. You can either manually add the relaxation rules or take advantage of the Web App Firewall’s recommended learned rules to deploy the required relaxations to avoid false positives.

The Citrix Web App Firewall offers visualizer support in GUI, which makes rule management very easy. You can easily view all the data on one screen, and take action on several rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate several rules. You can select a subset of the rules, basing your selection on the delimiter and Action URL. Visualizer support is available for viewing 1) learned rules and 2) relaxation rules.

1. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. You can also skip (ignore) rules.

2. The visualizer for deployed relaxations offers you the option to add a new rule or edit an existing one. You can also enable or disable a group of rules by selecting a node and clicking the Enable or Disable button in the relaxation visualizer.
**Q: What are signatures? How do I know which signatures to use?**

A signature is an object that can have multiple rules. Each rule consists of one or more patterns that can be associated with a specified set of actions. The Web App Firewall has a built-in default signature object consisting of more than 1,300 signature rules, with an option to get the latest rules by using the **auto-update** feature to get protection against new vulnerabilities. Rules created by other scan tools can also be imported.

Signatures are very powerful because they use pattern matching to detect malicious attacks and can be configured to check both the request and the response of a transaction. They are a preferred option when a customizable security solution is needed. Multiple action choices (for example, block, log, learn, and transform) are available for when a signature match is detected. The default signatures cover rules to protect different types of applications, such as web-cgi, web-coldfusion, web-frontpage, web-iis, web-php, web-client, web-activex, web-shell-shock, and web-struts. To match the needs of your application, you can select and deploy the rules belonging to a specific category.

**Signature-usage tips:**

- You can just make a copy of the default signature object and modify it to enable the rules you need and configure the actions you want.
- The signature object can be customized by adding new rules, which can work in conjunction with other signature rules.
- The signature rules can also be configured to work in conjunction with the security checks specified in the Web App Firewall profile. If a match indicating a violation is detected by a signature as well as a security check, the more restrictive action is the one that gets enforced.
- A signature rule can have multiple patterns and be configured to flag a violation only when all the patterns are matched, thereby avoiding false positives.
- Careful selection of a literal fast-match pattern for a rule can significantly optimize processing time.

**Q: Does the Web App Firewall work with other Citrix ADC features?**

The Web App Firewall is fully integrated into the Citrix ADC appliance and works seamlessly with other features. You can configure maximum security for your application by using other Citrix ADC security features in conjunction with the Web App Firewall. For example, **AAA-TM** can be used to authenticate the user, check the user’s authorization to access the content, and log the accesses, including invalid login attempts. **Rewrite** can be used to modify the URL or to add, modify or delete headers, and **Responder** can be used to deliver customized content to different users. You can define the maximum load for your website by using **Rate Limiting** to monitor the traffic and throttle the rate if it is too high. **HTTP Denial-of-Service (DoS)** protection can help distinguish between real HTTP clients and malicious DoS clients. You can narrow the scope of security-check inspection by binding the Web
Citrix ADC 13.0

App Firewall policies to virtual servers, while still optimizing the user experience by using the **Load Balancing** feature to manage heavily used applications. Requests for static objects such as images or text can bypass security check inspection, taking advantage of **integrated caching** or **compression** to optimize the bandwidth usage for such content.

**Q: How is the payload processed by the Web App Firewall and the other Citrix ADC features?**

A diagram showing details of the L7 packet flow in a Citrix ADC appliance is available in the **Processing Order of Features** section.

**Q: What is the recommended workflow for Web App Firewall deployment?**

Now that you know the advantages of using the state-of-the-art security protections of the Citrix Web App Firewall, you might want to collect additional information that can help you design the optimal solution for your security needs. Citrix recommends that you do the following:

- **Know your environment:** Knowing your environment will help you to identify the best security protection solution (signatures, security checks, or both) for your needs. Before you begin configuration, you should gather the following information.
  - **OS:** What kind of OS (MS Windows, Linux, BSD, Unix, others) do you have?
  - **Web Server:** What web server (IIS, Apache or Citrix ADC Enterprise Server) are you running?
  - **Application:** What type of applications are running on your application server (for example, ASP.NET, PHP, Cold Fusion, ActiveX, FrontPage, Struts, CGI, Apache Tomcat, Domino, and WebLogic)?
  - Do you have customized applications or off-the-shelf (for example, Oracle, SAP) applications? What version you are using?
  - **SSL:** Do you require SSL? If so, what key size (512, 1024, 2048, 4096) is used for signing certificates?
  - **Traffic Volume:** What is the average traffic rate through your applications? Do you have seasonal or time-specific spikes in the traffic?
  - **Server Farm:** How many servers do you have? Do you need to use load balancing?
  - **Database:** What type of database (MS-SQL, MySQL, Oracle, Postgres, SQLite, nosql, Sybase, Informix etc.) do you use?
  - **DB Connectivity:** What kind of data base connectivity do you have (DSN, per-file connection string, single file connection string) and what drivers are used?

- **Identify your security needs:** You might want to evaluate which applications or specific data need maximum security protection, which ones are less vulnerable, and the ones for which security inspection can safely be bypassed. This will help you in coming up with an optimal configuration, and in designing appropriate policies and bind points to segregate the traffic. For exam-
ple, you might want to configure a policy to bypass security inspection of requests for static web content, such as images, MP3 files, and movies, and configure another policy to apply advanced security checks to requests for dynamic content. You can use multiple policies and profiles to protect different contents of the same application.

- **License requirement**: Citrix offers a unified solution to optimize the performance of your application by taking advantage of a rich set of features such as load balancing, content switching, caching, compression, responder, rewrite, and content filtering, to name a few. Identifying the features that you want can help you decide which license you need.

- **Install and baseline a Citrix ADC appliance**: Create a virtual server and run test traffic through it to get an idea of the rate and amount of traffic flowing through your system. This information will help you to identify your capacity requirement and select the right appliance (VPX, MPX, or SDX).

- **Deploy the Web App Firewall**: Use the Web App Firewall wizard to proceed with a simple security configuration. The wizard walks you through several screens and prompts you to add a profile, policy, signature, and security checks.

  - **Profile**: Select a meaningful name and the appropriate type (HTML, XML or WEB 2.0) for your profile. The policy and signatures will be auto-generated using the same name.

  - **Policy**: The auto-generated policy has the default Expression (true), which selects all traffic and is bound globally. This is a good starting point unless you have in mind a specific policy that you want to use.

  - **Protections**: The wizard helps you take advantage of the hybrid security model, in which you can use the default signatures offering a rich set of rules to protect different types of applications. Simple edit mode allows you to view the various categories (CGI, Cold Fusion, PHP, etc.). You can select one or more categories to identify a specific set of rules applicable to your application. Use the Action option to enable all the signature rules in the selected categories. Make sure that blocking is disabled, so that you can monitor the traffic before tightening the security. Click Continue. In the Specify Deep protections pane, you can make changes as needed to deploy the security check protections. In most cases, basic protections are sufficient for initial security configuration. Run the traffic for a while to collect a representative sample of the security-inspection data.

  - **Tightening the security**: After deploying Web App Firewall and observing the traffic for a while, you can start tightening the security of your applications by deploying relaxations and then enabling blocking. Learning, Visualizer, and Click to deploy rules are useful features that make it very easy to tweak your configuration to come up with just the right level of relaxation. At this point, you can also change the policy expression and/or configure additional policies and profiles to implement desired levels of security for different types of content.

  - **Debugging**: If you see unexpected behavior of your application, the Web App Firewall offers various options for easy debugging:
**Log.** If legitimate requests are getting blocked, your first step is to check the ns.log file to see if any unexpected security-check violation is being triggered.

**Disable feature.** If you do not see any violations but are still seeing unexpected behavior, such as an application resetting or sending partial responses, you can disable the Web App Firewall feature for debugging. If the issue persists, it rules out the Web App Firewall as a suspect.

**Trace records with log messages.** If the issue appears to be Web App Firewall related and needs closer inspection, you have the option to include security violation messages in an nstrace. You can use “Follow TCP stream” in the trace to view the details of the individual transaction, including headers, payload, and the corresponding log message, together on the same screen. Details of how to use this functionality are available at Appendixes.

---

**Introduction to Citrix Web Application Firewall**

July 30, 2020

The Citrix Web Web App Firewall prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information. It does so by filtering both requests and responses, examining them for evidence of malicious activity, and blocking those that exhibit such activity. Your site is protected not only from common types of attacks, but also from new, as yet unknown attacks. In addition to protecting web servers and web sites from unauthorized access and misuse by hackers and malicious programs, the Web App Firewall provides protection against security vulnerabilities in legacy CGI code or scripts, other web frameworks, web server software, and the underlying operating systems.

The Citrix Web Web App Firewall is available as a stand-alone appliance, or as a feature on a Citrix ADC virtual appliance (VPX). In the Web App Firewall documentation, the term Citrix ADC refers to the platform on which the Web App Firewall is running, regardless of whether that platform is a dedicated firewall appliance, a Citrix ADC on which other features have also been configured, or a Citrix ADC VPX.

To use the Web App Firewall, you must create at least one security configuration to block connections that violate the rules that you set for your protected web sites. The number of security configurations that you might want to create depends on the complexity of your web site. In some cases, a single configuration is sufficient. In other cases, particularly those that include interactive web sites, web sites that access database servers, online stores with shopping carts, you might need several different configurations to best protect sensitive data without wasting significant effort on content that is not
vulnerable to certain types of attacks. You can often leave the defaults for the global settings, which affect all security configurations, unchanged. However, you can change the global settings if they conflict with other parts of your configuration or you prefer to customize them.

**Web application security**

Web application security is network security for computers and programs that communicate by using the HTTP and HTTPS protocols. This is an extremely broad area in which security flaws and weaknesses abound. Operating systems on both servers and clients have security issues and are vulnerable to attack. Web server software and web site enabling technologies such as CGI, Java, JavaScript, PERL and PHP have underlying vulnerabilities. Browsers and other client applications that communicate with web-enabled applications also have vulnerabilities. Web sites that use any technology but the simplest of HTML, including any site that allows interaction with visitors, often have vulnerabilities of their own.

In the past, a breach in security was often just an annoyance, but today that is seldom the case. For example, attacks in which a hacker gained access to a web server and made unauthorized modifications to (defaced) a web site used to be common. They were usually launched by hackers who had no motivation beyond demonstrating their skills to fellow hackers or embarrassing the targeted person or company. Most current security breaches, however, are motivated by a desire for money. The majority attempt to accomplish one or both of the following goals: to obtain sensitive and potentially valuable private information, or to obtain unauthorized access to and control of a web site or web server.

Certain forms of web attacks focus on obtaining private information. These attacks are often possible even against web sites that are secure enough to prevent an attacker from taking full control. The information that an attacker can obtain from a web site can include customer names, addresses, phone numbers, social security numbers, credit card numbers, medical records, and other private information. The attacker can then use this information or sell it to others. Much of the information obtained by such attacks is protected by law, and all of it by custom and expectation. A breach of this type can have extremely serious consequences for customers whose private information is compromised. At best, these customers will have to exercise vigilance to prevent others from abusing their credit cards, opening unauthorized credit accounts in their name, or appropriating their identities outright (identity theft). At worst, the customers may face ruined credit ratings or even be blamed for criminal activities in which they had no part.

Other web attacks are aimed at obtaining control of (or compromising) a web site or the server on which it operates, or both. A hacker who gains control of a web site or server can use it to host unauthorized content, act as a proxy for content hosted on another web server, provide SMTP services to send unsolicited bulk email, or provide DNS services to support such activities on other compromised web servers. Most web sites that are hosted on compromised web servers promote questionable or
outright fraudulent businesses. For example, the majority of phishing web sites and child exploitation web sites are hosted on compromised web servers.

Protecting your web sites and web services against these attacks requires a multilayered defense capable of both blocking known attacks with identifiable characteristics and protecting against unknown attacks, which can often be detected because they look different from the normal traffic to your web sites and web services.

**Known web attacks**

The first line of defense for your web sites is protection against the large number of attacks that are known to exist and have been observed and analyzed by web security experts. Common types of attacks against HTML-based web sites include:

- **Buffer overflow attacks.** Sending an extremely long URL, extremely long cookie, or other extremely long bit of information to a web server in hopes of causing it or the underlying operating system to hang, crash, or provide the attacker with access to the underlying operating system. A buffer overflow attack can be used to gain access to unauthorized information, to compromise a web server, or both.

- **Cookie security attacks.** Sending a modified cookie to a web server, usually in hopes of obtaining access to unauthorized content by using falsified credentials.

- **Forceful browsing.** Accessing URLs on a web site directly, without navigating to the URLs by means of hyperlinks on the home page or other common start URLs on the web site. Individual instances of forceful browsing may simply indicate a user who bookmarked a page on your web site, but repeated attempts to access nonexistent content, or content that users should never access directly, often represent an attack on web site security. Forceful browsing is normally used to gain access to unauthorized information, but can also be combined with a buffer overflow attack in an attempt to compromise your server.

- **Web form security attacks.** Sending inappropriate content to your web site in a web form. Inappropriate content can include modified hidden fields, HTML or code in a field intended for alphanumerical data only, an overly long string in a field that accepts only a short string, an alphanumerical string in a field that accepts only an integer, and a wide variety of other data that your web site does not expect to receive in that web form. A web form security attack can be used either to obtain unauthorized information from your web site or to compromise the web site outright, usually when combined with a buffer overflow attack.

Two specialized types of attacks on web form security deserve special mention:

- **SQL injection attacks.** Sending an active SQL command or commands in a web form or as part of a URL, with the goal of causing an SQL database to execute the command or commands. SQL injection attacks are normally used to obtain unauthorized information.
• **Cross-site scripting attacks.** Using a URL or a script on a web page to violate the same-origin policy, which forbids any script from obtaining properties from or modifying any content on a different web site. Since scripts can obtain information and modify files on your web site, allowing a script access to content on a different web site can provide an attacker the means to obtain unauthorized information, to compromise a web server, or both.

Attacks against XML-based web services normally fall into at least one of the following two categories: attempts to send inappropriate content to a web service, or attempts to breach security on a web service. Common types of attacks against XML-based web services include:

• **Malicious code or objects.** XML requests that contain code or objects that can either directly obtain sensitive information or can give an attacker control of the web service or underlying server.

• **Badly-formed XML requests.** XML requests that do not conform to the W3C XML specification, and that can therefore breach security on an insecure web service

• **Denial of service (DoS) attacks.** XML requests that are sent repeatedly and in high volume, with the intent of overwhelming the targeted web service and denying legitimate users access to the web service.

In addition to standard XML-based attacks, XML web services and Web 2.0 sites are also vulnerable to SQL injection and cross-site scripting attacks, as described below:

• **SQL injection attacks.** Sending an active SQL command or commands in an XML-based request, with the goal of causing an SQL database to execute that command or commands. As with HTML SQL injection attacks, XML SQL injection attacks are normally used to obtain unauthorized information.

• **Cross-site scripting attacks.** Using a script included in an XML based application to violate the same-origin policy, which does not allow any script to obtain properties from or modify any content on a different application. Since scripts can obtain information and modify files by using your XML application, allowing a script access to content belonging to a different application can give an attacker the means to obtain unauthorized information, to compromise the application, or both

Known web attacks can usually be stopped by filtering web site traffic for specific characteristics (signatures) that always appear for a specific attack and should never appear in legitimate traffic. This approach has the advantages of requiring relatively few resources and posing relatively little risk of false positives. It is therefore a valuable tool in fighting attacks on web sites and web services, and configuring basic signature protections that intercept most known web attacks is easy to do.

**Unknown web attacks**

The greatest threat against web sites and applications does not come from known attacks, but from unknown attacks. Most unknown attacks fall into one of two categories: newly-launched attacks for
which security firms have not yet developed an effective defense (zero-day attacks), and carefully-targeted attacks on a specific web site or web service rather than many web sites or web services (spear attacks). These attacks, like known attacks, are usually intended to obtain sensitive private information, compromise the web site or web service and allow it to be used for further attacks, or both of those goals.

Zero-day attacks are a major threat to all users. These attacks are usually of the same types as known attacks; zero-day attacks often involve injected SQL, a cross-site script, a cross-site request forgery, or another type of attack similar to known attacks. In most cases, they target vulnerabilities that the developers of the targeted software, web site, or web service either are unaware of or have just learned about. Security firms have therefore usually not developed defenses against these attacks, and even if they have, users have usually not obtained and installed the patches or performed the workarounds necessary to protect against these attacks. The time between discovery of a zero-day attack and availability of a defense (the vulnerability window) is shrinking, but perpetrators can still count on hours or even days in which many web sites and web services lack any specific protection against the attack.

Spear attacks are a major threat, but to a more select group of users. A common type of spear attack, a spear phish, is usually targeted at customers of a specific bank or financial institution, or (less commonly) at employees of a specific company or organization. Unlike other phishes, which are often crudely written forgeries that a user with any familiarity with the actual communications of that bank or financial institution can recognize, spear phishes are letter perfect and extremely convincing. They can contain information specific to the individual that, at first look, no stranger should know or be able to obtain. The spear phisher is therefore able to convince his or her target to provide the requested information, which the phisher can then use to loot accounts, to process illegitimately obtained money from other sources, or to gain access to other, even more sensitive information.

Both of these types of attack have certain characteristics that can usually be detected, although not by using static patterns that look for specific characteristics, as do standard signatures. Detecting these types of attacks requires more sophisticated and more resource-intensive approaches, such as heuristic filtering and positive security model systems. Heuristic filtering looks, not for specific patterns, but for patterns of behaviors. Positive security model systems model the normal behavior of the web site or web service that they are protecting, and then block connections that do not fit within that model of normal use. URL based and web-form based security checks profile normal use of your web sites, and then control how users interact with your web sites, using both heuristics and positive security to block anomalous or unexpected traffic. Both heuristic and positive security, properly designed and deployed, can catch most attacks that signatures miss. However, they require considerably more resources than do signatures, and you must spend some time configuring them properly to avoid false positives. They are therefore usually used, not as the primary line of defense, but as backups to signatures or other less resource-intensive approaches.

By configuring these advanced protections in addition to signatures, you create a hybrid security model, which enables the Web App Firewall to provide comprehensive protection against both known
and unknown attacks.

**How Citrix Web Application Firewall works**

When you install the Web App Firewall, you create an initial security configuration, which consists of a policy, a profile, and a signatures object. The policy is a rule that identifies the traffic to be filtered, and the profile identifies the patterns and types of behavior to allow or block when the traffic is filtered. The simplest patterns, which are called signatures, are not specified within the profile, but in a signatures object that is associated with the profile.

A signature is a string or pattern that matches a known type of attack. The Web App Firewall contains over a thousand signatures in seven categories, each directed at attacks on specific types of web servers and web content. Citrix updates the list with new signatures as new threats are identified. During configuration, you specify the signature categories that are appropriate for the web servers and content that you need to protect. Signatures provide good basic protection with low processing overhead. If your applications have special vulnerabilities or you detect an attack against them for which no signature exists, you can add your own signatures.

The more advanced protections are called security checks. A security check is a more rigorous, algorithmic inspection of a request for specific patterns or types of behavior that might indicate an attack or constitute a threat to your protected web sites and web services. It can, for example, identify a request that attempts to perform a certain type of operation that might breach security, or a response that includes sensitive private information such as a social security number or credit card number. During configuration, you specify the security checks that are appropriate for the web servers and content that you need to protect. The security checks are restrictive. Many of them can block legitimate requests and responses if you do not add the appropriate exceptions (relaxations) when configuring them. Identifying the needed exceptions is not difficult if you use the adaptive learning feature, which observes normal use of your web site and creates recommended exceptions.

The Web App Firewall can be installed as either a Layer 3 network device or a Layer 2 network bridge between your servers and your users, usually behind your company’s router or firewall. It must be installed in a location where it can intercept traffic between the web servers that you want to protect and the hub or switch through which users access those web servers. You then configure the network to send requests to the Web App Firewall instead of directly to your web servers, and responses to the Web App Firewall instead of directly to your users. The Web App Firewall filters that traffic before forwarding it to its final destination, using both its internal rule set and your additions and modifications. It blocks or renders harmless any activity that it detects as harmful, and then forwards the remaining traffic to the web server. The following figure provides an overview of the filtering process.

---

**Note:**

The figure omits the application of a policy to incoming traffic. It illustrates a security configura-
tion in which the policy is to process all requests. Also, in this configuration, a signatures object has been configured and associated with the profile, and security checks have been configured in the profile.

Figure 1. A Flowchart of Web App Firewall Filtering

As the figure shows, when a user requests a URL on a protected web site, the Web App Firewall first examines the request to ensure that it does not match a signature. If the request matches a signature, the Citrix Web Application Firewall either displays the error object (a web page that is located on the Web App Firewall appliance and which you can configure by using the imports feature) or forwards the request to the designated error URL (the error page). Signatures do not require as many resources as do security checks, so detecting and stopping attacks that are detected by a signature before running any of the security checks reduces the load on the server.

If a request passes signature inspection, the Web App Firewall applies the request security checks that have been enabled. The request security checks verify that the request is appropriate for your web site.
or web service and does not contain material that might pose a threat. For example, security checks examine the request for signs indicating that it might be of an unexpected type, request unexpected content, or contain unexpected and possibly malicious web form data, SQL commands, or scripts. If the request fails a security check, the Web App Firewall either sanitizes the request and then sends it back to the Citrix ADC appliance (or Citrix ADC virtual appliance), or displays the error object. If the request passes the security checks, it is sent back to the Citrix ADC appliance, which completes any other processing and forwards the request to the protected web server.

When the web site or web service sends a response to the user, the Web App Firewall applies the response security checks that have been enabled. The response security checks examine the response for leaks of sensitive private information, signs of web site defacement, or other content that should not be present. If the response fails a security check, the Web App Firewall either removes the content that should not be present or blocks the response. If the response passes the security checks, it is sent back to the Citrix ADC appliance, which forwards it to the user.

**Citrix Web Application Firewall features**

The basic Web App Firewall features are policies, profiles, and signatures, which provide a hybrid security model as described in *Known Web Attacks*, *Unknown Web Attacks*, and *How the Web App Firewall Works*. Of special note is the learning feature, which observes traffic to your protected applications and recommends appropriate configuration settings for certain security checks.

The imports feature manages files that you upload to the Web App Firewall. These files are then used by the Web App Firewall in various security checks, or when responding to a connection that matches a security check.

You can use the logs, statistics, and reports features to evaluate the performance of the Web App Firewall and identify possible needs for additional protections.

**How Citrix Web Application Firewall modifies application traffic**

The Citrix Web Application Firewall affects the behavior of a web application it protects by modifying the following:

- Cookies
- HTTP Headers
- Forms/Data

**Citrix Web Application Firewall session cookie**

To maintain the state of the session, Citrix ADC Web App Firewall generates its own session cookie. This cookie is passed only between the web browser and the Citrix ADC Web Application Firewall and
not to the web server. If any hacker tries to modify the session cookie, the Application Firewall drops the cookie before forwarding the request to the server and treats the request as a new user session. The session cookie is present as long as the web browser is open. When the web browser is closed, the Application Firewall session cookie becomes longer valid.

The configurable Web App Firewall session cookie is `citrix_ns_id`.

**Citrix Web App Firewall cookies**

Many web applications generate cookies to track user or session specific information. This information could be user preferences or shopping cart items. A web application cookie can be one of the following two types:

- **Persistent Cookies** - These cookies are stored locally on the computer and used again the next time you visit the site. This type of cookie usually contains information about the user, such as, logon, password, or preferences.
- **Session or Transient Cookies** - These cookies are used only for the duration of the session and are destroyed after the session is terminated. This type of cookie contains application state information, such as, shopping cart items or session credentials.

Hackers can attempt to modify or steal application cookies to hijack a user session or masquerade as a user. The Application Firewall prevents such attempts by hashing the application cookies and then adding additional cookies with the digital signatures. By tracking the cookies, the Application Firewall ensures that the cookies are not modified or compromised between the client browser and the Application Firewall. The Application Firewall does not modify the application cookies.

The Citrix Web Application Firewall generates the following default cookies to track the application cookies:

- **Persistent Cookies**: `citrix_ns_id_wlf`. Note: wlf stands for will live forever.
- **Session or Transient Cookies**: `citrix_ns_id_wat`. Note: wat stands for will act transiently.

To track the application cookies, the Application Firewall groups the persistent or session application cookies together and then hash and sign all the cookies together. Thus, the Application Firewall generates one `wlf` cookie to track all persistent application cookies and one `wat` cookie to track all application session cookies.

The Web App Firewall always generate an Application Firewall session cookie regardless of whether the web application generates any cookie.

The following table shows the number and types of cookies generated by the Application Firewall based on the cookies generated by the web application:

<table>
<thead>
<tr>
<th>Before Citrix ADC Web App Firewall</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>No cookies</td>
<td>Session cookie: <code>citrix_ns_id</code></td>
</tr>
</tbody>
</table>
Before Citrix ADC Web App Firewall | To
---|---
One persistent cookie | Session cookie: citrix_ns_id
Two persistent cookies | Two original persistent cookie from the application. Session cookie: citrix_ns_id,
| Persistent cookie: citrix_ns_id_wlf
One persistent cookie, One transient cookie | One original persistent cookie from the application. One original session cookie from the application. Session cookie: citrix_ns_id,
| Persistent cookie: citrix_ns_id_wlf,
| Transient cookie: citrix_ns_id_wat

Citrix Web App Firewall allows encrypting the application cookie. Application Firewall also provides an option to proxy the session cookie sent by the application, by storing it with the rest of the Application Firewall session data and not sending it to the client. When a client sends a request to the application that includes an Application Firewall session cookie, Application Firewall inserts the application sent cookie back into the request before sending the request on to the origin application. Application Firewall also allows adding the HTTPOnly and/or Secure flags to cookies.

How the application firewall affects HTTP headers

Both HTTP(s) requests and HTTP(s) responses use headers to send information about the HTTP(s) message. A header is a series of lines with each line containing a name followed by a colon and a space, and a value. For example, the Host header has the following format:

Host: www.citrix.com

Some header fields are used in both request and response headers, while others are appropriate only for either a request or a response. The Application Firewall might add, modify, or delete some headers in the HTTP(s) request or response to maintain the security of the application.

Request headers dropped by the Citrix Web Application Firewall

Many of the request headers related to caching might be dropped by Application Firewall in order to view every request within the context of a session. Similarly, if the request includes an encoding header to allow the web server to send compressed responses, the Application Firewall deletes this header so the contents in the uncompressed server response can be inspected by Application Firewall to prevent any leakage of sensitive data to the client.

The Application Firewall drops the following request headers:
- Range – Used to recover from a failed or partial file transfers.
- If-Range – Allows a client to retrieve a partial object when it contains a part of that object in its cache already (conditional GET).
- If-Modified-Since – If the requested object is not modified since the time specified in this field, an entity is not returned from the server. You get a HTTP 304 not modified error.
- If-None-Match – Allows efficient updates of cached information with a minimum amount of overhead.
- Accept-Encoding – What encoding methods are allowed for a particular object, such as gzip.

**Request header modified by the Citrix Web Application Firewall**

If a web browser uses the HTTP/1.0 or earlier protocols, the browser continually opens and closes the TCP socket connection after receiving each response. This adds overhead to the web server and prevents maintaining session state. The HTTP/1.1 protocol allows the connection to remain open for the duration of the session. The Application Firewall modifies the following request header to use HTTP/1.1 between the Application Firewall and the web server regardless of the protocol used by the web browser:

```
Connection: keep-alive
```

**Request headers added by the Citrix Web Application Firewall**

The Application Firewall acts as a reverse proxy and replaces the original source IP address of the session with the IP address of the Application Firewall. Therefore, all requests logged in the web server log indicates that the requests are sent from the Application Firewall.

**Response header dropped by the Citrix Web Application Firewall**

The Application Firewall might block or modify content such as removing credit card numbers or stripping comments, and this might result in a mismatch in size. To prevent such scenario, the Application Firewall drops the following header:

```
Content-Length – Indicates the size of the message sent to the recipient.
```

**Response Headers Modified by the Application Firewall**

Many of the response headers modified by the Application Firewall are related to caching. Caching headers in HTTP(S) responses must be modified to force the web browser to always send a request to the web server for the latest data and not use the local cache. However, some ASP applications use separate plug-ins to display dynamic contents and might require the ability to cache the data temporarily in the browser. To allow temporary caching of data when Advanced Security protections such as FFC, URL closure, or CSRF checks are enabled, Application Firewall adds or modifies the cache-control headers in the server response using the following logic:
• If Server sends Pragma:no-cache, then the Application Firewall does not do any modification.

• If Client Request is HTTP 1.0, then Application Firewall inserts Pragma:no-cache.

• If Client Request is HTTP 1.1 and has Cache-control: no-store, then Application Firewall does not make any modification.

• If Client Request is HTTP 1.1 and Server Response has Cache-Control header with no store or no cache directive, then Application Firewall does not make any modification.

• If Client Request is HTTP 1.1 and Server Response has either No Cache-control Header or Cache-Control header does not have no store or no-cache directive, the Application Firewall completes the following tasks:

  1. Inserts Cache-control: max-age=3, must-revalidate,private.
  2. Inserts X-Cache-Control-orig = Original value of Cache-Control Header.
  3. Deletes Last-Modified header.
  5. Inserts X-Expires-Orig=Original value of the Expire Header sent by the server.
  6. Modifies the Expires Header and sets the expiration date of the web page to the past, so it is always picked up again.
  7. Modifies Accept-Ranges and sets it to none.

To replace temporarily cached data in client browser when Application Firewall changes the response such as, for StripComments, X-out/Remove SafeObject, xout or remove Credit Card or URL Transform, Application Firewall takes the following actions:

  1. Deletes Last-Modified from server before forwarding to client.
  2. Replaces Etag with a value determined by Application Firewall.

**Response headers added by the Citrix Web App Firewall**

- **Transfer-Encoding**: Chunked. This header streams information back to a client without having to know the total length of the response before sending the response. This header is required because the content-length header is removed.

- **Set-Cookie**: The cookies added by the Application Firewall.

- **Xet-Cookie**: If the session is valid and if the response is not expired in cache, then you can serve from cache and do not have to send a new cookie because the session is still valid. In such a scenario, the Set-Cookie is changed to Xet-Cookie. For the web browser, Xet-Cookie is similar to any other custom header.

**How form data is affected**

The Application Firewall protects against attacks that attempt to modify the content of the original form sent by the server. It can also protect against Cross-site Request forgery attacks. The Application
Firewall accomplishes this by inserting hidden form tag as_fid in the page.

**Example:** `<input type="hidden" name="as_fid" value="VRgwq9Il96Jmg/+L0Y7C"/>

The hidden field as_fid is used for field consistency. This field is used by Application Firewall to track all fields of the form including the hidden field name/value pairs and to ensure that none of the fields of the form sent by the server are changed on the client side. The CSRF check also uses this unique form tag as_fid to ensure that the forms submitted by the user were served to the user in this session and no hacker is attempting to hijack the user session.

**Sessionless form check**

Application Firewall also offers an option to protect form data using sessionless field consistency. This is useful for applications where the forms might have large number of dynamic hidden fields that lead to high memory allocation per session by the Application Firewall. The sessionless field consistency check is accomplished by inserting another hidden field as_ffc_field for only POST requests or for both GET and POST requests based on the configured setting. The Application Firewall changes the method GET to POST when it forwards the form to the client. The appliance then reverts the method to GET when submitting it back to the server. The as_ffc_field value can be large because it contains the encrypted digest of the form being served. The following is an example of the sessionless form check:

```
1 <input type="hidden" name="as_ffc_field" value="CwAAAAVIGLD/lurRRiWulrbYrFYArgE05xVAXsEnMP1megXuQfiDTGbWk0fpQmdMhqfMbzfAFdjwR+T0m1oT"
2 +u+Svo9+NuloPhtnbkxGtnNe7gB/o8GlxeCk9ZkIIVv3oIL/nIPSRRjlgpWgafzVx7wtugNWnm8/GdnhnELCJTaYU7ScnC6LexJDLis1lxsesONWt8Zm
3 +vJTa3mTebDYGLYyhDpDQf8gII1XLgflTeaxAUzSNWHylyoqPrugYfnRPw+DIGf6gGwn1BYLesRHKNbjJBrKp0J09JzhEqdtZ1g3bMzEF9PocPvM1HpviST6VB
4 /YFunUFM4f+bD7EAVcugdovzb7ICsSQX5+qcC1B8WjQ="/>
```

**HTML comment stripping**

The Application Firewall also offers an option to strip all HTML comments in the responses before sending them to the client. This affects not only forms, but all response pages. The Application Firewall locates and removes any text embedded between “<!-“ and “->” comment tags. The tags remain to indicate that a comment existed in that location of the HTML source code. Any text embedded within any other HTML or JavaScript tags is ignored.

Some applications might not work correctly if they have JavaScript incorrectly embedded within comment tags. A comparison of the page source code before and after the comments were stripped by Application Firewall can help in identifying if any of the stripped comments had the required JavaScript embedded in them.
Credit card protection

The Application Firewall offers an option to inspect the headers as well as body of the response and either removes or x-outs the Credit Card numbers before forwarding the response to the client. Currently Application Firewall offers protection for the following major credit cards: American Express, Diners Club, Discover, JCB, MasterCard, and Visa. The x-out action works independent of the Block action.

Safe object protection

Similar to Credit Card numbers, leakage of other sensitive data can also be prevented by using Application Firewall Safe Object security check to either remove or x-out the sensitive content in the response.

XSS transform action

When the transform is enabled for XSS, Application Firewall changes "<" into "%26lt;" and ">") into "%26gt;" in the requests. If the checkRequestHeaders setting in Application Firewall is enabled, then the Application Firewall inspects the Request Headers and transforms these characters in Header and cookies also. The transform action does not block or transform values that were originally sent by the server. There are a set of default attributes and tags for XSS which are allowed by Application Firewall. A default list of denied XSS patterns is also provided. These can be customized by selecting the signatures object and clicking on the Manage SQL/XSS Patterns dialogue in Graphical User Interface.

Transforming SQL special characters

Application Firewall has the following default transformation rules for SQL special characters:

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
<th>Transformation</th>
</tr>
</thead>
<tbody>
<tr>
<td>’ (single quote that is, %27)</td>
<td>”</td>
<td>Another single quote</td>
</tr>
<tr>
<td>\ (backslash that is %5C)</td>
<td></td>
<td>Another backslash added</td>
</tr>
<tr>
<td>; (semicolon that is %3B)</td>
<td></td>
<td>Dropped</td>
</tr>
</tbody>
</table>

When transformation of special characters is enabled and the checkRequestHeaders is set to ON, then the transformation of special characters happens in Headers and cookies also.

Note: Some request headers such as User-Agent, Accept-Encoding usually contain semicolons and might be impacted by SQL transformation.
Cirix Web Application Firewall behavior wherein it corrupts EXPECT header

1. Whenever NetScaler receives HTTP request with EXPECT header in it, NetScaler sends EXPECT: 100-continue response to client on behalf of the back end server.
2. This behavior is because Application Firewall protections need to be run on entire request before forwarding the request to the server, NetScaler needs to get the entire request from client.
3. On reception of 100-continue response, client sends the remaining portion of request that completes the request.
4. NetScaler then runs all the protections and then forwards the request to the server.
5. Now as NetScaler is forwarding the complete request EXPECT header that came in initial request becomes obsolete as a result NetScaler corrupts this header and sends it to the server.
6. Server on receiving the request ignores any header which is corrupted.

Configuring the Web App Firewall

February 18, 2020

You can configure the Citrix Web App Firewall (Web App Firewall) by using any of the following methods:

- **Web App Firewall Wizard.** A dialog box consisting of a series of screens that step you through the configuration process.
- **Citrix Web Interface AppExpert Template.** A AppExpert template (a set of configuration settings) that are designed to provide appropriate protection for web sites. This AppExpert template contains appropriate Web App Firewall configuration settings for protecting many web sites.
- **Citrix ADC GUI.** The web-based configuration interface.
- **Citrix ADC Command Line Interface.** The command line configuration interface.

Citrix recommends that you use the Web App Firewall Wizard. Most users will find it the easiest method to configure the Web App Firewall, and it is designed to prevent mistakes. If you have a new Citrix ADC or VPX that you will use primarily to protect web sites, you may find the Web Interface AppExpert template a better option because it provides a good default configuration, not just for the Web App Firewall, but for the entire appliance. Both the GUI and the command line interface are intended for experienced users, primarily to modify an existing configuration or use advanced options.
The Web App Firewall Wizard

The Web App Firewall wizard is a dialog box that consists of several screens that prompt you to configure each part of a simple configuration. The Web App Firewall then creates the appropriate configuration elements from the information that you give it. This is the simplest and, for most purposes, the best way to configure the Web App Firewall.

To use the wizard, connect to the GUI with the browser of your choice. When the connection is established, verify that the Web App Firewall is enabled, and then run the Web App Firewall wizard, which prompts you for configuration information. You do not have to provide all of the requested information the first time you use the wizard. Instead, you can accept default settings, perform a few relatively straightforward configuration tasks to enable important features, and then allow the Web App Firewall to collect important information to help you complete the configuration.

For example, when the wizard prompts you to specify a rule for selecting the traffic to be processed, you can accept the default, which selects all traffic. When it presents you with a list of signatures, you can enable the appropriate categories of signatures and turn on the collection of statistics for those signatures. For this initial configuration, you can skip the advanced protections (security checks). The wizard automatically creates the appropriate policy, signatures object, and profile (collectively, the security configuration), and binds the policy to global. The Web App Firewall then begins filtering connections to your protected websites, logging any connections that match one or more of the signatures that you enabled and collecting statistics about the connections that each signature matches. After the Web App Firewall processes some traffic, you can run the wizard again and examine the logs and statistics to see if any of the signatures that you have enabled are matching legitimate traffic. After determining which signatures are identifying the traffic that you want to block, you can enable blocking for those signatures. If your website or web service is not complex, does not use SQL, and does not have access to sensitive private information, this basic security configuration will probably provide adequate protection.

You may need additional protection if, for example, your website is dynamic. Content that uses scripts may need protection against cross-site scripting attacks. Web content that uses SQL—such as shopping carts, many blogs, and most content management systems—may need protection against SQL injection attacks. Websites and web services that collect sensitive private information such as social security numbers or credit card numbers may require protection against unintentional exposure of that information. Certain types of web-server or XML-server software may require protection from types of attacks tailored to that software. Another consideration is that specific elements of your websites or web services may require different protection than do other elements. Examining the Web App Firewall logs and statistics can help you identify the additional protections that you might need.

After deciding which advanced protections are needed for your websites and web services, you can run the wizard again to configure those protections. Certain security checks require that you enter exceptions (relaxations) to prevent the check from blocking legitimate traffic. You can do so manually,
but it is usually easier to enable the adaptive learning feature and allow it to recommend the necessary relaxation. You can use the wizard as many times as necessary to enhance your basic security configuration and/or create additional security configurations.

The wizard automates some tasks that you would have to perform manually if you did not use the wizard. It automatically creates a policy, a signatures object, and a profile, and assigns them the name that you provided when you were prompted for the name of your configuration. The wizard also adds your advanced-protection settings to the profile, binds the signatures object to the profile, associates the profile with the policy, and puts the policy into effect by binding it to Global.

A few tasks cannot be performed in the wizard. You cannot use the wizard to bind a policy to a bind point other than Global. If you want the profile to apply to only a specific part of your configuration, you must manually configure the binding. You cannot configure the engine settings or certain other global configuration options in the wizard. While you can configure any of the advanced protection settings in the wizard, if you want to modify a specific setting in a single security check, it may be easier to do so on the manual configuration screens in the GUI.

For more information on using the Web App Firewall Wizard, see The Web App Firewall Wizard.

The Citrix Web Interface AppExpert Template

AppExpert Templates are a different and simpler approach to configuring and managing complex enterprise applications. The AppExpert display in the GUI consists of a table. Applications are listed in the left-most column, with the Citrix ADC features that are applicable to that application appearing each in its own column to the right. (In the AppExpert interface, those features that are associated with an application are called application units.) In the AppExpert interface, you configure the interesting traffic for each application, and turn on rules for compression, caching, rewrite, filtering, responder and the Web App Firewall, instead of having to configure each feature individually.

The Web Interface AppExpert Template contains rules for the following Web App Firewall signatures and security checks:

- **Deny URL check.** Detects connections to content that is known to pose a security risk, or to any other URLs that you designate.
- **Buffer Overflow check.** Detects attempts to cause a buffer overflow on a protected web server.
- **Cookie Consistency check.** Detects malicious modifications to cookies set by a protected web site.
- **FormField Consistency check.** Detects modifications to the structure of a web form on a protected web site.
- **CSRF Form Tagging check.** Detects cross-site request forgery attacks.
- **Field Formats check.** Detects inappropriate information uploaded in web forms on a protected web site.
- **HTML SQL Injection check.** Detects attempts to inject unauthorized SQL code.
**HTML Cross-Site Scripting check.** Detects cross-site scripting attacks.

For information on installing and using an AppExpert Template, see AppExpert Applications and Templates.

### The Citrix GUI

The GUI is a web-based interface that provides access to all configuration options for the Web App Firewall feature, including advanced configuration and management options that are not available from any other configuration tool or interface. Specifically, many advanced Signatures options can be configured only in the GUI. You can review recommendations generated by the learning feature only in the GUI. You can bind policies to a bind point other than Global only in the GUI.

For a description of the GUI, see The Web App Firewall Configuration Interfaces. For more information on using the GUI to configure the Web App Firewall, see Manual Configuration By Using the GUI.

For instructions on configuring the Web App Firewall by using the GUI, see Manual Configuration By Using the GUI. For information on the citrix-adc GUI, see The Web App Firewall Configuration Interfaces.

### The Citrix ADC command line interface

The Citrix ADC command line interface is a modified UNIX shell based on the FreeBSD bash shell. To configure the Web App Firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. You can configure most parameters and options for the Web App Firewall by using the NetScaler command line. Exceptions are the signatures feature, many of whose options can be configured only by using the GUI or the Web App Firewall wizard, and the learning feature, whose recommendations can only be reviewed in the GUI.

For instructions on configuring the Web App Firewall by using the Citrix ADC command line, see Manual Configuration By Using the Command Line Interface.

### Enable Citrix Web App Firewall

August 12, 2020

Before you can create a security configuration, you must enable the Citrix Web App Firewall feature on the appliance.
Points to remember

- If you are configuring a dedicated Citrix Web App Firewall appliance or upgrading an existing appliance, the feature is already enabled. You do not have to perform either of the procedures described here.
- If you have a new Citrix ADC or VPX, you must enable the Citrix Web App Firewall feature before you configure it.
- If you are upgrading a Citrix ADC or VPX from a previous version, you must first enable the Citrix Web App Firewall feature before you configure it.

Note:
If you are upgrading a Citrix ADC or VPX from a previous version, you might need to update the licenses on your appliance before you enable Citrix Web App Firewall. Check with your Citrix representative or reseller to obtain the correct license.

Enable Citrix Web App Firewall by using the command interface

At the command prompt, type the following command:

```
enable ns feature AppFW
```

Enable the Web App Firewall by using the GUI

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features page, select Citrix Web App Firewall.
4. Click OK.
Unlike most wizards, the Citrix Web Web App Firewall Wizard is designed not just to simplify the initial configuration process, but also to modify previously created configurations and to maintain your Web App Firewall setup. A typical user runs the wizard multiple times, skipping some of the screens each time.

The Web App Firewall Wizard automatically creates profiles, policies, and signatures.
Opening the wizard

To run the Web App Firewall Wizard, open the GUI and follow these steps:

1. Navigate to **Security > Application Firewall**.
2. In the details pane, under **Getting Started**, click **Application Firewall Wizard**. The wizard opens.

For more information about the GUI, see “The Web App Firewall Configuration Interfaces.”

The Wizard screens

The Web App Firewall wizard displays the following screens on a tabular page:

1. **Specify Name**: on this screen, when creating a new security configuration, specify a meaningful name and the appropriate type (HTML, XML or WEB 2.0) for your profile. The default policy and signatures are auto-generated by using the same name.

   **Profile Name**

   The name can begin with a letter, number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols. Choose a name that makes it easy for others to tell what content your new security configuration protects.

   **Note:**

   Because the wizard uses this name for both the policy and the profile, it is limited to 31 characters. Manually created policies can have names up to 127 characters in length.

   When modifying an existing configuration, you select Modify Existing Configuration and then, in the Name drop-down list, select the name of the existing configuration that you want to modify.

   **Note:**

   Only policies that are bound to global or to a bind point appear in this list; you cannot modify an unbound policy by using the Application Firewall wizard. You must either manually bind it to Global or a bind point, or modify it manually. (For manual modification, in the GUI) **Application Firewall > Policies > Firewall** pane, select the policy and click **Open**.

   **Profile Type**

   You also select a profile type on this screen. The profile type determines the types of advanced protection (security checks) that can be configured. Because certain kinds of content are not vulnerable to certain types of security threats, restricting the list of available checks saves time during configuration. The types of Web App Firewall profiles are:
• Web Application (HTML). Any HTML-based Web site that does not use XML or Web 2.0 technologies.
• XML Application (XML, SOAP). Any XML-based Web service.
• Web 2.0 Application (HTML, XML, REST). Any Web 2.0 site that combines HTML and XML-based content, such as an ATOM-based site, a blog, an RSS feed, or a wiki.

**Note:** If you are unsure which type of content is used on your website, you can choose Web 2.0 Application to ensure that you protect all types of web application content.

2. Specify Rule: on this screen, you specify the policy rule (expression) that defines the traffic the current configuration examines. If you create an initial configuration to protect your websites and web services, you can accept the default value, **true**, which selects all web traffic.

If you want this security configuration to examine, not all HTTP traffic that is routed through the appliance, but specific traffic, you can write a policy rule specifying the traffic that you want it to examine. Rules are written in Citrix ADC expressions language, which is a fully functional object-oriented programming language.

**Note:** In addition to the default expressions syntax, for backward compatibility the Citrix ADC operating system supports the Citrix ADC classic expressions syntax on Citrix ADC Classic and nCore appliances and virtual appliances. Classic expressions are not supported on Citrix ADC Cluster appliances and virtual appliances. Current users who want to migrate their existing configurations to the Citrix ADC cluster must migrate any policies that contain classic expressions to the default expressions syntax.

- For a simple description of using the Citrix ADC expressions syntax to create Web App Firewall rules, and a list of useful rules, see **Firewall Policies**.
- For a detailed explanation of how to create policy rules in Citrix ADC expressions syntax, see **Policies and Expressions**.

4. Select Signatures: on this screen, you select the categories of signatures that you want to use to protect your web sites and web services.

This is not a mandatory step, and you can skip it if you want to and go to the Specify Deep Protections screen. If the Select Signatures screen is skipped, only a profile and associated policies are created, and the signatures are not created.

You can select **Create New Signature** or **Select Existing Signature**.

If you are creating a new security configuration, the signature categories that you select are enabled, and by default they are recorded in a new signatures object. The new signatures object is assigned the same name that you entered on the Specify name screen as the name of the security configuration.

If you have previously configured signatures objects and want to use one of them as the signatures object associated with the security configuration that you are creating, click **Select Existing Signature** and select a signatures object from the Signatures list.
If you are modifying an existing security configuration, you can click Select Existing Signature and assign a different signatures object to the security configuration.

If you click Create New Signature, you can choose the edit mode as **Simple** or **Advanced**.

1. **Specify Signature Protections (Simple mode)**

The simple mode allows for easy configuration of the signature, with a preset list of protection definitions for common applications such as IIS (Internet Information Server), PHP and ActiveX. The default categories in Simple mode are:

- CGI. Protection against attacks on web sites that use CGI scripts in any language, including PERL scripts, Unix shell scripts, and Python scripts.
- Cold Fusion. Protection against attacks on web sites that use the Adobe Systems® ColdFusion® Web development platform.
- FrontPage. Protection against attacks on web sites that use the Microsoft® FrontPage® Web development platform.
- PHP. Protection against attacks on web sites that use the PHP open-source Web development scripting language.
- Client side. Protection against attacks on client-side tools used to access your protected web sites, such as Microsoft Internet Explorer, Mozilla Firefox, the Opera browser, and the Adobe Acrobat Reader.
- Microsoft IIS. Protection against attacks on Web sites that run the Microsoft Internet Information Server (IIS)
- Miscellaneous. Protection against attacks on other server-side tools, such as Web servers and database servers.

On this screen, you select the actions associated with the signature categories that you selected on the Select Signatures screen. The actions that you can configure are:

- Block
- Log
- Stats

By default the Log and Stats actions are enabled but not the Block action. To configure actions, click **Settings**. You can change the action settings of all the selected categories by using the **Action** drop-down menu.

1. **Specify Signature Protections (Advanced mode)**

The advanced mode allows for more granular control over the signature definitions and provides significantly more information. Use the advanced mode if you want complete control over signature definition.
The contents of this screen are the same as the contents of the Modify Signatures Object dialog box, as described in Configuring or Modifying a Signatures Object. In this screen, you can configure actions either by clicking the Actions drop-down menu or the actions menu, which appears as a circle with three dots.

7. Specify Deep Protections: on this screen, you choose the advanced protections (also called security checks or simply checks) that you want to use to protect your web sites and web services. Which checks are available depends on the profile type that you chose on the Specify Name screen. All checks are available for Web 2.0 Application profiles.

For more information, see Overview of Security Checks and see Advanced Form Protections Checks.

You configure the actions for the advanced protections that you have enabled. The actions that you can configure are:

- Block: blocks connections that match the signature. Disabled by default.
- Log: logs connections that match the signature for later analysis. Enabled by default.
- Stats: maintains statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.
- Learn. Observe traffic to this website or web service, and use connections that repeatedly violate this check to generate recommended exceptions to the check, or new rules for the check. Available only for some checks. For more information about the learning feature see Configuring and Using the Learning Feature, and how learning works and how to configure exceptions (relaxations) or deploy learned rules for a check, see Manual Configuration By Using the GUI.

To configure actions, select the protection by clicking the check box, and then click Action Settings to select the required actions. Select other parameters, if required, and then click OK to close the Action Settings window.

To view all logs for a specific check, select that check, and then click Logs to display the Syslog Viewer, as described in Web App Firewall Logs. If a security check is blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that security check by selecting a log that shows the unwanted blocking, and then clicking Deploy.

After you completing specifying Action Settings, click Finish to complete the wizard.

Following are four procedures that show how to perform specific types of configuration by using the Web App Firewall wizard.

Create a new configuration

Follow these steps to create a new firewall configuration and signature objects, by using the Application Firewall wizard.
1. Navigate to **Security > Application Firewall**.

2. In the details pane, under **Getting Started**, click **Application Firewall**. The wizard opens.

3. On the **Specify Name** screen, select **Create New Configuration**.

4. In the **Name** field, type a name, and then click **Next**.

5. In the **Specify Rule** screen, click **Next** again.

6. In the **Select Signatures** screen, select **Create New Signature** and **Simple** as the edit mode, and then click **Next**.

7. In the **Specify Signature Protections** screen, configure the required settings. For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see **Signatures**.

8. In the **Specify Deep Protections** screen configure the required actions and parameters in **Action Settings**.

9. When you complete, click **Finish** to close the Application Firewall wizard.

**Modify an existing configuration**

Follow these steps to modify an existing configuration and existing signature categories.
1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The wizard opens.
3. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during new configuration, and then click Next.
4. In the Specify Rule screen, click Next to keep the default value “true.” If you want to modify the rule, follow the steps described in Configure a Custom Policy Expression.
5. In the Select Signatures screen, click Select Existing Signature. From the Existing Signature drop-down menu, select the appropriate option, and then click Next. The advanced signature protection screen appears.
   **Note:** If you select an existing signature, the default edit mode for signature protected is advanced.
6. In the Specify Signature Protections screen, configure the required settings and click Next. For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see Signatures.
7. In the Specify Deep Protections screen, configure the settings and click Next.
8. After you complete, click Finish to close the Web App Firewall Wizard.

**Create a new configuration without signatures**

Follow these steps to use the Application Firewall Wizard to skip the Select Signatures screen and create a new configuration with just the profile and the associated policies but without any signatures.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The wizard opens.
3. On the Specify Name screen, select Create New Configuration.
4. In the Name field, type a name, and then click Next.
5. In the Specify Rule screen, click Next again.
6. In the Select Signatures screen, click Skip.
7. In the Specify Deep Protections screen configure the required actions and parameters in Action Settings.
8. When you complete, click Finish to close the Application Firewall Wizard.

**Configure a custom policy expression**

Follow these steps to use the Application Firewall Wizard to create a specialized security configuration to protect only specific content. In this case, you create a new security configuration instead of
modifying the initial configuration. This type of security configuration requires a custom rule, so that
the policy applies the configuration to only the selected Web traffic.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard.
3. On the Specify Name screen, type a name for your new security configuration in the Name text box, select the type of security configuration from the Type drop-down list, and then click Next.
4. On the Specify Rule screen, enter a rule that matches only that content that you want this web application to protect. Use the Frequently Used Expressions drop-down list and the Expression Editor to create a custom expression. When you complete, click Next.
5. In the Select Signatures screen, select the edit mode, and then click Next.
6. In the Specify Signature Protections screen, configure the required settings.
7. In the Specify Deep Protections screen configure the required actions and parameters in Action Settings.
8. When you complete, click Finish to close the Application Firewall Wizard.

Manual configuration

June 17, 2019

If you want to bind a profile to a bind point other than Global, you must manually configure the binding. Also, certain security checks require that you either manually enter the necessary exceptions or enable the learning feature to generate the exceptions that your Web sites and Web services need. Some of these tasks cannot be performed by using the Web App Firewall wizard.

If you are familiar with how the Web App Firewall works and prefer manual configuration, you can manually configure a signatures object and a profile, associate the signatures object with the profile, create a policy with a rule that matches the web traffic that you want to configure, and associate the policy with the profile. You then bind the policy to Global, or to a bind point, to put it into effect, and you have created a complete security configuration.

For manual configuration, you can use the GUI (a graphical interface) or the command line. Citrix recommends that you use the GUI. Not all configuration tasks can be performed at the command line. Certain tasks, such as enabling signatures and reviewing learned data, must be done in the GUI. Most other tasks are easier to perform in the GUI.
Citrix ADC 13.0

**Replicating configuration**

When you use the GUI (GUI) or the command line interface (CLI) to manually configure the Web App Firewall, the configuration is saved in the /nsconfig/ns.conf file. You can use the commands in that file to replicate the configuration on another appliance. You can cut and paste the commands into the CLI one by one, or you can save multiple commands in a text file in the /var/tmp folder and run them as a batch file. Following is an example of running a batch file containing commands copied from the /nsconfig/ns.conf file of a different appliance:

```
> batch -f /var/tmp/appfw_add.txt
```

**Warning**

Import commands are not saved in the ns.conf file. Before running commands from the ns.conf file to replicate the configuration on another appliance, you must import all the objects used in the configuration (for example, signatures, error page, WSDL, and Schema) to the appliance on which you will replicate the configuration. The add command to add an Web App Firewall profile saved in an ns.conf file might include the name of an imported object, but such a command might fail when executed on another appliance if the referenced object does not exist on that appliance.

**Manual configuration by using the Citrix ADC GUI**

August 19, 2020

If you need to manually configure the Web App Firewall feature, Citrix recommends you to use the Citrix ADC GUI procedure.

**To create and configure signatures object**

Before you can configure the signatures, you must create a signatures object from the appropriate default signatures object template. Assign the copy a new name, and then configure the copy. You cannot configure or modify the default signatures objects directly. The following procedure provides basic instructions for configuring a signatures object. For more detailed instructions, see [Manually Configuring the Signatures Feature](#).

1. Navigate to **Security > application firewall > Signatures**.
2. In the details pane, select the signatures object that you want to use as a template, and then click **Add**.

Your choices are:

- **Default Signatures.** Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
- **XPath Injection.** Contains all of the items in the Default Signatures, and in addition, contains the XPath injection rules.

3. In the **Add Signatures Object** dialog box, type a name for your new signatures object, click **OK**, and then click **Close**. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), and underscore (_) symbols.

4. Select the signatures object that you created, and then click **Open**.

5. In the **Modify Signatures Object** dialog box, set the **Display Filter Criteria** options at the left to display the filter items that you want to configure.

As you modify these options, the results that you specify are displayed in the Filtered Results window at the right. For more information about the categories of signatures, see **Signatures**.

6. In the **Filtered Results** area, configure the settings for a signature by selecting and clearing the appropriate check boxes.

7. When finished, finished, click **Close**.

---

**To create a Web App Firewall profile by using the GUI**

Creating a Web App Firewall profile requires that you specify only a few configuration details.

1. Navigate to **Security > application firewall > Profiles**.

2. In the details pane, click **Add**.

3. In the **Create Web App Firewall** Profile dialog box, type a name for your profile.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

4. Choose the profile type from the drop-down list.

5. Click **Create**, and then click **Close**.

---

**To configure a Web App Firewall profile by using the GUI**

1. Navigate to **Security > application firewall > Profiles**.
2. In the details pane, select the profile that you want to configure, and then click **Edit**.

3. In the **Configure Web App Firewall Profile** dialog box, on the **Security Checks** tab, configure the security checks.
   - To enable or disable an action for a check, in the list, select or clear the check box for that action.
   - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.
   You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.
   - To review learned exceptions or rules for a check, select the check, and then click **Learned Violations**. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
     - To edit the exception or rule, and then add it to the list, click **Edit & Deploy**.
     - To accept the exception or rule without modification, click **Deploy**.
     - To remove the exception or rule from the list, click **Skip**.
   - To refresh the list of exceptions or rules to be reviewed, click **Refresh**.
   - To open the **Learning Visualizer** and use it to review learned rules, click **Visualizer**.
   - To review the log entries for connections that matched a check, select the check, and then click **Logs**. You can use this information to determine which checks are matching attacks so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see **Logs, Statistics, and Reports**.
   - To completely disable a check, in the list, clear all of the check boxes to the right of that check.

4. On the **Settings** tab, configure the profile settings.
   - To associate the profile with the set of signatures that you previously created and configured, under **Common Settings**, choose that set of signatures in the Signatures drop-down list.
Note:
You may must use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

- To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

Note:
You must first upload the error object that you want to use in the Import pane.

- To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types.

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile. For more information, see Configure and Learning feature.

6. Click OK to save your changes and return to the Profiles pane.

Configuring a Web App Firewall rule or relaxation

You configure two different types of information in this dialog box, depending upon which security check you are configuring. In most cases, you configure an exception (or relaxation) to the security check. If you are configuring the Deny URL check or the Field Formats check, you configure an addition (or rule). The process for either of these is the same.

To configure a relaxation rule by using the Citrix ADC GUI

2. In the Profiles pane, select the profile you want to configure, and then click Edit.

3. In the Configure Web App Firewall Profile page, click Relaxation Rule from Advanced Settings section. The Relaxation Rule section contains the complete list of Web App Firewall relaxation rules.

4. Click a security rule that you want to configure, and then click Edit.

5. The URL Relaxation Rules page contains a list of actions and that you can configure for this rule and a list of existing relaxations or rules. The list might be empty if you have not either manually added any relaxations or approved any relaxations that were recommended by the learning engine. Beneath the list is a row of buttons that allow you to add, modify, delete, enable, or disable the relaxations on the list.

6. To add or modify a relaxation or a rule, do one of the following:
• To add a new relaxation, click Add.
• To modify an existing relaxation, select the relaxation that you want to modify, and then click Open.

The Start URL Relaxation Rule page is displayed. Except for the title, these dialog boxes are identical.

7. Fill in the dialog box as described below. The dialog boxes for each check are different. The list below covers all elements that might appear in any dialog box.

• Enabled check box—Select to place this relaxation or rule in active use; clear to deactivate it.

• Attachment Content Type—The Content-Type attribute of an XML attachment. In the text area, enter a regular expression that matches the Content-Type attribute of the XML attachments to allow.

• Action URL—in the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

• Cookie—in the text area, enter a PCRE-format regular expression that defines the cookie.

• Field Name—A web form field name element may be labeled Field Name, Form Field, or another similar name. In the text area, enter a PCRE-format regular expression that defines the name of the form field.

• From Origin URL—in the text area, enter a PCRE-format regular expression that defines the URL that hosts the web form.

• From Action URL—in the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

• Name—An XML element or attribute name. In the text area, enter a PCRE-format regular expression that defines the name of the element or attribute.

• URL—A URL element may be labeled Action URL, Deny URL, Form Action URL, Form Origin URL, Start URL, or simply URL. In the text area, enter a PCRE-format regular expression that defines the URL.

• Format—The format section contains multiple settings that include list boxes and text boxes. Any of the following can appear:
  
  – Type—Select a field type in the Type drop-down list. To add a new field type definition, click Manage—
  
  – Minimum Length—Type a positive integer that represents the minimum length in characters if you want to force users to fill in this field. Default: 0 (Allows field to be left blank.)
- **Maximum length**—To limit the length of data in this field, type a positive integer that represents the maximum length in characters. Default: 65535

- **Location**—Choose the element of the request that your relaxation applies to from the drop-down list. For HTML security checks, the choices are:
  - FORMFIELD—Form fields in web forms.
  - HEADER—Request headers.
  - COOKIE—Set-Cookie headers.

  For XML security checks, the choices are:
  - ELEMENT—XML element.
  - ATTRIBUTE—XML attribute.

  - **Maximum Attachment Size**—The maximum size in bytes allowed for an XML attachment.

  - **Comments**—In the text area, type a comment. Optional.

**Note:** For any element that requires a regular expression, you can type the regular expression, use the Regex Tokens menu to insert regular expression elements and symbols directly into the text box, or click **Regex Editor** to open the **Add Regular Expression** dialog box, and use it to construct the expression.

8. To remove a relaxation or rule, select it, and then click **Delete**.

9. To enable a relaxation or rule, select it, and then click **Enable**.

10. To disable a relaxation or rule, select it, and then click **Disable**.

11. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click **Visualizer**, and use the display tools.

  **Note:**
  The **Visualizer** button does not appear on all check relaxation dialog boxes.

12. To review learned rules for this check, click **Learning** and perform the steps in **To configure and use the Learning feature**

13. Click **OK**.

**To configure the Learned Rules by using the Citrix ADC GUI**

1. Navigate to **Security > Citrix Web App Firewall > Profiles**.

2. In the **Profiles** pane, select the profile, and then click **Edit**.

3. In the **Citrix Web App Firewall Profile** page, click **Learned Rules** from **Advanced Settings**. In the **Learned Rules** section you can see a list of security checks that are available in the current profile and that support the learning feature.
4. To configure the learning thresholds, select a security check, and click **Settings**.

5. In the **Dynamic Profiling and Learning Rules Settings** page, you can set the settings. For more information, see **Dynamic profile settings**

   - **Minimum number threshold.** Depending on which security check’s learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1

   - **Percentage of times threshold.** Depending on which security check’s learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0

6. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, select **Remove All Learned Data action**.

   **Note:**
   
   This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

7. To restrict the learning engine to traffic from a specific set of IPs, click **Trusted Learning Clients**, and add the IP addresses that you want to use to the list.
   
   a) To add an IP address or IP address range to the Trusted Learning Clients list, click **Add**.
   
   b) In the **AppFirewall Profile to Trusted Clint Binding** page, click **Add**.
   
   c) Select the **Enabled** check box to enable the feature.
   
   d) In Trusted Learning Client’s box, type the IP address or an IP address range in CIDR format.
   
   e) In the **Comments** text area, type a comment that describes this IP address or range.
   
   f) Click **Create and Close**.

8. To modify an existing IP address or range, click the IP address or range, and then click **Edit**. Except for the name, the dialog box that appears is identical to the Add Trusted Learning Clients dialog box.

9. To disable or enable an IP address or range, but leave it on the list, click the IP address or range, and then click **Disable** or **Enable**, as appropriate.

10. To remove an IP address or range completely, click the IP address or range, and then click **Delete**.

11. Click **Close** to return to the **Citrix Web App Firewall Profile** page.
To create a Citrix Web App Firewall policy by using the Citrix ADC GUI

2. In the Policies page, click Citrix Web App Firewall Policy link.
3. In the Citrix Web App Firewall Policies page, click Add.
4. In the Create Citrix Web App Firewall Policy page, set the following parameters.
   a) Name. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
   b) Profile. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
   c) Expression. In the Expression text area, create a rule for your policy.
   d) Log Action. Add a log action or you can modify an existing log action.
   e) Comments. A brief description about the policy.
5. Click Create or OK, and then click Close.

To create or configure a Web App Firewall rule (expression)

The policy rule, also called the expression, defines the web traffic that the Web App Firewall filters by using the profile associated with the policy. Like other Citrix ADC policy rules (or expressions), Web App Firewall rules use Citrix ADC expressions syntax. This syntax is powerful, flexible, and extensible.
It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the Web App Firewall wizard or the Citrix ADC GUI to create your policy rule:
   - If you are configuring a policy in the Web App Firewall wizard, in the navigation pane, click Citrix Web App Firewall Wizard, then in the details pane click Citrix Web App Firewall Wizard, and then navigate to the Specify Rule tab page.
   - In the Specify Rule page, choose the prefix for your expression from the drop-down list. Your choices are:
     - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
     - **SYS.** One or more protected websites. Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
     - **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
     - **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

   After you choose a prefix, the Web App Firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

2. Choose your next term.

   If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The Web App Firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

   When you have decided which term you want, double-click it to insert it into the Expression window.

3. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.

4. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

   Following are some examples of expressions for specific purposes.
• **Specific web host.** To match traffic from a particular web host:

HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

For shopping.example.com, substitute the name of the web host that you want to match.

• **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

• **Specific type of content: GIF images.** To match GIF format images:

HTTP.REQ.URL.ENDSWITH(".png")

To match other format images, substitute another string in place of .png.

• **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")

To match all JavaScripts with .js extensions:

HTTP.REQ.URL.ENDSWITH(".js")

For more information about creating policy expressions, see Policies and Expressions.

**Note:**

If you use the command line to configure a policy, remember to escape any double quotation marks within Citrix ADC expressions. For example, the following expression is correct if entered in the GUI:

HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

If entered at the command line, however, you must type this instead:

HTTP.REQ.HEADER("Host").EQ("shopping.example.com")

To add a firewall rule (expression) by using the Add Expression dialog box

The **Add Expression** dialog box (also referred to as the Expression Editor) helps users who are not familiar with the Citrix ADC expressions language to construct a policy that matches the traffic that they want to filter.
1. If you have not already done so, navigate to the appropriate location in the Web App Firewall wizard or the Citrix ADC GUI:
   - If you are configuring a policy in the Web App Firewall wizard, in the navigation pane, click Web App Firewall, then in the details pane click Web App Firewall Wizard, and then navigate to the Specify Rule screen.
   - If you are configuring a policy manually, in the navigation pane, expand Web App Firewall, then Policies, and then Firewall. In the details pane, to create a policy, click Add. To modify an existing policy, select the policy, and then click Open.
2. On the Specify Rule screen, in the Create Web App Firewall Profile dialog box, or in the Configure Web App Firewall Profile dialog box, click Add.
3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
   - HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
   - SYS. One or more protected websites. Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - SERVER. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.
4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the Web App Firewall treats requests and associated responses as a single unit and filters both, you do not need to specific responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.
5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.
6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or more terms that you added after the term that you modified is cleared.
7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.
To bind a Web App Firewall policy by using the Citrix ADC GUI

1. Do one of the following:
   - Navigate to Security > Web App Firewall, and in the details pane, click application firewall policy manager.
   - Navigate to Security > Citrix Web App Firewall > Policies > Firewall, and in the “Citrix Web App Firewall Policies” pane, click Policy Manager.

2. In the Application Firewall Policy Manager dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
   - Override Global. Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance, and are applied before any other policies.
   - LB Virtual Server. Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
   - CS Virtual Server. Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
   - Default Global. Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance.
   - Policy Label. Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
   - None. Do not bind the policy to any bind point.

3. Click Continue. A list of existing Web App Firewall policies appears.
4. Select the policy you want to bind by clicking it.
5. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double-click that field to open the Configure Web App Firewall Policy dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double-click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double-click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

6. Repeat steps 3 through 6 to add any additional Web App Firewall policies you want to globally bind.
7. Click OK. A message appears in the status bar, stating that the policy has been successfully bound.
Manual configuration By using the command line interface

April 21, 2020

Note:
If you need to manually configure the Web App Firewall feature, Citrix recommends you to use the Citrix ADC GUI procedure.

You can configure the Web App Firewall features from the Citrix ADC command interface. However, there are important exceptions. You cannot enable signatures from the command interface. There are around 1,000 default signatures in seven categories and the task is too complex for the command interface. You can enable or disable features and configure parameters from the command line, but cannot configure manual relaxations. While you can configure the adaptive learning feature and enable learning from the command line, you cannot review learned relaxations or learned rules and approve or skip them. The command line interface is intended for advanced users who are familiar in using the Citrix ADC appliance and Web App Firewall.

To manually configure the Web App Firewall by using the Citrix ADC command line, use a telnet or secure shell client of your choice to log on to the Citrix ADC command line.

To create a profile by using the command line interface

At the command prompt, type the following commands:

- add appfw profile <name> [-defaults ( basic | advanced )]
- set appfw profile <name> -type ( HTML | XML | HTML XML )
- save ns config

Example

The following example adds a profile named pr-basic, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML website.

```
1  add appfw profile pr-basic -defaults basic
2  set appfw profile pr-basic -type HTML
3  save ns config
```
To configure a profile by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> <arg1> [<arg2> ...]` where `<arg1>` represents a parameter and `<arg2>` represents either another parameter or the value to assign to the parameter represented by `<arg1>`. For descriptions of the parameters to use when configuring specific security checks, see Advanced Protections and its subtopics. For descriptions of the other parameters, see “Parameters for Creating a Profile.”

- `save ns config`

Example

The following example shows how to configure an HTML profile created with basic defaults to begin protecting a simple HTML-based website. This example turns on logging and maintenance of statistics for most security checks, but enables blocking only for those checks that have low false positive rates and require no special configuration. It also turns on transformation of unsafe HTML and unsafe SQL, which prevents attacks but does not block requests to your websites. With logging and statistics enabled, you can later review the logs to determine whether to enable blocking for a specific security check.

```
1 set appfw profile -startURLAction log stats
2 set appfw profile -denyURLAction block log stats
3 set appfw profile -cookieConsistencyAction log stats
4 set appfw profile -crossSiteScriptingAction log stats
5 set appfw profile -crossSiteScriptingTransformUnsafeHTML ON
6 set appfw profile -fieldConsistencyAction log stats
7 set appfw profile -SQLInjectionAction log stats
8 set appfw profile -SQLInjectionTransformSpecialChars ON
9 set appfw profile -SQLInjectionOnlyCheckFieldsWithSQLChars ON
10 set appfw profile -SQLInjectionParseComments checkall
11 set appfw profile -fieldFormatAction log stats
12 set appfw profile -bufferOverflowAction block log stats
13 set appfw profile -CSRFtagAction log stats
14 save ns config
```

To create and configure a policy

At the command prompt, type the following commands:

- `add appfw policy <name> <rule> <profile>`
- `save ns config`
Example

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog.

```
1 add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com ")" pr-blog
```

To bind a Web App Firewall policy

At the command prompt, type the following commands:

- bind appfw global <policyName> <priority>
- save ns config

Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
1 bind appfw global pl-blog 10
2 save ns config
```

To configure session limit per PE

At the command prompt, type the following commands:

- set appfw settings <session limit>

Example

The following example configures the session limit per PE.

```
1 > set appfw settings -sessionLimit 500000'
2
3 Done
4
5 Default value:100000 Max value:500000 per PE
```

Copied!

Signatures

July 30, 2020

The Web App Firewall signatures provide specific, configurable rules to simplify the task of protecting your websites against known attacks. A signature represents a pattern that is a component of a known attack on an operating system, web server, website, XML-based web service, or other resource. A rich set of preconfigured Web App Firewall built-in or native rules offers an easy to use security solution, applying the power of pattern matching to detect attacks and protect against application vulnerabilities.

You can create your own signatures or use signatures in the built-in templates. The Web App Firewall has two built-in templates:

- **Default Signatures**: This template contains a preconfigured list of over 1,300 signatures, in addition to a complete list of SQL injection keywords, SQL special strings, SQL transform rules, and SQL wildcard characters. It also contains denied patterns for cross-site scripting, and allowed attributes and tags for cross-site scripting. This is a read-only template. You can view the contents, but you cannot add, edit, or delete anything in this template. To use it, you must make a copy. In your own copy, you can enable the signature rules that you want to apply to your traffic, and specify the actions to be taken when the signature rules match the traffic.

The Web App Firewall signatures are derived from the rules published by Snort, which is an open source intrusion prevention system capable of performing real-time traffic analysis to detect various attacks and probes.

- **XPath Injection Patterns**: This template contains a preconfigured set of literal and PCRE keywords and special strings that are used to detect XPath (XML Path Language) injection attacks.

**Blank Signatures**: In addition to making a copy of the built-in *Default Signatures template, you can use a blank signatures template to create a signature object. The signature object that you create with the blank signatures option does not have any native signature rules, but, just like the *Default template, it has all the SQL/XSS built-in entities.

**External-Format Signatures**: The Web App Firewall also supports external format signatures. You can import the third party scan report by using the XSLT files that are supported by the Citrix Web App Firewall. A set of built-in XSLT files is available for the following scan tools to translate external format files to native format:

- Cenzic
- Deep Security for Web Apps
- IBM AppScan Enterprise
- IBM AppScan Standard.
- Qualys

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Security protection for your application

Tighter security increases processing overhead. Signatures provide the following deployment options to help you to optimize the protection of your applications:

- **Negative Security Model**: With the negative security model, you use a rich set of preconfigured signature rules to apply the power of pattern matching to detect attacks and protect against application vulnerabilities. You block only what you don’t want and allow the rest. You can add your own signature rules, based on the specific security needs of your applications, to design your own customized security solutions.

- **Hybrid security Model**: In addition to using signatures, you can use positive security checks to create a configuration ideally suited for your applications. Use signatures to block what you don’t want, and use positive security checks to enforce what is allowed.

To protect your application by using signatures, you must configure one or more profiles to use your signatures object. In a hybrid security configuration, the SQL injection and cross-site scripting patterns, and the SQL transformation rules, in your signatures object are used not only by the signature rules, but also by the positive security checks configured in the Web App Firewall profile that is using the signatures object.

The Web App Firewall examines the traffic to your protected websites and web services to detect traffic that matches a signature. A match is triggered only when every pattern in the rule matches the traffic. When a match occurs, the specified actions for the rule are invoked. You can display an error page or error object when a request is blocked. Log messages can help you to identify attacks being launched against your application. If you enable statistics, the Web App Firewall maintains data about requests that match a Web App Firewall signature or security check.

If the traffic matches both a signature and a positive security check, the more restrictive of the two actions are enforced. For example, if a request matches a signature rule for which the block action is disabled, but the request also matches an SQL Injection positive security check for which the action is block, the request is blocked. In this case, the signature violation might be logged as `<not blocked>`, although the request is blocked by the SQL injection check.

**Customization**: If necessary, you can add your own rules to a signatures object. You can also customize the SQL/XSS patterns. The option to add your own signature rules, based on the specific security needs of your applications, gives you the flexibility to design your own customized security
solutions. You block only what you don’t want and allow the rest. A specific fast-match pattern in a specified location can significantly reduce processing overhead to optimize performance. You can add, modify, or remove SQL injection and cross-site scripting patterns. Built-in RegEx and expression editors help you configure your patterns and verify their accuracy.

**Auto-update:** You can manually update the signature object to get the latest signature rules, or you can apply the auto-update feature so that the Web App Firewall can automatically update the signatures from the cloud-based Web App Firewall updates service.

**Note:**

If new signature rules are added during auto-update, they are disabled by default. You should periodically review the updated signatures and enable the newly added rules that are pertinent for protecting your applications.

You must configure CORS to host signatures on IIS servers.

Signature auto update feature does not work on the local web server when you access the URL from the Citrix ADC GUI.

**Getting started**

Using Citrix signatures to protect your application is easy and can be accomplished in a few simple steps:

1. **Add a signature object.**
   - You can use the Wizard that prompts you to create the entire Web App Firewall configuration, including adding the profile and policy, selecting and enabling signatures, and specifying actions for signatures and positive security checks. The signatures object is created automatically.
   - You can create a copy of the signatures object from the *Default Signatures template, use a blank template to create a signature with your own customized rules, or add an external format signature. Enable the rules and configure the actions that you want to apply.

2. **Configure the target Web App Firewall profile to use this signatures object.**

3. **Send traffic to validate the functionality**

**Highlights**

- The Default signatures object is a template. It cannot be edited or deleted. To use it, you must create a copy. In your own copy, you can enable the rules and the desired action for each rule as required for your application. To protect the application, you must configure the target profile to use this signature.
• Processing signature patterns has overhead. Try to enable only those signatures that are applicable for protecting your application, rather than enabling all signature rules.
• Every pattern in the rule must match to trigger a signature match.
• You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks. You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.
• You can make a copy of an existing signature object and tweak it, by adding or editing rules and SQL/XSS patterns, to protect another application.
• You can use auto-update to download the latest version of the Web App Firewall default rules without need for ongoing monitoring to check for the availability of the new update.
• A signature object can be used by more than one profile. Even after you have configured one or more profiles to use a signature object, you can still enable or disable signatures or change the action settings. You can manually create and modify your own custom signature rules. The changes apply to all the profiles that are currently configured to use this signature object.
• You can configure signatures to detect violations in various types of payloads, such as HTML, XML, JSON, and GWT.
• You can export a configured signatures object and import it to another Citrix ADC appliance for easy replication of your customized signature rules.

Signatures are patterns that are associated with a known vulnerability. You can use signature protection to identify the traffic that attempts to exploit these vulnerabilities, and take specific actions.

Signatures are organized into categories. You can optimize the performance and reduce the processing overhead by enabling only the rules in the categories that are appropriate for protecting your application.

Manually configuring the signatures feature

April 23, 2019

To use signatures to protect your web sites, you must review the rules, and enable and configure the ones that you want to apply. The rules are disabled by default. Citrix recommends that you enable all rules that are applicable to the type of content that your web site uses.

To manually configure the signatures feature, use a browser to connect to the GUI. Then, create a signatures object from a built-in template, an existing signatures object, or by importing a file. Next, configure the new signatures object as explained in Configuring or Modifying a Signatures Object.
Adding or removing a signature object

February 12, 2020

You can add a new signature object to the Web App Firewall by:

- Copying a built-in template.
- Copying an existing signatures object.
- Importing a signatures object from an external file.

The signature file includes CPU usage, latest applicable year, and severity level details. You can see the CPU usage, latest year, and CVE severity level every time a signature file is modified and uploaded periodically. After observing these values, you can decide to enable or disable the signature on the appliance.

You must use the GUI to copy a template or existing signatures object. You can use either the GUI or the command line to import a signatures object. You can also use either the GUI or the command line to remove a signatures object.

To create a signatures object from a template

1. Navigate to Security > Application Firewall > Signatures.

2. In the details pane, select the signatures object that you want to use as a template.

   Your choices are:

   - Default Signatures. Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
   - XPath Injection. Contains the XPath injection patterns.
   - Any existing signatures object.

   Attention:

   If you do not choose a signatures type to use as a template, the Web App Firewall prompts you to create signatures from scratch.

3. Click Add.

4. In the Add Signatures Object dialog box, type a name for your new signatures object, and then click OK. The name can begin with a letter, number, or the underscore symbol, and can consist
of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@),
equals (=), and underscore (_) symbols.

5. Click Close.

To create a signatures object by importing a file

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, click Add.
3. In the Add Signatures Object dialog box, select the format of the signatures you want to import.
   • To import a Citrix ADC format signatures file, select the Native Format tab.
   • To import an external signatures format file, select the External Format tab.
4. Choose the file that you want to use to create your signatures object.
   • To import a native Citrix ADC format signatures file, in the Import section select either Im-
      port from Local File or Import from URL, then type or browse to the path or URL to the
      file.
   • To import a Cenzic, IBM AppScan, Qualys, or Whitehat format file, in the XSLT section select
      Use Built-in XSLT File, Use Local File, or Reference from URL. Next, if you chose Use Built-
      in XSLT File, select the appropriate file format from the list. If you chose Use Local File or
      Reference from URL, then type or browse to the path or URL to the file.
5. Click Add, and then click Close.

To create a signatures object by importing a file by using the command line

At the command prompt, type the following commands:

- import appfw signatures <src> <name> [-xslt <string>] [-comment <string>
  >] [-overwrite] [-merge] [-shal <string>]
- save ns config

Example #1

The following example creates a signatures object from a file named signatures.xml and assigns it the
name MySignatures.

```
1 import appfw signatures signatures.xml MySignatures
2 save ns config
```
To remove a signatures object by using the GUI

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to remove.
3. Click Remove.

To remove a signatures object by using the command line

At the command prompt, type the following commands:

- `rm appfw signatures <name>`
- `save ns config`

Configuring or modifying a signatures object

February 12, 2020

You configure a signatures object after creating it, or modify an existing signatures object, to enable or disable signature categories or specific signatures, and configure how the Web App Firewall responds when a signature matches a connection.

To configure or modify a signatures object

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.

   As you modify these options, the results that you requested are displayed in the Filtered Results window at the right.

   - To display only selected categories of signatures, check or clear the appropriate signature-category check boxes. The signature categories are:
<table>
<thead>
<tr>
<th>Name</th>
<th>Type of Attack that this Signature Protects Against</th>
</tr>
</thead>
<tbody>
<tr>
<td>cgi</td>
<td>CGI scripts. Includes Perl and UNIX shell scripts.</td>
</tr>
<tr>
<td>client</td>
<td>Browsers and other clients.</td>
</tr>
<tr>
<td>coldfusion</td>
<td>Web sites that use the Adobe Systems ColdFusion application server.</td>
</tr>
<tr>
<td>frontpage</td>
<td>Web sites that use Microsoft’s FrontPage server.</td>
</tr>
<tr>
<td>iis</td>
<td>Web sites that use the Microsoft Internet Information Server (IIS).</td>
</tr>
<tr>
<td>misc</td>
<td>Miscellaneous attacks.</td>
</tr>
<tr>
<td>php</td>
<td>Web sites that use PHP</td>
</tr>
<tr>
<td>web-activex</td>
<td>Web sites that contain ActiveX controls.</td>
</tr>
<tr>
<td>web-struts</td>
<td>Web sites that contain Apache struts, which are java-ee based applets.</td>
</tr>
</tbody>
</table>

- To display only signatures that have specific check actions enabled, select the ON check box for each of those actions, clear the ON check boxes for the other actions, and clear all of the OFF check boxes. To display only signatures that have a specific check action disabled, select their respective OFF check boxes and clear all of the ON check boxes. To display signatures regardless of whether they have a check action enabled or disabled, select or clear both the ON and the OFF check boxes for that action. The check actions are:

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>The signature is enabled. The Web App Firewall checks only for signatures that are enabled when it processes traffic.</td>
</tr>
<tr>
<td>Block</td>
<td>Connections that match this signature are blocked.</td>
</tr>
<tr>
<td>Log</td>
<td>A log entry is produced for any connection that matches this signature.</td>
</tr>
<tr>
<td>Stats</td>
<td>The Web App Firewall includes any connection that matches this signature in the statistics that it generates for that check.</td>
</tr>
</tbody>
</table>
• To display only signatures that contain a specific string, type the string into the text box under the filter criteria, and then click Search.
• To reset all display filter criteria to the default settings and display all signatures, click Show All.

4. For information about a specific signature, select the signature, and then click the blue double arrow in the More field. The Signature Rule Vulnerability Detail message box appears. It contains information about the purpose of the signature and provides links to external web-based information about the vulnerability or vulnerabilities that this signature addresses. To access an external link, click the blue double arrow to the left of the description of that link.

5. Configure the settings for a signature by selecting the appropriate check boxes.

6. If you want to add a local signature rule to the signatures object, or modify an existing local signature rule, see The Signatures Editor.

7. If you have no need for SQL injection, cross-site scripting, or Xpath injection patterns, click OK, and then click Close. Otherwise, in the lower left-hand corner of the details pane, click Manage SQL/XSS Patterns.

8. In the Manage SQL/XSS Patterns dialog box, Filtered Results window, navigate to the pattern category and pattern that you want to configure. For information about the SQL injection patterns, see HTML SQL Injection Check. For information about the cross-site scripting patterns, see HTML Cross-Site Scripting Check.

9. To add a new pattern:
   a) Select the branch to which you want to add the new pattern.
   b) Click the Add button directly below the lower section of the Filtered Results window.
   c) In the Create Signature Item dialog box, fill in the Element text box with the pattern that you want to add. If you are adding a transformation pattern to the transform rules branch, under Elements, fill in the From text box with the pattern that you want to change and the To text box with the pattern to which you want to change the previous pattern.
   d) Click OK.

10. To modify an existing pattern:
    a) In the Filtered Results window, select the branch that contains the pattern that you want to modify.
    b) In the detail window beneath the Filtered Results window, select the pattern that you want to modify.
    c) Click Modify.
    d) In the Modify Signature Item dialog box, Element text box, modify the pattern. If you are modifying a transformation pattern, you can modify either or both patterns under Elements, in the From and the To text boxes.
e) Click OK.  

11. To remove a pattern, select the pattern that you want to remove, then click the **Remove** button below the details pane beneath the **Filtered Results** window. When prompted, confirm your choice by clicking **Close**.

12. To add the patterns category to the XSS branch:
   a) Select the branch to which you want to add the patterns category.
   b) Click the **Add** button directly below the **Filtered Results** window.

   **Note:** Currently you can add only one category, named patterns, to the XSS branch, so after you click **Add**, you must accept the default choice, which is patterns.

   c) Click **OK**.

13. To remove a branch, select that branch, and then click the Remove button directly below the **Filtered Results** window. When prompted, confirm your choice by clicking **OK**.

   **Note:** If you remove a default branch, you remove all of the patterns in that branch. Doing so can disable the security checks that use that information.

14. When you are finished modifying the SQL injection, cross-site scripting, and XPath injection patterns, click **OK**, and then click **Close** to return to the **Modify Signatures Object** dialog box.

15. Click **OK** at any point to save your changes, and when you are finished configuring the signatures object, click **Close**.

---

**Protecting JSON applications using signatures**

February 12, 2020

JavaScript Object Notation (JSON) is a text-based open standard derived from the JavaScript scripting language. JSON is preferred for human readable representation of simple data structures and associative arrays, called objects. It serves as an alternative to XML and is primarily used to transmit serialized data structures for communicating with web applications. The JSON files are typically saved with a .json extension.

The JSON payload is typically sent with the MIME type specified as **application/json**. The other “standard” content types for JSON are:

- **application/x-javascript**
Using the Citrix Web App Firewall signatures to protect JSON applications

To allow JSON requests, the appliance is preconfigured with the JSON content type as shown in the following show-command output:

```
$ sh appfw jsonContentType
1) JSONContentType value: "^application/json$" IsRegex: REGEX
Done
```

The Citrix Web App Firewall processes the post body for the following content-types only:

- application/x-www-form-urlencoded
- multipart/form-data
- text/x-gwt-rpc

The requests that are received with other content-type headers including application/json (or any other allowed content type) are forwarded to the backend after header inspection. The post body in such requests is not inspected for security check violations even when the profile’s security checks such as SQL or XSS are enabled.

In order to protect JSON applications and detect violations, Web App Firewall signatures can be used. All requests that contain the allowed content-type header are processed by the Web App Firewall for signature match. You can add your own customized signature rules to process JSON payload to perform various security check inspections (for example, XSS, SQL, and Field Consistency), to detect violations in the headers as well as the post body, and take specified actions.

**Tip**

Unlike the other built-in defaults, the preconfigured JSON content type can be edited or removed by using the CLI or the GUI (GUI). If legitimate requests for JSON applications are getting blocked and triggering content-type violations, check to make sure that the content type value is configured accurately. For additional details regarding how Web App Firewall processes content-type header, see [Content type protection](#).

To add or remove JSON content-type by using the command line interface

At the command prompt, type one of the following commands:

```
add appfw jsonContentType ^application/json$ IsRegEx REGEX
rm appfw JSONContentType "^application/json$"
```
To managing JSON content types by using the GUI

Navigate to Security > Web App Firewall and, in the Settings section, select Manage JSON Content Types.

In the Configure Web App Firewall JSON Content Type panel, add, edit, or delete JSON content types to suit the needs of your applications.

Configuring signature protection to detect attacks in JSON payload

In addition to a valid JSON content type, you need to configure signatures to specify the pattern(s) that, when detected in a JSON request, indicate a security breach. The specified actions, such as block and log, are taken when an incoming request triggers a match for all the target patterns in the signature rule.

To add a customized signature rule, Citrix recommends that you use the GUI. Navigate to System > Security > Web App Firewall > Signatures. Double click the target signature object to access the Edit Web App Firewall Signatures panel. Click on the Add button to configure the actions, category, log string, rule patterns and so on. Although Web App Firewall inspects all allowed content-type payload for signature match, you can optimize the processing by specifying the JSON expression in the rule. When you Add a new rule pattern, select Expression in the drop-down options for Match and provide the target match expression from your JSON payload to identify the specific requests that need to be inspected. An expression must begin with a TEXT. prefix. You can add other rule patterns to specify additional match patterns to identify the attack.

The following example shows a signature rule. If any cross-site script tag is detected in the POST body of the JSON payload that matches the specified XPATH_JSON expression, a signature match is triggered.

Example of a signature to detect XSS in JSON payload

```xml
<SignatureRule actions="log,stats" category="JSON" enabled="ON" id="1000001" severity="" source="" type="" version="1">
  <PatternList>
    <RequestPatterns>
      <Pattern>
        <Location area="HTTP_POST_BODY"/>
      </Pattern>
    </RequestPatterns>
  </PatternList>
</SignatureRule>
```
Example of the payload

The following payload triggers the signature match, because it includes the cross-site scripting tag <Gotcha!!>.

```json
{
  "glossary": {
    "title": "example glossary", "GlossDiv": {
      "title": "S", "GlossList": {
        "GlossEntry": {
          "ID": "SGML", "SortAs": "SGML", "GlossTerm": "Standard Generalized Markup Language", "GlossDefinition": "A standard for electronic publication, based on SGML but simplified for common use.", "GlossSeeAlso": []
        }
    }
  }
}
```
Example of the log message

Note

If you send the same payload after removing the cross-site script tag (<Gotcha!!>), the signature rule match is not triggered.

Highlights

- To protect JSON payload, use Web App Firewall signatures to detect XSS, SQL and other violations.
- Verify that the JSON content type is configured on the appliance as the allowed content type.
- Make sure that the content type in the payload matches the configured JSON content type.
- Make sure that all the patterns configured in the signature rule match for the signature violation to be triggered.
- When you add a signature rule, it MUST have at least one Rule pattern to match the Expression in the JSON payload. All the PI expressions in signature rules must start with the prefix TEXT and must be Boolean.

Protect application or JSON content-type with SQL and XSS encoded payload using policies and signatures

Citrix Web App Firewall can protect application or JSON content type using policies and signatures.
Inspect application or JSON content type for SQL injection using policies

You must add the following policies and bind it to virtual server globally for supporting SQL injection.

```
add appfw policy sqli_1 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE).
SET_TEXT_MODE(URL ENCODED).DECODE USING TEXT MODE.REGEX MATCH(re##((\A
|(?<=[^a-zA-Z0-9_]))(select|insert|delete|update|drop|create|alter|grant
|revoke|commit|rollback|shutdown|union|intersect|minus|case|decode|where
|group|begin|join|exists|distinct|add|modify|constraint|null|like|exec|
execute|char|or|and|sp_ssid_debug)(( Z)|(?=[^a-zA-Z0-9_]))##)APPFW_BLOCK
```

```
add appfw policy sqli_2 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE).
SET_TEXT_MODE(URL ENCODED).DECODE USING TEXT_MODE.REGEX MATCH(re##((\A
|(?<=[^a-zA-Z0-9_]))(xp_availablemedia|xp_cmdshell|xp_deletemail|xp_dirtree
|xp_dropwebtask|xp_dsninfo|xp_enumdsn|xp_errnologs|xp_enumgroups|
xp_enumqueuedtasks|xp_eventlog|xp_finnextmsg|xp_fixeddrives|xp_getfiledetails
|xp_getnetname|xp_grantlogin|xp_logevent|xp_loginconfig|xp_logininfo|
xp_makewebtask|xp_msver|xp_regread|xp_perfend|xp_perfmomitor|xp_perfsample
|xp_perfstart|xp_readerrorlog|xp_readmail|xp_revokelogin|xp_runwebtask|
xp_schedulersignal|xp_sendmail|xp_servicecontrol|xp_snmp_getstate|xp_snmp_raisetrap
|xp_sprintf|xp_sqlinventory|xp_sqlregister|xp_sqltrace|xp_sscanf|xp_startmail
|xp_stopmail|xp_subdirs|xp_unc_to_drive)(( Z)|(?=[^a-zA-Z0-9_]))##)APPFW_BLOCK
```

```
add appfw policy sqli_3 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE).
SET_TEXT_MODE(URL ENCODED).DECODE USING TEXT_MODE.REGEX MATCH(re##((\A
|(?<=[^a-zA-Z0-9_]))(sysobjects|syscolumns|MSysACEs|MSysObjects|MSysQueries
|MSysRelationships)(( Z)|(?=[^a-zA-Z0-9_]))##)APPFW_BLOCK
```

```
add appfw policy sqli_4 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE).
SET_TEXT_MODE(URL ENCODED).DECODE USING TEXT_MODE.REGEX MATCH(re##((\A
|(?<=[^a-zA-Z0-9_]))(SYS\.USER\_OBJECTS\SYS\.TAB\SYS\.USER\_TABLES\SYS\.\nUSER\_VIEWS\SYS\.ALL\_TABLES\SYS\.USER\_TAB\_COLUMNS\SYS\.USER\_CONSTRAINTS\SYS
\.USER\_TRIGGERS\SYS\.USER\_CATALOG\SYS\.ALL\_CATALOG\SYS\.ALL\_CONSTRAINTS\SYS
\.ALL\_OBJECTS\SYS\.ALL\_TAB\_COLUMNS\SYS\.ALL\_TAB\_PRIVS\SYS\.ALL\_TRIGGERS\SYS
\.ALL\_USERS\SYS\.ALL\_VIEWS\SYS\.USER\_ROLE\_PRIVS\SYS\.USER\_SYS\_PRIVS\SYS\.USER
\_TAB\_PRIVS)(( Z)|(?=[^a-zA-Z0-9_]))##)APPFW_BLOCK
```

Inspect application or JSON content type using signatures

You can add the following signature rules to the signature object in the application firewall profile to support SQL injection for JSON content-type.
Note:

Post body signatures are cpu-intensive.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!-- Copyright 2013-2018 Citrix Systems, Inc. All rights reserved. -->
<SignaturesFile schema_version="6" version="0" minor_schema_version="0">
  <Signatures>
    <SignatureRule id="4000000" enabled="ON" actions="log,block"
      category="sql" source="" severity="" type="" version="1"
      sourceid="" harmscore="">
      <RequestPatterns>
        <Pattern>
          <Location area="HTTP_POST_BODY"/>
          <Match type="Expression">TEXT.SET_TEXT_MODE(IGNORECASE).SET_TEXT_MODE(URLENCODED).
            DECODE_USING_TEXT_MODE.REGEX_MATCH(re#(((?=[^a-zA-Z0-9_]))(select|insert|delete|update|drop|create|alter|grant|revoke|commit|rollback|shutdown|union|intersect|minus|case|decode|where|group|begin|join|exists|distinct|add|modify|constraint|null|like|exec|execute|char|or|and|sp_sdidebug)((Z)|(?![^a-zA-Z0-9_]))#)</Match>
        </Pattern>
      </RequestPatterns>
    </SignatureRule>
    <SignatureRule id="4000001" enabled="ON" actions="log,block"
      category="sql" source="" severity="" type="" version="1"

Updating a signature object

June 12, 2020

You should update your signatures objects frequently to ensure that your Web App Firewall is providing protection against current threats. You should regularly update both the default Web App Firewall signatures and any signatures that you import from a supported vulnerability scanning tool.

Citrix regularly updates the default signatures for the Web App Firewall. You can update the default signatures manually or automatically. In either case, ask your Citrix representative or Citrix reseller for the URL to access the updates. You can enable automatic updates of the Citrix native format signatures in the “Engine Settings” and “Signature Auto Update Settings” dialog boxes.

Most makers of vulnerability scanning tools regularly update the tools. Most websites also change frequently. You should update your tool and rescan your websites regularly, exporting the resulting signatures to a file and importing them into your Web App Firewall configuration.

Tip

When you update the Web App Firewall signatures from the Citrix ADC command line, you must first update the default signatures, and then issue more update commands to update each custom signatures file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents updating of the custom signatures files.

Note

The following applies to merging a third-party signature object with a user-defined signature object with Native rules and user-added rules:

When a version 0 signatures is merged with a new imported file, the resultant signatures remain as version 0.

This means all native (or built-in) rules in the imported file will be ignored after the merge. This is to ensure that the version 0 signatures are maintained as is after a merge.

To include the native rules in the imported file for merge, you must update the existing signatures from version 0 first before the merge. This means you need to abandon the version 0 nature of the existing signatures.

When there is a Citrix ADC release upgrade, the file “default_signatures.xml” is added to the new build and the file “updated_signature.xml” is removed from the older build. After the upgrade, if the signature auto update feature is enabled, the appliance updates the existing signature to
the latest version of the build and generates the “updated_signature.xml” file.

**To update the Web App Firewall signatures from the source by using the command line**

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergedefault]`
- `save ns config`

**Example**

The following example updates the signatures object named MySignatures from the default signatures object, merging new signatures in the default signatures object with the existing signatures. This command does not overwrite any user-created signatures or signatures imported from another source, such as an approved vulnerability scanning tool.

```
1 update appfw signatures MySignatures -mergedefault
2 save ns config
```

**Updating a signatures object from a Citrix format file**

Citrix regularly updates the signatures for the Web App Firewall. You should regularly update the signatures on your Web App Firewall to ensure that your Web App Firewall is using the most current list. Ask your Citrix representative or Citrix reseller for the URL to access the updates.

**To update a signatures object from a Citrix format file by using the command line**

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergeDefault]`
- `save ns config`

**To update a signatures object from a Citrix format file by using the GUI**

1. Navigate to **Security > Web App Firewall > Signatures**.
2. In the details pane, select the signatures object that you want to update.
3. In the **Action** drop-down list, select **Merge**.
4. In the **Update Signatures Object** dialog box, choose one of the following options.
   - **Import from URL**—Choose this option if you download signature updates from a web URL.
- Import from Local File—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.

5. In the text area, type the URL, or type or browse to the local file.

6. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box. The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.

7. Review and configure the new and modified signatures.

8. When you are finished, click OK, and then click Close.

Updating a signatures object from a supported vulnerability scanning tool

Note:
Before you update a signatures object from a file, you must create the file by exporting signatures from the vulnerability scanning tool.

To import and update signatures from a vulnerability scanning tool

2. In the details pane, select the signatures object that you want to update, and then click Merge.

3. In the Update Signatures Object dialog box, on the External Format tab, Import section, choose one of the following options:
   - Import from URL—Choose this option if you download signature updates from a Web URL.
   - Import from Local File—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.

4. In the text area, type the URL, or browse or type the path to the local file.

5. In the XSLT section, choose one of the following options:
   - Use Built-in XSLT File—Choose this option if you want to use a built-in XSLT file.
   - Use Local XSLT File—Choose this option to use an XSLT file on your local computer.
   - Reference XSLT from URL—Choose this option to import an XSLT file from a web URL.

6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list select the file that you want to use from the following options:
   - Cenzic.
   - Deep_Security_for_Web_Apps.
   - Hewlett_Packard_Enterprise_WebInspect.
   - IBM-AppScan-Enterprise.
   - IBM-AppScan-Standard.
   - Qualys.
   - Whitehat.
7. Click **Update**. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in Configuring or Modifying a Signatures Object. The **Update Signatures Object** dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.

8. Review and configure the new and modified signatures.

9. When you are finished, click **OK**, and then click **Close**.

**Snort rule integration**

April 2, 2020

With malicious attacks on web applications, it is important to protect your internal network. Malicious data not only affect your web applications at the interface level but malicious packets also reach the application layer. To overcome such attacks, it is important to configure an intrusion detection and prevention system that examines your internal network.

Snort rules are integrated into the appliance for examine malicious attacks in data packets at the application layer. You can download the snort rules and convert it into WAF signatures rules. The signatures have rule-based configuration that can detect malicious activities such as DOS attacks, buffer overflows, stealth port scans, CGI attacks, SMB probes, and OS fingerprinting attempts. By integrating Snort rules, you can strengthen your security solution at the interface and at the application level.

**Configure snort rules**

The configuration begins by first downloading the Snort rules and then importing it into WAF signature rules. Once you have converted the rules into WAF signatures, the rules can be used as WAF security checks. The snort based signature rules examine the incoming data packet to detect if there are malicious attacks on your network.

A new parameter, “VendorType” is added to the import command to convert Snort rules to WAF signatures.

The parameter “VendorType” is set on SNORT only for Snort rules.

**Download snort rules by using the command interface**

You can download the Snort rules as a text file from the below URL:
Import snort rules by using the command interface

After you download, you can import the Snort rules into your appliance.

At the command prompt, type:

```
import appfw signatures <src> <name> [-xslt <string>] [-comment <string>]
[-overwrite] [-merge [-preservedefactions]] [-sha1 <string>] [-VendorType Snort]
```

Example:

```
import appfw signatures http://www.example.com/ns/signatures.xml sig-snort -comment “signatures from snort rules” -VendorType snort
```

Arguments:

Src. URL (protocol, host, path, and file name) for the location at which to store the imported signatures object.

Note:
The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access. Mandatory argument of maximum length: 2047

Name. Name to assign to the signatures object on the Citrix ADC. Mandatory argument of maximum length: 31

Comment. Description of how to preserve information about the signatures object. Maximum Length: 255

overwrite. Overwrite any existing signatures object of the same name.

Merge. Merges existing Signature with new signature rules.

Preservedefactions. Preserves def actions of signature rules.

VendorType. Third-party vendor to generate the WAF signatures. Possible values: Snort.

Configure snort rules by using the Citrix ADC GUI

The GUI configuration for Snort rules is similar to configuring other external web application scanners like Cenzic, Qualys, Whitehat.

Follow the steps below to configure Snort:

2. In the **Signatures** page, click **Add**.

3. In the **Add Signatures** page, set the following parameters to configure Snort rules.
   a) File format. Select the file format as external.
   b) Import from. Select the import option as a snort file or URL to enter the URL.
   c) Snort V3 Vendor. Select the check box to import Snort rules from a file or from a URL.

4. Click **Open**.

   ![Add Signatures form]

The appliance imports the Snort rules as snort-based WAF signature rules.
As a best practice, you must use filter actions to enable snort rules that you prefer to import as WAF signature rules on the appliance.

5. To confirm, click Yes.

6. The selected rules are enabled on the appliance.
7. Click OK.

Copied!
Failed!

Exporting a signatures object to a file

April 23, 2019

You export a signatures object to a file so that you can import it to another Citrix ADC.

To export a signatures object to a file

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure.
3. In the Actions drop-down list, select Export.
4. In the Export Signatures Object dialog box, Local File text box, type the path and name of the file to which you want to export the signatures object, or use the Browse dialog to designate a path and name.
5. Click OK.
The Signatures editor

February 12, 2020

You can use the signatures editor, which is available in the GUI, to add a new user-defined (local) signature rule to an existing signatures object, or to modify a previously configured local signature rule. Except that it is defined by the user (you), a local signature rule has the same attributes as a default signature rule from Citrix, and it functions in the same way. You enable or disable it, and configure the signature actions for it, just as you do for a default signature.

Add a local rule if you need to protect your web sites and services from a known attack that the existing signatures do not match. For example, you might discover a new type of attack and determine its characteristics by examining the logs on your web server, or you might obtain third-party information about a new type of attack.

At the heart of a signature rule are the rule patterns, which collectively describe the characteristics of the attack that the rule is designed to match. Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting patterns.

You might want to modify a signature rule by adding a new pattern or modifying an existing pattern to match an attack. For example, you might find out about changes to an attack, or you might determine a better pattern by examining the logs on your web server, or from third-party information.

To add or modify a local signature rule by using the Signatures Editor

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to edit, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, do one of the following:
   - To add a new local signature rule, click Add.
   - To modify an existing local signature rule, select that rule, and then click Open.
4. In the Add Local Signature Rule or the Modify Local Signature Rule dialog box, configure the actions for a signature by selecting the appropriate check boxes.
   - **Enabled.** Enables the new signature rule. If you do not select this, this new signature rule is added to your configuration, but is inactive.
   - **Block.** Blocks connections that violate this signature rule.
   - **Log.** Logs violations of this signature rule to the Citrix ADC log.
   - **Stat.** Includes violations of this signature rule in the statistics.
• **Remove.** Strips information that matches the signature rule from the response. (Applies only to response rules.)

• **X-Out.** Masks information that matches the signature rule with the letter X. (Applies only to response rules.)

• **Allow Duplicates.** Allows duplicates of this signature rule in this signatures object.

5. Choose a category for the new signature rule from the **Category** drop-down list.

You can also create a new category by clicking the icon to the right of the list and using the Add Signature Rule Category dialog box to add a new category to the list, The rule you are modifying is automatically added to the new category. For instructions, see To add a signature rule category.

6. In the **LogString** text box, type a brief description of the signature rule to be used in the logs.

7. In the **Comment** text box, type a comment. (Optional)

8. Click More…, and modify the advanced options.

   a) To strip HTML comments before applying this signature rule, in the Strip Comments dropdown list choose All or Exclude Script Tag.

   b) To set CSRF Referer Header checking, in the CSRF Referer Header checking radio button array, select either the If Present or Always radio button.

   c) To manually modify the Rule ID assigned to this local signature rule, modify the number in the Rule ID text box. The ID must be a positive integer between 1000000 and 1999999 that has not already been assigned to a local signature rule.

   d) To assign a version number to the new signature rule, modify the number in the Version Number text box.

   e) To assign a Source ID, modify the string in the Source ID text box.

   f) To specify the source, choose Local or Snort from the Source drop-down list, or click the Add icon to the right of the list and add a new source.

   g) To assign a harm score to violations of this local signature rule, type a number between 1 and 10 in the Harm Score text box.

   h) To assign a severity rating to this local signature rule, in the Severity drop-down list choose High, Medium, or Low, or click the Add icon to the right of the list and add a new severity rating.

   i) To assign a violation type to this local signature rule, in the Type drop-down list choose Vulnerable or Warning, or click the Add icon to the right of the list and add a new violation type.

9. In the **Patterns** list, add or edit a pattern.

   a) To add a pattern, click **Add**. In the Create New Signature Rule Pattern dialog box, add one or more patterns for your signature rule, and then click **OK**.
• To edit a pattern, select the pattern, and then click Open. In the Edit Signature Rule Pattern dialog box, modify the pattern, and then click OK.

For more information about adding or editing patterns, see Signature Rule Patterns.

10. Click OK.

To add a signature rule category

April 23, 2019

Putting signature rules into a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

• **Ease of selection.** For example, assume that all of signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected web sites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.

• **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to individual signatures as needed.

• **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

2. In the details pane, select that signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen, beneath the Filtered Results window, click Add.
4. In the Add Local Signature Rule dialog box, click the icon to the right of the Category dropdown list.
5. In the Add Signature Rule Category dialog box, New Category text box, type a name for your new signature category. The name can consist of from one to 64 characters.
6. Click OK.
Signature rule patterns

July 29, 2020

You can add a pattern or modify an existing pattern to specify a string or expression that characterize an attack if the signature matches. To detect the patterns an attack exhibits, you can examine the logs on your web server. You can use a tool to observe connection data in real time, or obtain the string or expression from a third-party report about the attack.

Caution:

Any new pattern that you add to a signature rule is in an AND relationship with the existing patterns. Do not add a pattern to an existing signature rule if you do not want a potential attack to have to match all patterns to match the signature.

Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting pattern. Before you attempt to add a pattern that is based on a regular expression, you should make sure that you understand PCRE-format regular expressions. PCRE expressions are complex and powerful. If you do not understand how they work, you can unintentionally create a pattern that matches something that you did not want (a false positive) or that fails to match something that you did want (a false negative).

Custom signature pattern for non-default content types

The Citrix ADC Web App Firewall (WAF) now supports new location to inspect canonicalized content. By default, WAF does not block encoded payload with non-default content types. When these content types are whitelisted, and no configured action is applied, the SQL and cross-site scripting protection check do not filter SQL or cross-site scripting attacks in the encoded payloads. To resolve the issue, a user can create custom signature rule with this new location (HTTP_CANON_POST_BODY) that examines the encoded payloads for non-default content-types and if there is any SQL or cross-site scripting attack, it blocks the traffic after canonicalization of the post body.

Note:

That support is applicable only for HTTP requests.

If you are not already familiar with PCRE-format regular expressions, you can use the following resources to learn the basics, or for help with some specific issue:

- “Regular Expressions Cookbook”. Copyright (c) 2009 by Jan Goyvaerts and Steven Levithan. O’Reilly Media, ISBN: 9780596520687
If you need to encode non-ASCII characters in a PCRE-format regular expression, the Citrix ADC platform supports encoding of hexadecimal UTF-8 codes. For more information, see PCRE Character Encoding Format.

To configure a signature rule pattern

1. Navigate to Security > Application Firewall > Signatures.

2. In the details pane, select that signatures object that you want to configure, and then click Open.

3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, either click Add to create a signature rule, or select an existing signature rule and click Open.

   Note:
   You can modify only signature rules that you added. You cannot modify the default signature rules.

   Depending on your action, either the Add Local Signature Rule or the Modify Local Signature Rule dialog box appears. Both dialog boxes have the same contents.

4. Under the Patterns window in the dialog box, either click Add to add a new pattern, or select an existing pattern from the list beneath the Add button and click Open. Depending on your action, either the Create New Signature Rule Pattern or the Edit Signature Rule Pattern dialog box appears. Both dialog boxes have the same contents.

5. In the Pattern Type drop-down list, choose the type of connection that the pattern is intended to match.
   - If the pattern is intended to match request elements or features, such as injected SQL code, attacks on web forms, cross-site scripts, or inappropriate URLs, choose Request.
   - If the pattern is intended to match response elements or features, such as credit card numbers or safe objects, choose Response.

6. In the Location area, define the elements to examine with this pattern.
   The Location area describes what elements of the HTTP request or response to examine for this pattern. The choices that appear in the Location area depend upon the chosen pattern type. If you chose Request as the pattern type, items relevant to HTTP requests appear. If you chose
Response, items relevant to HTTP responses appear. In addition, as you choose a value from the Area drop-down list, the remaining parts of the Location area change interactively. Following are all configuration items that might appear in this section.

- **Area.** Drop-down list of elements that describe a particular portion of the HTTP connection. The choices are as follows:
  - **HTTP_ANY.** All parts of the HTTP connection.
  - **HTTP_COOKIE.** All cookies in the HTTP request headers after any cookie transformations are performed.
    Note: Does not search HTTP response “Set-Cookie:” headers.
  - **HTTP_FORM_FIELD.** Form fields and their contents, after URL decoding, percent decoding, and removal of excess whitespace. You can use the `<Location>` tag to further restrict the list of form field names to be searched.
  - **HTTP_HEADER.** The value portions of the HTTP header after any cross-site scripting or URL decoding transformations.
  - **HTTP_METHOD.** The HTTP request method.
  - **HTTP_ORIGIN_URL.** The origin URL of a web form.
  - **HTTP_POST_BODY.** The HTTP post body and the web form data that it contains.
  - **HTTP_RAW_COOKIE.** All HTTP request cookie, including the “Cookie:” name portion.
    Note: Does not search HTTP response “Set-Cookie:” headers.
  - **HTTP_RAW_HEADER.** The entire HTTP header, with individual headers separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).
  - **HTTP_RAW_RESP_HEADER.** The entire response header, including the name and value parts of the response header after URL transformation has been done, and the complete response status. As with HTTP_RAW_HEADER, individual headers are separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).
  - **HTTP_RAW_SET_COOKIE.** The entire Set-Cookie header after any URL transformations have been performed.
    Note: URL transformation can change both the domain and path parts of the Set-Cookie header.
  - **HTTP_RAW_URL.** The entire request URL before any URL transformations is performed, including any query or fragment parts.
  - **HTTP_RESP_HEADER.** The value part of the complete response headers after any URL transformations have been performed.
  - **HTTP_RESP_BODY.** The HTTP response body
  - **HTTP_SET_COOKIE.** All “Set-Cookie” headers in the HTTP response headers.
  - **HTTP_STATUS_CODE.** The HTTP status code.
  - **HTTP_STATUS_MESSAGE.** The HTTP status message.
  - **HTTP_URL.** The value portion of the URL in the HTTP headers, excluding any query or
fragment ports, after conversion to the UTF-* character set, URL decoding, stripping of whitespace, and conversion of relative URLs to absolute. Does not include HTML entity decoding.

- **URL.** Examines any URLs found in the elements specified by the Area setting. Select one of the following settings.
  - **Any.** Checks all URLs.
  - **Literal.** Checks URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.
  - **PCRE.** Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click Regex Editor to display the Regular Expression Editor dialog box, which provides more assistance in constructing the regular expression that you want.
  - **Expression.** Checks URLs that match a Citrix ADC default expression.

- **Field Name.** Examines any form field names found in the elements specified by the Area selection.
  - **Any.** Checks all URLs.
  - **Literal.** Checks URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.
  - **PCRE.** Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements or you can use the Regex Editor for assistance in constructing a regular expression that you want.
  - **Expression.** Checks URLs that match a Citrix ADC default expression.

7. In the Pattern area, define the pattern. A pattern is a literal string or PCRE-format regular expression that defines the pattern that you want to match. The Pattern area contains the following elements:
   - **Match.** A drop-down list of search methods that you can use for the signature. This list differs depending on whether the pattern type is Request or Response.

**Request Match Types**

- **PCRE.** A PCRE-format regular expression.

**Note:**

When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.

- **Injection.** Directs the Web App Firewall to look for injected SQL in the specified location. The Pattern window disappears, because the Web App Firewall already has the patterns for SQL injection.
- **CrossSiteScripting.** Directs the Web App Firewall to look for cross-site scripts in the specified location. The Pattern window disappears, because the Web App Firewall already has the patterns for cross-site scripts.

- **Expression.** An expression in the Citrix ADC default expressions language is the same expression language for creating Web App Firewall policies on the Citrix ADC appliance. Although the Citrix ADC expressions language was originally developed for policy rules, it is a highly flexible general purpose language that can also be used to define a signature pattern.

When you choose Expression, the Citrix ADC Expression Editor appears beneath Pattern window. For more information about the Expression Editor and instructions on how to use it, see [To add a firewall rule (expression) by using the Add Expression dialog box](#).  

### Response Match Types:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Literal. A literal string</td>
</tr>
<tr>
<td>2</td>
<td>PCRE. A PCRE-format regular expression.</td>
</tr>
</tbody>
</table>

**Note**

When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.

- **Credit Card.** A built-in pattern to match one of the six supported types of credit card number.

**Note:**  

The Expression match type is not available for Response-side signatures.

- **Pattern Window (unlabeled)**

In this window, type the pattern that you want to match, and fill in any additional data.

- **Literal.** Type the string you want to search for in the text area.
- **CRE.** Type the regular expression in the text area. Use the Regex Editor for more assistance in constructing the regular expression that you want, or the Regex Tokens to insert common regular expression elements at the cursor. To enable UTF-8 characters, click UTF-8.
- **Expression.** Type the Citrix ADC advanced expression in the text area. Use Prefix to choose the first term in your expression, or Operator to insert common operators at the cursor. Click Add to open the Add Expression dialog box for more assistance in constructing the regular expression that you want. Click Evaluate to open the Advanced Expression Evaluator to help determine what effect your expression has.
- **Offset.** The number of characters to skip over before starting to match on this pattern. You use this field to start examining a string at some point other than the first character.
• Depth. How many characters from the starting point to examine for matches. You use this field to limit searches of a large string to a specific number of characters.
• Min-Length. The string to be searched must be at least the specified number of bytes in length. Shorter strings are not matched.
• Max-Length. The string to be searched must be no longer than the specified number of bytes in length. Longer strings are not matched.
• Search method. A check box labeled fastmatch. You can enable fastmatch only for a literal pattern, to improve performance.

8. Click **OK**.

9. Repeat the previous four steps to add or modify more patterns.

10. When finished adding or modifying patterns, click **OK** to save your changes and return to the Signatures pane.

Caution:

Until you click **OK** in the **Add Local Signature Rule** or **Modify Local Signature Rule** dialog box, your changes are not saved. Do not close either of these dialog boxes without clicking **OK** unless you want to discard your changes.

---

**To Import and merge rules**

July 8, 2020

When using the signature editor to perform an import and merge operation from the GUI, you can now see the new, updated, duplicate, and invalid rules.

The signature editor displays the following four new rows:

1. New Rules
2. Updated Rules
3. Duplicate Rules
4. Invalid Rules

The output of the New Rules Only and Updated Rules Only filters also appears in the Category filter pane of the Edit window in signature editor.

You will need to import the files from GUI to see the corresponding links for New, duplicate, invalid and updated rules.

**Procedure to import signature rules:**
1. In the Citrix ADC web GUI, go to **Configuration** > **Security** > **Application Firewall** > **Signatures**. In the Signatures window, click **Add**. Then select **File Format** > **Native**, **Import From** > **URL** and in the **URL** field, add the above link. If you are unable to access the URL, you can download the **XML data** in a text file format.

2. After you click **Open**, the signature file will open and you can see links for new rule and invalid rules.

3. If you import a 3<sup>rd</sup> party signature rule, you can see 90 new rules and 9 duplicate rules in the imported .xml file. If you are unable to access the URL, you can download the **XML data** in a text file format.

**Signature updates in high availability deployment and build upgrades**

February 12, 2020

The signature update occurs on the primary node. While the signatures are updated on the primary node, in parallel the updated files are simultaneously synchronized with the secondary node.

The Default signature is always updated first and then the rest of the user-defined signatures are updated.

**Connecting to Amazon AWS**

The default route NSIP is used to connect to the Amazon AWS. If there is a specific use case scenario where SNIP is used, and if there are multiple SNIPs, the first one to receive the ARP response from the hosting site will hold the route.

**Signature updates during version upgrades**

In case of an upgrade, if the NS has an older base version for the signatures, *Default signature is automatically updated if a newer signature version is available.*

If the schema has changed, the schema version of all the signature objects gets updated when the version is upgraded.

However, for the base version of the user-defined signatures, the behavior is different in release 10.5 versus release 11.0.
In release 10.5, only the default signature was updated and the base version of the rest of the signatures remained unchanged after the build upgrade.

In release 11.0, this behavior has changed. When the appliance is upgraded to install a new build, not only the *Default signature object but all the other user-defined signatures that currently exist in the appliance are also updated and will have the same version after the build upgrade.

In both 10.5 and 11.0 release builds, if auto-update is configured, the *Default Signatures as well as all non-zero version signatures get auto-updated to the latest released signature version and will have the same base version.

**Overview of security checks**

February 12, 2020

The Web App Firewall advanced protections (security checks) are a set of filters designed to catch complex or unknown attacks on your protected web sites and web services. The security checks use heuristics, positive security, and other techniques to detect attacks that may not be detected by signatures alone. You configure the security checks by creating and configuring an Web App Firewall profile, which is a collection of user-defined settings that tell the Web App Firewall which security checks to use and how to handle a request or response that fails a security check. A profile is associated with a signatures object and with a policy to create a security configuration.

The Web App Firewall provides twenty security checks, which differ widely in the types of attacks that they target and how complex they are to configure. The security checks are organized into the following categories:

- **Common security checks.** Checks that apply to any aspect of web security that either does not involve content or is equally applicable to all types of content.
- **HTML security checks.** Checks that examine HTML requests and responses. These checks apply to HTML-based web sites and to the HTML portions of Web 2.0 sites, which contain mixed HTML and XML content.
- **XML security checks.** Checks that examine XML requests and responses. These checks apply to XML-based web services and to the XML portions of Web 2.0 sites.

The security checks protect against a wide range of types of attack, including attacks on operation system and web server software vulnerabilities, SQL database vulnerabilities, errors in the design and coding of web sites and web services, and failures to secure sites that host or can access sensitive information.
All security checks have a set of configuration options, the check actions, which control how the Web App Firewall handles a connection that matches a check. Three check actions are available for all security checks. They are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature, for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.

A fourth check action, **Learn**, is available for more than half of the check actions. It observes traffic to a protected Web site or web service and uses connections that repeatedly violate the security check to generate recommended exceptions (relaxations) to the check, or new rules for the check. In addition to the check actions, certain security checks have parameters that control the rules that the check uses to determine which connections violate that check, or that configure the Web App Firewall’s response to connections that violate the check. These parameters are different for each check, and they are described in the documentation for each check.

To configure security checks, you can use the Web App Firewall wizard, as described in The Web App Firewall Wizard, or you can configure the security checks manually, as described in Manual Configuration By Using the GUI. Some tasks, such as manually entering relaxations or rules or reviewing learned data, can be done only by using the GUI, not the command line. Using the wizard is usually best configuration method, but in some cases manual configuration might be easier if you are thoroughly familiar with it and simply want to adjust the configuration for a single security check.

Regardless of which method you use to configure the security checks, each security check requires that certain tasks be performed. Many checks require that you specify exceptions (relaxations) to prevent blocking of legitimate traffic before you enable blocking for that security check. You can do this manually, by observing the log entries after a certain amount of traffic has been filtered and then creating the necessary exceptions. However, it is usually much easier to enable the learning feature and let it observe the traffic and recommend the necessary exceptions.

Web App Firewall uses packet engines (PE) during processing the transactions. Each packet engine has a limit of 100K sessions which is sufficient for most deployment scenarios. However, when Web App Firewall is processing heavy traffic and the session timeout is configured at a higher value, the sessions might get accumulated. If the number of alive Web App Firewall sessions exceed the 100K per PE limit, the Web App Firewall security check violations might not be sent to the Security Insight appliance. Lowering the session timeout to a smaller value, or using sessionless mode for the security checks with sessionless URL closure or sessionless field consistency might help in preventing the sessions getting accumulated. If this is not a viable option in scenarios where transactions might require longer sessions, upgrading to a higher-end platform with more packet engine is recommended.

Support for cached AppFirewall is added, and the max session setting through the CLI per core is set to 50K sessions.
Four of the Web App Firewall protections are especially effective against common types of Web attacks, and are therefore more commonly used than any of the others. They are:

- **HTML Cross-Site Scripting.** Examines requests and responses for scripts that attempt to access or modify content on a different Web site than the one on which the script is located. When this check finds such a script, it either renders the script harmless before forwarding the request or response to its destination, or it blocks the connection.

- **HTML SQL Injection.** Examines requests that contain form field data for attempts to inject SQL commands into an SQL database. When this check detects injected SQL code, it either blocks the request or renders the injected SQL code harmless before forwarding the request to the Web server.

  **Note:** If both of the following conditions apply to your configuration, you should make certain that your Web App Firewall is correctly configured:

  - If you enable the HTML Cross-Site Scripting check or the HTML SQL Injection check (or both), and
  - Your protected Web sites accept file uploads or contain Web forms that can contain large POST body data.

  For more information about configuring the Web App Firewall to handle this case, see *Configuring the Application Firewall*.

- **Buffer Overflow.** Examines requests to detect attempts to cause a buffer overflow on the Web server.

- **Cookie Consistency.** Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is striped from the request before the request is forwarded to the Web server.

The Buffer Overflow check is simple; you can usually enable blocking for it immediately. The other three top-level checks are considerably more complex and require configuration before you can safely use them to block traffic. Citrix strongly recommends that, rather than attempting to configure these checks manually, you enable the learning feature and allow it to generate the necessary exceptions.
The HTML Cross-Site Scripting (cross-site scripting) check examines both the headers and the POST bodies of user requests for possible cross-site scripting attacks. If it finds a cross-site script, it either modifies (transforms) the request to render the attack harmless, or blocks the request.

Note:
The HTML Cross-Site Scripting (cross-site scripting) check works only for content type, content length, and so forth. It does not work for the cookie. Also ensure to have the 'checkRequestHeaders' option enabled in your Web Application Firewall profile.

You can prevent misuse of the scripts on your protected websites by using the HTML Cross-Site Scripting scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the HTML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

The Web App Firewall offers various action options for implementing HTML Cross-Site Scripting protection. In addition to the Block, Log, Stats and Learn actions, you also have the option to Transform cross-site scripts to render an attack harmless by entity encoding the script tags in the submitted request. You can configure Check complete URLs for cross-site scripting parameter to specify if you want to inspect not just the query parameters but the entire URL to detect cross-site scripting attack. You can configure InspectQueryContentTypes parameter to inspect request query portion for the cross-site scripting attack for the specific content-types.

You can deploy relaxations to avoid false positives. The Web App Firewall learning engine can provide recommendations for configuring relaxation rules.

To configure an optimized HTML Cross-Site Scripting protection for your application, configure one of the actions:

- **Block**—If you enable block, the block action is triggered if the cross-site scripting tags are detected in the request.
- **Log**—If you enable the log feature, the HTML Cross-Site Scripting check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for
each header or form field in which the cross-site scripting violation was detected. However, only one message is generated when the request is blocked. Similarly, 1 log message per request is generated for the transform operation, even when cross-site scripting tags are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

• **Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you must configure new relaxation rules or modify the existing ones.

• **Learn**—If you are not sure which relaxation rules might be ideally suited for your application, you can use the learn feature to generate HTML Cross-Site Scripting rule recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

• **Transform cross-site scripts**—If enabled, the Web App Firewall makes the following changes to requests that match the HTML Cross-Site Scripting check:
  - Left angle bracket (<) to HTML character entity equivalent (&lt;)
  - Right angle bracket (>) to HTML character entity equivalent (&gt;)

This ensures that browsers do not interpret unsafe html tags, such as <script>, and thereby run malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified. If the scripts on your protected website contain cross-site scripting features, but your website does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.

• **Check complete URLs for cross-site scripting.** If checking of complete URLs is enabled, the Web App Firewall examines entire URLs for HTML cross-site scripting attacks instead of checking just the query portions of URLs.

• **Check Request headers.** If Request header checking is enabled, the Web App Firewall examines the headers of requests for HTML cross-site scripting attacks, instead of just URLs. If you use the GUI, you can enable this parameter in the Settings tab of the Web App Firewall profile.

• **InspectQueryContentTypes.** If Request query inspection is configured, the App Firewall examines the query of requests for cross-site scripting attacks for the specific content-types. If you use the GUI, you can configure this parameter in the Settings tab of the App Firewall profile.

**Important:**
As part of the streaming changes, the Web App Firewall processing of the cross-site scripting
tags has changed. This change is applicable to 11.0 builds onwards. This change is also pertinent for the enhancement builds of 10.5.e that support request side streaming. In earlier releases, presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>), was flagged as cross-site scripting violation. The behavior has changed in the builds that include support for request side streaming. Only the close bracket character (>) is no longer considered as an attack. Requests are blocked even when an open bracket character (<) is present, and is considered as an attack. The Cross-site scripting attack gets flagged.

**Cross-site scripting Fine grained Relaxations**

The Web App Firewall gives you an option to exempt a specific form field, header, or Cookie from cross-site scripting inspection check. You can completely bypass the inspection for one or more of these fields by configuring relaxation rules.

The Web App Firewall allows you to implement tighter security by fine-tuning the relaxation rules. An application might require the flexibility to allow specific patterns, but configuring a relaxation rule to bypass the security inspection might make the application vulnerable to attacks, because the target field is exempted from inspection for any cross-site scripting attack patterns. Cross-site scripting fine grained relaxation provides the option to allow specific attributes, tags, and patterns. The rest of the attributes, tags, and patterns are blocked. For example, the Web App Firewall currently has a default set of more than 125 denied patterns. Because hackers can use these patterns in Cross-site script attacks, the Web App Firewall flags them as potential threats. You can relax one or more patterns that are considered safe for the specific location. The rest of the potentially dangerous cross-site scripting patterns are still checked for the target location and continue to trigger the security check violations. You now have much tighter control.

The commands used in relaxations have optional parameters for **Value Type** and **Value Expression**. The value type can be left blank or you have an option to select **Tag** or **Attribute** or **Pattern**. If you leave the value type blank, the configured field of the specified URL is exempted from the Cross-Site Scripting check inspection. If you select a value type, you must provide a value expression. You can specify whether the value expression is a regular expression or a literal string. When the input is matched against the allowed and denied list, only the specified expressions configured in the relaxation rules are exempted.

The Web App Firewall has the following cross-site scripting built-in lists:

1. **XSS Allowed Attributes**: There are 52 defaults allowed attributes, such as, `abbr`, `accesskey`, `align`, `alt`, `axis`, `bgcolor`, `border`, `cell padding`, `cell spacing`, `char`, `charoff`, `charset` and so forth
2. **XSS Allowed Tags**: There are 47 defaults allowed tags, such as, `address`, `basefont`, `bgsound`, `big`, `blockquote`, `bg`, `br`, `caption`, `center`, `cite`, `dd`, `del` and so forth
3. **XSS Denied Patterns**: There are 129 defaults denied patterns, such as, `FSCommand`, `javascript`, `onAbort`, `onActivate` and so forth
Warning

Web App Firewall action URLs are regular expressions. When configuring HTML cross-site scripting relaxation rules, you can specify **Name**, and **Value Expression** to be literal or RegEx. Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the rule that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\.*) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML Cross-Site Scripting check would otherwise have blocked.

Points to Consider:

- Value expression is an optional argument. A field name might not have any value expression.
- A field name can be bound to multiple value expressions.
- Value expressions should be assigned a value type. The cross-site scripting value type can be:
  1) Tag, 2) Attribute, or 3) Pattern.
- You can have multiple relaxation rules per field name/URL combination
- The form field names and the action URLs are not case sensitive.

Using the Command Line to Configure the HTML Cross-Site Scripting check

To configure HTML Cross-Site Scripting check actions and other parameters by using the command line

If you use the command-line interface, you can enter the following commands to configure the HTML Cross-Site Scripting Check:

- `set appfw profile "Parameter descriptions provided at bottom of the page."`  
- `<name> -crossSiteScriptingAction (([block] [learn] [log] [stats])| [**none**])`  
  - `set appfw profile "Parameter descriptions provided at bottom of the page."`  
  - `<name> **-crossSiteScriptingTransformUnsafeHTML** (ON | OFF)`  
  - `set appfw profile Parameter descriptions provided at bottom of the page.`  
  - `<name> -crossSiteScriptingCheckCompleteURLs (ON | OFF)`  
  - `set appfw profile Parameter descriptions provided at bottom of the page.`  
  - `<name> -checkRequestHeaders (ON | OFF) Parameter descriptions provided at bottom of the page.”`  
  - `<name> -CheckRequestQueryNonHtml (ON | OFF) Parameter descriptions provided at bottom of the page.”`

To configure an HTML Cross-Site Scripting check relaxation rule by using the command line

Use the bind or unbind command to add or delete binding, as follows:
Using the GUI to configure the HTML cross-site scripting check

In the GUI, you can configure the HTML Cross-Site Scripting check in the pane for the profile associated with your application.

To configure or modify the HTML Cross-Site Scripting check by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you want to enable or disable Block, Log, Stats, and Learn actions for the HTML Cross-Site Scripting, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b. If you want to configure more options for this security check, double-click HTML Cross-Site Scripting, or select the row and click Action Settings, to display the following options:

- Transform cross-site scripts—Transform unsafe script tags.
- Check complete URLs for Cross-site scripting—Instead of checking just the query part of the URL, check the complete URL for cross-site script violations.

After changing any of the above settings, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section, and then click Save and Close to close the Security Check pane.

To enable or disable the Check request Header setting, in the Advanced Settings pane, click Profile Settings. In Common Settings, Select or clear the Check Request Headers check box. Click OK. You can either use the X icon at the top right hand side of the Profile Settings pane to close this section or, if you have finished configuring this profile, you can click Done to return to the Application Firewall > Profile.

To enable or disable the Check request Query Non HTML setting, in the Advanced Settings pane, click Profile Settings. In Common Settings, Select or clear the Check request Query Non HTML setting.
check box. Click OK. You can either use the X icon at the top right hand side of the Profile Settings pane to close this section or, if you have finished configuring this profile, you can click Done to return to the App Firewall > Profile.

To configure an HTML Cross-Site Scripting relaxation rule by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Relaxation Rules.
3. In the Relaxation Rules table, double-click the HTML Cross-Site Scripting entry, or select it and click Edit.
4. In the HTML Cross-Site Scripting Relaxation Rules dialogue box, perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

**Note**

When you add a new rule, the Value Expression field is not displayed unless you select Tag or Attribute or Pattern option in the Value Type Field.

To manage HTML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the HTML Cross-Site Scripting row in the Relaxation Rules table, and click Visualizer. The visualizer for deployed relaxations offers you the option to Add a new rule or Edit an existing one. You can also Enable or Disable a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of cross-site scripting allowed attributes or allowed tags. You can also view or customize the default list of cross-site scripting denied Patterns.

The default lists are specified in Application Firewall > Signatures > Default Signatures. If you do not bind any signature object to your profile, the default cross-site scripting allowed and denied list specified in the Default Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the allowed or denied lists in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized allowed and denied lists.

1. To view default cross-site scripting patterns:
   a. Navigate to Application Firewall > Signatures, select Default Signatures, and click Edit. Then click Manage SQL/XSS Patterns.

The Manage SQL/XSS Paths table shows following three rows pertaining to cross-site scripting:

- `xss/allowed/attribute`
- `xss/allowed/tag`
xss/denied/pattern

b. Select a row and click Manage Elements to display the corresponding cross-site scripting Elements (Tag, Attribute, Pattern) used by the Web App Firewall Cross-Site Scripting check.

1. **To customize XSS Elements**: You can edit the User-Defined signature object to customize the allowed Tag, allowed Attributes and denied Patterns. You can add new entries or remove the existing ones.

   a. Navigate to Application Firewall > Signatures, highlight the target User-defined signature, and click Edit. Click Manage SQL/XSS Patterns to display the Manage SQL/XSS paths table.

   b. Select the target cross-site scripting row.

   i. Click Manage Elements, to Add, Edit or Remove the corresponding cross-site scripting element.

   ii. Click Remove to remove the selected row.

**Warning:**
You must be careful before you remove or modify any default cross-site scripting element, or delete the cross-site scripting path to remove the entire row. The signature rules and the Cross-Site Scripting security check rely on these elements for detecting attacks to protect your applications. Customizing the cross-site scripting Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.

**Using the Learn Feature with the HTML Cross-Site Scripting Check**

When the “learn” action is enabled, the Citrix Web App Firewall learning engine monitors the traffic and learns the XSS URL violations. You can periodically inspect cross-site scripting URL rules and deploy it for false positive scenarios.

**Note:**
In a cluster configuration, all nodes must be of the same version to deploy the XSS URL rules.

**HTML Cross-Site Scripting Learning enhancement.** An Web App Firewall learning enhancement was introduced in release 11.0 of the Citrix ADC software. To deploy fine grained HTML Cross-Site Scripting relaxation, the Web App Firewall offers fine grained HTML Cross-Site Scripting learning. The learning engine makes recommendations regarding the observed Value Type (Tag, Attribute, Pattern) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in the relaxation rules.
Note:
The Web App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from HTML Cross-Site Scripting inspection.

Tip
Cross-site scripting tags which are longer than 12 characters are not learned or logged correctly.

If you need a larger tag length for learning, you can add a large non-appearing tag in the AS_XSS_ALLOWED_TAGS_LIST for length ‘x’.

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

- show appfw learningdata <profilename> crossSiteScripting
- rm appfw learningdata <profilename> -crossSiteScripting <string> <formActionURL> [location] [valueType] [valueExpression]
- export appfw learningdata <profilename> **crossSiteScripting**

To view or use learned data by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Learned Rules. You can select the HTML Cross-Site Scripting entry in the Learned Rules table and double-click it to access the learned rules. The table displays the Field Name, Action URL, Value Type, Value, and Hits columns. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the Skip button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the HTML Cross-Site Scripting entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.
Using the log feature with the HTML Cross-Site Scripting check

When the log action is enabled, the HTML Cross-Site Scripting security check violations are logged in the audit log as APPFW_XSS violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.log in the /var/log/ folder to access the log messages pertaining to the HTML Cross-Site Scripting violations:

```
Shell
tail -f /var/log/ns.log | grep APPFW_XSS
```

Example of a Cross-Site Scripting security check violation log message in CEF log format:

```
1 Jul 11 00:45:51 <local0.info> 10.217.31.98 CEF:0|Citrix|Citrix ADC|NS11.0|APPFW|**APPFW_XSS**|6|src=10.217.253.62 geolocation=Unknown spt=4840 method=GET request=http://aaron.stratum8.net/FFC/CreditCardMind.html?abc=%3Cdef%3E msg=**Cross-site script check failed for field abc="Bad tag: def"** cn1=133 cn2=294 cs1=pr_ffc cs2=PPE1 cs3=eUljpvl0BbabwfGE52Sewg9U0001 cs4=ALERT cs5=2015 act=**not blocked**
```

Example of a Cross-Site Scripting security check violation log message in Native log format showing transform action

```
1 Jul 11 01:00:28 <local0.info> 10.217.31.98 07/11/2015:01:00:28 GMT ns 0-PPE-0 : default APPFW **APPFW_XSS** 132 0 : 10.217.253.62 392-PPE0 eUljpvl0BbabwfGE52Sewg9U0001 pr_ffc http://aaron.stratum8.net/FFC/login.php?login_name=%3CB0B%3E&passwd=&drinking_pref=on & text_area=&loginButton=ClickToLogin&as_sfid=AAAAAAAVFgY68Igvkcn2pzehfIKm5E6E29FL8YLVlW_41AvAAuKYe9N7uGThSpEAxbboiBx55j-FC41LF **Cross-site script special characters seen in fields < transformed>**
```

Access the log messages by using the GUI

The Citrix GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the HTML Cross-Site Scripting row and click Logs. When you access the logs directly from the HTML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
• You can also access the Syslog Viewer by navigating to Citrix ADC > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

• Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the HTML Cross-Site Scripting check, filter by selecting APPFW in the drop-down list options for Module. The EventType list offers a rich set of options to further refine your selection. For example, if you select the APPFW_XSS check box and click the Apply button, only log messages pertaining to the HTML Cross-Site Scripting security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, EventType, Event ID, Client IP and so forth appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click to Deploy functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy HTML Cross-Site Scripting relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the Syslog Viewer box of the selected row. Select the check box, and then select an option from the Action list to deploy the relaxation rule. Edit & Deploy, Deploy, and Deploy All are available as Action options.

The HTML Cross-Site Scripting rules that are deployed by using the Click to Deploy option do not include the fine grain relaxation recommendations.

Configure click to deploy feature by using the GUI

1. In the Syslog Viewer, select APPFW in the Module options.
2. Select the APP_XSS as the Event Type to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the Action drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.
Statistics for the HTML Cross-Site Scripting violations

When the stats action is enabled, the counter for the HTML Cross-Site Scripting check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 HTML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display HTML Cross-Site Scripting check statistics by using the command line

At the command prompt, type:

> sh appfw stats

To display stats for a specific profile, use the following command:

> **stat appfw profile** <profile name>

Display HTML Cross-Site Scripting statistics by using the GUI

1. Navigate to Security > Application Firewall > Profiles > Statistics.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about HTML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Highlights

- **Built-in Support for HTML Cross-Site Scripting attack Protection**—The Citrix Web Web App Firewall protects against Cross-Site Scripting attacks by monitoring a combination of allowed attributes and tags, and denied patterns in the received payload. All the built-in default allowed tags, allowed attributes and denied patterns used by the cross-site scripting check are specified in the /netscaler/default_custom_settings.xml file.
- **Customization**—You can change the default list of tags, attributes, and patterns to customize the Cross-Site Scripting security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.
- **Hybrid Security Model**—Both signatures and deep security protections use the SQL/XSS patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/XSS patterns present in the default signature object are used.
• **Transform**—Note the following about the transform operation:

The transform operation works independently of the other Cross-Site Scripting action settings. If transform is enabled and block, log, stats, and learn are all disabled, cross-site scripting tags are transformed.

If the block action is enabled, it takes precedence over the transform action.

- **Fine Grained Relaxation and Learning.** Fine tune the relaxation rule to relax a subset of cross-site scripting elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.

- **Click to Deploy**—Select one, or multiple cross-site scripting violation log messages in the syslog viewer and deploy them as relaxation rules.

- **Charset**—The default charset for the profile should be set based on the need of the application. By default, the profile charset is set to English US (ISO-8859-1). If a request is received without the specified charset, the Web App Firewall processes the request as if it is ISO-8859-1. The open bracket character (<) or the close bracket character (>) will not get interpreted as cross-site scripting tags if these characters are encoded in other charsets. For example, if a request contains a UTF-8 character string “%uff1cscript%uff1e” but the charset is not specified on the request page, the cross-site scripting violation might not get triggered unless the default charset for the profile is specified as Unicode.

**HTML SQL injection check**

March 13, 2020

Many web applications have web forms that use SQL to communicate with relational database servers. Malicious code or a hacker can use an insecure web form to send SQL commands to the web server. The Web App Firewall HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. If the Web App Firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request. The Web App Firewall examines the request payload for injected SQL code in three locations: 1) POST body, 2) headers, and 3) cookies. In order to examine query portion in requests for injected SQL code, please configure appfw profile setting 'InspectQueryContentTypes' for the specific content-types.

A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch SQL attacks. You can add new patterns, and you can edit the default set to customize the SQL check inspection. The Web App Firewall offers various action options for
implementing SQL Injection protection. In addition to the Block, Log, Stats and Learn actions, the Web App Firewall profile also offers the option to transform SQL special characters to render an attack harmless.

In addition to actions, there are several parameters that can be configured for SQL injection processing. You can check for SQL wildcard characters. You can change the SQL Injection type and select one of the 4 options (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, SQLSplCharORKeyword) to indicate how to evaluate the SQL keywords and SQL special characters when processing the payload. The SQL Comments Handling parameter gives you an option to specify the type of comments that need to be inspected or exempted during SQL Injection detection.

You can deploy relaxations to avoid false positives. The Web App Firewall learning engine can provide recommendations for configuring relaxation rules.

Following options are available for configuring an optimized SQL Injection protection for your application:

**Block**—If you enable block, the block action is triggered only if the input matches the SQL injection type specification. For example, if SQLSplCharANDKeyword is configured as the SQL injection type, a request is not blocked if it contains no key words, even if SQL special characters are detected in the input. Such a request is blocked if the SQL injection type is set to either SQLSplChar, or SQLSplCharORKeyword.

**Log**—If you enable the log feature, the SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each input field in which the SQL violation was detected. However, only one message is generated when the request is blocked. Similarly, one log message per request is generated for the transform operation, even when SQL special characters are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

**Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

**Learn**—If you are not sure which SQL relaxation rules might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides SQL learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

**Transform SQL special characters**—The Web App Firewall considers three characters, Single straight quote (’), Backslash (\), and Semicolon (;) as special characters for SQL security check processing. The
SQL Transformation feature modifies the SQL Injection code in an HTML request to ensure that the request is rendered harmless. The modified HTML request is then sent to the server. All default transformation rules are specified in the /netscaler/default_custom_settings.xml file.

The transform operation renders the SQL code inactive by making the following changes to the request:

- Single straight quote (') to double straight quote (").
- Backslash (\) to double backslash (\\).
- Semicolon (;) is dropped completely.

These three characters (special strings) are necessary to issue commands to an SQL server. Unless an SQL command is prefaced with a special string, most SQL servers ignore that command. Therefore, the changes that the Web App Firewall performs when transformation is enabled prevent an attacker from injecting active SQL. After these changes are made, the request can safely be forwarded to your protected web site. When web forms on your protected web site can legitimately contain SQL special strings, but the web forms do not rely on the special strings to operate correctly, you can disable blocking and enable transformation to prevent blocking of legitimate web form data without reducing the protection that the Web App Firewall provides to your protected web sites.

The transform operation works independently of the SQL Injection Type setting. If transform is enabled and the SQL Injection type is specified as SQL keyword, SQL special characters are transformed even if the request does not contain any keywords.

Tip

You normally enable either transformation or blocking, but not both. If the block action is enabled, it takes precedence over the transform action. If you have blocking enabled, enabling transformation is redundant.

Check for SQL Wildcard Characters—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with **LIKE** and **NOT LIKE** operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```
SELECT * from customer WHERE name like "%D%":
```

The following example combines the operators to find any salary values that have 0 in the second and third place.

```
SELECT * from customer WHERE salary like '_00%':
```
Different DBMS vendors have extended the wildcard characters by adding extra operators. The Citrix Web Web App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (ˆ), opening square bracket ([), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the *Default Signatures:

- `<wildchar type="LITERAL">%</wildchar>
- `<wildchar type="LITERAL">_</wildchar>
- `<wildchar type="LITERAL">^</wildchar>
- `<wildchar type="LITERAL">[</wildchar>
- `<wildchar type="LITERAL">]</wildchar>

Wildcard characters in an attack can be PCRE, like [ˆA-F]. The Web App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

**Note**
The SQL wildcard character check is different from the SQL special character check. This option must be used with caution to avoid false positives.

**Check Request Containing SQL Injection Type**—The Web App Firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:

- **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the input to trigger SQL violation. This least restrictive setting is also the default setting.
- **SQL Special Character**—At least one of the special characters must be present in the input to trigger SQL violation.
- **SQL keyword**—At least one of the specified SQL keywords must be present in the input to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
- **SQL Special Character or Keyword**—Either the key word or the special character string must be present in the input to trigger the security check violation.

**Tip**
If you configure the Web App Firewall to check for inputs that contain an SQL special character, the Web App Firewall skips web form fields that do not contain any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the Web App Firewall and speed up processing without placing your protected web sites at risk.

**SQL comments handling**—By default, the Web App Firewall checks all SQL comments for injected
SQL commands. Many SQL servers ignore anything in a comment, however, even if preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the Web App Firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:

- **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases. For example:
  - – (Two Hypens) - This is a comment that begins with two hyphens and ends with end of line.
  - {} - Braces (Braces enclose the comment. The { precedes the comment, and the } follows it. Braces can delimit single- or multiple-line comments, but comments cannot be nested)
  - /* */: C style comments (Does not allow nested comments). Please note /*! <comment that begin with slash followed by asterisk and exclamation mark is not a comment */
  - MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form: /*! MySQL-specific code */
  - . # : Mysql comments : This is a comment that begins with # character and ends with end of the line

- **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server. For example; – (Two Hypens), and / * / (Allows nested comments)

- **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.

- **Check all Comments**—Check the entire request for injected SQL without skipping anything. This is the default setting.

**Tip**

In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.

**Check Request headers**—Enable this option if, in addition to examining the input in the form fields, you want to examine the request headers for HTML SQL Injection attacks. If you use the GUI, you can enable this parameter in the Advanced Settings -> Profile Settings pane of the Web App Firewall profile.

**Note**

If you enable the Check Request header flag, you might have to configure relaxation rule for the
User-Agent header. Presence of the SQL keyword like and SQL special character semi-colon (;) might trigger false positive and block requests that contain this header.

Warning

If you enable both request header checking and transformation, any SQL special characters found in headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (;). Enabling both Request header checking and transformation simultaneously might cause errors.

InspectQueryContentTypes — Configure this option if you want to examine the request query portion for SQL Injection attacks for the specific content-types. If you use the GUI, you can configure this parameter in the Advanced Settings -> Profile Settings pane of the App Firewall profile.

SQL Fine grained Relaxations

The Web App Firewall gives you an option to exempt a specific form field, header, or Cookie from SQL Injection inspection check. You can completely bypass the inspection for one or more of these fields by configuring relaxation rules for the SQL Injection check.

The Web App Firewall allows you to implement tighter security by fine tuning the relaxation rules. An application might require the flexibility to allow specific patterns, but configuring a relaxation rule to bypass the security inspection might make the application vulnerable to attacks, because the target field is exempted from inspection for any SQL attack patterns. SQL fine grained relaxation provides the option to allow specific patterns and block the rest. For example, the Web App Firewall currently has a default set of more than 100 SQL keywords. Because hackers can use these keywords in SQL Injection attacks, the Web App Firewall flags them as potential threats. You can relax one or more keyword(s) that are considered safe for the specific location. The rest of the potentially dangerous SQL keywords are still checked for the target location and continue to trigger the security check violations. You now have much tighter control.

The commands used in relaxations have optional parameters for Value Type and Value Expression. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank or you have an option to select Keyword or SpecialString or WildChar.

Warning

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.*) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML SQL Injection check would otherwise have blocked.

Points to Consider:
• Value expression is an optional argument. A field name might not have any value expression.
• A field name can be bound to multiple value expressions.
• Value expressions should be assigned a value type. The SQL value type can be: 1) Keyword, 2) SpecialString, or 3) WildChar.
• You can have multiple relaxation rules per field name/URL combination.

Using the Command Line to Configure the SQL Injection Check

To configure SQL Injection actions and other parameters by using the command line:

In the command line interface, you can use either the `set appfw profile` command or the `add appfw profile` command to configure the SQL Injection protections. You can enable the block, learn, log, stats action(s) and specify whether you want to transform the special characters used in SQL Injection attack strings to disable the attack. Select the type of SQL attack pattern (key words, wildcard characters, special strings) you want to detect in the payloads, and indicate whether you want the Web App Firewall to also inspect the request Headers for SQL Injection violations. Use the `unset appfw profile` command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

• `set appfw profile “Parameter descriptions provided at bottom of the page.”`
• `<name> -SQLInjectionAction ([block] [learn] [log] [stats]) | [none])`
• `set appfw profile “Parameter descriptions provided at bottom of the page.”`
• `<name> -SQLInjectionTransformSpecialChars (**ON** | OFF)`
• `set appfw profile “Parameter descriptions provided at bottom of the page.”`
• `<name> -**SQLInjectionCheckSQLWildChars** (**ON** | **OFF**) `
• `set appfw profile “Parameter descriptions provided at bottom of the page.”`
• ***<name> -**SQLInjectionType** ([**SQLKeyword**] | [**SQLSplChar**] | [**SQLSplCharANDKeyword**] | [**SQLSplCharORKeyword**])`
• `set appfw profile “Parameter descriptions provided at bottom of the page.”`
• `<name> -**SQLInjectionParseComments** ([**checkall**] | [**ansi|nested**] | [**ansinested**])`
• `**set appfw profile “Parameter descriptions provided at bottom of the page.”`
• `<name> -CheckRequestHeaders (ON | OFF) Parameter descriptions provided at bottom of the page.`
• `<name> - CheckRequestQueryNonHtml (ON | OFF) Parameter descriptions provided at bottom of the page.`

To configure a SQL Injection relaxation rule by using the command line

Use the bind or unbind command to add or delete binding, as follows:

• `bind appfw profile <name> -SQLInjection <String> [isRegex(REGEX NOTREGE)] <formActionURL> [-location <location>] [-valueType (Keyword`
Using the GUI to Configure the SQL Injection Security Check

In the GUI, you can configure the SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the SQL Injection check by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you just want to enable or disable Block, Log, Stats, and Learn actions for HTML SQL Injection, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b. If you want to configure additional options for this security check, double click HTML SQL Injection, or select the row and click Action Settings, to display the following options:

- **Transform SQL Special character**—Transform any SQL Special characters in the request.
- **Check for SQL Wildcard Characters**—Consider SQL Wildcard characters in the payload to be attack patterns.
- **Check Request Containing**—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.
- **SQL Comments Handling**—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

After changing any of the above settings, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section, and then click Save and Close to close the Security Check pane.

To configure an SQL Injection relaxation rule by using the GUI
• Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
• In the **Advanced Settings** pane, click **Relaxation Rules**.
• In the Relaxation Rules table, double-click the **HTML SQL Injection** entry, or select it and click **Edit**.
• In the **HTML SQL Injection Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

**Note**

When you add a new rule, the **Value Expression** field is not displayed unless you select **Keyword** or **SpecialString** or **WildChar** option in the **Value Type** Field.

To manage SQL Injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **HTML SQL Injection** row and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the SQL Injection patterns by using the GUI

You can use the GUI to view or customize the SQL patterns.

The default SQL patterns are specified in **Application Firewall > Signatures > Default Signatures**. If you do not bind any signature object to your profile, the default SQL patterns specified in the Default Signatures object will be used by the profile for the SQL Injection security check processing. The rules and patterns, specified in the default signatures object, are read-only. You cannot edit or modify them.

If you want to modify or change these patterns, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the SQL patterns in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized SQL patterns.

For more information, see **Signatures**

1. **To view default SQL patterns:**

   a. Navigate to **Application Firewall > Signatures**, select **Default Signatures**, and click **Edit**.

   Then click **Manage SQL/XSS patterns**.

   The **Manage SQL/XSS paths** table shows following four rows pertaining to SQL Injection:

   • Injection (not_alphanum, SQL)/ Keyword
   • Injection (not_alphanum, SQL)/ specialstring
   • Injection (not_alphanum, SQL)/ transformrules/transform
   • Injection (not_alphanum, SQL)/ wildcard

   b. Select a row and click **Manage Elements** to display the corresponding SQL patterns (keywords, special strings, transformation rules or the wildcard characters) used by the Web App
2. **To customize SQL patterns**: You can edit the User-Defined signature object to customize the SQL key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the SQL special strings.

   a. Navigate to Application Firewall > Signatures, highlight the target User-defined signature, and click **Edit**. Click **Manage SQL/XSS patterns** to display the Manage SQL/XSS paths table.

   b. Select the target SQL Injection row.

      i. Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding SQL element.

      ii. Click **Remove** to remove the selected row.

<table>
<thead>
<tr>
<th><strong>Warning</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You must be very careful before you remove or modify any default SQL element, or delete the SQL path to remove the entire row. The signature rules as well as the SQL Inject security check rely on these elements for detecting SQL Injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to SQL attacks if the required pattern is removed during editing.</td>
</tr>
</tbody>
</table>

**Using the Learn Feature with the SQL Injection Check**

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as an SQL Injection relaxation rule.

**SQL Injection Learning enhancement**—An Web App Firewall learning enhancement was introduced in release 11.0 of the Citrix ADC software. To deploy fine grained SQL Injection relaxation, the Web App Firewall offers fine grained SQL Injection learning. The learning engine makes recommendations regarding the observed Value Type (keyword, SpecialString, Wildchar) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in relaxation rules.

<table>
<thead>
<tr>
<th><strong>Important</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>The Web App Firewall's learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from SQL Injection inspection.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Note</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>To bypass SQL check in User-Agent header, use the following relaxation rule:</td>
</tr>
</tbody>
</table>
bind appfw profile your_profile_name -SQLInjection User-Agent ".*" location HEADER

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

• show appfw learningdata <profilename> SQLInjection
• rm appfw learningdata <profilename> -SQLInjection <string> <formActionURL>
  > [<string>] [<valueType> <valueExpression>]
• export appfw learningdata <profilename> SQLInjection

To view or use learned data by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the **HTML SQL Injection** entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the **HTML SQL Injection** entry in the Learned Rules table and clicking **Visualizer** to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

**Using the Log Feature with the SQL Injection Check**

When the log action is enabled, the HTML SQL Injection security check violations are logged in the audit log as **APPFW_SQL** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the SQL Injection violations:

```
> Shell
## tail -f /var/log/ns.log | grep APPFW_SQL
```
Example of a HTML SQL Injection log message when the request is transformed

```
1 Jun 26 21:08:41 <local0.info> 10.217.31.98  CE:F:0|Citrix|Citrix ADC|NS11.0|APPFW|APPFW_SQL|6|src=10.217.253.62 geolocation=Unknown spt=54001 method=GET request=http://aaron.stratum8.net/FFC/login.php?login_name=%27+or+password=and+%3B&drinking_pref=on&text_area=select+++from+%5C+%3B&loginButton=ClickToLogin&as_sfid=AAAAAAAAjGN5gLH-hvhT0piSEiqES7bjFr5Mq0fwPp-3ZHdi5ylRWByj0cVbMyy-Ens2vaaiULKoUri4004kBXwWy5s7I3QkDsrvIgCYMC9BMVWy2wbNcSqCw5k52lfE0k %3D&as_fid=feeecc8758b41740edeeeb6b35b85dfd3d5def30c msg= Special characters seen in fields cn1=74 cn2=762 cs1=pr_ffc cs2=PPE1 cs3=9 ztIlf9p1H7p6Xtzn6NMygtTv/QM0002 cs4=ALERT cs5=2015 act=transformed
```

Example of a HTML SQL Injection log message when the post request is blocked

```
1 Jun 26 21:30:34 <local0.info> 10.217.31.98  CE:F:0|Citrix|Citrix ADC|NS11.0|APPFW|APPFW_SQL|6|src=10.217.253.62 geolocation=Unknown spt=9459 method=POST request=http://aaron.stratum8.net/FFC/login_post.php msg=SQL Keyword check failed for field text_area="(')" cn1=78 cn2=834 cs1=pr_ffc cs2=PPE1 cs3=eVJMMPtZ2XgylGrHjkk3rZLfbC10002 cs4=ALERT cs5=2015 act=blocked
```

Note

As part of the streaming changes in 10.5.e build (enhancement builds) as well as 11.0 build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input could be separated by a large number of bytes. We now keep track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message now includes the SQL keyword, or the SQL special character, or both the SQL keyword and the SQL special character, as determined by the configured setting. The rest of the input is no longer included in the log message, as shown in the following example:

Example:

In 10.5, when the Web App Firewall detects the SQL violation, the entire input string might be included in the log message, as shown below:

```
SQL Keyword check failed for field text="\"select a name from testbed1 \n;()\".".*<blocked>
```

In enhancement builds of 10.5.e that support request side streaming as well as 11.0 build onwards, we log only the field name, keyword and special character (if applicable) in the log mes-
SQL Keyword check failed for field **text="select();"**<blocked>

This change is applicable to requests that contain application/x-www-form-urlencoded, or multipart/form-data, or text/x-gwt-rpc content-types. Log messages generated during processing of JSON or XML payloads are not affected by this change.

To access the log messages by using the GUI

The Citrix GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the HTML SQL Injection row and click Logs. When you access the logs directly from the HTML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to Citrix ADC > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the HTML SQL Injection check, filter by selecting APPFW in the dropdown options for Module. The Event Type list offers a rich set of options to further refine your selection. For example, if you select the APPFW_SQL check box and click the Apply button, only log messages pertaining to the SQL Injection security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, Event Type, Event ID, Client IP etc. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click to Deploy functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy HTML SQL Injection relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the Syslog Viewer box of the selected row. Select the check box, and then select...
an option from the Action list to deploy the relaxation rule. **Edit & Deploy**, **Deploy**, and **Deploy All** are available as **Action** options.

The SQL Injection rules that are deployed by using the Click to Deploy option do not include the fine grain relaxation recommendations.

**To use Click to Deploy functionality in the GUI:**

1. In the Syslog Viewer, select **Application Firewall** in the **Module** options.
2. Select the **APP_SQL** as the **Event Type** to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the **Action** drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

**Statistics for the SQL Injection violations**

When the stats action is enabled, the counter for the SQL Injection check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 SQL Injection violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

**To display SQL Injection check statistics by using the command line:**

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

**To display HTML SQL Injection statistics by using the GUI**

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about HTML SQL Injection violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Highlights**

**Note the following points about the SQL Injection check:**
• **Built-in Support for SQL Injection Protection**—The Citrix Web Web App Firewall protects against SQL injection by monitoring a combination of SQL keywords and special characters in the form parameters. All SQL keywords, special characters, wildcard characters, and default transformation rules are specified in the /netscaler/default_custom_settings.xml file.

• **Customization**—You can change the default key words, special characters, wildcard characters and transformation rules to customize the SQL security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.

• **Hybrid Security Model**—Both signatures and deep security protections use the SQL/XSS patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/XSS patterns present in the default signature object are used.

• **Transform**—Note the following about the transform operation:
  – The transform operation works independently of the other SQL Injection action settings. If transform is enabled and block, log, stats, and learn are all disabled, SQL special characters will be transformed.
  – When SQL Transformation is enabled, user requests are sent to the backend servers after the SQL special characters are transformed in non-block mode. If the block action is enabled, it takes precedence over the transform action. If the injection type is specified as SQL special character and block is enabled, the request is blocked despite the transform action.

• **Fine Grained Relaxation and Learning**—Fine tune the relaxation rule to relax a subset of SQL elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.

• **Click to Deploy**—Select one, or multiple SQL violation log messages in the syslog viewer and deploy them as relaxation rules.

**HTML command injection protection check**

August 19, 2020

The HTML command injection check examines if the incoming traffic has unauthorized commands that break the system security or modify the system. If the traffic has any malicious commands when detected, the appliance blocks the request or performs the configured action.

The Citrix Web App Firewall profile is now enhanced with a new security check for command injection attacks. When the command injection security check examines the traffic and detects any malicious
commands, the appliance blocks the request or performs the configured action.

In a command injection attack, the attacker aims to run unauthorized commands on the Citrix ADC operation system. To achieve this, the attacker injects operating system commands using a vulnerable application. A Citrix ADC appliance is vulnerable to injection attacks if the application passes any unsafe data (forms, cookies, or header) to the system shell.

**How command injection protection works**

1. For an incoming request, WAF examines the traffic for keywords or special characters. If the incoming request has no patterns that match any of the denied keywords or special characters, the request is allowed. Otherwise, the request is blocked, dropped, or redirected based on the configured action.

2. If you prefer to exempt a keyword or a special character from the list, you can apply a relaxation rule to bypass the security check under specific conditions.

3. You can enable logging to generate log messages. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

4. You can also enable the statistics feature to gather statistical data about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you must configure new relaxation rule or modify the existing one.

**Keywords and special characters denied for command injection check**

To detect and block command injection attacks, the appliance has a set of patterns (keywords and special characters) defined in the default signature file. Following is a list of keywords blocked during command injection detection.

```xml
1  <commandinjection>
2   <keyword type="LITERAL" builtin="ON">7z</keyword>
3   <keyword type="LITERAL" builtin="ON">7za</keyword>
4   <keyword type="LITERAL" builtin="ON">7zr</keyword>
5   ...
6  </commandinjection>
```

Special characters defined in the signature file are:

| ; & $ > < ' ` ! >> # # |
Configuring command injection check by using the CLI

In the command line interface, you can use either the set the profile command or the add the profile command to configure the command injection settings. You can enable the block, log, and stats actions. You must also set the key words and string characters that you want to detect in the payloads.

At the command prompt, type:

```
set appfw profile <profile-name> -cmdInjectionAction <action-name> -CMDInjectionType <CMDInjectionType>
```

**Note:**
By default, the command injection action is set as “None.” Also, the default command injection type is set as CmdSplCharANDKeyWord.

**Example:*

```
set appfw profile profile1 -cmdInjectionAction block -CMDInjectionType CmdSplChar
```

Where, the available command injection actions are:

- None - Disable command injection protection.
- Log - Log command injection violations for the security check.
- Block - blocks traffic that violates the command injection security check.
- Stats - Generates statistics for command injection security violations.

Where, the available command injection types are:

- Cmd SplChar. Checks special characters
- CmdKeyWord. Checks command injection Keywords
- CmdSplCharANDKeyWord. Checks special characters and command injection. Keywords and blocks only if both are present.
- CmdSplCharORKeyWord. Checks special characters and command injection Keywords and blocks if either of them is found.

Configuring relaxation rules for command injection protection check

If your application requires you to bypass the command injection inspection for a specific ELEMENT or ATTRIBUTE in the payload, you can configure a relaxation rule.

The command Injection inspection relaxation rules have the following syntax:

```
bind appfw profile <profile name> -cmdInjection <string> <URL> -isregex <REGEX/NOTREGEX>
```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
**Example for relaxation rule for Regex in header**

```
bind appfw profile sample -CMDInjection hdr "http://10.10.10.10/"-location heaDER -valueType Keyword '^[a-z]+grep'$-isvalueRegex REGEX
```

As a result, the injection exempts the command injection check allows header ‘hdr’ containing variants of “grep.”

**Example for relaxation rule with valueType as regex in cookie**

```
bind appfw profile sample -CMDInjection ck_login "http://10.10.10.10/"-location cookie -valueType Keyword 'pkg[a-z]+'$-isvalueRegex REGEX
```

**Configuring command injection check by using Citrix ADC GUI**

Complete the following steps to configure the command injection check.

1. Navigate to **Security > Citrix Web App Firewall and Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **Citrix Web App Firewall Profile** page, go to the **Advanced Settings** section and click **Security Checks**.
1. In the Security Checks section, select **HTML Command Injection** and click **Action** settings.

2. In the **HTML Command Injection Settings** page, set the following parameters:
   
   a) Actions. Select one or more actions to perform for command injection security check.

   b) Check Request Containing. Select a command injection pattern to check if the incoming request has the pattern.

3. Click **OK**.
**Viewing command injection traffic and violation statistics**

The **Citrix Web App Firewall Statistics** page shows security traffic and security violation details in a tabular or graphical format.

To view security statistics by using the command interface.

At the command prompt, type:

```
stat appfw profile profile1
```

**XML external entities (XXE) Attack Protection**

July 20, 2020

The XML external entities (XXE) attack protection examines if an incoming payload has any unauthorized XML input regarding entities outside the trusted domain where the web application resides. The XXE attack occurs if you have a weak XML parser that parses an XML payload with input containing references to external entities.

In a Citrix ADC appliance, if the XML parser is improperly configured, the impact of exploiting the vulnerability can be dangerous. It allows an attacker to read sensitive data on the web server, perform denial of service attack and so forth. Therefore, it is important protect the appliance from XXE attacks.
Web Application Firewall is able to protect the appliance from XXE attacks as long as the content-type is identified as XML. To prevent a malicious user from bypassing this protection mechanism, WAF blocks an incoming request if the “inferred” content-type in the HTTP headers does not match with the content-type of the body. This mechanism prevents XXE attack protection bypass when a whitelisted default or non-default content-type is used.

Some of the potential XXE threats that affect a Citrix ADC appliance are:

- Confidential data leaks
- Denial-of-service (DOS) attacks
- Server side forgery requests
- Port scanning

**How XML external entities (XXE) protection works**

1. When there is an incoming request, WAF examines the first 512 bytes of the XML payload for any mismatch in the content-type header and the content-type of the payload.
2. If the content types match, the XML XXE protection is enabled and applied on the HTTP request.
3. But, if the content-type header does not match with the content-type of the body, the request is blocked, dropped, or logged based on the configured action.
4. You can enable logging to generate log messages. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
5. You can also enable the statistics feature to gather statistical data about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack.

**Configure XML external entities (XXE) injection protection**

To configure XML external entities (XXE) check by using the command interface:

In the command line interface, you can add or modify the application firewall profile command to configure the XXE settings. You can enable the block, log, and stats actions.

At the command prompt, type:

```
set appfw profile <name> [-inferContentTypeXmlPayloadAction <inferContentTypeXmlPayloadAction <block | log | stats | none>]
```

**Note:**

By default, the XXE action is set as “none.”

**Example:**

```
set appfw profile profile1 -inferContentTypeXmlPayloadAction Block
```
Citrix ADC 13.0

Where, action types are:

Block: The request is blocked without any exception to the urls in the request.

Log: If a mismatch between content-type in an HTTP request header and payload occurs, information about the violating request must be contained in the log message.

Stats: If a mismatch in the content-types is detected, the corresponding statistics for this violation type is incremented.

None: No action is taken if mismatch in content-types is detected. None cannot be combined with any other action type. Default action is set to None.

**Configure XXE injection check by using Citrix ADC GUI**

Complete the following steps to configure the XXE injection check.

1. Navigate to **Security > Citrix Web App Firewall > Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **Citrix Web App Firewall Profile** page, go to the **Advanced Settings** section and click **Security Checks**.
4. In the **Security Checks** section, select **Infer Content Type XML Payload** and click **Action** settings.
5. In the Infer Content Type XML Payload Settings page, set the following parameters:
   a) Actions. Select one or more actions to perform for XXE injection security check.
6. Click **OK**.
Viewing XXE injection traffic and violation statistics

The Citrix Web App Firewall Statistics page shows security traffic and security violation details in a tabular or graphical format.

To view security statistics by using the command interface.

At the command prompt, type:

```
stat appfw profile profile1
```

Viewing XXE injection statistics by using the Citrix ADC GUI

Complete the following steps to view the XXE injection statistics:

2. In the details pane, select a Web App Firewall profile and click Statistics.
3. The Citrix Web App Firewall Statistics page displays the XXE command injection traffic and violation details.
4. You can select Tabular View or switch to Graphical View to display the data in a tabular or graphical format.
The Buffer Overflow check detects attempts to cause a buffer overflow on the web server. If the Web App Firewall detects that the URL, cookies, or header are longer than the configured length, it blocks the request because it can cause a buffer overflow.

The Buffer Overflow check prevents attacks against insecure operating-system or web-server software that can crash or behave unpredictably when it receives a data string that is larger than it can handle. Proper programming techniques prevent buffer overflows by checking incoming data and either rejecting or truncating overlong strings. Many programs, however, do not check all incoming data and are therefore vulnerable to buffer overflows. This issue especially affects older versions of web-server software and operating systems, many of which are still in use.

The Buffer Overflow security check allows you to configure the Block, Log, and Stats actions.
tion, you can also configure the following parameters:

- **Maximum URL Length.** The maximum length the Web App Firewall allows in a requested URL. Requests with longer URLs are blocked. **Possible Values:** 0–65535. **Default:** 1024
- **Maximum Cookie Length.** The maximum length the Web App Firewall allows for all cookies in a request. Requests with longer cookies trigger the violations. **Possible Values:** 0–65535. **Default:** 4096
- **Maximum Header Length.** The maximum length the Web App Firewall allows for HTTP headers. Requests with longer headers are blocked. **Possible Values:** 0–65535. **Default:** 4096
- **Query string length.** Maximum length allowed for query string in an incoming request. Requests with longer queries are blocked. **Possible Values:** 0–65535. **Default:** 1024
- **Total request length.** Maximum request length allowed for an incoming request. Requests with longer length are blocked. **Possible Values:** 0–65535. **Default:** 24820

**Using the command line to configure the Buffer Overflow security check**

To configure Buffer Overflow security check actions and other parameters by using the command line

At the command prompt, type:

```
add appfw profile <name> -bufferOverflowMaxURLLength <positive_integer> -bufferOverflowMaxHeaderLength <positive_integer> -bufferOverflowMaxCookieLength <positive_integer> -bufferOverflowMaxQueryLength <positive_integer> -bufferOverflowMaxTotalHeaderLength <positive_integer>
```

Example:

```
add appfw profile profile1 -bufferOverflowMaxURLLength 7000 -bufferOverflowMaxHeaderLength 7250 -bufferOverflowMaxCookieLength 7100 -bufferOverflowMaxQueryLength 7300 -bufferOverflowMaxTotalHeaderLength 7300
```

**Configure buffer overflow security check by using the Citrix ADC GUI**

1. Navigate to **Security > Citrix Web App Firewall** and **Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **Citrix Web App Firewall Profile** page, go to **Advanced Settings** section and click **Security Checks**.
4. In **Security Checks** section, select **Buffer Overflow** and click **Action Settings**.
5. In the **Buffer Overflow Settings** page, set the following parameters.
   a. Actions. Select one or more actions to perform for command injection security check.
   b. Maximum URL Length. Maximum length, in characters, for URLs on your protected websites.
Requests with longer URLs are blocked.
c. Maximum Cookie Length. Maximum length, in characters, for cookies sent to your protected websites. Requests with longer cookies are blocked.
d. Maximum Header Length. Maximum length, in characters, for HTTP headers in requests sent to your protected websites. Requests with longer headers are blocked.
e. Maximum Query Length. Maximum length, in bytes, for query string sent to your protected websites. Requests with longer query strings are blocked.
f. Maximum Total Header Length. Maximum length, in bytes, for the total HTTP header length in requests sent to your protected websites. The minimum value of this and maxHeaderLen in httpProfile will be used. Requests with longer length are blocked.

6. Click OK and Close.

Using the Log Feature with the Buffer Overflow Security Check

When the log action is enabled, the Buffer Overflow security check violations are logged in the audit log as APPFW_BUFFEROVERFLOW_URL, APPFW_BUFFEROVERFLOW_COOKIE, and APPFW_BUFFEROVERFLOW_HDR violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

If you use the GUI to review the logs, you can use the click-to-deploy feature to apply relaxations indicated by the logs.

To access the log messages by using the command line
Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Buffer overflow violations:

```bash
1 > **Shell**
2 > **tail -f /var/log/ns.log | grep APPFW_BUFFEROVERFLOW**
```

Example of a CEF log message showing bufferOverflowMaxCookieLength violation in non-block mode

```plaintext
Oct 22 17:35:20 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|**APPFW_BUFFEROVERFLOW_COOKIE**|6|src=10.217.253.62
golocation=Unknown spt=41198 method=GET request=http://aaron.stratum8.net/FFC/sc11.html **msg=Cookie header length(43) is greater than maximum allowed(16).** cn1=119 cn2=465 cs1=owa_profile cs2=PPE1 cs3=wv000b+cJ2ZRBstZpyeNXIqLj7Y0001 cs4=ALERT cs5=2015 **act=not blocked**
```

Example of a CEF log message showing bufferOverflowMaxURLLength violation in non-block mode

```plaintext
Oct 22 18:39:56 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|**APPFW_BUFFEROVERFLOW_URL**|6|src=10.217.253.62
golocation=Unknown spt=19171 method=GET request=http://aaron.stratum8.net/FFC/sc11.html **msg=URL length(39) is greater than maximum allowed(20).** cn1=707 cn2=402 cs1=owa_profile cs2=PPE0 cs3=kW49GcnKnk5ByByi3+jeNzfgWa80000 cs4=ALERT cs5=2015 **act=not blocked**
```

Example of a Native Format Log message showing bufferOverflowMaxHeaderLength violation in block mode

```plaintext
Oct 22 18:44:00 <local0.info> 10.217.31.98 10/22/2015:18:44:00 GMT ns-0-PPE-2 : **default** APPFW **APPFW_BUFFEROVERFLOW_HDR** 155 0 : 10.217.253.62 374-PPE2 khhBeey4DB8V2D3H2sMLkXmFwA8002 owa_profile **Header(User-Agent) length(82) is greater than maximum allowed(10)** ** : http://aaron.stratum8.net/ **<blocked>**
```

To access the log messages by using the GUI

The Citrix GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the Buffer Overflow row and click Logs. When you access the logs directly from the Buffer Overflow Security Check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
• You can also access the Syslog Viewer by navigating to NetScaler > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

• Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the Buffer Overflow check, filter by selecting APPFW in the drop-down list options for Module. The Event Type list offers three options, APPFW_BUFFEROVERFLOW_URL, APPFW_BUFFEROVERFLOW_COOKIE, and APPFW_BUFFEROVERFLOW_HDR, to view all the log messages pertaining to buffer overflow security check. You can select one or more options to further refine your selection. For example, if you select the APPFW_BUFFEROVERFLOW_COOKIE check box and click the Apply button, only log messages pertaining to the Buffer Overflow security check violations for the Cookie header appear in the Syslog Viewer. If you place the cursor in the row for a specific log message, multiple options, such as Module, Event Type, Event ID, and Client IP, appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click-to-Deploy: The GUI provides click-to-deploy functionality, which is currently supported only for the buffer overflow log messages pertaining to the URL Length violations. You can use the Syslog Viewer to not only view the triggered violations, but also execute informed decisions based on the observed lengths of the blocked messages. If the current value is too restrictive and is triggering false positives, you can select a message and deploy it to replace the current value with the URL length value seen in the message. The log messages must be in CEF log format for this operation. If the relaxation can be deployed for a log message, a check box appears at the right edge of the Syslog Viewer box in the row. Select the check box, and then select an option from the Action list to deploy the relaxation. Edit & Deploy, Deploy, and Deploy All are available as Action options. You can use the APPFW_BUFFEROVERFLOW_URL filter to isolate all the log messages pertaining to the configured URL length violations.

If you select an individual log message, all three action options Edit & Deploy, Deploy, and Deploy All are available. If you select Edit & Deploy, the Buffer Overflow settings dialogue is displayed. The new URL length that was observed in the request is inserted into the Maximum URL length input field. If you click Close without any edits, the current configured values remain unchanged. If you click the OK button, the new value of the Maximum URL length replaces the previous value.

Note

The block, log and stats action check boxes are unchecked in the displayed Buffer Overflow settings dialogue, and need to be reconfigured if you select the Edit & Deploy option. Make sure
to enable these check boxes before clicking **OK**, otherwise the new URL length gets configured but the actions are set to **none**.

If you select the check boxes for multiple log messages, you can use the **Deploy** or **Deploy All** option. If the deployed log messages have different URL lengths, the configured value gets replaced by the highest URL Length value observed in the selected messages. Deploying the rule results only in changing the `bufferOverflowMaxURLLength` value. Configured actions are retained and remain unchanged.

To use Click-to-Deploy functionality in the GUI

1. In the Syslog Viewer, select **APPFW** in the **Module** options.
2. Enable the **APPFW_BUFFEROVERFLOW_URL** check box as the **Event Type** to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the **Action** drop-down list of options to deploy the relaxation.
5. Navigate to **Application Firewall > Profiles**, select the target profile, and click **Security Checks** to access the **Buffer Overflow** settings pane to verify that the **Maximum URL Length** value is updated.

**Statistics for the Buffer Overflow violations**

When the stats action is enabled, the counter for the Buffer Overflow Security Check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three Buffer Overflow violations increments the stats counter by one, because the page is blocked when the first violation is detected. However, if block is disabled, processing the same request increments the stat counter for violations because each violation generates a separate log message.

To display Buffer Overflow Security Check statistics by using the command line

At the command prompt, type:

```bash
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```bash
> stat appfw profile <profile name>
```

To display Buffer Overflow statistics by using the GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about Buffer Overflow violations and logs. The statistics table provides real-time data and is updated every 7 seconds.
Highlights

- The buffer overflow security check allows you to configure limits to enforce the maximum length of allowed URLs, Cookies, and Headers.

- **Block, Log and Stats** actions enable you to monitor the traffic and configure optimal protection for your application.

- Syslog viewer enables you to filter and view all the log messages pertaining to buffer overflow violations.

- **Click-to-Deploy** functionality is supported for the `bufferOverflowMaxURLLength` violations. You can select and deploy an individual rule, or you can select multiple log messages to tweak and relax the current configured value of the maximum allowed length of the URL. The highest value of the URL from the selected group is set as the new value, to allow all these requests that are currently flagged as violations.

- The Web App Firewall now evaluates individual cookies when inspecting the incoming request. If length of any one cookie received in the Cookie header exceeds the configured `BufferOverflowMaxCookieLength`, the Buffer Overflow violation is triggered.

---

**Important**

In release 10.5.e (in a few interim enhancements builds prior to 59.13xx.e build) and in the 11.0 release (in builds prior to 65.x), Web App Firewall processing of the Cookie header was changed. In those releases, every cookie is evaluated individually, and if the length of any one cookie received in the Cookie header exceeds the configured `BufferOverflowMaxCookieLength`, the Buffer Overflow violation is triggered. As a result of this change, requests that were blocked in 10.5 and earlier release builds might be allowed, because the length of the entire cookie header is not calculated for determining the cookie length. **In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”**.

This change has been reverted. The behavior in the 10.5.e ->59.13xx.e and subsequent 10.5.e enhancement builds in addition to 11.0 release 65.x and subsequent builds is now similar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.
The Cookie Consistency check examines cookies returned by users, to verify that they match the cookies that your website set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the web server. You can also configure the Cookie Consistency check to transform all of the server cookies that it processes, by encrypting the cookies, proxying the cookies, or adding flags to the cookies. This check applies to requests and responses.

An attacker would normally modify a cookie to gain access to sensitive private information by posing as a previously authenticated user, or to cause a buffer overflow. The Buffer Overflow check protects against attempts to cause a buffer overflow by using a long cookie. The Cookie Consistency check focuses on the first scenario.

If you use the wizard or the GUI, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the following actions:

- Block
- Log
- Learn
- Statistics
- Transform. If enabled, the Transform action modifies all cookies as specified in the following settings:
  - **Encrypt Server Cookies.** Encrypt cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list, before forwarding the response to the client. Encrypted cookies are decrypted when the client sends a subsequent request, and the decrypted cookies are reinserted into the request before it is forwarded to the protected web server. Specify one of the following types of encryption:
    - **None.** Do not encrypt or decrypt cookies. The default.
    - **Decrypt only.** Decrypt encrypted cookies only. Do not encrypt cookies.
    - **Encrypt session only.** Encrypt session cookies only. Do not encrypt persistent cookies. Decrypt any encrypted cookies.
    - **Encrypt all.** Encrypt both session and persistent cookies. Decrypt any encrypted cookies.

  **Note:** When encrypting cookies, the Web App Firewall adds the **HttpOnly** flag to the cookie. This flag prevents scripts from accessing and parsing the cookie. The flag therefore prevents a script-based virus or trojan from accessing a decrypted cookie and using that information to breach security. This is done regardless of the
Flags to Add in Cookies parameter settings, which are handled independently of the Encrypt Server Cookies parameter settings.

- **Proxy Server Cookies.** Proxy all non-persistent (session) cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list. Cookies are proxied by using the existing Web App Firewall session cookie. The Web App Firewall strips session cookies set by the protected web server and saves them locally before forwarding the response to the client. When the client sends a subsequent request, the Web App Firewall reinserts the session cookies into the request before forwarding it to the protected web server. Specify one of the following settings:
  - **None.** Do not proxy cookies. The default.
  - **Session only.** Proxy session cookies only. Do not proxy persistent cookies
    Note: If you disable cookie proxying after having enabled it (set this value to None after it was set to Session only), cookie proxying is maintained for sessions that were established before you disabled it. You can therefore safely disable this feature while the Web App Firewall is processing user sessions.

- **Flags to Add in Cookies.** Add flags to cookies during transformation. Specify one of the following settings:
  - **None.** Do not add flags to cookies. The default.
  - **HTTP only.** Add the HttpOnly flag to all cookies. Browsers that support the HttpOnly flag do not allow scripts to access cookies that have this flag set.
  - **Secure.** Add the Secure flag to cookies that are to be sent only over an SSL connection. Browsers that support the Secure flag do not send the flagged cookies over an insecure connection.
  - **All.** Add the HttpOnly flag to all cookies, and the Secure flag to cookies that are to be sent only over an SSL connection.

If you use the command-line interface, you can enter the following commands to configure the Cookie Consistency Check:

- `set appfw profile <name> -cookieConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- `set appfw profile <name> -cookieTransforms ([**ON**] | [**OFF**])`
- `set appfw profile <name> -cookieEncryption ([**none**] | [**decryptOnly**] | [**encryptSession**] | [**encryptAll**])`
- `set appfw profile <name> -cookieProxying ([**none**] | [**sessionOnly**])`
- `set appfw profile <name> -addCookieFlags ([**none**] | [**httpOnly**] | [**secure**] | [**all**])`

To specify relaxations for the Cookie Consistency check, you must use the GUI. On the Checks tab of the Modify Cookie Consistency Check dialog box, click Add to open the Add Cookie Consistency
Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Cookie Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Cookie Consistency check relaxations:

- **Logon Fields.** The following expression exempts all cookie names beginning with the string logon_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1 ^logon_[0-9A-Za-z]{2,15}
2 2,15 }
3 $
```

- **Logon Fields (special characters).** The following expression exempts all cookie names beginning with the string türkçe-logon_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1 ^txC3xBCrkxC3xA7e-logon_[0-9A-Za-z]{2,15}
2 2,15 }
3 $
```

- **Arbitrary strings.** Allow cookies that contain the string sc-item_, followed by the ID of an item that the user has added to his shopping cart ([0-9A-Za-z]+), a second underscore (_), and finally the number of these items he wants ([1-9][0-9]?), to be user-modifiable:

```
1 ^sc-item_[0-9A-Za-z]+_\[1-9\][0-9]?
2 $
culated for determining the cookie length. In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”.

**Note** that this change has been reverted. The behavior in the 10.5.e ->59.13xx.e and subsequent 10.5.e enhancement builds as well as in the 11.0 release 65.x and subsequent builds is now similar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

**Note**

**Sessionless Cookie Consistency:** The cookie consistency behavior has changed in release 11.0. In earlier releases, the cookie consistency check invokes sessionization. The cookies are stored in the session and signed. A “wlt_” suffix is appended to transient cookies and a “wlf_” suffix is appended to the persistent cookies before they are forwarded to the client. Even if the client does not return these signed wlf/wlt cookies, the Web App Firewall uses the cookies stored in the session to perform the cookie consistency check.

In release 11.0, the cookie consistency check is sessionless. The Web App Firewall now adds a cookie that is a hash of all the cookies tracked by the Web App Firewall. If this hash cookie or any other tracked cookie is missing or tampered with, the Web App Firewall strips the cookies before forwarding the request to the back end server and triggers a cookie-consistency violation. The server treats the request as a new request and sends new Set-Cookie header(s). The Cookie Consistency check in Citrix ADC version 13.0, 12.1, and NetScaler 12.0 and 11.1 does not have sessionless option.

**Web App Firewall support for Google web toolkit**

February 28, 2020

**Note:** This feature is available in Citrix ADC release 10.5.e.

Web servers following Google Web Toolkit (GWT) Remote Procedure Call (RPC) mechanisms can be secured by the Citrix Web Web App Firewall without a need for any specific configuration to enable the GWT support.
What is GWT

The GWT is used for building and optimizing complex high-performance web applications by people who do not have expertise in XMLHttpRequest, and JavaScript. This open source, free development toolkit is used extensively for developing small and large scale applications and is quite frequently used for displaying browser based data such as search results for flights, hotels, and so on. The GWT provides a core set of Java APIs and widgets for writing optimized JavaScript scripts that can run on most browsers and mobile devices. The GWT RPC framework makes it easy for the client and server components of the web application to exchange Java objects over HTTP. GWT RPC services are not the same as web services based on SOAP or REST. They are simply a lightweight method for transferring data between the server and the GWT application on the client. GWT handles serialization of the Java objects exchanging the arguments in the method calls and the return value.

For popular websites that use GWT, see

How a GWT request works

The GWT RPC request is pipe delimited and has variable number of arguments. It is carried as a payload of HTTP POST and has the following values:

1. Content-type = text/x-gwt-rpc. Charset can be any value.
2. Method = POST.

Both GET and POST HTTP requests are considered valid GWT requests if content-type is “text/x-gwt-rpc”. Query strings are now supported as part of GWT requests. Configure the “InspectQueryContentTypes” parameter of the App Firewall profile to “OTHER” to examine the request query portion for content-type “text/x-gwt-rpc”.

The following example shows a valid payload for a GWT request:

```
```

The request can be divided into three parts:

a) Header: 5|0|8|

The first 3 digits 5|0|8| in the above request, represent “version, subversion, and size of table”, respectively. These must be positive integers.

b) String Table:
The members of the above pipe delimited string table contain the user-provided inputs. These inputs are parsed for the Web App Firewall checks and are identified as follows:

- **1st**: http://localhost:8080/test/
  This is the Request URL.
- **2nd**: 16878339F02B83818D264AE430C20468
  Unique HEX identifier. A request is considered malformed if this string has non-hex characters.
- **3rd**: com.test.client.TestService
  Service Class name
- **4th**: testMethod
  Service method name
- **5th onwards**: java.lang.String|java.lang.Integer|myInput1|java.lang.Integer/3438268394
  Data-types and data. Non-primitive data-types are specified as <container>.<sub-cntnr>.name/integer<identifier>

**c) Payload**: 1|2|3|4|2|5|6|7|8|1|

The payload consists of references to the elements in the string table. These integer values cannot be larger than the number of elements in the string table.

**Web App Firewall protection for GWT applications**

The Web App Firewall understands and interprets GWT RPC requests, inspects the payload for security check violations, and takes specified actions.

The Web App Firewall headers and cookies checks for GWT requests are similar to those for other request formats. After appropriate URL decoding and charset conversion, all the parameters in the string table are inspected. The GWT request body does not contain field names, just the field values. The input values can be validated against the specified format by using the Web App Firewall Field Format check, which can also be used to control the length of the input. The Cross-site Scripting and SQL Injection attacks in the inputs can be easily detected and thwarted by the Web App Firewall.

**Learning and relaxation rules**: Learning and deployment of relaxation rules are supported for GWT requests. Web App Firewall rules are in the form of <actionURL> <fieldName> mapping. The GWT request format does not have the field names and thus requires special handling. The Web App Firewall
inserts dummy field names in the learned rules that can be deployed as relaxation rules. The -isRegex flag works as it does for non-GWT rules.

- **Action URL:**

  Multiple services responding to an RPC can be configured on the same web server. The HTTP request has the URL of the web server, not of the actual service handling the RPC. Therefore, relaxation is not applied on the basis of the HTTP request URL, because that would relax all the services on that URL for the target field. For GWT requests, the Web App Firewall uses the URL of the actual service found in the GWT payload, in the fourth field in the string table.

- **Field name:**

  Since the GWT request body contains only field values, the Web App Firewall inserts dummy field names such as 1, 2, and so on when recommending learned rules.

**Example of a GWT learned rule**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POST /abcd/def/gh HTTP/1.1</td>
</tr>
<tr>

</tr>
<tr>
<td>15</td>
<td>Done</td>
</tr>
</tbody>
</table>

**Example of a GWT relaxation rule**

bind appfw profile pr1 -crossSiteScripting 1 abcd -isregex NOTREGEX

**Log Messages:** The Web App Firewall generates log messages for the security check violations that are detected in the GWT requests. A log message generated by a malformed GWT request contains the string “GWT” for easy identification.

**Example of a Log message for malformed GWT request:**

Dec 5 21:48:02 <local@notice> 10.217.31.247 12/05/2014:21:48:02 GMT ns 0–PPE–0 : APPFW Message 696 0 : ”GWT RPC request with malformed payload. <
**Difference in processing of GWT vs non-GWT requests:**

The same payload can trigger different Web App Firewall security check violations for different Content-types. Consider the following example:

```
```

**Content-type: application/x-www-form-urlencoded:**

A request sent with this content type results in a SQL violation if the SQL Injection Type is configured to use any of the four available options: SQLSplCharANDKeyword, SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. The Web App Firewall considers '&' to be the field separator and '=' to be the name-value separator when processing the above payload. Since neither of these characters appears anywhere in the post body, the entire content is treated as a single field name. The field name in this request contains both an SQL special character (;) and an SQL Keyword (select). Therefore violations are caught for all four SQL Injection type options.

**Content-type: text/x-gwt-rpc:**

A request sent with this content type triggers an SQL violation only if the SQL injection type is set to one of the following three options: SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. No violation is triggered if the SQL injection type is set to SQLSplCharANDKeyword, which is the default option. The Web App Firewall considers the vertical bar | to be the field separator for the above payload in the GWT request. Therefore, the post body is divided into various form-field values, and form-field names are added (in accordance with the convention described earlier). Because of this splitting, the SQL special character and SQL keyword become parts of separate form fields.

```
Form field 8: java.lang.String%3b -> %3b is the (;)
```

```
Form Field 10: select
```

As a result, when SQL Injection Type is set to SQLSplChar, field 8 indicates the SQL violation. For SQLKeyword, field 10 indicates the violation. Either of these two fields can indicate a violation if the SQL Inject type is configured with the SQLSplCharORKeyword option, which looks for the presence of either a keyword or a special character. No violation is caught for the default SQLSplCharANDKeyword option, because there is no single field that has a value that contains both SQLSplChar and SQLKeyword together.

**Tips:**

- No special Web App Firewall configuration is needed to enable GWT support.
- The Content-type must be text/x-gwt-rpc.
- Learning and deploying of the relaxation rules for all the pertinent Web App Firewall security checks applied to GWT payload works the same as it does for the other supported content-types.
• Only POST requests are considered valid for GWT. All other request methods are blocked if the content-type is text/x-gwt-rpc.
• GWT requests are subject to the configured POST body limit of the profile.
• The sessionless setting for the security checks is not applicable and will be ignored.
• CEF log format is supported for the GWT log messages.

Data leak prevention checks

April 23, 2019

The data-leak-prevention checks filter responses to prevent leaks of sensitive information, such as credit card numbers and social security numbers, to unauthorized recipients.

Credit card check

February 12, 2020

If you have an application that accepts credit cards, or your websites have access to database servers that store credit card numbers, you must use Data Leak Prevention (DLP) measures and configure protection for each type of credit card that you accept.

The Citrix Web App Firewall Credit Card check prevents attackers from exploiting Data Leak Prevention flaws to obtain credit card numbers of your customers. By following simple configuration steps, you can enforce protection of one or more of the following credit cards: 1) Visa, 2) Master Card, 3) Discover, 4) American Express (Amex), 5) JCB, and 6) Diners Club.

The Credit Card security check examines server responses to identify instances of the target credit card numbers, and applies a specified action when such a number is found. The action can be to transform the response by X’ing out all but the last group of digits in the credit card number, or to block the response if it contains more than a specified number of credit card numbers. If you specify both, the block action takes precedence. The Maximum credit cards allowed per page setting determines when the block action is invoked. The default setting, 0 (no credit card numbers allowed on the page), is the safest, but you can allow up to 255. Depending on where the violation is detected in the response
and the block action gets triggered, you might get fewer than the maximum allowed number of credit cards in the response.

To avoid false positives, you can apply relaxations to exempt specific numbers from the Credit Card check. For example, a social security number, purchase order number, or Google account number might be similar to a credit card number. You can specify individual numbers or use a regular expression to indicate the string of digits to be bypassed when processing the response URL for credit card inspection.

If you’re not sure which credit card numbers to exempt, you can use the learn feature to generate recommendations based on the learned data. To get optimal benefit without compromising performance, you might want to enable this option for a short time to get a representative sample of the rules, and then deploy the relaxations and disable learning.

If you enable the log feature, the Credit Card check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate thwarted attempts to gain access. By default, the doSecureCreditCardLogging parameter is ON, so the credit card number is not included in the log message generated by the safe commerce (Credit Card) violation.

The stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack.

To configure the Credit Card security check for protecting your application, configure the profile that governs inspecting the traffic to and from this application.

**Note:**

A website that does not access a SQL database usually does not have access to sensitive private information such as credit card numbers.

**Using the command line to configure the credit card check**

In the command line interface, you can use either the set appfw profile command or the add appfw profile command to activate credit-card checking and specify which actions to perform. You can use the unset appfw profile command to revert back to the default settings. To specify relaxations, use the bind appfw command to bind credit card numbers to the profile.

To configure a credit card check by using the command line

Use either the set appfw profile command or the add appfw profile command, as follows:

- `set appfw profile <name> -creditCardAction {([block][learn] [log][stats]) | [none]}`
- `set appfw profile <name> -creditCard (VISA | MASTERCARD | DISCOVER | AMEX | JCB | DINERSCLUB)`
• set appfw profile <name> -creditCardMaxAllowed <integer>

• set appfw profile <name> -creditCardXOut ([ON] | [OFF])<name> -doSecureCreditCardLogging ([ON] | [OFF])

• To configure a Credit Card relaxation rule by using the command line

Use the bind command to bind the credit card number to the profile. To remove a credit card number from a profile, use the unbind command, with the same arguments that you used for the bind command. You can use the show command to display the credit card numbers bound to a profile.

• To bind a credit card number to a profile

bind appfw profile <profile-name> -creditCardNumber <any number/regex>
"<url>"

Example: bind appfw profile test_profile -creditCardNumber 378282246310005 http://www.example.com/credit_card_test.html

- To unbind a credit card number from a profile

unbind appfw profile <profile-name> -creditCardNumber <credit card number / regex> <url>

- To show the list of credit card numbers bound to a profile.

show appfw profile <profile>

Using the GUI to configure the credit card check

In the GUI, you configure the credit card security check in the pane for the profile associated with your application.

To add or modify the Credit Card security check by using the GUI

1. Navigate to Web App Firewall > Profiles, highlight the target profile, and click Edit.

2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a) If you just want to enable or disable Block, Log, Stats, and Learn actions for Credit Card, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b) If you want to configure additional options for this security check, double click Credit Card, or select the row and click Action Settings to display additional options as follows:
• Out—Mask any credit card number detected in a response by replacing each digit, except the digits in the final group, with the letter “X.
• Maximum credit cards allowed per page—Specify the number of credit cards that can be forwarded to the client without triggering a block action.
• Protected Credit Cards. Select or clear a check box to enable or disable protection for each type of credit card.
• You can also edit the Block, Log, Stats and Learn actions in the Credit Card Settings pane.

After making any of the above changes, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section and then click Save and Close to close the Security Check pane.

3. In the **Advanced Settings** pane, click **Profile settings**. To enable or disable secure logging of credit card Numbers, select or clear the **Secure Credit Card Logging** check box. (By default, it is selected).

Click **OK** to save the changes.

• To configure a Credit Card relaxation rule by using the GUI

  1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
  2. In the **Advanced Settings** pane, click **Relaxation Rules**. The Relaxation Rules table has a Credit Card entry. You can double click, or select this row and click **Edit** to access the **Credit Card Relaxation Rules** dialogue. You can perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

**Using the learn feature with the credit card check**

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, if you want to exempt a specific string of digits from the Credit Card security check, you can by deploy the learned rule as a relaxation rule.

• To view or use learned data by using the command line interface

  ```
  show appfw learningdata <profilename> creditCardNumber
  rm appfw learningdata <profilename> -creditcardNumber <credit card number> "<url>"
  export appfw learningdata <profilename> creditCardNumber
  ```

• To view or use learned data by using the GUI

  1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click Learned Rules. You can select the Credit Card entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the Skip button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the Credit Card entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the credit card check

When the log action is enabled, the Credit Card security check violations are logged in the audit log as APPFW_SAFECommerce or APPFW_SAFECommerce_XFORM violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

The default setting for doSecureCreditCardLogging is ON. If you change it to OFF, both credit card number and type are included in the log message.

Depending on the settings configured for the Credit Card checks, the application-firewall generated log messages might include the following information:

- Response was blocked or not blocked.
- Credit card numbers were transformed (X’d out). A separate log message is generated for each transformed credit card number, so multiple log messages might be generated during processing of a single response.
- Response contained the maximum number of potential credit card numbers.
- Credit card numbers and their corresponding types.
- To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Credit Card violations:

- Shell
To access the log messages by using the GUI

1. The Citrix GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have a couple of options for accessing the Syslog Viewer: Navigate to the **target profile > Security Checks**. Highlight the Credit Card row and click Logs. When you access the logs directly from the Credit Card security check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.

2. You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Credit Card security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the APPFW_SAFECOMMERCE and APPFW_SAFECOMMERCE_XFORM check boxes and click the Apply button, only log messages pertaining to the Credit Card security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

---

Example of a Native format log message when the response is not blocked

```

```

Statistics for the credit card violations

When the stats action is enabled, the corresponding counter for the Credit Card check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled and the Max Allowed credit card setting is 0, the request for a page that contains 20 credit card numbers increments the stats counter by one when the page is blocked as soon as the first credit card number is detected. However, if block is disabled and transform is enabled, processing the same request increments the statistics counter for logs by 20, because each credit card transformation generates a separate log message.

- To display Credit Card statistics by using command line
  
  At the command prompt, type:

  `sh appfw stats`

  To display stats for a specific profile, use the following command:

  `stat appfw profile <profile name>`

- To display Credit Card statistics by using GUI
  
  1. Navigate to **System > Security > Web App Firewall.**
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about Credit Card violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Highlights**

Note the following points about the Credit Card security check:

- The Web App Firewall enables you to protect credit card information and detect any attempts to access this sensitive data.
- To use the Credit Card protection check, you must specify at least one type of credit card and an action. The check is then applied to HTML, XML, and Web 2.0 profiles.

| You can pipe the output of `sh appfw profile` command and grep for `CreditCard` to see all the Credit Card specific configuration. For example, `sh appfw profile my_profile` | grep `CreditCard` displays the configured settings of various parameters as well as the relaxation rules pertaining to the Credit Card check for the Web App Firewall profile named `my_profile`. |

- You can exclude specific numbers from Credit Card inspection without bypassing the security check inspection for the rest of the credit card numbers.
- Relaxation is available for all Web App Firewall protected credit card patterns. In the GUI, you can use the visualizer to specify Add, Edit, Delete, Enable, or Disable operations on relaxation rules.
- The Web App Firewall learning engine can monitor the outgoing traffic to recommend rules based on observed violations. Visualizer support is also available for managing the learned credit card rules in the GUI. You can edit and deploy the learned rules, or skip them after careful inspection.
- The setting for number of allowed credit cards applies to each response. It does not pertain to the cumulative total of credit card numbers observed during the entire user session.
- The number of X’d out digits depends on the length of the credit card numbers. Ten digits are X’d out for credit cards that have 13 through 15 digits. Twelve digits are X’d out for credit cards that have 16 digits. If your application does not require sending the entire credit card number in the response, Citrix recommends that you enable this action to mask the digits in the credit card numbers.
- The X-out operation transforms all the credit cards and works independently of the configured
settings for the maximum number of allowed credit cards. For example, if there are 4 credit cards in the response and the creditCardMaxAllowed parameter is set to 10, all 4 credit cards are X’d-out, but they are not blocked. If the credit card numbers are spread out in the document, a partial response with X’d-out numbers might be sent to the client before the response is blocked.

• Do not disable the doSecureCreditCardLogging parameter before due consideration. When this parameter is turned off, the credit card numbers are displayed and are accessible in the log messages. These numbers are not masked in the logs, even if the X-out action is enabled. If you are sending logs to a remote syslog server, and the logs are compromised, the credit card numbers can be exposed.

• When the response page is blocked because of a Credit Card violation, the Web App Firewall does not redirect to the error page.

Safe object check

March 9, 2020

The Safe Object check provides user-configurable protection for sensitive business information, such as customer numbers, order numbers, and country-specific or region-specific telephone numbers or postal codes. A user-defined regular expression or custom plug-in tells the Web App Firewall the format of this information and defines the rules to be used to protect it. If a string in a user request matches a safe object definition, the Web App Firewall either blocks the response, masks the protected information, or removes the protected information from the response before sending it to the user, depending on how you configured that particular safe object rule.

The Safe Object check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain sensitive private information, such as company credit card numbers or social security numbers. If your web sites do not have access to these types of information, you do not need to configure this check. If you have a shopping cart or other application that can access such information, or your web sites have access to database servers that contain such information, you should configure protection for each type of sensitive private information that you handle and store.

Note:
A web site that does not access an SQL database usually does not have access to sensitive private information.
The Safe Object Check dialog box is unlike that for any other check. Each safe object expression that you create is the equivalent of a separate security check, similar to the Credit Card check, for that type of information. If you use the wizard or the GUI, you add a new expression by clicking Add and configuring the expression in the Add Safe Object dialog box. You modify an existing expression by selecting it, then clicking Open, and then configuring the expression in the Modify Safe Object dialog box.

In the Safe Object dialog box for each safe object expression, you can configure the following:

- **Safe Object Name.** A name for your new safe object. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 255 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

- **Actions.** Enable or disable the Block, Log, and Statistics actions, and the following actions:
  - **X-Out.** Mask any information that matches the safe object expression with the letter “X”.
  - **Remove.** Remove any information that matches the safe object expression.

- **RegularExpression.** Enter a PCRE-compatible regular expression that defines the safe object. You can create the regular expression in one of three ways: by typing the regular expression directly into the text box, by using the Regex Tokens menu to enter regular expression elements and symbols directly into the text box, or by opening the Regular Expressions Editor and using it to construct the expression. The regular expression must consist of ASCII characters only. Do not cut and paste characters that are not part of the basic 128-character ASCII set. If you want to include non-ASCII characters, you must manually type those characters in PCRE hexadecimal character encoding format.

  Note: Do not use start anchors (ˆ) at the beginning of Safe Object expressions, or end anchors ($) at the end of Safe Object expressions. These PCRE entities are not supported in Safe Object expressions, and if used, will cause your expression not to match what it was intended to match.

- **Maximum Match Length.** Enter a positive integer that represents the maximum length of the string that you want to match. For example, if you want to match U.S. social security numbers, enter the number eleven (11) in this field. That allows your regular expression to match a string with nine numerals and two hyphens. If you want to match California driver’s license numbers, enter the number eight (8).

  **Caution:**

  If you do not enter a maximum match length in this field, the Web App Firewall uses a default value of one (1) when filtering for strings that match your safe object expressions. As a result, most safe object expressions fail to match their target strings.

You cannot use the command-line interface to configure the Safe Object check. You must configure it by using either the Web App Firewall wizard or the GUI.

Following are examples of Safe Object check regular expressions:
• Look for strings that appear to be U.S. social security numbers, which consist of three numerals (the first of which must not be zero), followed by a hyphen, followed by two more numerals, followed by a second hyphen, and ending with a string of four more numerals:

```
1  [1-9][0-9]{3,3}
2   3,3 }
3   -[0-9]{}
4   2,2 }
5   -[0-9]{}
6   4,4 }
```

• Look for strings that appear to be California driver’s license IDs, which start with a letter and are followed by a string of exactly seven numerals:

```
1  [A-Za-z][0-9]{7,7}
2   7,7 }
```

• Look for strings that appear to be customer IDs which consist of a string of five hexadecimal characters (all the numerals and the letters A through F), followed by a hyphen, followed by a three-letter code, followed by a second hyphen, and ending with a string of ten numerals:

```
1  [0-9A-Za-f]{5,5}
2   5,5 }
3   -[A-Za-z]{}
4   3,3 }
5   -[0-9]{}
6   10,10 }
```

**Caution:**

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write to ensure that they define exactly the type of string you want to add as a safe object definition, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\*) metacharacter/wildcard combination, can have results you did not want or expect, such as blocking access to web content that you did not intend to block.

Advanced form protection checks

February 12, 2020

The advanced Form Protection checks examine web form data to prevent attackers from compromising your system by modifying the web forms on your web sites or sending unexpected types and quantities of data to your web site in a form.

Note

SQL, XSS, FFC, and FieldFormat protection checks are applied if the Exclude Upload Files From Security Checks is unset.

A file upload is also a form element that has control-name name field that is submitted as part of form submission.

Refer to this page, for more information: Forms

Field formats check

February 28, 2020

The Field Formats check verifies the data that users send to your web sites in web forms. It examines both the length and type of data to ensure that it is appropriate for the form field in which it appears. If the Web App Firewall detects inappropriate web form data in a user request, it blocks the request.

By preventing an attacker from sending inappropriate web form data to your web site, the Field Formats check prevents certain types of attacks on your web site and database servers. For example, if a particular field expects the user to enter a phone number, the Field Formats check examines the user-submitted input to ensure that the data matches the format of a phone number. If a particular field expects a first name, the Field Formats check ensures that the data in that field is of a type and length appropriate for a first name. It does the same thing for each form field that you configure it to protect.

This check applies to HTML requests only. It does not apply to XML requests. You can configure Field Format Checks in HTML profiles or Web 2.0 profiles to inspect HTML payload for protecting your applications. The Web App Firewall also supports Field Format Check protection for Google Web Toolkit (GWT) applications.
The Field Formats check requires that you enable one or more actions. The Web App Firewall examines the submitted inputs and applies the specified actions.

Note

Field format rules are tightening rules. Adding them to relaxation list from learned data acts as a blocking rule.

To relax field format rules, please remove particular “fieldname” from the fieldformat relaxations list.

You have the option to set the default field formats to specify Field Type and the minimum and maximum length of data expected in each form field on each web form that you want to protect. You can deploy relaxation rules to configure a Field Format for an individual field of a specific form. Multiple rules can be added to specify the field name, the action URL, and Field Formats. Specify Field Formats to accept different types of inputs in different form fields. The learning feature can provide recommendations for the relaxation rules.

Field Format Actions—You can enable Block, Log, Stats, and Learn actions. At least one of these actions must be enabled to engage the Field Format Check protection.

- **Block.** If you enable block, the block action is triggered if the input does not conform to the specified Field Format. If a rule was configured for the target field, the input is checked against the specified rule. Otherwise, it is checked against the default field format specification. Any mismatch in the Field Type or min/max length specification results in blocking the request.

- **Log.** If you enable the log feature, the Field Format check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate malicious attempts to launch an attack.

- **Stats.** If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack, or you might have to revisit the configuration to see if the specified field format is too restrictive.

- **Learn.** If you are not sure which Field Types or minimum and maximum length values might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides field format recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

  Note: The Web App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Default Field Format—In addition to configuring the actions, you can configure the default Field For-
mat to specify the type of data expected in all the form fields for your application. A Field Type can be selected as the Field Format type. Minimum length and Maximum length parameters can be used to specify the length of the allowed inputs. As an alternative to Field Types, you can use Character Maps to specify what’s allowed in a field (except in cluster deployments).

- **Field Type**—Field Types are named expression to which you assign assigned priority values. Field Type expressions specify the allowed inputs and are matched against the submitted data to determine whether the received values are consistent with the allowed values. The Field Types are checked in the order of their priority numbers. A lower number indicates a higher priority. The Web App Firewall gives you the option to add your own Field Types and assign them the priorities you want. The priority value can range from 0 through 64000. The following built-in Field Types are provided to help simplify the configuration process:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; sh appfw fieldtype</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1) Name: integer RegEx: “^[+-]?[0-9]+$”</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Priority: 30 Comment: Integer</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Builtin: IMMUTABLE</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>2) Name: alpha RegEx: “^[a-zA-Z]+$”</td>
<td></td>

<td></td>
</tr>
<tr>
<td>17</td>
<td>Done</td>
<td></td>
</tr>
<tr>
<td>18</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The built-in Field Types are IMMUTABLE. They cannot be modified or removed. Any Field Types that you add are MODIFIABLE. You can edit them or remove them.

Configuring a Field Type as a default Field Format might be useful when you have a PCRE expression that can identify the valid inputs in all or most of the form fields for your application and exclude the invalid inputs. For example, if all the inputs in your application forms are expected to contain only numbers and letters, you might want to use the built-in Field Type alphanum as the default Field Type. Any non-alphanumeric character such as a backslash () or semicolon ; in the input will trigger a violation. You can also add your own customized Field Types and use them to configure default Field Formats. For example, if you want to make the lowercase “x”,
“y”, and “z” the only allowed alpha characters, you can configure a customized Field Type with regular expression “^[x-z]+$". You could assign it a higher priority (lower priority number) then the built-in Field Types and use it as the default Field Type.

- **Minimum Length** — The default minimum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 0 by default, which allows the user to leave the field blank. Any higher setting forces users to fill in the field.

  **Caution:** If the minimum length value is 0 but the Field Type is integer, alpha, or alphanum, a request is blocked if any input field is left empty, despite the minimum length setting. That is because the regEx for these Field Types contains a + character, which means one or more characters. Distinguishing an integer from an alpha character requires at least one character.

- **Maximum Length**—The default maximum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 65535 by default.

  **Note:** Characters vs bytes. The minimum and the maximum lengths for the field formats represent the number of bytes, not the number of characters. Languages that have greater than one-byte character representation can cause the limit to be exceeded with fewer characters than the number configured for the maximum value. For example, with double-byte character representation, the maximum value of 9 allows no more than 4 characters.

  **Tip:** The GUI allows you to cut and paste UTF-8 characters directly into the GUI without having to convert them to hex.

- **Character Maps:** In addition to recommending the Field Types, the Web App Firewall learning engine offers you an additional option, Use Character Maps, to deploy the Format Check rules. A Character Map is a set of all the characters allowed in a particular form field. You can fine tune the Field format specification to allow or disallow specific characters by using Character Maps. A separate Character Map is generated for each form field. The alpha and numeric characters are treated differently in Character Maps. If any alpha character is seen in the input, all alpha characters [A-Za-z] will be allowed by the recommended PCRE expression in the Character Map. Similarly, if any digit is included, all digits [0-9] will be allowed. Non-printable characters are specified by using the x construct. Only single Byte characters with values between 0-255 are considered for Character Map recommendations.

  A Character Map can be more specific than the corresponding Field Type recommendation. In some situations, Character Maps might be a better option, because they give you tighter control over the set of characters allowed as inputs. The deployed character maps are displayed as strings that start with prefix “CM” followed by digits. The priority for the Character Maps starts at 10000. As with user-added Field Types, you can add, edit or remove a Character Map. Character Maps that are currently used in deployed rules cannot be modified or removed.

  **Note:** Character Maps are not supported in cluster deployments.
Note
When you add a field formats rule with any built-in Field Type and use character map instead of Field Type and save it, the changes do not get saved and rule still shows with Field Type.
When the character map matches one of the built-in type, the field type is reused instead of creating a new character map.

Using the command line to configure the field format check

In the command line interface, you can use the add appfw fieldtype command to add a new Field Type. You can use either the set appfw profile command or the add appfw profile command to configure the Field Format check and specify which actions to perform. You can use the unset appfw profile command to revert the configured settings back to their defaults. To specify a Field Format rule, use the bind appfw command to bind a Field Type to a form Field and the action URL, along with the minimum and maximum length specifications.

To add, remove or view a Field Type by using the command line:

Use the add command to add a Field Type. You must specify the Name, Regular expression and Priority when adding a new Field Type. You also have the option to add a Comment. You can use the show command to display the configured Field Types. You can also delete a Field Type by using the remove command, which requires only the Name of the Field Type.

add [appfw] fieldType <name> <regex> <priority> [-comment <string>]

where:

<regex> is a regular expression
<priority> is a positive_integer

Example:

```
1  add      fieldtype "Cust_Zipcode" "^[0-9]{5 }[-] [0-9]{4 }$"
2
3  -   show [appfw] fieldType [<name>]
4
5  Example: sh fieldType
6
7  sh appfw fieldType
8
9  sh appfw fieldType cust_zipcode
```
Note: As shown above, use of “appfw” in the command is optional. For example, “Add Field-Type” or “Add appfw fieldType” are both valid options. The names of the Field Types are case insensitive due to normalization. As shown in the above examples, Cust_Zipcode, cust_zipcode, and cUsT_ziPcode refer to the same Field Type.

To configure a Field Format check by using the command line

Use either the set appfw profile command or the add appfw profile command, as follows:

• set appfw profile <name> -fieldFormatAction (([block] [learn] [log] [stats]) [none])
• set appfw profile <name>-defaultFieldFormatType <string>
• set appfw profile <name>-defaultFieldFormatMinLength <integer>
• set appfw profile <name>-defaultFieldFormatMaxLength <integer>

To configure a Field Format relaxation rule by using the command line

Example:

Using the GUI to configure the field formats security check

In the GUI, you can manage the Field Types. You can also configure the Field Formats security check in the pane for the profile associated with your application.

To add, modify or remove a Field Type using the GUI

1. Navigate to Application Firewall node. In the Settings, click Manage Field Types to display the Configure Application Firewall Field Type dialogue box.
2. Click **Add** to add a new Field Type. Follow the instructions in this pane and click Create. You can also edit or delete any user-added Field Type if it is currently not being used by a deployed rule.

**To add or modify the Field Formats security check by using the GUI**

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Security Checks**.

   The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

   a) If you just want to enable or disable **Block**, **Log**, **Stats**, and **Learn** actions for Field Formats, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the Security Check pane.

   b) If you want to configure additional options for this security check, double click Field Formats, or select the row and click **Action Settings**, to display the following options for Default Field Format:

   - **Field Type**—Select the Field Type that you want to configure as the default Field Type. You can select the built-in and user-defined Field Types. The deployed Character Maps are also included in the list and can be selected.

   - **Minimum Length**—Specify the minimum number of characters that must be in each field. Possible values: 0-65535.

   - **Maximum Length**—Specify the maximum number of characters that must be in each field. Possible values: 1-65535.

   You can also edit the **Block**, **Log**, **Stats** and **Learn** actions in the Field Formats Settings pane.

   After making any of the above changes, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

**To configure a Field Formats relaxation rule by using the GUI**

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Relaxation Rules**. The Relaxation Rules table has a Field Formats entry. You can double click, or select this row and click the **Edit** button, to access the Field Formats Relaxation Rules dialogue. You can perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

For a consolidated view of all the relaxation rules, you can highlight the Field Formats row and click **Visualizer**. The visualizer for deployed relaxations offers you the option to Add a new rule or Edit an existing one. You can also Enable or Disable a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.
Using the learn feature with the Field Formats Check

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as a Field Format relaxation rule.

**Field formats learning enhancement**—An Web App Firewall learning enhancement was introduced in release 11.0. In the previous releases, once the learned field format recommendation is deployed, the Web App Firewall learning engine stops monitoring the valid requests for the purpose of recommending new rules on the basis of the new data points. This limits the configured security protection, because the learning database does not include any representations of the new data seen in the valid requests processed by the security check.

Violations are no longer coupled with learning. The learning engine learns and makes recommendations for the field formats regardless of the violations. In addition to checking the blocked requests to determine whether the current field format is too restrictive and needs to be relaxed, the learning engine also monitors the allowed requests to determine whether the current field format is too permissive, and allows elevating the security by deploying a more restrictive rule.

Following is a summary of the Field Formats learning behavior:

**No Field format is bound**—The behavior remains unchanged in this scenario. All learn data is sent to the aslearn engine. The learning engine suggests a field format rule based on the data set.

**Field format is bound**: In the previous releases, observed data is sent to the aslearn engine only in the case of a violation. The learning engine suggests a field format rule based on the data set. In the 11.0 release, all data is sent to aslearn engine even if no violation is triggered. The learning engine suggests a field format rule based on the entire data set of all received inputs.

**Use Case for learning enhancement:**

If the initial field format learned rules are based on a small sample of data, a few non typical values might result in a recommendation that is too lenient for the target field. The ongoing learning allows the Web App Firewall to observe data points from every request to collect a representative sample for the learned recommendations. This is helpful in further tightening the security to deploy the optimal input format with an adequate range value.
The field format learning makes use of the priority of the Field Types as well as the configured settings of the following learning thresholds:

- **FieldFormatMinThreshold**—Minimum number of times a specific form field must be observed before a learned relaxation is generated. Default: 1.
- **FieldFormatPercentThreshold**—Percentage of times a form field matched a particular Field Type, before a learned relaxation is generated. Default: 0.

The field format rule recommendations are based on the following criteria:

- **Field Type recommendations**—The Field Type recommendations are determined by the assigned priorities of the existing Field Types and the specified Field Format thresholds. The priorities determine the order in which the Field Types are matched against the inputs. A lower number specifies a higher priority. For example, Field Type integer has the higher priority (30) and is therefore evaluated before Field Type alphanum (50). The thresholds determine the number of inputs evaluated to collect a representative sample for the data point. Assigning the right priority to the configured Field Types, and configuring an appropriate `learningsetting` value for the `fieldFormatPercentThreshold` and `fieldFormatMinThreshold` parameters, is essential for getting the correct Field Format recommendation. The Field Type with the highest priority, based on the configured thresholds, is matched first against the inputs. If there is a match, this Field Type is suggested without considering the other Field Types. For example, three default Field Types, integer, alphanum, and any will match if all the inputs contain only numbers. However, integer will be recommended since it has the highest priority.
- **Minimum and Maximum length recommendations**—Calculations for the minimum and maximum lengths for the Field Format are done independently of the determination for the Field Type.
Type. The field format length calculations are based on the average length of all the observed inputs. Half of this calculated average is suggested as the min value, and twice the value of this average is suggested as the max value. The range for the Minimum Length is 0-65535 and the range for the Maximum Length is 1-65535. The configured value for the minimum length cannot exceed the maximum length.

- **Handling of space character**—The Field Format check counts every space character when checking for the Field Formats length. Leading or trailing spaces are not stripped, and multiple consecutive spaces in the middle of the input string are no longer consolidated to a single space during input processing.

Example to illustrate the Field Format recommendations:

<p>| | |</p>
<table>
<thead>
<tr>

To view or use learned data by using the command line interface:

```
1 show appfw learningdata <profilename> FieldFormat
2 rm appfw learningdata <profilename> -fieldFormat <string> <formActionURL>
3 export appfw learningdata <profilename> FieldFormat
```

To view or use learned data by using the GUI:

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the Field Formats entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

   You also have the option to show a summarized view of the learned relaxations by selecting
the Field Formats entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the field formats check

When the log action is enabled, the Field Formats security check violations are logged in the audit log as APPFW_FIELDFORMAT violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Field Formats violations:

   - Shell
   - `tail -f /var/log/ns.log | grep APPFW_FIELDFORMAT`

To access the log messages by using the GUI

The Citrix GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

   - Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the Field Formats row and click Logs. When you access the logs directly from the Field Formats security check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.

   - You can also access the Syslog Viewer by navigating to Citrix ADC > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

   - Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Field Formats security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set
of options to further refine your selection. For example, if you select the `APPFW_FIELDFORMAT` check box and click the **Apply** button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

**Example of a Native format log message when the request is not blocked**

```
1 Jun 10 22:32:26 <local0.info> 10.217.31.98 06/10/2015:22:32:26 GMT ns 0-PPE-0 :
2     default APPFW APPFW_FIELDFORMAT 97 0 : 10.217.253.62 562-PPE0
3     x1MV+YnNGzQFM3Bsyt4bXio0001 pr_fcc http://aaron.stratum8.net/FFC/login_post.php
4 Field format check failed for field passwd=’65568888sz-_’ <not blocked>
```

**Statistics for the field formats violations**

When the stats action is enabled, the corresponding counter for the Field Formats check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 Field Format violations increments the stats counter by one, because the page is blocked as soon as the first Field Formats violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by 3, because each Field Formats violation generates a separate log message.

To display Field Formats statistics by using command line

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
stat appfw profile <profile name>
```
To display Field Formats statistics by using GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about Field Formats violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Deployment Tip**

- Enable Field format actions log, learn and stats.
- After running a representative sample of the traffic to your application, review the learned recommendations.
- If a Field Type is recommended by most of the learned rules, configure that Field Type as the Default Field Type. For minimum and maximum lengths, use the widest range suggested by these rules.
- Deploy rules for other fields for which different Field Types or different minimum/maximum lengths are better suited.
- Enable blocking and disable learning.
- Monitor stats and logs. If a significant number of violations are still being triggered, you might want to review the log messages to confirm that the violations represent malicious requests that should have been blocked. If valid requests are being flagged as violations, you can either edit the configured Field Format rule to further relax it or enable learning again to get recommendations based on the new data points.

| Note: You can fine tune your configuration by getting new learning recommendations. |

**Highlights**

Note the following points about the Field Format security check:

- **Protection**—By configuring optimal field format rules, you can protect against many attacks. For example, if you specify that a field can only have integers, hackers will not be able to launch SQL Injection or XSS attacks by using this field, because the inputs required to launch such attacks will not meet the configured field format requirement.
- **Performance**—You can limit the minimum and the maximum allowed length for the inputs in the field format rules. This can prevent a malicious user from entering excessively large input strings in an attempt to add processing overhead to the server, or worse, cause the server to dump core because of stack overflow. By limiting the input size, you can shorten the time required for processing legitimate requests.
- **Configuring Field Formats**—You must enable one of the actions (block, log, stats, learn) to engage the field Format protection. You can also specify the Field format rules to identify the allowed inputs in your form fields.

- **Selecting Character Maps vs. Field Types**—Both Character Maps and Field Types use regular expressions. However, a Character Map provides a more specific expression by narrowing down the list of allowed characters. For example, for an input such as janedoe@citrix.com, the learning engine might recommend the Field Type nohtml but the Character Map \[.@-Za-z\] might be more specific, because it narrows down the allowed set of non-alpha characters. The Character Map option allows, in addition to alpha characters, only two non-alpha characters: period (.) and at (@).

- **Ongoing Learning**—The Web App Firewall monitors and takes into account all the incoming data (violations as well as allowed inputs) to build a learning table for recommending rules. The rules are revised and updated as new incoming data arrives. New field format rules are suggested for a field even if it already has a bound field format rule. If the configured Field Formats are too restrictive and are blocking the valid requests, you can deploy a more relaxed Field Format. Similarly, if the current Field Formats are too generic, you can further refine and tighten the security by deploying a more restrictive Field Format.

- **Overwriting Rules**—If a rule has already been deployed for a field/URL combination, the GUI allows the user to update the field format. A dialog box asks for confirmation to replace the existing rule. If you are using the command line interface, you have to explicitly unbind the previous binding and then bind the new rule.

- **Multiple match**—If multiple field formats match a given field name and its action URL, the Web App Firewall arbitrarily selects one of them to apply.

- **Buffer boundary**—If a field value extends across multiple streaming buffers, and the format for these two parts of the field value is different, a field format corresponding to “any” is sent to the learn database.

- **Field Format vs. Field Consistency Check**—Both the Field Format check and the Field Consistency check are form-based protection checks. The Field Formats check provides a different type of protection than does the Form Field Consistency check. The Form Field Consistency check verifies that the structure of the web forms returned by users is intact, that data format restrictions configured in the HTML are respected, and that data in hidden fields has not been modified. It can do this without any specific knowledge about your web forms other than what it derives from the web form itself. The Field Formats check verifies that the data in each form field matches the specific formatting restrictions that you configured manually, or that the learning feature generated and you approved. In other words, the Form Field Consistency check enforces general web form security, while the Field Formats check enforces the specific rules for the allowed inputs for your web forms.
The Form Field Consistency check examines the web forms returned by users of your web site, and verifies that web forms were not modified inappropriately by the client. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The Form Field Consistency check prevents clients from making unauthorized changes to the structure of the web forms on your web site when they fill out and submit a form. It also ensures that the data a user submits meets the HTML restrictions for length and type, and that data in hidden fields is not modified. This prevents an attacker from tampering with a web form and using the modified form to gain unauthorized access to web site, redirect the output of a contact form that uses an insecure script and thereby send unsolicited bulk email, or exploit a vulnerability in your web server software to gain control of the web server or the underlying operating system. Web forms are a weak link on many web sites and attract a wide range of attacks.

The Form Field Consistency check verifies all of the following:

- If a field is sent to the user, the check ensures that it is returned by the user.
- The check enforces HTML field lengths and types.
- If your web server does not send a field to the user, the check does not allow the user to add that field and return data in it.
- If a field is a read-only or hidden field, the check verifies that the data has not changed.
- If a field is a list box or radio button field, the check verifies that the data in the response corresponds to one of the values in that field.

If a web form returned by a user violates one or more of the Form Field consistency checks, and you have not configured the Web App Firewall to allow that web form to violate the Form Field Consistency checks, the request is blocked.

If you use the wizard or the GUI, in the Modify Form Field Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions.

You also configure Sessionless Field Consistency in the General tab. If Sessionless Field Consistency is enabled, the Web App Firewall checks only the web form structure, dispensing with those parts of the Form Field Consistency check that depend upon maintaining session information. This can speed
the Form Field Consistency check with little security penalty for web sites that use many forms. To use Sessionless Field Consistency on all web forms, select On. To use it only for forms submitted with the HTTP POST method, select postOnly.

If you use the command-line interface, you can enter the following command to configure the Form Field Consistency Check:

```bash
set appfw profile <name> -fieldConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
```

To specify relaxations for the Form Field Consistency check, you must use the GUI. On the Checks tab of the Modify Form Field Consistency Check dialog box, click Add to open the Add Form Field Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Form Field Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in Manual Configuration By Using the GUI.

Following are examples of Form Field Consistency check relaxations:

**Form Field Names:**

- Choose form fields with the name UserType:
  ```
  ^UserType$
  ```

- Choose form fields with names that begin with UserType_ and are followed by a string that begins with a letter or number and consists of from one to twenty-one letters, numbers, or the apostrophe or hyphen symbol:
  ```
  ^UserType_[0-9A-Za-z][0-9A-Za-z'-]{20,20}$
  ```

- Choose form fields with names that begin with Turkish-UserType_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:
  ```
  ^T\xC3\xBCrk\xC3\xA7e-UserType_(\[0-9A-Za-z]\|\xC3\xA7E\[0-9A-\Fa-f]\[0-9A-\Fa-f]\)+$
  ```

**Note:**

See PCRE Character Encoding Format for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:
  ```
  ^\[0-9A-Za-z]\*[0-9A-Za-z]Num\[0-9A-Za-z]\*$
  ```
Form Field Action URLs:

- Choose URLs beginning with `http://www.example.com/search.pl?` and containing any string after the query except for a new query:
  
  ```
  ^http://www\.[.]example\.[.]com/search\.[.]pl?[^?]*$
  ```

- Choose URLs that begin with `http://www.example-español.com` and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

  ```
  ^http://www\.[.]example-espa\xC3\xB1ol\.[.]com/\([\[0-9A-Za-z_]\\x[0-9A-Fa-f][0-9A-Fa-f]\\)\*(\[0-9A-Za-z_]\\x[0-9A-Fa-f]\\)\*(\[0-9A-Za-z_]\\x[0-9A-Fa-f]\\)\*(\[0-9A-Za-z_]\\x[0-9A-Fa-f]\\)\*(\[0-9A-Za-z_]\\x[0-9A-Fa-f]\\)\*\.(asp|htp|php|s?html)?$
  ```

- Choose all URLs that contain the string `/search.cgi?:`

  ```
  ^[^?<>]*\[/search\.[.]cgi\?[^<>]*$
  ```

Caution:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

**CSRF form tagging check**

February 12, 2020

The Cross Site Request Forgery (CSRF) Form Tagging check tags each web form sent by a protected web site to users with a unique and unpredictable FormID, and then examines the web forms returned
by users to ensure that the supplied FormID is correct. This check protects against cross-site request forgery attacks. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The CSRF Form Tagging check prevents attackers from using their own web forms to send high volume form responses with data to your protected web sites. This check requires relatively little CPU processing capacity compared to certain other security checks that analyze web forms in depth. It is therefore able to handle high volume attacks without seriously degrading the performance of the protected web site or the Web App Firewall itself.

Before you enable the CSRF Form Tagging check, you should be aware of the following:

- You need to enable form tagging. The CSRF check depends on form tagging and does not work without it.
- You should disable the Citrix ADC Integrated Caching feature for all web pages containing forms that are protected by that profile. The Integrated Caching feature and CSRF form tagging are not compatible.
- You should consider enabling Referer checking. Referer checking is part of the Start URL check, but it prevents cross-site request forgeries, not Start URL violations. Referer checking also puts less load on the CPU than does the CSRF Form Tagging check. If a request violates Referer checking, it is immediately blocked, so the CSRF Form Tagging check is not invoked.
- The CSRF Form Tagging check does not work with web forms that use different domains in the form-origin URL and form-action URL. For example, CSRF Form Tagging cannot protect a web form with a form-origin URL of http://www.example.com and a form action URL of http://www.example.org/form.pl, because example.com and example.org are different domains.

If you use the wizard or the GUI, in the Modify CSRF Form Tagging Check dialog box, on the General tab you can enable or disable the Block, Log, Learn and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the CSRF Form Tagging Check:

```
set appfw profile <name> -CSRFtagAction [**block**] [**log**] [**learn**] [**stats**] [**none**]
```

To specify relaxations for the CSRF Form Tagging check, you must use the GUI. On the Checks tab of the Modify CSRF Form Tagging Check dialog box, click Add to open the Add CSRF Form Tagging Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify CSRF Form Tagging Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

An alert is generated when you set the Citrix Web App Firewall session limit to a value of 0 or lower, because such a setting affects advanced protection check functionality that requires a properly functioning Web App Firewall session.

Following are examples of CSRF Form Tagging check relaxations:
Note: The following expressions are URL expressions that can be used in both the Form Origin URL and Form Action URL roles.

- Choose URLs beginning with `http://www.example.com/search.pl` and containing any string after the query, except for a new query:

  ```plaintext
  ^http://www[.]example[.]com/search[.]pl[^[^?]*$
  ```

- Choose URLs that begin with `http://www.example-español.com` and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

  ```plaintext
  ```

- Choose all URLs that contain the string `/search.cgi`:

  ```plaintext
  ^[^<>]*[/search[.]cgi]?[^<>]*$
  ```

Important

Regular expressions are powerful. If you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`*`) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the check would otherwise have blocked.

Tip

When `enableValidate referrer header` is enabled under the Start URL Action, ensure that the Referrer Header URL is added to StartURL as well.

Note

When Citrix ADC reaches the `appfw_session_limit` and CSRF checks are enabled, the web application freezes.

To prevent web application freeze, decrease the session timeout and increase the session limit by using the following commands:

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Managing CSRF form tagging check relaxations

February 12, 2020

You configure an exception (or relaxation) to the CSRF Form Tagging security check in the Add Cross-Site Request Forgery Tagging Check Relaxation dialog box or the Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box.

To configure a CSRF form tagging check relaxation by using the GUI

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile you want to configure, and then click Open.
3. In the Configure Web App Firewall Profile dialog box, click the Security Checks tab. The Security Checks tab contains the list of Web App Firewall security checks.
4. To add or modify a CSRF relaxation, do one of the following:
   • To add a new relaxation, click Add.
   • To modify an existing relaxation, select the relaxation that you want to modify, and then click Open.

   The Add Cross-Site Request Forgery Tagging Check Relaxation or Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box is displayed. Except for the title, these dialog boxes are identical.
5. Fill in the dialog box as described below.

   • Enabled check box—Select to place this relaxation or rule in active use; clear to deactivate it.
   • Form Origin URL—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the form.
• **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the form is delivered.

• **Comments**—In the text area, type a comment. Optional.

**Note:**
For any element that requires a regular expression, you can type the regular expression, use the **Regex Tokens** menu to insert regular expression elements and symbols directly into the text box, or click **Regex Editor** to open the **Add Regular Expression** dialog box, and use it to construct the expression.

6. Click **OK**. The **Add Cross-Site Request Forgery Tagging Check Relaxation** or **Modify Cross-Site Request Forgery Tagging Check Relaxation** dialog box closes and you return to the **Modify Cross-Site Request Forgery Tagging Check** dialog box.

7. To remove a relaxation or rule, select it, and then click **Remove**.

8. To enable a relaxation or rule, select it, and then click **Enable**.

9. To disable a relaxation or rule, select it, and then click **Disable**.

10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click **Visualizer**, and use the display tools.

11. To review and configure learned rules for the CSRF check, click **Learning** and perform the steps in **To configure and use the Learning feature**.

12. Click **OK**.

---

**URL protection checks**

April 23, 2019

The URL Protection checks examine request URLs to prevent attackers from aggressively attempting to access multiple URLs (forceful browsing) or using a URL to trigger a known security vulnerability in web server software or web site scripts.
Start URL check

February 12, 2020

The Start URL check examines the URLs in incoming requests and blocks the connection attempt if the URL does not meet the specified criteria. To meet the criteria, the URL must match an entry in the Start URL list, unless the Enforce URL Closure parameter is enabled. If you enable this parameter, a user who clicks a link on your Web site is connected to the target of that link.

The primary purpose of the Start URL check is to prevent repeated attempts to access random URLs on a Web site, (forceful browsing) through bookmarks, external links, or jumping to pages by manually typing in the URLs to skip the pages required to reach that part of the website. Forceful browsing can be used to trigger a buffer overflow, find content that users were not intended to access directly, or find a back door into secure areas of your Web server. The Web App Firewall enforces a website’s given traversal or logic path by allowing access to only the URL’s that are configured as start URLs.

If you use the wizard or the GUI, in the Modify Start URL Check dialog box, on the General tab you can enable or disable Block, Log, Statistics, Learn actions, and the following parameters:

- **Enforce URL Closure.** Allow users to access any web page on your web site by clicking a hyperlink on any other page on your web site. Users can navigate to any page on your web site that can be reached from the home page or any designated start page by clicking hyperlinks.
  Note: The URL closure feature allows any query string to be appended to and sent with the action URL of a web form submitted by using the HTTP GET method. If your protected web sites use forms to access an SQL database, make sure that you have the SQL injection check enabled and properly configured.

- **Sessionless URL Closure.** From the client’s point of view, this type of URL closure functions in exactly the same way as standard, session-aware URL Closure, but uses a token embedded in the URL instead of a cookie to track the user’s activity, which consumes considerably fewer resources. When sessionless URL closure is enabled, the Web App Firewall appends a “as_url_id” tag to all the URL’s that are in URL closure.
  Note: When enabling sessionless (Sessionless URL Closure), you must also enable regular URL closure (Enforce URL Closure) or sessionless URL closure does not work.

- **Validate Referer Header.** Verify that the Referer header in a request that contains web form data from your protected web site instead of another web site. This action verifies that your web site, not an outside attacker, is the source of the web form. Doing so protects against cross-site request forgeries (CSRF) without requiring form tagging, which is more CPU-intensive than header checks. The Web App Firewall can handle the HTTP Referer header in one of the following four ways, depending on which option you select in the drop-down list:
  - **Off**—Do not validate the Referer header.
– **If-Present**—Validate the Referer header if a Referer header exists. If an invalid Referer header is found, the request generates a referer-header violation. If no Referer header exists, the request does not generate a referer-header violation. This option enables the Web App Firewall to perform Referer header validation on requests that contain a Referer header, but not block requests from users whose browsers do not set the Referer header or who use web proxies or filters that remove that header.

– **Always Except Start URLs**—Always validate the Referer header. If there is no Referer header and the requested URL is not exempted by the startURL relaxation rule, the request generates a referer-header violation. If the Referer header is present but it is invalid, the request generates a referer-header violation.

– **Always Except First Request**—Always validate the referer header. If there is no referer header, only the URL that is accessed first is allowed. All other URL’s are blocked without a valid referer header. If the Referer header is present but it is invalid, the request generates a referer-header violation.

One Start URL setting, **Exempt Closure URLs from Security Checks**, is not configured in the Modify Start URL Check dialog box, but is configured in the Settings tab of the Profile. If enabled, this setting directs the Web App Firewall not to run further form based checks (such as Cross-Site Scripting and SQL Injection inspection) on URLs that meet the URL Closure criteria.

**Note**

Although the referer header check and Start URL security check share the same action settings, it is possible to violate the referer header check without violating the Start URL check. The difference is visible in the logs, which log referer header check violations separately from Start URL check violations.

The Referer header settings (OFF, if-Present, AlwaysExceptStartURLs, and AlwaysExceptFirstRequest) are arranged in order of least restrictive to most restrictive and work as follows:

**OFF:**
- Referer Header Not checked.

**If-Present:**
- Request has no referer header - Request is allowed.
- Request has referer header and the referer URL is in URL closure - Request is allowed.
- Request has referer header and the referer URL is not in URL closure - Request is blocked.

**AlwaysExceptStartURLs:**
- Request has no referer header and the request URL is a start URL - Request is allowed.
- Request has no referer header and the request URL is not a start URL - Request is blocked.
- Request has referer header and the referer URL is in URL closure - Request is allowed.
- Request has referer header and the referer URL is not in URL closure - Request is blocked.

© 1999-2020 Citrix Systems, Inc. All rights reserved.
**AlwaysExceptFirstRequest:**

- Request has no referer header and is the first request URL of the session -> Request is allowed.
- Request has no referer header and is **not** the first request URL of the session -> Request is blocked.
- Request has referer header and is either the first request URL of the session or is in URL closure -> Request is allowed.
- Request has referer header and is neither the first request URL of the session nor is in URL closure -> Request is blocked.

If you use the command-line interface, you can enter the following commands to configure the Start URL Check:

- set appfw profile <name> -startURLAction [block] [learn] [log] [stats] [none]
- set appfw profile <name> -startURLClosure ([ON] | [OFF])
- set appfw profile <name> -sessionlessURLClosure ([ON] | [OFF])
- set appfw profile <name> -exemptClosureURLsFromSecurityChecks ([ON] | [OFF])
- set appfw profile <name> -RefererHeaderCheck ([OFF] | [if-present] | [AlwaysExceptStartURLs] | [AlwaysExceptFirstRequest])

To specify relaxations for the Start URL check, you must use the GUI. On the Checks tab of the Modify Start URL Check dialog box, click Add to open the Add Start URL Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Start URL Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Start URL check relaxations:

- Allow users to access the home page at www.example.com:

  ```
  ^http://www[.]example[.]com$
  ```

- Allow users to access all static HTML (.htm and .html), server-parsed HTML (.htp and .shtml), PHP (.php), and Microsoft ASP (.asp) format web pages at www.example.com:

  ```
  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)*/.*[.]([asp|htp|php|s?html?]$)
  ```

- Allow users to access web pages with pathnames or file names that contain non-ASCII characters at www.example-español.com:

  ```
  )
  ```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
**Note:** In the above expression, each character class has been grouped with the string \[0-9A-Fa-f][0-9A-Fa-f], which matches all properly-constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (\) is an escaped backslash, which tells the Web App Firewall to interpret it as a literal backslash. If you included only one backslash, the Web App Firewall would instead interpret the following left square bracket ([) as a literal character instead of the opening of a character class, which would break the expression.

- Allow users to access all GIF (.png), JPEG (.jpg and .jpeg), and PNG (.png) format graphics at www.example.com:

```
1 ^http://www[.].example[.].com/([^0-9A-Za-z][0-9A-Za-z_-.]*)*/
2 \[0-9A-Za-z][0-9A-Za-z_-.]*\.[(gif|jpe?g|png)
```

- Allow users to access CGI (.cgi) and PERL (.pl) scripts, but only in the CGI-BIN directory:

```
1 ^http://www[.].example[.].com/CGI-BIN/([^0-9A-Za-z][0-9A-Za-z_-.]*\.[(cgi|pl)
```

- Allow users to access Microsoft Office and other document files in the docsarchive directory:

```
1 ^http://www[.].example[.].com/docsarchive/([^0-9A-Za-z][0-9A-Za-z_-.]*\.[(doc|xls|pdf|ppt)
```

**Note**

By default, all Web App Firewall URLs are considered to be regular expressions.

**Caution:** Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions that you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\.*\) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the Start URL check would otherwise have blocked.

**Tip**

You can add the `-and-` to the allowed list of SQL keywords for URL naming scheme. For example, example `https://FQDN/bread-and-butter`.  

**Copied!**  
**Failed!**
Deny URL check

February 12, 2020

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many web sites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

In the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

```
set appfw profile <name> -denyURLAction [block] [log] [stats] [none]
```

To create and configure your own deny URLs, you must use the GUI. On the Checks tab of the Modify Deny URL Check dialog box, click Add to open the Add Deny URL dialog box, or select an existing user-defined deny URL and click Open to open the Modify Deny URL dialog box. Either dialog box provides the same options for creating and configuring a deny URL.

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at images.example.com directly:

  ```
  ^http:/images[.]*example[.]*com$
  ```

- Do not allow users to access CGI (.cgi) or PERL (.pl) scripts directly:

  ```
  ^http:/www[.]*example[.]*com/([0-9A-Za-z][0-9A-Za-z_]*[.]*)(cgi|pl)$
  ```

- Here is the same deny URL, modified to support non-ASCII characters:

  ```
  ^http:/www[.]*example[.]*com/([0-9A-Za-z][0-9A-Za-z_]*[.]*)(cgi|pl)$
  ```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Caution:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL or pattern that you want to block, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\*) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block.

XML protection checks

February 12, 2020

The XML Protection checks examine requests for XML-based attacks of all types.

Caution:

The XML security checks apply only to content that is sent with an HTTP content-type header of text/xml. If the content-type header is missing, or is set to a different value, all XML security checks are bypassed. If you plan to protect XML or Web 2.0 web applications, the webmasters of each web server that hosts those applications should ensure that the proper HTTP content-type header is sent.

XML format check

April 23, 2019

The XML Format check examines the XML format of incoming requests and blocks those requests that are not well formed or that do not meet the criteria in the XML specification for properly-formed XML documents. Some of those criteria are:

- An XML document must contain only properly-encoded Unicode characters that match the Unicode specification.
- No special XML syntax characters—such as <, > and &—can be included in the document except when used in XML markup.
• All begin, end, and empty-element tags must be correctly nested, with none missing or overlapping.
• XML element tags are case-sensitive. All beginning and end tags must match exactly.
• A single root element must contain all the other elements in the XML document.

A document that does not meet the criteria for well-formed XML does not meet the definition of an XML document. Strictly speaking, it is not XML. However, not all XML applications and web services enforce the XML well-formed standard, and not all handle poorly-formed or invalid XML correctly. Inappropriate handling of a poorly-formed XML document can cause security breaches. The purpose of the XML Format check is to prevent a malicious user from using a poorly-formed XML request to breach security on your XML application or web service.

If you use the wizard or the GUI, in the Modify XML Format Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Format Check:

```
set appfw profile <name> -xmlFormatAction [**block**] [**log**] [**stats**] [**none**]
```

You cannot configure exceptions to the XML Format check. You can only enable or disable it.

Copied!
Failed!

**XML Denial-of-Service check**

April 23, 2019

The XML Denial of Service (XML DoS or XDoS) check examines incoming XML requests to determine whether they match the characteristics of a denial-of-service (DoS) attack, and blocks those requests that do. The purpose of the XML DoS check is to prevent an attacker from using XML requests to launch a denial-of-service attack on your web server or web site.

If you use the wizard or the GUI, in the Modify XML Denial-of-Service Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Denial-of-Service check:

```
set appfw profile <name> -xmlDoSAction [**block**] [**log**] [**learn**] [**stats**] [**none**]
```
To configure individual XML Denial-of-Service rules, you must use the GUI. On the Checks tab of the Modify XML Denial-of-Service Check dialog box, select a rule and click Open to open the Modify XML Denial-of-Service dialog box for that rule. The individual dialog boxes differ for the different rules but are extremely simple. Some only allow you to enable or disable the rule; others allow you to modify a number by typing a new value in a text box.

The individual XML Denial-of-Service rules are:

- **Maximum Element Depth**
  Restrict the maximum number of nested levels in each individual element to 256. If this rule is enabled, and the Web App Firewall detects an XML request with an element that has more than the maximum number of allowed levels, it blocks the request. You can modify the maximum number of levels to any value from one (1) to 65,535.

- **Maximum Element Name Length**
  Restrict the maximum length of each element name to 128 characters. This includes the name within the expanded namespace, which includes the XML path and element name in the following format:

```
{ http://prefix.example.com/path/ } target_page.xml
```

The user can modify the maximum name length to any value between one (1) character and 65,535.

- **Maximum # Elements**
  Restrict the maximum number of any one type of element per XML document to 65,535. You can modify the maximum number of elements to any value between one (1) and 65,535.

- **Maximum # Element Children**
  Restrict the maximum number of children (including other elements, character information, and comments) each individual element is allowed to have to 65,535. You can modify the maximum number of element children to any value between one (1) and 65,535.

- **Maximum # Attributes**
  Restrict the maximum number of attributes each individual element is allowed to have to 256. You can modify the maximum number of attributes to any value between one (1) and 256.

- **Maximum Attribute Name Length**
  Restrict the maximum length of each attribute name to 128 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.
• Maximum Attribute Value Length

Restrict the maximum length of each attribute value to 2048 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

• Maximum Character Data Length

Restrict the maximum character data length for each element to 65,535. You can modify the length to any value between one (1) and 65,535.

• Maximum File Size

Restrict the size of each file to 20 MB. You can modify the maximum file size to any value.

• Minimum File Size

Require that each file be at least 9 bytes in length. You can modify the minimum file size to any positive integer representing a number of bytes.

• Maximum # Entity Expansions

Limit the number of entity expansions allowed to the specified number. Default: 1024.

• Maximum Entity Expansion Depth

Restrict the maximum number of nested entity expansions to no more than the specified number. Default: 32.

• Maximum # Namespaces

Limit the number of namespace declarations in an XML document to no more than the specified number. Default: 16.

• Maximum Namespace URI Length

Limit the URL length of each namespace declaration to no more than the specified number of characters. Default: 256.

• Block Processing Instructions

Block any special processing instructions included in the request. This rule has no user-modifiable values.

• Block DTD

Block any document type definitions (DTD) included with the request. This rule has no user-modifiable values.

• Block External Entities

Block all references to external entities in the request. This rule has no user-modifiable values.

• SOAP Array Check

Enable or disable the following SOAP array checks:
- **Maximum SOAP Array Size.** The maximum total size of all SOAP arrays in an XML request before the connection is blocked. You can modify this value. Default: 20000000.

- **Maximum SOAP Array Rank.** The maximum rank or dimensions of any single SOAP array in an XML request before the connection is blocked. You can modify this value. Default: 16.

**XML cross-site scripting check**

February 12, 2020

The XML Cross-Site Scripting check examines the user requests for possible cross-site scripting attacks in the XML payload. If it finds a possible cross-site scripting attack, it blocks the request.

To prevent misuse of the scripts on your protected web services to breach security on your web services, the XML Cross-Site Scripting check blocks scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

The Web App Firewall offers various action options for implementing XML Cross-Site Scripting protection. You have the option to configure **Block**, **Log**, and **Stats** actions.

The Web App Firewall XML XSS check is performed on the payload of the incoming requests and attack strings are identified even if they are spread over multiple lines. The check looks for XSS attack strings in the **element** and the **attribute** values. You can apply relaxations to bypass security check inspection under specified conditions. The logs and statistics can help you identify needed relaxations.

The CDATA section of the XML payload might be an attractive area of focus for the hackers because the scripts are not executable outside the CDATA section. A CDATA section is used for content that is to be treated entirely as character data. HTML mark up tag delimiters `<`, `>`, and `/>` will not cause the parser to interpret the code as HTML elements. The following example shows a CDATA Section with XSS attack string:

```xml
1   <![CDATA[rn
2   <script language="Javascript" type="text/javascript">alert ("Got you")</script>rn
```
Action Options

An action is applied when the XML Cross-Site Scripting check detects an XSS attack in the request. The following options are available for optimizing XML Cross-Site Scripting protection for your application:

- **Block**—Block action is triggered if the XSS tags are detected in the request.
- **Log**—Generate log messages indicating the actions taken by the XML Cross-Site Scripting check. If block is disabled, a separate log message is generated for each location (ELEMENT, ATTRIBUTE) in which the XSS violation is detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
- **Stats**—Gather statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

Relaxation Rules

If your application requires you to bypass the Cross-Site Scripting check for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML Cross-Site Scripting check relaxation rules have the following parameters:

- **Name**—You can use literal strings or regular expressions to configure the name of the ELEMENT or the Attribute. The following expression exempts all ELEMENTS beginning with the string name_ followed by a string of uppercase or lowercase letters, or numbers, that is at least two and no more than fifteen characters long:

    ```regex
    ^name_[0-9A-Za-z]{ 2,15 }
    ```

**Note**

The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

1. **XMLXSS**: ABC IsRegex: NOTRESEX Location: ATTRIBUTE State: ENABLED
2. **XMLXSS**: ABC IsRegex: NOTRESEX Location: ELEMENT State: ENABLED
3. **XMLXSS**: abc  
   **IsRegex**: NOTREGEX  
   **Location**: ELEMENT  
   **State**: ENABLED

4. **XMLXSS**: abc  
   **IsRegex**: NOTREGEX  
   **Location**: ATTRIBUTE  
   **State**: ENABLED

- **Location**—You can specify the Location of the Cross-site Scripting Check exception in your XML payload. The option ELEMENT is selected by default. You can change it to ATTRIBUTE.
- **Comment**—This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.

**Warning**

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML Cross-Site Scripting check would otherwise have blocked.

**Using the Command Line to Configure the XML Cross-Site Scripting check**

To configure XML Cross-Site Scripting check actions and other parameters by using the command line.

If you use the command-line interface, you can enter the following commands to configure the XML Cross-Site Scripting Check:

```bash
> set appfw profile <name> -XMLXSSAction ([block] [log] [stats])| [none])
```

To configure a XML Cross-Site Scripting check relaxation rule by using the command line.

You can add relaxation rules to bypass inspection of XSS script attack inspection in a specific location. Use the bind or unbind command to add or delete the relaxation rule binding, as follows:

```bash
bind appfw profile <name> -XMLXSS <string> [isRegex (REGEX | NOTREGEX)] [-location ( ELEMENT | ATTRIBUTE )] -comment <string> [-state ( ENABLED | DISABLED )]
```  

```bash
unbind appfw profile <name> -XMLXSS <String>
```

**Example:**

```bash
> bind appfw profile test_pr -XMLXSS ABC
```

After executing the above command, the following relaxation rule is configured. The rule is enabled, the name is treated as a literal (NOTREGEX), and ELEMENT is selected as the default location:

```
1)  XMLXSS:  ABC  IsRegex:  NOTREGEX
```
Using the GUI to configure the XML Cross-Site scripting check

In the GUI, you can configure the XML Cross-Site scripting check in the pane for the profile associated with your application.

To configure or modify the XML Cross-Site Scripting check by using the GUI

1. Navigate to Web App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a) If you just want to enable or disable Block, Log, and Stats actions for the XML Cross-Site Scripting check, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b) You can double click XML Cross-Site Scripting, or select the row and click Action Settings, to display the action options. After changing any of the action settings, click OK to save the changes and return to the Security Checks table.

You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section, and then click Save and Close to close the Security Check pane.

To configure a XML Cross-Site Scripting relaxation rule by using the GUI

1. Navigate to Web App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Relaxation Rules.
3. In the Relaxation Rules table, double-click the XML Cross-Site Scripting entry, or select it and click Edit.
4. In the XML Cross-Site Scripting Relaxation Rules dialogue box, perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.
To manage XML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **XML Cross-Site Scripting** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of XSS allowed attributes or allowed tags. You can also view or customize the default list of XSS denied Patterns.

The default lists are specified in **Web App Firewall > Signatures > Default Signatures**. If you do not bind any signature object to your profile, the default XSS Allowed and Denied list specified in the Default Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the Allowed or Denied lists in the new user-defined signature object and use this signature object in the profile that is processing the traffic for which you want to use these customized allowed and denied lists.

For more information about signatures, see [http://support.citrix.com/proddocs/topic/ns-security-10-map/appfw-signatures-con.html](http://support.citrix.com/proddocs/topic/ns-security-10-map/appfw-signatures-con.html).

**To view default XSS patterns:**

1. Navigate to **Web App Firewall > Signatures**, select **Default Signatures**, and click **Edit**. Then click **Manage SQL/XSS Patterns**.

The **Manage SQL/XSS Paths** table shows following three rows pertaining to XSS:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>xss/allowed/attribute</td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>xss/allowed/tag</td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>xss/denied/pattern</td>
</tr>
</tbody>
</table>

Select a row and click **Manage Elements** to display the corresponding XSS Elements (Tag, Attribute, Pattern) used by the Web App Firewall **Cross-Site Scripting** check.

**To customize XSS Elements**: You can edit the user-defined signature object to customize the allowed Tag, allowed Attributes and denied Patterns. You can add new entries or remove the existing ones.

1. **Navigate to Web App Firewall > Signatures**, highlight the target user-defined signature, and click **Edit**. Click **Manage SQL/XSS Patterns** to display the **Manage SQL/XSS paths** table.
2. Select the target XSS row.

a) Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding XSS element.
b) Click **Remove** to remove the selected row.

**Warning**

Be very careful when you remove or modify any default XSS element, or delete the XSS path to remove the entire row. The signatures, HTML Cross-Site Scripting security check, and XML Cross-Site Scripting security check rely on these Elements for detecting attacks to protect your applications. Customizing the XSS Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.

**Using the log feature with the XML cross-site scripting check**

When the log action is enabled, the XML Cross-Site Scripting security check violations are logged in the audit log as **APPFW_XML_XSS** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.log in the /var/log/ folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

```
1 > **Shell**
2
3 > **tail -f /var/log/ns.log | grep APPFW_XML_XSS**
```

**Example of a XML Cross-Site Scripting security check violation log message in Native log format showing <blocked> action**

```
```

**Example of a XML Cross-Site Scripting security check violation log message in CEF log format showing <not blocked> action**

```
1 Oct 7 01:46:52 <local0.warn> 10.217.31.98 CEF:0|Citrix|Citrix ADC|NS11.0|APPFW|APPFW_XML_XSS|4|src=10.217.30.17 geolocation=Unknown spt=33141 method=GET request=http://10.217.31.101/FFC/login.html msg=Cross-site script check failed for field script="Bad tag: script" cn1=1607 cn2=3538 cs1=owa_profile cs2=PPE0 cs4=ERROR cs5=2015 act=**not blocked**
```

To access the log messages by using the GUI
The Citrix GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Web App Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the XML Cross-Site Scripting row and click **Logs**. When you access the logs directly from the XML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to **Citrix ADC > System > Auditing**. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

- Navigate to **Web App Firewall > policies > Auditing**. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the XML Cross-Site Scripting check, filter by selecting **APPFW** in the dropdown options for **Module**. The **EventType** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_XML_XSS** check box and click the **Apply** button, only log messages pertaining to the XML Cross-Site Scripting security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **EventType**, **Event ID**, **Client IP** etc. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

**Statistics for the XML cross-site scripting violations**

When the stats action is enabled, the counter for the XML Cross-Site Scripting check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three XML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML Cross-Site Scripting check statistics by using the command line

At the command prompt, type:

```
> **sh appfw stats**
```
To display stats for a specific profile, use the following command:

> **stat appfw profile** <profile name>

To display XML Cross-Site Scripting statistics by using the GUI

1. Navigate to **System > Security > Web App Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about XML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

XML SQL injection check

February 12, 2020

The XML SQL injection check examines the user requests for possible XML SQL Injection attacks. If it finds injected SQL in XML payloads, it blocks the requests.

A XML SQL attack can inject source code into a web application such that it can be interpreted and executed as a valid SQL query to perform a database operation with malicious intent. For example, XML SQL attacks can be launched to gain unauthorized access to the contents of a database or to manipulate the stored data. XML SQL Injection attacks are not only common, but can also be very harmful and costly.

Compartmentalizing the privileges of the database users can assist in protecting the database to some extent. All database users should be given only the required privileges to complete their intended tasks, so that they cannot execute SQL queries to perform other tasks. For example, a read-only user should not be allowed to write or manipulate data tables. The Web App Firewall XML SQL Injection check inspects all XML requests to provide special defenses against injection of unauthorized SQL code that might break security. If the Web App Firewall detects unauthorized SQL code in any XML request of any user, it can block the request.

The Citrix Web Web App Firewall inspects the presence of SQL keywords and special characters to identify the XML SQL Injection attack. A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch XML SQL attacks. The Web App Firewall considers three characters, single straight quote (‘), backslash (\), and semicolon (;) as special characters for SQL security check processing. You can add new patterns, and you can edit the default set to customize the XML SQL check inspection.

The Web App Firewall offers various action options for implementing XML SQL Injection protection.
You can **Block** the request, **Log** a message in the ns.log file with details regarding the observed violations, and collect **Stats** to keep track of the number of observed attacks.

In addition to actions, there are several parameters that can be configured for XML SQL injection processing. You can check for **SQL wildcard characters**. You can change the XML SQL Injection type and select one of the 4 options (*SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, SQLSplCharORKeyword*) to indicate how to evaluate the SQL keywords and SQL special characters when processing the XML payload. The XML **SQL Comments Handling** parameter gives you an option to specify the type of comments that need to be inspected or exempted during XML SQL Injection detection.

You can deploy relaxations to avoid false positives. The Web App Firewall XML SQL check is performed on the payload of the incoming requests, and attack strings are identified even if they are spread over multiple lines. The check looks for SQL injection strings in the **element** and the **attribute** values. You can apply relaxations to bypass security check inspection under specified conditions. The logs and statistics can help you identify needed relaxations.

**Action options**

An action is applied when the XML SQL Injection check detects an SQL Injection attack string in the request. The following actions are available for configuring an optimized XML SQL Injection protection for your application:

**Block**—If you enable block, the block action is triggered only if the input matches the XML SQL injection type specification. For example, if *SQLSplCharANDKeyword* is configured as the XML SQL injection type, a request is not blocked if it does not contain any key words, even if SQL special characters are detected in the payload. Such a request is blocked if the XML SQL injection type is set to either *SQLSplChar*, or *SQLSplCharORKeyword*.

**Log**—If you enable the log feature, the XML SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each location (**ELEMENT, ATTRIBUTE**) in which the XML SQL violation was detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

**Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.
XML SQL parameters

In addition to the block, log and stats actions, you can configure the following parameters for XML SQL Injection check:

Check for XML SQL wildcard Characters—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with LIKE and NOT LIKE operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```sql
SELECT * from customer WHERE name like "%D%"
```

The following example combines the operators to find any salary values that have 0 as the second and third character.

```sql
SELECT * from customer WHERE salary like '._00%
```

Different DBMS vendors have extended the wildcard characters by adding extra operators. The Citrix Web Web App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (^), opening square bracket ([), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the *Default Signatures:

```
1 - <wildchar type="LITERAL" >%</wildchar>
2 - <wildchar type="LITERAL" >_</wildchar>
3 - <wildchar type="LITERAL" >^</wildchar>
4 - <wildchar type="LITERAL" >[</wildchar>
5 - <wildchar type="LITERAL" >]></wildchar>
```

Wildcard characters in an attack can be PCRE, like [^A-F]. The Web App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

Note

The XML SQL wildcard character check is different from the XML SQL special character check. This option must be used with caution to avoid false positives.

Check Request Containing SQL Injection Type—The Web App Firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:
• **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the inspected location to trigger SQL violation. This least restrictive setting is also the default setting.

• **SQL Special Character**—At least one of the special characters must be present in the processed payload string to trigger SQL violation.

• **SQL keyword**—At least one of the specified SQL keywords must be present in the processed payload string to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.

• **SQL Special Character or Keyword**—Either the keyword or the special character string must be present in the payload to trigger the security check violation.

**Tip**

If you select the SQL Special Character option, the Web App Firewall skips strings that do not contain any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the Web App Firewall and speed up processing without placing your protected web sites at risk.

**SQL comments handling**—By default, the Web App Firewall parses and checks all comments in XML data for injected SQL commands. Many SQL servers ignore anything in a comment, even if preceded by an SQL special character. For faster processing, if your XML SQL server ignores comments, you can configure the Web App Firewall to skip comments when examining requests for injected SQL. The XML SQL comments handling options are:

• **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.

• **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server.

• **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.

• **Check all Comments**—Check the entire request for injected SQL, without skipping anything. This is the default setting.

**Tip**

In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.
Relaxation rules

If your application requires you to bypass the XML SQL Injection inspection for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML SQL Injection inspection relaxation rules have the following parameters:

- **Name**: You can use literal strings or regular expressions to configure the name of the ELEMENT or the ATTRIBUTE. The following expression exempts all ELEMENTS beginning with the string `PurchaseOrder_` followed by a string of numbers that is at least two and no more than ten characters long:

  Comment: “Exempt XML SQL Check for Purchase Order Elements”

```
1 XMLSQLInjection: "PurchaseOrder_[0-9A-Za-z]{2,10}
2   
3 IsRegex: REGEX   Location: ELEMENT
4 State: ENABLED
```

**Note**: The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

```
1 1) XMLSQLInjection: XYZ   IsRegex: NOTREGEX
2   Location: ELEMENT   State: ENABLED
3 2) XMLSQLInjection: xyz   IsRegex: NOTREGEX
4   Location: ELEMENT   State: ENABLED
5 3) XMLSQLInjection: xyz   IsRegex: NOTREGEX
6   Location: ATTRIBUTE  State: ENABLED
7 4) XMLSQLInjection: XYZ   IsRegex: NOTREGEX
8   Location: ATTRIBUTE  State: ENABLED
```

- **Location**: You can specify the Location of the XML SQL Inspection exception in your XML payload. The option **ELEMENT** is selected by default. You can change it to **ATTRIBUTE**.
- **Comment**: This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.
Warning

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML SQL Injection inspection would otherwise have blocked.

Using the command line to configure the XML SQL Injection Check

To configure XML SQL Injection actions and other parameters by using the command line:

In the command line interface, you can use either the `set appfw profile` command or the `add appfw profile` command to configure the XML SQL Injection protections. You can enable the block, log, and stats action(s). Select the type of SQL attack pattern (key words, wildcard characters, special strings) you want to detect in the payloads. Use the `unset appfw profile` command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

- `set appfw profile <name> XMLSQLInjectionAction (([block] [log] [stats])| [none])`
- `set appfw profile <name> XMLSQLInjectionCheckSQLWildChars (ON |OFF)`
- `set appfw profile <name> XMLSQLInjectionType ([SQLKeyword] | [SQLSplChar] | [SQLSplCharANDKeyword] | [SQLSplCharORKeyword])`
- `set appfw profile <name> XMLSQLInjectionParseComments ([checkall] | [ansi|nested] | [ansinested])`

To configure a SQL Injection relaxation rule by using the command line

Use the bind or unbind command to add or delete relaxation rules, as follows:

```plaintext
1 - bind appfw profile <name> -XMLSQLInjection <string> [isRegex (REGEX | NOTREGEX)] [-location ( ELEMENT | ATTRIBUTE )] -comment <string> [-state ( ENABLED | DISABLED )]
2 - unbind appfw profile <name> -XMLSQLInjection <String>
```

Example:

```plaintext
1 > bind appfw profile test_profile -XMLSQLInjection "PurchaseOrder_[0-9A-Za-z]{
2   2,15 }
3   " -isregex REGEX -location ATTRIBUTE
```
Using the GUI to configure the XML SQL injection security check

In the GUI, you can configure the XML SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the XML SQL Injection check by using the GUI

1. Navigate to **Web App Firewall** > **Profiles**, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you just want to enable or disable Block, Log, and Stats actions for XML SQL Injection, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b. If you want to configure additional options for this security check, double click XML SQL Injection, or select the row and click **Action Settings**, to display the following options:

   - **Check for SQL Wildcard Characters**—Consider SQL Wildcard characters in the payload to be attack patterns.
   - **Check Request Containing**—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.
   - **SQL Comments Handling**—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

   After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save** and **Close** to close the Security Check pane.

To configure a XML SQL Injection relaxation rule by using the GUI

1. Navigate to **Web App Firewall** > **Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **XML SQL Injection** entry, or select it and click **Edit**.
4. In the **XML SQL Injection Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

To manage XML SQL Injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **XML SQL Injection** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

**To view or customize the SQL Injection patterns by using the GUI:**

You can use the GUI to view or customize the SQL patterns.

The default SQL patterns are specified in **Web App Firewall > Signatures > *Default Signatures**. If you do not bind any signature object to your profile, the default SQL patterns specified in the Default Signatures object will be used by the profile for XML SQL Injection security check processing. The rules and patterns in the Default Signatures object are read-only. You cannot edit or modify them. If you want to modify or change these patterns, create a user-defined signature object by making a copy of the Default Signatures object and changing the SQL patterns. Use the user-defined signature object in the profile that processes the traffic for which you want to use these customized SQL patterns.

For more information, see **Signatures**.

**To view default SQL patterns:**

a. Navigate to **Web App Firewall > Signatures**, select ***Default Signatures**, and click **Edit**. Then click **Manage SQL/XSS Patterns**.

The Manage SQL/XSS Paths table shows following four rows pertaining to SQL Injection:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><strong>Injection</strong> (not_alphanum, SQL)/ Keyword</td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><strong>Injection</strong> (not_alphanum, SQL)/ specialstring</td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td><strong>Injection</strong> (not_alphanum, SQL)/ transformrules/transform</td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td><strong>Injection</strong> (not_alphanum, SQL)/ wildcard</td>
</tr>
</tbody>
</table>

b. Select a row and click **Manage Elements** to display the corresponding SQL patterns (keywords, special strings, transformation rules or the wildcard characters) used by the Web App Firewall SQL injection check.

**To customize SQL Patterns:** You can edit a user-defined signature object to customize the SQL key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the SQL special strings.
a. Navigate to **Web App Firewall > Signatures**, highlight the target user-defined signature, and click **Edit**. Click **Manage SQL/XSS Patterns** to display the **Manage SQL/XSS paths** table.

b. Select the target SQL row.

   i. Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding SQL element.

   ii. Click **Remove** to remove the selected row.

**Warning**

You must be very careful when removing or modifying any default SQL element, or deleting the SQL path to remove the entire row. The signature rules as well as the XML SQL Injection security check rely on these elements for detecting SQL Injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to XML SQL attacks if the required pattern is removed during editing.

**Using the log feature with the XML SQL injection check**

When the log action is enabled, the **XML SQL Injection** security check violations are logged in the audit log as **APPFW_XML_SQL** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

**To access the log messages by using the command line:**

Switch to the shell and tail the ns.log in the `/var/log/` folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

```bash
1  > Shell
2 3  > tail -f /var/log/ns.log | grep APPFW_XML_SQL
```

**To access the log messages by using the GUI**

The Citrix GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to **Web App Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **XML SQL Injection** row and click **Logs**. When you access the logs directly from the XML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to **System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
• Navigate to **Web App Firewall > Policies > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the **Syslog Viewer**, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **XML SQL Injection** check, filter by selecting **APPFW** in the dropdown options for **Module**. The **EventType** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_XML_SQL** check box and click the **Apply** button, only log messages pertaining to the **XML SQL Injection** security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **EventType**, **EventID**, and **ClientIP** appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

**Statistics for the XML SQL injection violations**

When the stats action is enabled, the counter for the **XML SQL Injection** check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three **XML SQL Injection** violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML SQL Injection check statistics by using the command line

At the command prompt, type:

```bash
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```bash
> stat appfw profile <profile name>
```

To display XML SQL Injection statistics by using the GUI

1. Navigate to **System > Security > Web App Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about **XML SQL Injection** violations and logs. The statistics table provides real-time data and is updated every 7 seconds.
XML attachment check

March 11, 2020

The XML Attachment check examines incoming requests for malicious attachments, and it blocks those requests that contain attachments that might breach applications security. The purpose of the XML Attachment check is to prevent an attacker from using an XML attachment to breach security on your server.

If you use the wizard or the GUI, in the Modify XML Attachment Check dialog box, on the General tab you can enable or disable the Block, Learn, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Attachment Check:

```
set appfw profile <name> -xmlAttachmentAction [block] [learn] [log] [stats] [none]
```

You must configure the other XML Attachment check settings in the GUI. In the Modify XML Attachment Check dialog box, on the Checks tab, you can configure the following settings:

- **Maximum Attachment Size.** Allow attachments that are no larger than the maximum attachment size you specify. To enable this option, first select the Enabled check box, and then type the maximum attachment size in bytes in the Size text box.

- **Attachment Content Type.** Allow attachments of the specified content type. To enable this option, first select the Enabled check box, and then enter a regular expression that matches the Content-Type attribute of the attachments that you want to allow.
  - You can type the URL expression directly in the text window. If you do so, you can use the Regex Tokens menu to enter a number of useful regular expressions at the cursor instead of typing them manually.
  - You can click Regex Editor to open the Add Regular Expression dialog box and use it to construct the URL expression.

Web services interoperability check

February 12, 2020

The Web Services Interoperability (WS-I) check examines both requests and responses for adherence to the WS-I standard, and blocks those requests and responses that do not adhere to this standard.
The purpose of the WS-I check is to block requests that might not interact with other XML appropriately. An attacker can use inconsistencies in interoperability to launch an attack on your XML application.

If you use the wizard or the GUI, in the Modify Web Services Interoperability Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions.

If you use the command-line interface, you can enter the following command to configure the Web Services Interoperability check:

```
set appfw profile <name> -xmlWSIAction [block] [log] [learn] [stats] [none]
```

To configure individual Web Services Interoperability rules, you must use the GUI. On the Checks tab of the Modify Web Services Interoperability Check dialog box, select a rule and click Enable or Disable to enable or disable the rule. You can also click Open to open the Web Services Interoperability Detail message box for that rule. The message box displays read-only information about the rule. You cannot modify or make other configuration changes to any of these rules.

The WS-I check uses the rules listed in WS-I Basic Profile 1.0. WS-I delivers best practices for developing interoperable Web Services solutions. WS-I checks are performed only on SOAP Messages.

Description of each WSI standard rule is provided below:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BP1201</td>
<td>Message body should be a soap:envelope with namespace.</td>
</tr>
<tr>
<td>R1000</td>
<td>When an ENVELOPE is a Fault, the soap:Fault element MUST NOT have element children other than faultcode, faultstring, faultactor and detail.</td>
</tr>
<tr>
<td>R1001</td>
<td>When an ENVELOPE is a Fault, the element children of the soap:Fault element MUST be unqualified.</td>
</tr>
<tr>
<td>R1003</td>
<td>A RECEIVER MUST accept fault messages that have any number of qualified or unqualified attributes, including zero, appearing on the detail element. The namespace of qualified attributes can be anything other than the namespace of the qualified document element Envelope.</td>
</tr>
<tr>
<td>Rule</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>R1004</td>
<td>When an ENVELOPE contains a faultcode element, the content of that element SHOULD be either one of the fault codes defined in SOAP 1.1 (supplying additional information if necessary in the detail element), or a QName whose namespace is controlled by the fault’s specifying authority (in that order of preference).</td>
</tr>
<tr>
<td>R1005</td>
<td>An ENVELOPE MUST NOT contain soap:encodingStyle attribute on any of the elements whose namespace is the same as the namespace of the qualified document element Envelope.</td>
</tr>
<tr>
<td>R1006</td>
<td>An ENVELOPE MUST NOT contain soap:encodingStyle attributes on any element that is a child of soap:Body.</td>
</tr>
<tr>
<td>R1007</td>
<td>An ENVELOPE described in an rpc-literal binding MUST NOT contain soap:encodingStyle attribute on any element that is a grandchild of soap:Body.</td>
</tr>
<tr>
<td>R1011</td>
<td>An ENVELOPE MUST NOT have any element children of soap:Envelope following the soap:Body element.</td>
</tr>
<tr>
<td>R1012</td>
<td>A MESSAGE MUST be serialized as either UTF-8 or UTF-16.</td>
</tr>
<tr>
<td>R1013</td>
<td>An ENVELOPE containing a soap:mustUnderstand attribute MUST only use the lexical forms 0 and 1.</td>
</tr>
<tr>
<td>R1014</td>
<td>The children of the soap:Body element in an ENVELOPE MUST be namespace qualified.</td>
</tr>
<tr>
<td>R1015</td>
<td>A RECEIVER MUST generate a fault if they encounter an envelope whose document element is not soap:Envelope.</td>
</tr>
<tr>
<td>Rule</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>R1031</td>
<td>When an ENVELOPE contains a faultcode element the content of that element SHOULD NOT use of the SOAP 1.1 dot notation to refine the meaning of the fault.</td>
</tr>
<tr>
<td>R1032</td>
<td>The soap:Envelope, soap:Header, and soap:Body elements in an ENVELOPE MUST NOT have attributes in the same namespace as that of the qualified document element Envelope.</td>
</tr>
<tr>
<td>R1109</td>
<td>The value of the SOAPAction HTTP header field in a HTTP request MESSAGE MUST be a quoted string.</td>
</tr>
<tr>
<td>R1111</td>
<td>An INSTANCE SHOULD use a 200 OK HTTP status code on a response message that contains an envelope that is not a fault.</td>
</tr>
<tr>
<td>R1126</td>
<td>An INSTANCE MUST return a 500 Internal Server Error HTTP status code if the response envelope is a Fault.</td>
</tr>
<tr>
<td>R1132</td>
<td>A HTTP request MESSAGE MUST use the HTTP POST method.</td>
</tr>
<tr>
<td>R1140</td>
<td>A MESSAGE SHOULD be sent using HTTP/1.1.</td>
</tr>
<tr>
<td>R1141</td>
<td>A MESSAGE MUST be sent using either HTTP/1.1 or HTTP/1.0.</td>
</tr>
<tr>
<td>R2113</td>
<td>An ENVELOPE MUST NOT include the soapenc:arrayType attribute.</td>
</tr>
<tr>
<td>R2211</td>
<td>An ENVELOPE described with an rpc-literal binding MUST NOT have the xsi:nil attribute with a value of 1 or true on the part accessors.</td>
</tr>
<tr>
<td>R2714</td>
<td>For one-way operations, an INSTANCE MUST NOT return a HTTP response that contains an envelope. Specifically, the HTTP response entity-body must be empty.</td>
</tr>
</tbody>
</table>
XML message validation check

February 12, 2020

The XML Message Validation check examines requests that contain XML messages to ensure that they are valid. If a request contains an invalid XML message, the Web App Firewall blocks the request. The purpose of the XML Validation check is to prevent an attacker from using specially constructed invalid XML messages to breach the security of your application.

If you use the wizard or the GUI, in the Modify XML Message Validation Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.
If you use the command-line interface, you can enter the following command to configure the XML Message Validation Check:

```
set appfw profile <name> -xmlValidationAction [**block**] [**log**] [**stats**] [**none**]
```

You must use the GUI to configure the other XML Validation check settings. In the Modify XML Message Validation Check dialog box, on the Checks tab, you can configure the following settings:

- **XML Message Validation.** Use one of the following options to validate the XML message:
  - **SOAP Envelope.** Validate only the SOAP envelope of XML messages.
  - **WSDL.** Validate XML messages by using an XML SOAP WSDL. If you choose WSDL validation, in the WSDL Object drop-down list you must choose a WSDL. If you want to validate against a WSDL that has not already been imported to the Web App Firewall, you can click the Import button to open the Manage WSDL Imports dialog box and import your WSDL. See WSDL for more information.
  * If you want to validate the entire URL, leave the Absolute radio button in the End Point Check button array selected. If you want to validate only the portion of the URL after the host, select the Relative radio button.
  * If you want the Web App Firewall to enforce the WSDL strictly, and not allow any additional XML headers not defined in the WSDL, you must clear the Allow additional headers not defined in the WSDL check box.
  Caution: If you uncheck the Allow Additional Headers not defined in the WSDL check box, and your WSDL does not define all XML headers that your protected XML application or Web 2.0 application expects or that a client sends, you may block legitimate access to your protected service.
  - **XML Schema.** Validate XML messages by using an XML schema. If you choose XML schema validation, in the XML Schema Object drop-down list you must choose an XML schema. If you want to validate against an XML schema that has not already been imported to the Web App Firewall, you can click the Import button to open the Manage XML Schema Imports dialog box and import your WSDL. See WSDL for more information.

- **Response Validation.** By default, the Web App Firewall does not attempt to validate responses. If you want to validate responses from your protected application or Web 2.0 site, select the Validate Response check box. When you do, the Reuse the XML Schema specified in request validation check box and the XML Schema Object drop-down list are activated.
  - Check the Reuse XML Schema check box to use the schema you specified for request validation to do response validation as well.
  Note: If you check this check box, the XML Schema Object drop-down list is grayed out.
  - If you want to use a different XML schema for response validation, use the XML Schema
Object drop-down list to select or upload that XML schema.

XML SOAP fault filtering check

April 23, 2019

The XML SOAP fault filtering check examines responses from your protected web services and filters out XML SOAP faults. This prevents leaking of sensitive information to attackers.

If you use the wizard or the GUI, in the Modify XML SOAP Fault Filtering Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the Remove action, which removes SOAP faults before forwarding the response to the user.

If you use the command-line interface, you can enter the following command to configure the XML SOAP Fault Filtering Check:

```bash
set appfw profile <name> -XMLSOAPFaultAction [block] [log] [stats] [none]
```

You cannot configure exceptions to the XML SOAP Fault Filtering check. You can only enable or disable it.

JSON Protection Checks

June 17, 2020

Citrix Web App Firewall protects your JSON applications from content-level DoS, SQL, or cross-site scripting attacks. When an JSON request has a DoS, SQL, or cross-site scripting attack, you must protection your application by configuring limits on JSON structures such as arrays and strings.

**Note:**

The JSON security checks apply only to content that is sent with a JSON content-type header. If the content-type header is missing, or is set to a different value, all JSON security checks are bypassed. If you want to protect your JSON applications, the webmasters of each web server that hosts those applications must ensure a proper JSON content-type header is sent.
JSON Denial-of-Service protection check

August 26, 2019

The JSON denial-of-service (DoS) check examines an incoming JSON request and validates if there is any data that matches the characteristics of a DoS attack. If the request had JSON violations, the appliance blocks the request, logs the data, sends an SNMP alert, and also displays a JSON error page. The purpose of the JSON DoS check is to prevent an attacker from sending JSON request to launch DoS attacks on your JSON applications or website.

When a client sends a request to a Citrix ADC appliance, the JSON parser parses the request payload and if a violation is observed, the appliance enforces constraints on the JSON structure. The constraint enforces a size limit on the JSON request. As a result, if any JSON violation was observed, the appliance applies an action and responds with the JSON error page.

JSON DoS rules

When the appliance receives a JSON request, The JSON DOS protection enforces size limit on the following DoS parameters in the request payload.

1. maximum depth: Maximum nesting (depth) of JSON document. This check protects against documents that have excessive depth of hierarchy.
2. maximum document length: Maximum document length of JSON document.
3. maximum array length: Maximum array length in the any of JSON object. This check protects against arrays having large lengths.
4. maximum string length: Maximum string length in the JSON. This check protects against strings that have large length.
5. maximum object key count: Maximum key count in the any of JSON object. This check protects against objects that have large number of keys.
6. maximum object key length: Maximum key length in the any of JSON object. This check protects against objects that have large keys.

Following is a list of JSON DoS rules validated during JSON parsing.

1. JSONMaxContainerDepth. This check can be enabled by configuring the JSONMaxContainerDepth check and by default the option is OFF.
2. JSONMaxContainerDepth. This check can be enabled/disabled by configurable option JSONMaxContainerDepthCheck and default value could be changed by option JSONMaxContainerDepth. However, you can vary the maximum levels to a value ranging from 1 to 127. Default value: 5, Minimum value: 1, Maximum value: 127

3. JSONMaxDocumentLength. This check can be enabled by configuring the JSONMaxDocumentLength check and the default option is OFF.

4. JSONMaxDocumentLength. This check can be enabled by configuring the JSONMaxDocumentLength check and the default length is set to 20000000 bytes. Minimum value: 1, Maximum value: 2147483647

5. JSONMaxObjectKeyCount. The rule validates if the JSON maximum object key count check is turned on or off. Possible values: ON, OFF, Default value: OFF

6. JSONMaxObjectKeyCount. This check can be enabled by configuring the JSONMaxObjectKeyCount check. The check protects against objects that have large number of keys and the default value is set to 1000 bytes. Minimum value: 0, Maximum value: 2147483647

7. JSONMaxObjectKeyLength. This check can be enabled by configuring the JSONMaxObjectKeyLength check. The rule validates if the JSON maximum object key length check is turned on or off. By default it is turned OFF.

8. JSONMaxObjectKeyLength. The check protects against objects that have large key length. Default value: 128. Minimum value: 1, Maximum value: 2147483647

9. JSONMaxArrayLength. The rule validates if the JSON maximum array length check is ON or OFF. By default it is turned off.

10. JSONMaxArrayLength. The check protects against arrays that has large lengths. By default, the value is set to 10000. Minimum value: 1, Maximum value: 2147483647

11. JSONMaxStringLength. This check can be enabled by configuring the JSONMaxStringLength check. The check validates if the JSON maximum string length is ON or OFF. By default it is turned off.

12. JSONMaxStringLength. The check protects against strings that has large length. By default, it is set to 1000000. Minimum value: 1, Maximum value: 2147483647

**Configure JSON DoS protection check**

For configure JSON DoS protection, you must complete the following steps:

1. Add application firewall profile for JSON.
2. Set application firewall profile for JSON DoS settings.
3. Configure JSON DoS variables by binding the application firewall profile.
Add application firewall profile for JSON DoS protection

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON DoS attack.
At the command prompt, type:

```
add appfw profile <name> -type (HTML | XML | JSON)
```

*Note:*
When you set the profile type as JSON, other checks such as HTML or XML will not applicable.

**Example**

```
add appfw profile profile1 -type JSON
```

Set application firewall profile for JSON DoS protection

You must configure the profile for one or more JSON DoS actions and JSON DoS error object to be set on the application firewall profile.
At the command prompt, type:

```
set appfw profile <name> -JSONDoSAction [block] | [log] | [stats] | [none]
```

- Block - Block connections that violate this security check.
- Log - Log violations of this security check.
- Stats - Generate statistics for this security check.
- None - Disable all actions for this security check.

*Note:*
To enable one or more actions, type “set appfw profile -JSONDoSAction” followed by the actions to be enabled.

**Example**

```
set appfw profile profile1 -JSONDoSAction block log stat
```

Configure DoS variables by binding application firewall profile

To provide JSON DoS protection, you must bind the application firewall profile with JSON DoS settings.
At the command prompt, type:
bind appfw profile <name> -JSONDoSURL <expression> [-JSONMaxContainerDepthCheck
( ON | OFF )][-JSONMaxContainerDepth <positive_integer>]]] [-JSONMaxDocumentLengthCheck
( ON | OFF )][-JSONMaxDocumentLength <positive_integer>]]] [-JSONMaxObjectKeyCountCheck
( ON | OFF )][-SONMaxObjectKeyCount <positive_integer>]]] [-JSONMaxObjectKeyLengthCheck
( ON | OFF )][-JSONMaxObjectKeyLength <positive_integer>]]] [-JSONMaxArrayLengthCheck
( ON | OFF )][-JSONMaxArrayLength <positive_integer>]]] [-JSONMaxStringLengthCheck
( ON | OFF )][-JSONMaxStringLength <positive_integer>]]]

Example

bind appfw profile profile1 -JSONDoSURL ".*" -JSONMaxContainerDepthCheck ON

Note:
The JSON DoS checks will be applicable only if the profile type is selected as JSON. Also, the SQL,
XSS, Field format and Form field signatures are applied on Query parameters in cases of JSON
profile.

Import JSON errorpage

If an incoming request had a DoS attack and when you block the request, the appliance displays an
error message. For doing this, you must import the JSON error page.
At the command prompt, type:

import appfw jsonerrorpage <src> <name> [-comment <string>] [-overwrite]

Where,

src. URL (protocol, host, path, and name) for the location at which to store the imported JSON error
object.

Note:
The import fails if the object to be imported is on an HTTPS server that requires client certificate
authentication for access. This is a mandatory argument. Maximum Length: 2047.

Name. Name to assign to the JSON error object on the Citrix ADC. This is a mandatory argument.
Maximum Length: 31
Comment. Any comments to preserve information about the JSON error object. Maximum Length:
255
Overwrite. Overwrite any existing JSON error object of the same name.

Sample configuration
Add appfw prof profjson - type JSON

Bind appfw prof profjson - JSONDoSURL ".*" –
  JSONMaxDocumentLengthCheck ON -JSONMaxDocumentLength 30 -
  JSONMaxContainerDepthCheck ON -JSONMaxContainerDepth 3
  JSONMaxObjectKeyCountCheck ON -JSONMaxObjectKeyCount 4 -
  JSONMaxObjectKeyLengthCheck ON -JSONMaxObjectKeyLength 10 -
  JSONMaxArrayLengthCheck ON -JSONMaxArrayLength 5 -
  JSONMaxStringLengthCheck ON -JSONMaxStringLength 30

Sample Payloads, Log Messages and Counters:

Configure JSON DoS protection by using Citrix GUI

Follow the procedure below to set the JSON DoS protection settings.

1. On the navigation pane, navigate to Security > Profiles.
2. In the Profiles page, click Add.
3. In the Citrix Web App Firewall Profile page, click Security Checks under Advanced Settings.
4. In the Security Checks section, go to JSON Denial of Service settings.
5. Click the executable icon near the checkbox.

![Security Checks](Image)

6. Click **Action Settings** to access the **JSON Denial of Service Settings** page.

7. Select the JSON DoS action.

8. Click **OK**.

![JSON Denial of Service Settings](Image)

9. In the **Citrix Web App Firewall Profile** page, click **Relaxation Rules** under **Advanced Settings**.

10. In **Relaxation Rules** section, select **JSON Denial of Service** settings and click **Edit**.
11. In the Application Firewall JSON Denial of Service Check set the JSON DoS validation values.

12. Click OK.

13. In the Citrix Web App Firewall Profile page, click Profile Settings under Advanced Settings.
14. In the Profile Settings section, go to JSON Error Settings sub section to set JSON DoS error page.

![Profile Settings](image)

15. In the JSON Error Page Import Object page, set the following parameters:

   a) Import from. Import the error page as text, file or URL.

   b) URL. URL to redirect the user to the error page.

   1 File. Select a file to be imported as JSON DoS error file.

   c) Text. Enter the JSON file contents.

   d) Click Continue.

   e) File. Enter the file name.

   f) File Content. Add the error file content.

   g) Click OK.

![JSON Error Page Import Object](image)
16. Click **OK**.

17. Click **Done**.

**JSON SQL Injection protection check**

August 22, 2019

An incoming JSON request can have SQL injection in the form of partial SQL query strings or unauthorized commands in the code. This leads to stealing of data from the JSON database of your web servers. On receiving such request, the appliance blocks such request to protect your data.

Consider a scenario, where a client sends a JSON SQL request to a Citrix ADC appliance, the JSON parser parses the request payload and if an SQL Injection is observed, the appliance enforces constraints on the JSON SQL content. The constraint enforces a size limit on the JSON SQL request. As a result, if any JSON SQL Injection is observed, the appliance applies an action and responds with the JSON SQL error page.

**Configure JSON SQL Injection protection**

For configure JSON SQL protection, you must complete the following steps:

1. Add application firewall profile as JSON.
2. Set application firewall profile for JSON SQL Injection settings
3. Configure JSON SQL action by binding the application firewall profile.

**Add application firewall profile of type JSON**

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON SQL Injection attack.

At the command prompt, type:

```
add appfw profile <name> -type (HTML | XML | JSON)
```

*Note:*

When you set the profile type as JSON, other checks such as HTML or XML will not applicable.
Example

add appfw profile profile1 -type JSON

Configure JSON SQL Injection action

You must configure one or more JSON SQL Injection actions to protect your application against JSON SQL injection attacks.

At the command prompt, type:

```
set appfw profile <name> - JSONSQLInjectionAction [block] [log] [stats] [none]
```

SQL Injection actions are:
- Block - Block connections that violate this security check.
- Log - Log violations of this security check.
- Stats - Generate statistics for this security check.
- None - Disable all actions for this security check.

Configure JSON SQL Injection type

To configure the JSON SQL Injection type on an application firewall profile, at the command prompt, type:

```
set appfw profile <name> - JSONSQLInjectionType <JSONSQLInjectionType>
```

Example

```
set appfw profile profile1 -JSONSQLInjectionType SQLKeyword
```

Where the available SQL Injection types are:
- Available SQL injection types.
- SQLSplChar. Checks for SQL Special Characters.
- SQLKeyword. Checks for SQL Keywords.
- SQLSplCharANDKeyword. Checks for both and blocks if found.
- SQLSplCharORKeyword. Blocks if SQL special character or spl keyword is found.

Possible values:
- SQLSplChar
- SQLKeyword
- SQLSplCharORKeyword
- SQLSplCharANDKeyword

Note:
To enable one or more actions, type “set appfw profile - JSONSQLInjectionAction” followed by the actions to be enabled.
Example

```bash
set appfw profile profile1 -JSONSQLInjectionAction block log stat
```

The following example shows a sample payload, its corresponding log message and statistics counters:

```json
Payload:
=======
{
  "test": "data",
  "username": "waf",
  "password": "select * from t1;",
  "details": {
    "surname": "test",
    "age": "23"
  }
}

Log Message:
============

```

Configure JSON SQL Injection protection by using Citrix GUI

Follow the procedure below to set the JSON SQL Injection protection settings.

1. On the navigation pane, navigate to Security > Profiles.
2. In the Profiles page, click Add.
3. In the Citrix Web App Firewall Profile page, click Security Checks under Advanced Settings.
4. In the **Security Checks** section, go to **JSON SQL Injection** settings.

5. Click the executable icon near the check box.

6. Click **Action Settings** to access the **JSON SQL Injection Settings** page.

7. Select the **JSON SQL Injection** actions.

8. Click **OK**.

9. In the **Citrix Web App Firewall Profile** page, click **Relaxation Rules** under **Advanced Settings**.

10. In **Relaxation Rules** section, select **JSON SQL Injection** settings and click **Edit**.
11. In the JSON SQL Injection Relaxation Rule page, enter the URL to which the request has to be sent. All requests sent to this URL will not be blocked.

12. Click **Create**.
JSON Cross-Site Scripting protection check

August 23, 2019

If an incoming JSON payload has a malicious cross-site scripting data, WAF blocks the request. The following procedures explain how you can configure this through CLI and GUI interfaces.

Configure JSON Cross-Site Scripting protection

For configure JSON XSS protection, you must complete the following steps:

1. Add application firewall profile as JSON.
2. Configure JSON XSS action to block XSS malicious payload

Add application firewall profile of type JSON

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON XSS attack.

At the command prompt, type:
add appfw profile <name> -type (HTML | XML | JSON)

Note:
When you set the profile type as JSON, other checks such as HTML or XML will not applicable.

Example

add appfw profile profile1 -type JSON

Sample output for JSON XSS violation

| 1 | JSONXSSAction: block log stats |
| 2 | Payload: | |
| 3 | "username": "<a href="javascripT:alert(1)">X</a>", "password": "xyz" |

Log message: Aug 19 06:57:33 <local0.info> 10.106.102.21
08/19/2019:06:57:33 GMT 0-PPE-0 : default APPFW APPFW_JSON_XSS 58 0 :
10.102.1.98 12-PPE0 - profjson http://10.106.102.24/ Cross-site
script check failed for object value(with violation="Bad URL:
jAvAsCrIpT:alert(1)") starting at offset(12). <blocked>

Counters
1 357000 1 as_viol_json_xss
3 0 1 as_log_json_xss
5 0 1 as_viol_json_xss_profile appfw__(profjson)
7 0 1 as_log_json_xss_profile appfw__(profjson)

Configure JSON Cross-Site Scripting action

You must configure one or more JSON XSS actions to protection your application from JSON Cross-Site Scripting attacks.
At the command prompt, type:

set appfw profile <name> - JSONXSSAction [block] [log] [stats] [none]

Example

set appfw profile profile1 -JSONXSSAction block
The available Cross-Site Scripting actions are:
Block - Block connections that violate this security check.
Log - Log violations of this security check.
Stats - Generate statistics for this security check.
None - Disable all actions for this security check.

**Note:**
To enable one or more actions, type “set appfw profile - JSONXSSAction “ followed by the actions to be enabled.

**Example**

```
set appfw profile profile1 -JSONSQLInjectionAction block log stat
```

**Configure JSON Cross Site Scripting (XSS) protection by using Citrix GUI**

Follow the procedure below to set the Cross Site Scripting (XSS) protection settings.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **Citrix Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, go to **JSON Cross-Site Scripting (XSS)** settings.
5. Click the executable icon near the checkbox.
6. Click **Action Settings** to access the **JSON Cross-Site Scripting Settings** page.

7. Select the JSON XSS actions.

8. Click **OK**.

9. In the **Citrix Web App Firewall Profile** page, click **Relaxation Rules** under **Advanced Settings**.

10. In **Relaxation Rules** section, select JSON Cross-Site Scripting settings and click **Edit**.
11. In the **JSON Cross-Site Scripting Relaxation Rule** page, click **Add** to add a JSON Cross-Site Scripting relaxation rule.

12. Enter the URL to which the request has to be sent. All requests sent to this URL will not be blocked.

13. Click **Create**.
Managing content types

February 12, 2020

Web servers add a Content-Type header with a MIME/type definition for each content type. Web servers serve many different types of content. For example, standard HTML is assigned the “text/html” MIME type. JPG images are assigned the “image/jpeg” or “image/jpg” content type. A normal web server can serve different types of content, all defined in the Content Type header by the assigned MIME/type.

Many Web App Firewall filtering rules are designed to filter a specific content type. The filtering rules apply to one type of content such as HTML and are often inappropriate when filtering a different type of content (such as images). As a result, the Web App Firewall attempts to determine the content type of requests and responses before it filters them. If a web server or browser does not add a Content-Type header to a request or response, the Web App Firewall applies a default content type and filters content accordingly.

The default content type is usually “application/octet-stream” with the most generic MIME/type definition. The MIME/type is appropriate for any content type a web server is likely to serve. But does not
provide much information to the Web App Firewall to allow it to choose appropriate filtering. If a protected web server is configured to add accurate content type headers, you can then create a profile for the web server and assign a default content type to it. This is done to improve both the speed and the accuracy of filtering.

You can also configure a list of allowed request content types for a specific profile. When this feature is configured, if the Web App Firewall filters a request that does not match one of the allowed content types, it blocks the request. After upgrade from release 10.5 to 11.0, unknown content-types which are not in the default allowed content-type list do not bind. You can add other content-types which you want to be allowed to the relaxed rules.

Requests must always be of either the “application/x-www-form-urlencoded”, “multipart/form-data,” or “text/x-gwt-rpc” types. The Web App Firewall blocks any request that has any other content type designated.

You cannot include the “application/x-www-form-urlencoded” or “multipart/form-data” content types on the allowed response content types list.

To set the default request content type by using the command line interface

At the command prompt, type the following commands:

- set appfw profile <name> -requestContentType <type>
- save ns config

Example

The following example sets the “text/html” content type as the default for the specified profile:

```
1 set appfw profile profile1 -requestContentType "text/html"
2 save ns config
```

To remove the user-defined default request content type by using the command line interface

At the command prompt, type the following commands:

- unset appfw profile <name> -requestContentType <type>
- save ns config
Example

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```
1    unset appfw profile profile1 -requestContentType "text/html"
2    save ns config
```

Note

Always use last content-type header for processing and remove remaining content-type headers if any that ensures that the back-end server receives a request with only one content-type.

To block requests that can be bypassed, add a Web App Firewall policy with rule as HTTP.REQ.HEADER (“content-type”).COUNT.GT(1)’ and profile as `appfw_block`.

If a request is received without a Content-Type header or if the request has Content-Type header without any value, Web App Firewall applies the configured `RequestContentType` value and processes the request accordingly.

To set the default response content type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -responseContentType <type>`
- `save ns config`

Example

The following example sets the “text/html” content type as the default for the specified profile:

```
1    set appfw profile profile1 -responseContentType "text/html"
2    save ns config
```

To remove the user-defined default response content type by using the command line interface

At the command prompt, type the following commands:

- `unset appfw profile <name> -responseContentType <type>`
- `save ns config`
Example

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```bash
1 unset appfw profile profile1 -responseContentType "text/html"
2 save ns config
```

To add a content type to the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `bind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`

Example

The following example adds the “text/shtml” content type to the allowed content types list for the specified profile:

```bash
1 bind appfw profile profile1 -contentType "text/shtml"
2 save ns config
```

To remove a content type from the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `unbind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`

Example

The following example removes the “text/shtml” content type from the allowed content types list for the specified profile:

```bash
1 unbind appfw profile profile1 -contentType "text/shtml"
2 save ns config
```
Manage urlencoded and multipart-form content types

The Citrix ADC Web App Firewall now enables you to configure Urlencoded and Multipart-Form content types for forms. The content type configuration is similar to XML and JSON list. Based on the configuration, Web App Firewall classifies the requests and inspects for urlencoded or multipart-form content type.

To configure Web App Firewall profile with Urlencoded and Multipart-Form content types

At the command prompt, type:

```
bind appfw profile p2 -contentType <string>
```

**Example:**

```
bind appfw profile p2 -contentType UrlencodedFormContentType
bind appfw profile p2 -ContentType appfwmultipartform
```

To manage the default and allowed content types by using the GUI

2. In the details pane, select the profile that you want to configure, and then click Edit. The Configure Web App Firewall Profile dialog box is displayed.
3. The Configure Web App Firewall Profile dialog box, click the Settings tab.
4. On the Settings tab, scroll down about halfway to the Content Type area.
5. In the Content Type area, configure the default request or response content type:
   - To configure the default request content type, type the MIME/type definition of the content type you want to use in the Default Request text box.
   - To configure the default response content type, type the MIME/type definition of the content type you want to use in the Default Response text box.
   - To create a new allowed content type, click Add. The Add Allowed Content Type dialog box is displayed.
   - To edit an existing allowed content type, select that content type, and then click Open. The Modify Allowed Content Type dialog box is displayed.
6. To manage the allowed content types, click Manage Allowed Content Types.
7. To add a new content type or modify an existing content type, click Add or Open, and in the Add Allowed Content Type or Modify Allowed Content Type dialog box, do the following steps.
   - Select/clear the Enabled check box to include the content type in, or exclude it from, the list of allowed content types.
   - In the Content Type text box, type a regular expression that describes the content type that you want to add, or change the existing content type regular expression. Content types are formatted exactly as MIME type descriptions are.
Note:
You can include any valid MIME type on the allowed contents type list. Since many
types of document can contain active content and therefore can potentially contain
malicious content, you should exercise caution when adding MIME types to this list.
c) Provide a short description that explains the reason for adding this particular MIME type
to the allowed contents type list.
d) Click Create or OK to save your changes.
8. Click Close to close the Manage Allowed Content Types dialog box and return to the Settings
tab.
9. Click OK to save your changes.

To manage Urlencoded and Multipart-form content types by using the Citrix ADC GUI

2. In the details pane, select the profile that you want to configure, and then click Edit.
3. In the Configure Web App Firewall Profile page, select the Profile Settings in the Advanced
   Settings section.
4. Under Inspected Content Type section, set the following parameters:
   a) application/x-www-form-urlencoded. Select the checkbox to inspect Urlencoded content
type.
   b) multipart/form-data. Select the check to inspect Multipart-form content type.
5. Click OK.
Profiles

April 23, 2019

A profile is a collection of security settings that are used to protect specific types of web content or specific parts of your web site. In a profile, you determine how the Web App Firewall applies each of its filters (or checks) to requests to your web sites, and responses from them. The Web App Firewall supports two types of profile: four built-in (default) profiles that do not require further configuration, and user-defined profiles that do require further configuration.

Built-in profiles

The four Web App Firewall built-in profiles provide simple protection for applications and web sites that either do not require protection, or that should not be directly accessed by users at all. These profile types are:
Citrix ADC 13.0

- **APPFW_BYPASS.** Skips all Web App Firewall filtering and sends the unmodified traffic to the protected application or web site, or to the client.
- **APPFW_RESET.** Resets the connection, requiring that the client re-establish his or her session by visiting a designated start page.
- **APPFW_DROP.** Drops all traffic to or from the protected application or web site, and sends no response of any kind to the client.
- **APPFW_BLOCK.** Blocks traffic to or from the protected application or web site.

You use the built-in profiles exactly as you do user-defined profiles, by configuring a policy that selects the traffic to which you want to apply the profile and then associating the profile with your policy. Since you do not have to configure a built-in policy, it provides a quick way to allow or block specified types of traffic or traffic that is sent to specific applications or web sites.

**User-defined profiles**

User-defined profiles are profiles that are build and configured by users. Unlike the default profiles, you must configure a user-defined profile before it will be of use filtering traffic to and from your protected applications.

There are three types of user-defined profile:

- **HTML.** Protects HTML-based web pages.
- **XML.** Protects XML-based web services and web sites.
- **Web 2.0.** Protects Web 2.0 content that combines HTML and XML content, such as ATOM feeds, blogs, and RSS feeds.

The Web App Firewall has a number of security checks, all of which can be enabled or disabled, and configured in a number of ways in each profile. Each profile also has a number of settings that control how it handles different types of content. Finally, rather than manually configuring all of the security checks, you can enable and configure the learning feature. This feature observes normal traffic to your protected web sites for a period of time, and uses those observations to provide you with a tailored list of recommended exceptions (relaxations) to some security checks, and additional rules for other security checks.

During initial configuration, whether by using the Web App Firewall Wizard or manually, you normally create one general purpose profile to protect all content on your web sites that is not covered by a more specific profile. After that, you can create as many specific profiles as you want to protect more specialized content.

The Profiles pane consists of a table that contains the following elements:

**Name.** Displays all the Web App Firewall profiles configured in the appliance.

**Bound signature.** Displays the signatures object that is bound to the profile in the previous column, if any.
**Policies.** Displays the Web App Firewall policy that invokes the profile in the leftmost column of that row, if any.

**Comments.** Displays the comment associated with the profile in the leftmost column of that row, if any.

**Profile Type.** Displays the type of profile. Types are Built-In, HTML, XML, and Web 2.0.

Above the table is a row of buttons and a drop-down list that allow you to create, configure, delete, and view information about your profiles:

- **Add.** Add a new profile to the list.
- **Edit.** Edit the selected profile.
- **Delete.** Delete the selected profile from the list.
- **Statistics.** View the statistics for the selected profile.
- **Action.** Drop-down list that contains additional commands. Currently allows you to import a profile that was exported from another Web App Firewall configuration.

**Creating Web App Firewall profiles**

February 12, 2020

You can create an Web App Firewall profile in one of two ways: by using the command line, and by using the GUI. Creating a profile by using the command line requires that you specify options on the command line. The process is similar to that of configuring an profile, and with a few exceptions the two commands take the same parameters.

Creating a profile by using the GUI requires that you specify only two options. You specify basic or advanced defaults, the default configuration for the various security checks and settings that are part of a profile, and choose the profile type to match the type of content that the profile is intended to protect. You can also, optionally, add a comment. After you create the profile, you must then configure it by selecting it in the data pane, and then clicking **Edit.**

If you plan to use the learning feature or to enable and configure a large number of advanced protections, you should choose advanced defaults. In particular, if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check, you should plan to use the learning feature. Unless you include the proper exceptions for your protected Web sites when configuring these checks, they can block legitimate traffic. Anticipating all of the necessary exceptions without creating any that are
too broad is difficult. The learning feature makes this task much easier. Otherwise, basic defaults are quick and should provide the protection that your web applications need.

There are three profile types:

- **HTML.** Protects standard HTML-based web sites.
- **XML.** Protects XML-based web services and web sites.
- **Web 2.0 (HTML XML).** Protects sites that contain both HTML and XML elements, such as ATOM feeds, blogs, and RSS feeds.

There are also a few restrictions on the name that you can give to a profile. A profile name cannot be the same as the name assigned to any other profile or action in any feature on the NetScaler appliance. Certain action or profile names are assigned to built-in actions or profiles, and can never be used for user profiles. A complete list of disallowed names can be found in the Web App Firewall Profile Supplemental Information. If you attempt to create a profile with a name that has already been used for an action or a profile, an error message is displayed and the profile is not created.

**To create an Web App Firewall profile by using the command line interface**

At the command prompt, type the following commands:

- `add appfw profile <name> [-defaults ( *basic | *advanced )]`
- `set appfw profile <name> -type ( *HTML | *XML | *HTML XML )`
- `set appfw profile <name> -comment "<comment>"`
- `save ns config`

**Example**

The following example adds a profile named pr-basic, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
1 add appfw profile pr-basic -defaults basic -comment "Simple profile for web sites."
2 set appfw profile pr-basic -type HTML
3 save ns config
```

**To create an Web App Firewall profile by using the GUI**

Creating an Web App Firewall profile requires that you specify only a few configuration details.

1. Navigate to **Security > Application Firewall > Profiles.**
2. In the details pane, click **Add.**
3. In the **Create Web App Firewall Profile** dialog box, type a name for your profile.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

4. Choose the profile type from the drop-down list.

5. Click **Create**, and then click **Close**.

**Enforce HTTP RFC compliance**

February 12, 2020

Citrix Web App Firewall inspects the incoming traffic for HTTP RFC compliance and drops any request that has RFC violations by default. However, there are certain scenarios, where the appliance might have to bypass or block a non-RFC compliance request. In such cases, you can configure the appliance to bypass or block such requests at global or profile level.

**Block or bypass non-RFC compliant requests at global level**

The HTTP module tags a request as invalid if it is incomplete or invalid and such requests cannot be processed by WAF. For example, an incoming HTTP request having host header missing. To block or bypass such invalid requests, you must configure the “malformedReqAction” option in the application firewall global settings.

**Note:**

If you disable the “block” option in the “malformedReqAction” parameter, the appliance bypasses the entire app firewall processing for all non-RFC compliance requests and forwards the requests to the next module.

**To block or bypass invalid non-RFC complaint HTTP requests by using the command line interface**

To block or bypass invalid requests, enter the following command:

```
set appfw settings -malformedreqaction <action>
```

**Example:**
**Citrix ADC 13.0**

**set appfw settings -malformedReqAction block**

**To display malformed request action settings**

To display malformed request action settings, enter the following command:

`show appfw settings`

**Output:**

<table>
<thead>
<tr>
<th>DefaultProfile: APPFW_BYPASS</th>
<th>UndefAction: APPFW_BLOCK</th>
<th>SessionTimeout: 900</th>
<th>LearnRateLimit: 400</th>
<th>SessionLifetime: 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SessionCookieName: citrix_ns_id</td>
<td>ImportSizeLimit: 134217728</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CookiePostEncryptPrefix: ENC</td>
<td>GeoLocationLogging: OFF</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CEFLogging: OFF</td>
<td>EntityDecoding: OFF</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>UseConfigurableSecretKey: OFF</td>
<td>SessionLimit: 100000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MalformedReqAction: block log stats</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**To block or bypass invalid non-RFC complaint HTTP requests by using the Citrix ADC GUI**

1. Navigate to **Security > Citrix Web App Firewall**.
2. In the **Citrix Web App Firewall** page, click **Change Engine Settings** under **Settings**.
3. In the **Configure Citrix Web App Firewall Settings** page, select the **Log Malformed Request** option as Block, Log or Stats.
4. Click **OK** and **Close**.

**Note:**

If you unselect the “block” action or do not select any malformed request action, the appliance bypasses the request without intimating the user.

**Block or bypass non-RFC compliant requests at profile level**

Other non-RFC compliant requests can be configured to block or bypass at profile level. You must set the RFC profile either in “Block” or “Bypass” mode. By doing this, any invalid traffic that matches the Web App Firewall profile is either bypassed or blocked accordingly.

**Note:**

When you set the RFC profile in “Bypass” mode, you must make sure you disable the transformation option in the “HTML Cross-Site Scripting Settings” and in the “HTML SQL Injection Settings”
If you enable the option and set the rfc profile in “Bypass” mode, the appliance displays a warning message, “Transform cross-site scripts” and “Transform SQL special characters” are both currently ON. Recommend to turn it off when used with APPFW_RFC_BYPASS”.

**Important:**

Also, the appliance displays a warning note, “Appfw Security checks enabled might not be applicable to requests which violates RFC checks when this profile is set. Enabling any transformation setting is not recommended as requests might be partially transformed that contains RFC violations.”

**To configure RFC profile in the Web App Firewall profile by using the command line interface**

At the command prompt, type the following commands:

```
set appfw profile <profile_name> -rfcprofile <rfcprofile_name>
```

**Example**

```
set appfw profile P1 -rfcprofile APPFW_RFC_BLOCK
```

**Note:**

By default, the rfc profile is bound to the Web App Firewall profile in “Block” mode.

**To configure RFC profile in the Web App Firewall profile by using the GUI**

1. Navigate to **Security > Application Firewall > Profiles**.
2. In the **Profiles** page, select a profile and click **Edit**.
3. In the **Web App Firewall Profile** page, click **Profile settings** from **Advanced Settings** section.
4. In the **HTTP Settings** section, set the RFC profile in APPFW_RFC_BYPASS mode.

The system displays a warning message, “Appfw Security checks enabled might not be applicable to requests which violates RFC checks when this profile is set. Enabling any transformation setting is not recommended as requests might be partially transformed that contains RFC violations”.

```
Copied!
Failed!
```
Configuring Web App Firewall profiles

February 12, 2020

To configure a user-defined Web App Firewall profile, first configure the security checks, which are called deep protections or advanced protections in the Web App Firewall wizard. Certain checks require configuration if you are to use them at all. Others have default configurations that are safe but limited in scope; your web sites might need or benefit from a different configuration that takes advantage of additional features of certain security checks.

After you have configured the security checks, you can also configure a number of other settings that control the behavior, not of a single security check, but the Web App Firewall feature. The default configuration is sufficient to protect most web sites, but you should review them to make sure that they are right for your protected web sites.

For more information about the Web App Firewall security checks, see Advanced Protections.

To configure an Web App Firewall profile by using the command line

At the command prompt, type the following commands:

- `set appfw profile <name> <arg1> [<arg2> ...]
  
  where:
  - `<arg1>` = a parameter and any associated options.
  - `<arg2>` = a second parameter and any associated options.
  - `...` = additional parameters and options.
  
  For descriptions of the parameters to use when configuring specific security checks, see Advanced Protections.

- `save ns config`

Example

The following example shows how to enable blocking for the HTML SQL Injection and HTML Cross-Site Scripting checks in a profile named pr-basic. This command enables blocking for those actions while making no other changes to the profile.

```
set appfw profile pr-basic -crossSiteScriptingAction block -SQLInjectionAction block
```
To configure an Web App Firewall profile by using the GUI

1. Navigate to Security > Application Firewall > Profiles.

2. In the details pane, select the profile that you want to configure, and then click Edit.

3. In the Configure Web App Firewall Profile dialog box, on the Security Checks tab, configure the security checks.

   - To enable or disable an action for a check, in the list, select or clear the check box for that action.

   - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

     You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

   - To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.

     - To edit the exception or rule, and then add it to the list, click Edit & Deploy.

     - To accept the exception or rule without modification, click Deploy.

     - To remove the exception or rule from the list, click Skip.

   - To refresh the list of exceptions or rules to be reviewed, click Refresh.

   - open the Learning Visualizer and use it to review learned rules, click Visualizer.

   • review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see Logs, Statistics, and Reports.

   • To completely disable a check, in the list, clear all of the check boxes to the right of that check.

4. On the Settings tab, configure the profile settings.
• To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the **Signatures** drop-down list.

  **Note:**
  You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

• To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

  **Note:**
  You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see **Imports**.

• To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types. »More…

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in **Configuring and Using the Learning Feature**.

6. Click **OK** to save your changes and return to the **Profiles** pane.

---

**Web Application Firewall profile settings**

July 27, 2020

Following are the profile settings that you must configure on the appliance.

At the command prompt, type:

```
add appfw profile <name> [-invalidPercentHandling <invalidPercentHandling>]
 [-checkRequestHeaders ( ON | OFF )] [-URLDecodeRequestCookies ( ON | OFF )]
 [-optimizePartialReqs ( ON | OFF )] [-errorURL <expression>]
```

**Example:**

```
add appfw profile profile1 [-invalidPercentHandling secure_mode] [-checkRequestHeaders ON] [-URLDecodeRequestCookies OFF] [-optimizePartialReqs OFF]
```

Where,
invalidPercentHandling. Configure the method for handling percent-encoded names and values.

Available settings function as follows:

asp_mode - Strips and Parses Invalid Percent for Parsing. Example: `curl -v "http://<vip>/forms/login.html?field=sel%zzect"` -> Invalid percent encoded char(\%zz) is stripped of and the rest of the content is inspected and action taken for the SQLInjection check.

secure_mode - We detect the Invalid Percent coded value and ignore it. Example: `curl -v "http://<vip>/forms/login.html?field=sel%zzect"` -> Invalid percent encoded char(\%zz) is detected, counters are incremented and content is passed as is to the server.

apache_mode - This mode works similar to secure mode.

Possible values: apache_mode, asp_mode, secure_mode

Default value: secure_mode

optimizePartialReqs. When OFF/ON (without safe object), a Citrix ADC appliance sends the partial request to the back-end server. This partial response sent back to the client. OptimizePartialReqs makes sense when the Safe object is configured. The appliance sends requests for full response from the server when OFF, requests only partial response when ON.

Available settings are as follows:

ON - Partial requests by the client result in partial requests to the back-end server.
OFF - Partial requests by the client are changed to full requests to the back-end server

Possible values: ON, OFF

Default value: ON

URLDecodeRequestCookies. URL Decode request cookies before subjecting them to SQL and cross-site scripting checks.

Possible values: ON, OFF

Default value: OFF

Signature Post Body Limit (Bytes). Limits the request payload (in bytes) inspected for signatures with the location specified as ‘HTTP_POST_BODY’.

Default value: 8096
Minimum value: 0
Maximum Value: 4294967295

Post Body Limit (Bytes). Limits the request payload (in bytes) inspected by Web Application Firewall.

Default value: 20000000
Minimum value: 0
Maximum Value: 10 GB

postBodyLimitAction. PostBodyLimit honors error settings when you specify the maximum size of HTTP body to be allowed. To honor error settings you must configure one or more Post Body Limit
actions. The configuration is also applicable for requests where the transfer encoding header is chunked.

```
set appfw profile <profile_name> -PostBodyLimitAction block log stats
```

Where,
Block - This action blocks connection that violates the security check and it is based on the maximum size of the configured HTTP body (post body limit). The option must always be enabled.

Log - Log violations of this security check.

Stats - Generate statistics for this security check.

`inspectQueryContentTypes` Inspect request query and web forms for injected SQL and cross-site scripts for the following content types.

```
set appfw profile test_profile -inspectQueryContentTypes HTML XML JSON OTHER
```

Possible values: HTML, XML, JSON, OTHER

By default, this parameter is set as “InspectQueryContentTypes: HTML JSON OTHER” for both basic and advanced appfw profiles.

`errorURL expression`. The URL that the Citrix Web App Firewall uses as an error URL. Maximum Length: 2047.

Note: For blocking violations in a requested URL, if the error URL is similar to the signature URL the appliance resets the connection.

**Changing an Web App Firewall profile type**

February 12, 2020

If you chose the wrong profile type for an Web App Firewall profile, or the type of content on the protected web site has changed, you can change the profile type.

Note When you change the profile type, you lose all configuration settings and learned relaxations or rules for the features that the new profile type does not support. For example, if you change the profile type from Web 2.0 to XML, you lose any configuration options for Start URL, Form Field Consistency Check, and the other HTML-specific security checks. The configuration
To change an Web App Firewall profile type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -type ( HTML | XML | HTML XML )`
- `save ns config`

**Example**

The following example changes the type of a profile named pr-basic, from HTML to HTML XML, which is equivalent to the Web 2.0 type in the GUI.

```
1 set appfw profile pr-basic -type HTML XML
2 save ns config
```

To change an Web App Firewall profile type by using the GUI

1. Navigate to Security > Application Firewall > Policies.
2. In the details pane, click Action, and then Change Profile Type.
3. In the Change Web App Firewall Profile Type dialog box, Profile Type drop-down list, select a new profile type.
4. Click OK to save your changes and return to the Profiles pane.

Exporting and importing an Web App Firewall profile

July 27, 2020

You can replicate the entire configuration of an Web App Firewall profile (including all bound objects, such as HTML error object, XML error object, WSDL or XML schema, signatures, and so on) across multiple appliances. You can select a target profile and export the configuration to save it in your computer’s local file system, or you can transfer the archived configuration to store it on a server. Similarly, you can browse your computer’s local file system or import the archive from the server to select a previously exported profile and import it into your NetScaler appliance.
The option to export the entire profile configuration and then import it into another appliance can be useful in various use cases. For example, you might want to configure an Web App Firewall profile in a test bed set-up to test and validate that it is working as expected. Once you are satisfied, you can export the profile and import the profile configuration to your production NetScaler appliances. This functionality is also useful for backing up your configuration. You can export the profile before making changes, so that you can easily roll back the configuration to a known state if necessary.

Note

Web App Firewall profiles that are exported and archived from one build cannot be restored to a system running a different build, because changes introduced in the newer releases can lead to compatibility issues. If you attempt to restore an archived profile to a different build than the one from which it was exported, an error message is logged in ns.log.

The export and import profile functionality is available in both the GUI (GUI) and the command line interface (CLI). The GUI is recommended, because it offers easy to use Action options. With a click of a button you can Export or Import the entire configuration of a profile.

Exporting Web App Firewall profiles with the CLI

If you use CLI to export a profile, you must archive the configuration and then export it. To import a profile, you must import the archive into the NetScaler appliance and then execute the restore command to extract the configuration. The following set of CLI commands can be used for exporting, importing and managing the profile configurations.

CLI commands to export archives:

- `archive appfw profile <name> <archivename> [-comment <string>]`
- `export appfw archive <name> <target>`

CLI commands to import archives:

- `import appfw archive <src> <name> [-comment <string>]`
- `restore appfw profile <archivename>`

CLI commands to manage archives:

- `show appfw archive`
- `rm appfw archive <name>`

Exporting a profile from one appliance and importing it to another requires five steps in CLI. The first 3 steps are performed on the source appliance on which profile configuration is originally created, and the next 2 steps are performed on the target appliance on which the profile configuration is to be replicated.

Export profile from the source NetScaler appliance:
**Step 1:** Create an archive of the configured profile.

**Step 2:** Export the archive to the NetScaler file system.

**Step 3:** Use a file transfer utility such as scp to transfer the exported archive file from NetScaler appliance A to the target NetScaler appliance.

**Import profile to the target NetScaler appliance:**

**Step 4:** Execute the import command to import the archived file. You can import the archive from your NetScaler’s local file system, or you can use HTTP or HTTPS protocol to import the archive from a server by using the URL.

**Step 5:** Execute the restore command to restore the profile configuration from the imported archive.

**To export an Web App Firewall profile by using the command line interface:**

First, **archive** the profile’s configuration, and then **export** the archive to a target location. At the command prompt, type the following commands:

```
archive appfw profile <profileName> <archiveName>
```

where:

- `<profileName>` is the name of the profile to archive.
- `<archiveName>` is the name of the archive file to create.

Execution of the above command creates 2 instances of the archive file. One in /var/tmp folder and another in the /var/archive/appfw folder.

```
export appfw archive <archiveName> <target>
```

where:

- `<archiveName>` is the name of the archive to export. (The same name as in the previous command.
- `<target>` is a file path starting with local: as the prefix, followed by `<archiveName>`.

Execution of the export command saves the exported archive file on the file system of your NetScaler appliance in the /var/tmp folder.

**Examples:**

```
> archive appfw profile test_pr archived_test_pr
> export appfw archive archived_test_pr local:dutA_test_pr
```

After the above two commands are executed, the /var/tmp folder contains the archived_test_pr file and the exported copy, dutA_test_pr, which are identical in size. From the CLI, you can drop into the shell to navigate to the folder to verify that these files are there.
After exporting the archive file, you can use `scp` or some other such file transfer utility to transfer a copy of the archive file from the NetScaler appliance on which they were created to your target NetScaler appliance.

**Importing Web App Firewall Profiles with the CLI**

After you have successfully scp'd the archived file from the source appliance to the target appliance, you are ready to import the profile’s archive, and then execute the `restore` command to replicate the profile’s configuration on the target appliance.

Log onto the target appliance. Drop into the shell and cd to the `/var/tmp` folder to verify that the size of the scp'd file on this appliance matches the size of the original archived file on the source appliance. Exit the shell to return to the command line.

**To import a profile by using the CLI:**

At the command prompt, type the following commands:

```bash
import appfw archive <src> <name> [-comment <string>]
```

where

- `<src>` is the location of the archive file after it has been transferred from the source appliance on which it was created. You can use a local file system and file name. If you have placed the archive on a server, you can use a URL to import the archived file. If the path or file name contains spaces, enclose the URL in straight double quotation marks.
- `<name>` is the name of the archive file to be imported.
- `<string>` is an optional description of the purpose of the Archive.

```bash
restore appfw profile <archiveName>
```

**Examples:**

**A. Import from local file followed by restore:**

```bash
> import appfw archive local:dutA_test_pr dut2_test_pr
> restore appfw profile dut2_test_pr
```

**B. Import from URL followed by restore:**

```bash
import appfw archive http://10.217.30.16/FFC/Profile_ImportExport/
dutA_test_pr.tgz my_archive
restore appfw profile my_archive
```

This example restores the `test_pr` profile along with all bound objects (such as signatures, html error page, relaxation rules and so on) on the target NetScaler appliance.

You can use the following CLI commands to access man pages for additional details.
• man archive appfw profile
• man export appfw archive
• man import appfw archive
• man restore appfw profile
• man show appfw archive
• man rm appfw archive

Exporting and Importing Web App Firewall Profiles with the GUI

The GUI is easier to use than the CLI. The utility performs both archive and export operations when you click Export. Similarly it executes both import and restore when you click Import. The GUI can access the local file system of the computer from which you access the utility. You can export a copy of the archive and save it on your local computer. You can then import this copy directly in the target appliance without having to manually transfer the archive file from one appliance to the other(s).

To export an Web App Firewall profile by using the GUI:

2. In the details pane, select a profile to export. Click Actions and select Export to download and save a copy in your computer’s local file system.

To import an Web App Firewall profile by using the GUI:

2. In the details pane, click Actions and select Import. In the Import Web App Firewall Profile pane, the Import From* selection box gives you 2 options:

   **URL:** You can choose to import an archive by specifying a URL. When this option is selected, you must provide an absolute path for the archived file in the URL input box.

   **File:** You can choose to import an archive from the local File. When this option is selected, a Local File selection field is displayed. You can browse your computer’s local files to select the target archive file.

Click Create to import the specified archive. Successful completion of the import operation creates the profile configuration on the target appliance.

**Highlights**

- You can replicate the entire configuration (including all import objects as well as configured relaxation rules for the profile) on multiple appliances, without needing to repeat configuration steps, by using export and import profile functionality.
- The imported objects, such as signatures, WSDL, Schema, error page and so on, are included in the archived tar file and replicated on the target appliance.
• Customized field types are included in the archived tar file and replicated on the target appliance.
• The policy bindings of the archived profile are not replicated when the configuration is restored. You must configure the policy and bind it to the profile after importing the profile to the appliance.
• The name of the archive file can be up to 31 character long. As with profile names, an archive name must begin with an alphanumeric character or underscore and contain only alphanumeric and underscore (_), number (#), period (.), space ( ), colon (:), at (@), equals (=) or hyphen (-) characters.
• Comments associated with the archive should be descriptive enough to convey the purpose of the archived configuration. The maximum allowed length for a comment is 255 characters.
• The clear config ‒force basic command does not remove the archived profiles.
• The import and export profile functionality is supported in high availability (HA) deployments.

Debugging Tips

• Monitor the /var/log/ns.log during command executions to see if there are any ERROR messages.
• Additional logs (_restore.log, remove.log, import.log) are generated in the /var/tmp/folder. They can help debug issues during the corresponding operations. When these logs reach one MB in size, the log messages are purged to shrink the log file to one fourth of the original size.
• If the import command fails when you are using the URL option instead of the local file system, verify that DNS name server and route settings are accurately configured.
• If you are using the HTTPS protocol to import the archive, the command might fail if the HTTPS server requires client certificate authentication.

Ease of troubleshooting with Web Application Firewall logs

October 24, 2019

When there is a security attack, it is important to capture detailed WAF logging on the appliance. For this, you can configure the “VerboseLogLevel” parameter on an Application Firewall profile.

Consider a web traffic having a security attack. When the appliance receives the traffic, violation details such as HTTP header details, log pattern, and pattern payload information are logged and sent to the ADM server. The ADM server monitors the detailed logs and displays it on the Security Insight page for monitoring and tracking purpose.
Configuring verbose log level by using the command interface

To capture detailed WAF logs, configure the following command. At the command interface, type:

```
set appfw profile <profile_name> -VerboseLogLevel (pattern|patternPayload|patternPayloadHeader)
```

**Example**

```
set appfw profile profile1 -VerboseLogLevel patternPayloadHeader
```

The available log levels are:

1. Pattern. Logs only violation pattern.
2. Pattern payload. Logs violation pattern and 150 bytes of extra field element payload.
3. Pattern payload header. Logs violation pattern, 150 bytes of extra field element payload and HTTP header information.

Configuring verbose log level by using the Citrix ADC GUI

Follow the procedure below to configure the verbose log level in the WAF profile.

1. On the navigation pane, navigate to Security > Profiles.
2. In the Profiles page, click Add.
3. In the Citrix Web App Firewall Profile page, click Profile Settings under Advanced Settings.
4. In the Profile Settings section, select the detailed WAF log level in the Verbose Log Level field.
5. Click OK and Done.
File upload protection

March 24, 2020

Many attackers try to upload malicious code, virus, or malware as file attachments during multi-form submission. It is important to protect our network and overcome such threats. To prevent such malicious file uploads, a Citrix ADC admin can now configure a set of allowable file upload formats in the WAF profile. By doing this, you restrict file uploads to specific formats and protect the appliance against malicious file uploads. But, the protection works only when you disable the “ExcludeFileUploadFormChecks” option in the WAF profile.
How file upload works

When you configure allowable file upload formats, the component interaction is as follows:

- Client request has a form submission with a file upload type, for example PDF.
- As part of security check, WAF inspects the request payload and validates the file type (based on magic signature numbers).
- If the file type is an allowable file format, the corresponding action based on file type binding is applied.
- To validate the file type the appliance inspects the payload and checks for the known magic numbers at known offsets. Each file type has a sequence of magic numbers that validates the file type.
- Only if the validation passes, WAF identifies the file as an allowable format and the associated action is applied.

Configure file type upload by using Citrix ADC CLI

To configure allowable file formats, the appliance uses a WAF profile that is bound to file upload parameters.

1. Configure Web Application Firewall profile

To configure a web application firewall profile, type the following:

```
set appfw profile <profile_name> [-fileUploadTypesAction <fileUploadTypesAction> | fileUploadTypesAction] = ( none | block | log | stats )
```

Example

```
set appfw profile profile1 -fileUploadTypesAction block
```

1. Bind Web Application Firewall profile with file upload parameters.

To bind a profile with file upload parameters, type the following:

```
bind appfw profile <profile_name> - fileUploadType <form_field> <form_action_url > -fileType <fileType> ( pdf | msdoc | text | image | any)
```

Example

```
bind appfw profile profile1 -fileuploadType image action_url -fileType image
```
Configure file upload security protection by using Citrix ADC GUI

Follow the procedure below to set the file upload settings.

1. In the navigation pane, navigate to Security > Profiles.
2. In the Profiles page, click Add.
3. In the Citrix Web App Firewall Profile page, click Security Checks under Advanced Settings.
4. In the Security Checks section, go to File Upload Types settings.

5. Select the check box and click Action Settings.
6. In the File Upload Types Settings page, set the file upload action.
7. Click OK.
8. In the Citrix Web App Firewall Profile page, click OK and Done.
Configure file upload relaxation rule by using Citrix ADC GUI

You can relax a file upload security protection to avoid false positives. For example, the appliance might block file uploads but you can add a relaxation rule to allow file uploads from specific websites. By doing this, the appliance bypasses security inspection for the specified form field and allow users to upload files from the website mentioned in the action URL.

Follow the procedure below to create a relaxation rule.

1. In the navigation pane, navigate to Security > Citrix Web App Firewall > Profiles.
2. In the Profiles page, click Add.
3. In the Citrix Web App Firewall Profile page, click Relaxation Rules under Advanced Settings.
4. In the Relaxation Rules section, select File Upload Types and click Edit.

5. In the File Upload Types Relaxation Rules page, click Add.
6. In the File Upload Types Relaxation Rule page, set the following parameters:
   a) Enabled. Select this check box to enable the relaxation rule.
   b) Form Field Name. Enter the field name that does not require security check.
   c) Action URL. The form submission URL that must be exempted from security check.
   d) File Type. File type that must be allowed for the user to upload.
   e) Comments. A brief description about the file upload.
7. Click Create.
8. In the **Citrix Web App Firewall Profile** page, click **OK** and **Done**.

**Configuring and using the Learning feature**

February 12, 2020

The learning feature is a repetitive pattern filter that observes activity on a web site or application protected by the Web App Firewall, to determine what constitutes normal activity on that web site or application. It then generates a list of up to 2,000 suggested rules or exceptions (relaxations) for each
security checks that includes support for the learning feature. Users normally find it easier to configure relaxations by using the learning feature than by entering the necessary relaxations manually.

The security checks that support the learning feature are:

- Start URL check
- Cookie Consistency check
- Form Field Consistency check
- Field Formats check
- CSRF Form Tagging check
- HTML SQL Injection check
- HTML Cross-Site Scripting check
- XML Denial-of-Service check
- XML Attachment check
- Web Services Interoperability check

You perform two different types of activities when using the learning feature. First, you enable and configure the feature to use it. You can use learning on all traffic to your protected web applications, or you can configure a list of IPs (called the `Add Trusted Learning Clients` list) from which the learning feature should generate recommendations. Second, after the feature has been enabled and has processed a certain amount of traffic to your protected web sites, you review the list of suggested rules and relaxations (learned rules) and mark each with one of the following designations:

- **Edit & Deploy.** The rule is pulled into the Edit dialog box so that you can modify it, and the modified form is deployed.
- **Deploy.** The unmodified learned rule is placed on the list of rules or relaxations for this security check.
- **Skip.** The learned rule is placed on a list of rules or relaxations that are not deployed. The learned rule is removed when skipped. However, as they are not added to relaxations, they might get learned again.

Learning is not performed only when relaxations are in place, except for field format rules. When rules are skipped, they are only removed from learned database. As relaxations are not added, they might get learned again. When rules are deployed, they are removed from learned database and also relaxations are added for the rules. As relaxations are added, they would not be learned again. For field format protection, learning is performed irrespective of relaxations.

Although you can use the command line interface for basic configuration of the learning feature, the feature is designed primarily for configuration through the Web App Firewall wizard or the GUI. You can perform only limited configuration of the learning feature by using the command line.

The wizard integrates configuration of learning features with configuration of the Web App Firewall as a whole, and is therefore the easiest method for configuring this feature on a new Citrix ADC appliance or when managing a simple Web App Firewall configuration. The GUI visualizer and manual interface
both provide direct access to all learned rules for all security checks, and are therefore often preferable when you must review learned rules for a large number of security checks.

The learning database is limited to 20 MB in size, which is reached after approximately 2,000 learned rules or relaxations are generated per security check for which learning is enabled. If you do not regularly review and either approve or ignore learned rules and this limit is reached, an error is logged to the NetScaler log and no more learned rules are generated until you review the existing learned rules and relaxations.

If learning stops because the database has reached its size limit, you can restart learning either by reviewing the existing learned rules and relaxations or by resetting the learning data. After learned rules or relaxations are approved or ignored, they are removed from the database. After you reset the learning data, all existing learning data is removed from the database and it is reset to its minimum size. When the database falls below 20 MB in size, learning restarts automatically.

To configure the learning settings by using the command line interface

Specify the Web App Firewall profile to be configured and, for each security check that you want to include in that profile, specify the minimum threshold or the percent threshold. The minimum threshold is an integer representing the minimum number of user sessions that the Web App Firewall must process before it learns a rule or relaxation (default: 1). The percent threshold is an integer representing the percentage of user sessions in which the Web App Firewall must observe a particular pattern (URL, cookie, field, attachment, or rule violation) before it learns a rule or relaxation (default: 0). Use the following commands:

- save ns config
Example

The following example enables and configures the learning settings in the profile pr-basic for the HTML SQL Injection security check. This is an appropriate initial test bed learning configuration, where you have complete control over the traffic that is sent to the Web App Firewall.

```
1 set appfw learningsettings pr-basic -SQLInjectionMinThreshold 10
2 set appfw learningsettings pr-basic -SQLInjectionPercentThreshold 70
3 save ns config
```

To reset learning settings to their defaults by using the command line interface

To remove any custom configuration of the learning settings for the specified profile and security check, and return the learning settings to their defaults, at the command prompt type the following commands:

```
• save ns config
```

To display the learning settings for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningsettings <profileName>
```

To display unreviewed learned rules or relaxations for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningdata <profileName> <securityCheck>
```
To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface

At the command prompt, type the following command:

```
rm appfw learningdata <profileName> (-startURL <expression> | -cookieConsistency <string> | (¬fieldConsistency <string> <formActionURL>)| (¬crossSiteScripting <string> <formActionURL>)| (¬SQLInjection <string> <formActionURL>)| (¬fieldFormat <string><formActionURL>))| (¬CSRFTag <expression> <CSRFFormOriginURL>)| -XMLDoSCheck <expression> | -XMLWISICheck <expression> | -XMLAttachmentCheck <expression>)[-TotalXMLRequests]
```

**Example**

The following example removes all unreviewed learned relaxations for the pr-basic profile, HTML SQL Injection security check, that apply to the LastName form field.

```
1 rm appfw learningdata pr-basic -SQLInjection LastName
```

To remove all unreviewed learned data by using the command line interface

At the command prompt, type the following command:

```
reset appfw learningdata
```

To export learning data by using the command line interface

At the command prompt, type the following command:

```
export appfw learningdata <profileName> <securitycheck>[-target <string>]
```

**Example**

The following example exports learned relaxations for the pr-basic profile and the HTML SQL Injection security check to a comma-separated values (CSV) format file in the /var/learnt_data/ directory under the filename specified in the -target parameter.

```
1 export appfw learningdata pr-basic SQLInjection -target sqli_ld
```
To configure the Learning feature by using the GUI

1. Navigate to **Security > Web App Firewall > Profiles**.

2. In the **Profiles** pane, select the profile, and then click **Edit**.

3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.

4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:

   **Minimum number threshold.** Depending on which security check's learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1

   **Percentage of times threshold.** Depending on which security check's learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0

5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click **Remove All Learned Data**.
   
   **Note:** This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

6. To restrict the learning engine to traffic from a specific set of IPs, click **Trusted Learning Clients**, and add the IP addresses that you want to use to the list.
   
   a) To add an IP address or IP address range to the Trusted Learning Clients list, click **Add**.
   
   b) In the **Add Trusted Learning Clients** dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
   
   c) In the Comments text area, type a comment that describes this IP address or range.
   
   d) Click **Create** to add your new IP address or range to the list.
   
   e) To modify an existing IP address or range, click the IP address or range, and then click **Open**. Except for the name, the dialog box that appears is identical to the **Add Trusted Learning Clients** dialog box.
   
   f) To disable or enable an IP address or range, but leave it on the list, click the IP address or range, and then click **Disable or Enable**, as appropriate.
   
   g) To remove an IP address or range completely, click the IP address or range, and then click **Remove**.
7. Click **Close** to return to the Configure Web App Firewall Profile dialog box.

8. Click **Close** to close the **Configure Web App Firewall Profile** dialog box, and return to the **Web App Firewall Profile** screen.

**To review learned rules or relaxations by using the GUI**

1. Navigate to **Security > Web App Firewall > Profiles**.

2. Select the security check for which you want to review learned rules or relaxations, and then click **Manage Rules**.

3. In the **Manage Learned Rules** dialog box, choose how you want to review the learned rules.
   - To review the actual learned patterns as displayed in the window, do nothing and proceed to the next step.
   - To review the learned data hierarchically as a branching tree, enabling you to choose general patterns that match many of the learned patterns, click **Visualizer**.

4. If you have chosen to review actual learned patterns, perform the following steps.

5. Select the first learned relaxation and choose how to handle it.
   - To modify and then accept the relaxation, click **Edit & Deploy**, edit the relaxation regular expression, and then click **OK**.
   - To accept the relaxation without modifications, click **Deploy**.
   - To remove the relaxation from the list without deploying it, click **Skip**.
     a) Repeat the previous step to review each additional learned relaxation.

6. If you have chosen to use the Learning Visualizer, perform the following steps.

   a) In the branching hierarchical display, select a node that contains a learned pattern, and choose how to handle it.

   The screen area beneath the tree structure, under Regex of Selected Node, displays a generalized expression that matches all of the patterns in that node. If you want to display an expression that matches just one of the branches or just one of the leaves, select that branch or leaf.

   - To modify and then accept the learned relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click **OK**.
   - To accept the relaxation without modifications, click Deploy.
   - To remove the modification from the list without deploying it, click **Skip**.

   b) Repeat the previous step to review other portions of the display.

7. Click **Close** to return to the **Manage Learned Rules** dialog box.
8. Click **Close** to return to the **Configure Web App Firewall Profile** dialog box.

9. Click **Close** to close the **Configure Web App Firewall Profile** dialog box, and return to the **Web App Firewall Profile** screen.

**Dynamic profiling**

April 14, 2020

The learning feature is a pattern filter that observes and learns activities on the back-end server. Based on the observation, the learning engine generates up to 2000 rules or exceptions (relaxations) for each security check. To automate the process and auto deploy the relaxation rules, Citrix ADC appliance uses dynamic profiling.

With dynamic profiling, the appliance records the learnt data for a pre-defined threshold and sends an SNMP alert to the user. If the user does not skip the data within a grace period, the appliance auto deploys it as relaxation rule. Earlier, the user had to manually deploy the relaxation rules. Currently, dynamic profiling is available only for the follow security checks:

1. HTML SQL injection
2. HTML Cross Site scripting
3. Field format
4. Start URL
5. Content-type
6. Field formats
7. CSRF form tagging
8. Cookie consistency

For example, consider the HTML SQL Injection security check enabled with dynamic profiling. You can use learning for a list of IPs (called the Trusted Learning Clients list) from which the learning feature should generate recommendations. To configure a list of trusted clients, see Learning Trusted Clients topic. If the incoming traffic has violations, it is recorded as a learnt data. If the learned data is recorded in the learning engine, the appliance sends an SNMP alert to the user. If the learned data is recorded in the learning engine, the appliance sends an SNMP alert to the user. If the user does not recognize a false positive and does not skip the learnt data within a grace period, the appliance auto deploys it as a relaxation rule.

**Note:**
After you configure dynamic profile, you must periodically review the appliance configuration for the auto-deployment of relaxation rules and save it on the appliance.

**Configure dynamic profiling by using the Citrix ADC command interface**

Dynamic profiling is available for Start URL, HTML Cross-Site Scripting, Field Format, or HTML SQL Injection security checks. To configure dynamic profiling, you must complete the following steps.

1. Configure dynamic learning
2. Configure auto deployment grace period

**Configure dynamic learning**

As a first step, you must configure dynamic learning on your appliance. At the command prompt, type:

```
set appfw profile <profile_name> dynamicLearning <security_checks>
```

**Example**

```
set appfw profile test1 dynamicLearning SQLInjection CrossSiteScripting fieldFormat startURL
```

**Configure auto deployment grace period**

Once you enable the feature on specific security checks, you must configure the grace period for the auto deployment.

```
set appfw learningsettings <profile name> -crossSiteScriptingAutoDeployGracePeriod <seconds>
set appfw learningsettings <profile name> fieldFormatAutoDeploymentGracePeriod <seconds>
set appfw learningsettings <profile name> SQLInjectionAutoDeploymentGracePeriod <seconds>
set appfw learningsettings <profile name> -startURLAutoDeployGracePeriod <seconds>
```

**Example**

```
set appfw learningsettings test1 -crossSiteScriptingAutoDeployGracePeriod 30
set appfw learningsettings test1 -startURLAutoDeployGracePeriod 7
```
set appfw learningsettings test1 -fieldFormatAutoDeploymentGracePeriod 10
set appfw learning settings test1 -SQLInjectionAutoDeploymentGracePeriod 12

Note:
Here, the auto deployment grace period is in minutes.

Configuring dynamic profiling by using the Citrix ADC GUI

1. Navigate to Security > Application Firewall > Profile.
2. In the details pane, select a profile and click Edit.
3. In the Citrix Web App Profile page, click Dynamic Profiling under Advanced Settings.
4. In the Dynamic Profiling section, select a security check and click Edit.
5. In the **Dynamic Profiling and Learning Settings** page, set the grace period the security check.

6. Click **OK** and **Done**.
**Export and import of relaxation rules**

When you enable dynamic profiling, the learnt data is auto deployed as relaxation rules. Along with this, the appliance also enables you to export the dynamic profiling based relaxation rules and regular relaxation rules. You can export the rules from staging environment and import it into production environment.

**Note:**
When you import rules to production environment, you must ensure the process is additive and does not override the existing configuration.

**How to export and import relaxation rules**

To export and import the relaxation rules, you must complete the following steps:

1. You must first export the dynamic profiling-based data. For this, the export option is available for the relaxation rules in the WAF profile. When you select this option, you export the dynamic profiling relaxation rules and regular relaxation rules. You can use the export option to download the configuration as a compressed bundle on the appliance.

2. Once you have exported the data from the staging environment, you must import it to another Citrix ADC appliance. For this, you must use the import option available in the relaxation rules of the WAF profile. When you select this option, the appliance imports the specified relaxation rules bundled and restores it to the WAF profile of the selected appliance.

**Note:**
If you are going to import relaxation rules in a WAF profile, there are two types of action:
- **Augment** – This action ensures import is additive, thus not overriding any existing configuration.
- **Overwrite** – This action overwrites the existing configuration with configuration present in the compressed export bundle.

**Import archived relaxation rules file by using CLI**

To import relaxation rules, you must import the archive into the Citrix ADC appliance and then execute the restore command to extract the configuration. The following set of CLI commands can be used for exporting, importing, and managing the configurations.

To import the archived file from specific location and restore, at the command prompt, type:

```
import appfw archive <src> <name> [-comment <string>]
```

Where,
- **“src”**: Indicates the source of the tar archive file in the form, `<protocol>://<host>[:<port>][/<path>]`
“name”: Indicates name of archive.
“comment”: Comments associated with this archive.

where,
“archivename”: Indicates source for tar archive. This is a mandatory argument.
“relaxationRules”: Option to import all appfw relaxation rules
“importProfileName”: Indicates profile name created or updated to associate the relaxation rules during restore operation.
“matchUrlString”: Indicates action URL string to match in archived relaxation rules.
“replaceUrlString”: Indicates string to replace in action URL while restoring relaxation rules.
“overwrite”: Existing rules action to purge existing relaxation rules and replace during import
“augment”: Existing rules action to augment relaxation rules during import

Example:
import appfw archive local: dutA_test_pr.tgz demo
restore appfw profile dutA_test_pr

Export archived file to the selected appliance by using the CLI

If you use CLI to export appfw relaxation rules, you must archive the configuration and then export it. To archive and export the archived file, at the command prompt, type:

archive appfw profile <name> <archivename> [-comment <string>]

Where,
“archivename”: Indicates source for tar archive. This is a mandatory argument.
“name”: Indicates the appfw profile name containing the relaxation rules to export

export appfw archive <name> <target>

Where,
Name. Name of tar archive. This is a mandatory argument. Maximum Length: 31
Target. Path to the file to be exported. This is a mandatory argument. Maximum Length: 2047

Example:
archive appfw profile test_pr archived_test_pr
export appfw archive archived_test_pr local:dutA_test_pr
To export relaxation rules by using Citrix ADC GUI

Follow the steps given below to export relaxation rules:

1. Navigate to Security > Citrix Web App Firewall.
2. In the details page, click Citrix Web App Firewall Profiles link under Configuration Summary section.
3. In the Citrix Web App Firewall Profile page, click the Relaxation Rules link under Advanced Settings section.
4. In the Relaxation Rules section, click Export All Relaxation Rules. The action applies to all security checks and on the ones which dynamic learning is enabled on that profile.

To import relaxation rules by using Citrix ADC GUI

Follow the steps given below to import relaxation rules:

1. Navigate to Security > Citrix Web App Firewall.
2. In the details page, click the Citrix Web App Firewall Profiles link under Configuration Summary section.
3. In the Citrix Web App Firewall Profile page, click the Relaxation Rules link under Advanced Settings section.
4. In the Relaxation Rules section, click Import All Relaxation Rules.
5. In the Configure Citrix Web App Firewall Profile page, set the following parameters:
   a) Local file. Name of the compressed archived file containing relaxation rules.
   b) Profile Name. Name of the profile to which the relaxation rules are bound.
   c) Matching URL String. Portion of the URL that matches.
   d) Replace URL String. Portion of the URL that replaces the URL string.
e) Existing Rule Action. Select if the rule must overwrite existing rules or augment the existing rules.

6. Click **OK**.

### Supplemental Information about profiles

**February 12, 2020**

Following is supplemental information about particular aspects of Web App Firewall profiles. This information explains how to include special characters in a security check rule or relaxation, and how to use variables when configuring profiles.

**Configuration variable support**

Instead of using static values, to configure the Web App Firewall’s security checks and settings, you can now use standard Citrix ADC named variables. By creating variables, you can more easily export and
then import configurations to new Citrix ADC appliances, or update existing Citrix ADC appliances from a single set of configuration files. This simplifies updates when you use a test bed setup to develop a complex Web App Firewall configuration that is tuned for your local network and servers and then transfer that configuration to your production Citrix ADC appliances.

You create Web App Firewall configuration variables in the same manner as you do any other Citrix ADC named variables, following standard Citrix ADC conventions. To create a named expression variable by using the GUI, you use the Add Expression dialog box. To create a named expression variable by using the Citrix ADC command line, you use the add expression command followed by the appropriate parameter.

The following URLs and expressions can be configured with variables instead of static values:

- **Start URL** (-starturl)
- **Deny URL** (-denyurl)
- **Form Action URL** for **Form Field Consistency Check** (-fieldconsistency)
- **Action URL** for **XML SQL Injection Check** (-xmlSQLInjection)
- **Action URL** for **XML Cross-Site Scripting Check** (-xmlXSS)
- **Form Action URL** for **HTML SQL Injection Check** (-sqlInjection)
- **Form Action URL** for **Field Format Check** (-fieldFormat)
- **Form Origin URL** and **Form Action URL** for **Cross-Site Request Forgery (CSRF) Check** (-csrfTag)
- **Form Action URL** for **HTML Cross-Site Scripting Check** (-crossSiteScripting)
- **Safe Object** (-safeObject)
- **Action URL** for **XML Denial-of-Service (XDoS) check** (-XMLDoS)
- **URL** for **Web Services Interoperability check** (-XMLWSIURL)
- **<URL** for **XML Attachment check** (-XMLAttachmentURL)
- **URL** for **XML Attachment check** (-XMLAttachmentURL)

For more information, see Policies and Expressions.

To use a variable in the configuration, you enclose the variable name between two at (@) symbols and then use it exactly as you would the static value that it replaces. For example, if you are configuring the Deny URL check by using the GUI and want to add the named expression variable myDenyURL to the configuration, you would type @myDenyURL@ into the Add Deny URL dialog box, Deny URL text area. To do the same task by using the Citrix ADC command line, you would type add appfw profile <name> -denyURLAction @myDenyURL@.

**PCRE character encoding format**

The Citrix ADC operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your Web App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.
A number of character types require encoding using a PCRE regular expression if you include them in your Web App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The Citrix ADC appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the Web App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.

- **Chinese Traditional (Big5).** The Web App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The Web App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The Web App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

- **Korean (EUC-KR).** The Web App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The Web App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.
• **Unicode (UTF-8).** The Web App Firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the Web App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the Web App Firewall configuration is “xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an Web App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

**Note:**

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the Web App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- **A URL containing extended ASCII characters.**
  
  **Actual URL:** [http://www.josénuñez.com](http://www.josénuñez.com)
  
  **Encoded URL:** ^http://www[.\]jos\xC3\xA9nu\xC3\xB1ez[.\]com$

- **Another URL containing extended ASCII characters.**
  
  **Actual URL:** [http://www.example.de/tröms0.html](http://www.example.de/tröms0.html)
  
  **Encoded URL:** ^http://www[.\]example[.\]de/tr\xC3\xB6ms0[.\]html$

- **A form field name containing extended ASCII characters.**
  
  **Actual Name:** nome_do_usuário
  
  **Encoded Name:** ^nome_do_usu\xC3\xA1rio$

- **A safe object expression containing extended ASCII characters.**
Unencoded Expression: [A-Z]{3,6}\¥[1-9][0-9]{6,6}

Encoded Expression: [A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

http://www.utf8-chartable.de/unicode-utf8-table.pl

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

Inverted PCRE Expressions

In addition to matching content that contains a pattern, you can match content that does not contain a pattern by using an inverted PCRE expression. To invert an expression, you simply include an exclamation point (!) followed by white space as the first character in the expression.

**Note:** If an expression consists only of an exclamation point with nothing following, the exclamation point is treated as a literal character, not syntax indicating an inverted expression.

The following Web App Firewall commands support inverted PCRE expressions:

- Start URL (URL)
- Deny URL (URL)
- Form Field Consistency (form action URL)
- Cookie Consistency (form action URL)
- Cross Site Request Forgery (CSRF) (form action URL)
- HTML Cross-site Scripting (form action URL)
- Field Format (form action URL)
- Field Type (type)
- Confidential Field (URL)

Note: If the security check contains an isRegex flag or check box, it must be set to YES or checked to enable regular expressions in the field. Otherwise the contents of that field are treated as literal and no regular expressions (inverted or not) are parsed.

Disallowed Names for Web App Firewall Profiles

The following names are assigned to built-in actions and profiles on the Citrix ADC appliance, and cannot be used as names for a user-created Web App Firewall profile.
• AGGRESSIVE
• ALLOW
• BASIC
• CLIENTAUTH
• COMPRESS
• CSSMINIFY
• DEFLATE
• DENY
• DNS-NOP
• DROP
• GZIP
• HTMLMINIFY
• IMGOPTIMIZE
• JSMINIFY
• MODERATE
• NOCLIENTAUTH
• NOCOMPRESS
• NONE
• NOOP
• NOREWRITE
• RESET
• SETASLEARNNSLOG_ACT
• SETNSLOGPARAMS_ACT
• SETSYSLOGPARAMS_ACT
• SETTMSESSPARAMS_ACT
• SETVPNPARAMS_ACT
• SET_PREAUTHPARAMS_ACT
• default_DNS64_action
• dns_default_act_Cachebypass
• dns_default_act_Drop
• nshttp_default_profile
• nshttp_default_strict_validation
• nstcp_default_Mobile_profile
• nstcp_default_AXD_profile
• nstcp_default_profile
• nstcp_default_tcp_interactive_stream
• nstcp_default_tcp_lan
• nstcp_default_tcp_lan_thin_stream
• nstcp_default_tcp_lfp
Cookie hijacking protection

August 19, 2020

Cookie hijacking protection mitigates cookie stealing attacks from hackers. In the security attack, an attacker takes over a user session to gain unauthorized access to a web application. When a user browses a website, for example banking application, the website establishes a session with the browser. During the session, the application saves the user details such as login credentials, page visits in a cookie file. The cookie file is then sent to the client browser in the response. The browser stores the cookies to maintain active sessions. The attacker can steal these cookies either manually from the cookie store of the browser or through some rouge browser extension. The attacker then use these cookies to gain access into the user’s web application sessions.

To mitigate cookie attacks, the Citrix ADC Web App Firewall (WAF) challenges the TLS connection from the client along with WAF cookie consistency validation. For every new client request, the appliance validates the TLS connection and also verifies the consistency of application and session cookie in the request. If an attacker tries to mix and match application cookies and session cookies stolen from the victim, the cookie consistency validation fails, and the configured cookie hijack action is applied. For more information about cookie consistency, see Cookie Consistency Check topic.

Note:
The Cookie hijacking feature supports logging and SNMP traps. For more information about logging, see ADM topic and for more information about SNMP configuration see SNMP topic.

Limitations

- JavaScript must be enabled in the client browser.
- Cookie Hijacking protection is not supported on TLS version 1.3.

How cookie hijacking protection works

The following scenarios explain how cookie hijacking protection works in a Citrix ADC appliance.
Scenario 1: User accessing the first webpage without session cookie

1. The user attempts to authenticate into a web application and begins to access the first webpage without any ADC session cookie in the request.

2. When the request is received, the appliance creates an Application Firewall session with a session cookie ID.

3. This initiates a TLS connection for the session. Since the JavaScript is not sent and ran on the client browser, the appliance marks the TLS connection as validated and no challenge is required.

Note:
Even if an attacker tries to send all the app cookie IDs from a victim without sending the session cookie, the appliance detects the issue and strips off all the app cookies in the request before forwarding the request to the back-end server. The back end server considers this request without no app cookie and takes necessary as per its configuration.

1. When the back-end server sends a response, the appliance receives the response and forwards it with a JavaScript session token and seed cookie. The appliance then marks the TLS connection as verified.

2. When the client browser receives the response, the browser runs the JavaScript and generates a morphed cookie ID using the session token and seed cookie.

3. When a user sends a subsequent request over the TLS connection, the appliance bypasses the morphed cookie validation. This is because the TLS connection is already validated.
Scenario 2: User accessing successive webpages over new TLS connection with session cookie

1. When a user sends an HTTP request for successive pages over a new TLS connection, the browser sends session cookie ID and morphed cookie ID.
2. Since this is a new TLS connection, the appliance detects the TLS connection and challenges the client with redirect response with seed cookie.
3. The client upon receiving the response from the ADC, calculates the morphed cookie using the session’s token and new seed cookie.
4. The client then sends this newly calculated morphed cookie along with a session ID.
5. If the morphed cookie calculated within the ADC appliance and the one sent over the request matches, then the TLS connection is marked as verified.
6. If the calculated morphed cookie differs from the one present in the client request, then validation fails. After which, the appliance sends the challenge back to the client, to send a proper morphed cookie.

Scenario 3: Attacker impersonating as a non-authenticated user
1. When a user authenticates into the web application, the attacker uses different techniques to steal the cookies and replay them.
2. Since this is a new TLS connection from the attacker, the ADC sends a redirect challenge along with a new seed cookie.
3. Since the attacker does not have JavaScript running, the response from the attacker for the redirected request does not contain the morphed cookie.
4. This results in morphed cookie validation failure at the ADC appliance side. The appliance again sends a redirect challenge to the client.
5. If the number of morphed cookie validation attempts exceeds the threshold limit, the appliance flags the status as cookie hijacking.
6. If the attacker tries to mix and match application cookies and session cookies stolen from the victim, the cookie consistency check fails, and the appliance applies the configured cookie hijack action.

Scenario 4: Attacker impersonating as an authenticated user

1. Attackers can also attempt to authenticate into a web application as a genuine user and replay the victim’s cookies to gain access to the web session.
2. The ADC appliance detects such impersonated attackers also. Although a verified TLS connection is used by the attacker in replaying a victim’s cookie, the ADC appliance still verifies if the session cookie and application cookie in the request are consistent. The appliance verifies the consistency of an application cookie using the session cookie in the request. Since the request contains an attacker’s session cookie and a victim’s app cookie, the cookie consistency validation fails.
3. As a result, the appliance applies the configured cookie hijack action. If the configured action is set as “block,” then the appliance strips off all the application cookies and sends the request to the back-end Server.
4. The back-end server receives a request with no application cookie and so it responds an error response to the attacker, such as “User not logged in”.

Configure cookie hijacking by using the CLI

You can select a specific application firewall profile and set one or more actions that prevent cookie hijacking.

At the command prompt, type:

```
set appfw profile <name> [-cookieHijackingAction <action-name> <block | log | stats | none>]
```

**Note:**
By default, the action is set to “none.”

**Example:**

```
set appfw profile profile1 - cookieHijackingAction Block
```

Where, action types are:

- **Block:** Block connections that violate this security check.
- **Log:** Log violations of this security check.
- **Stats:** Generate statistics for this security check.
- **None:** Disable all actions for this security check.

Configure cookie hijacking by using the Citrix ADC GUI

2. On the Profiles page, select a profile and click Edit.
3. On the Citrix Web App Firewall Profile page, go to Advanced Settings section and click Security Checks.
1. In the **Security Checks** section, select **Cookie Hijacking** and then click **Action** settings.
2. In the **Cookie Hijacking Settings** page, select one or more actions to prevent cookie hijacking.
3. Click **OK**.

Add a relaxation rule for cookie consistency validation by using the Citrix ADC GUI

To handle false positives in cookie consistency validation, you can add a relaxation rule for cookies that can be exempted from cookie validation.

1. Navigate to **Security > Citrix Web App Firewall > Profiles.**
2. On the Profiles page, select a profile and click Edit.

3. On the Citrix Web App Firewall Profile page, go to Advanced Settings section and click Relaxation rules.

4. In the Relaxation Rules section, select Cookie Consistency and click Action.

5. In the Cookie Consistency Relaxation Rule page, set the following parameters.
   a) Enabled. Select if you want to enable the relaxation rule.
   b) Is Cookie Name Regex. Select if the cookie name is a regular expression.
   c) Cookie Name. Enter the name of the cookie that can be exempted from cookie validation.
   d) Regex Editor. Click this option to provide the regular expression details.
   e) Comments. A brief description about the cookie.

6. Click Create and Close.

View cookie hijacking traffic and violation statistics by using the CLI

View security traffic and security violation details in a tabular or graphical format.

To view security statistics:

At the command prompt, type:

```
stat appfw profile profile1
```

**View cookie hijacking traffic and violation statistics by using the GUI**

1. Navigate to **Security > Citrix Web App Firewall > Profiles**.
2. In the details pane, select a **Web App Firewall** profile and click **Statistics**.
3. The **Citrix Web App Firewall Statistics** page displays the cookie hijacking traffic and violation details.
4. You can select **Tabular View** or switch to **Graphical View** to display the data in a tabular or graphical format.
Policy labels

February 12, 2020

A policy label consists of a set of policies, other policy labels, and virtual server-specific policy banks. The Web App Firewall evaluates each policy bound to the policy label in order of priority. If the policy matches, it filters the connection as specified in the associated profile. Then it does whatever the Goto parameter specifies, which can be to terminate policy evaluation, go to the next policy, or go to the policy with the specified priority. If the Invoke parameter is set, it terminates processing of the current policy label and begins to process the specified policy label or virtual server.

To create an Web App Firewall policy label by using the command line

At the command prompt, type the following commands:

- add appfw policylabel <labelName> http_req
- save ns config
**Example**

The following example creates a policy label named policylbl1.

```
1  add appfw policylabel policylbl1 http_req
2  save ns config
```

**To bind a policy to a policy label by using the command line**

At the command prompt, type the following commands:

- `bind appfw policylabel <labelName> <policyName> <priority> [gotoPriorityExpression] [-invoke (<labelType> <labelName>))]`
- `save ns config`

**Example**

The following example binds the policy policy1 to the policy label policylbl1 with a priority of 1.

```
1  bind appfw policylabel policylbl1 policy1 1
2  save ns config
```

**To configure an Web App Firewall policy label by using the GUI**

1. Navigate to **Security > Application Firewall > Policy Labels**.
2. In the details pane, do one of the following:
   - To add a new policy label, click **Add**.
   - To configure an existing policy label, select the policy label and the click **Open**.

   The **Create Web App Firewall Policy Label** or the **Configure Web App Firewall Policy Label** dialog box opens. The dialog boxes are nearly identical.
3. If you are creating a new policy label, in the Create Web App Firewall Policy Label dialog box, type a name for your new policy label.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
4. Select **Insert Policy** to insert a new row and display a drop-down list with all existing Web App Firewall policies.
5. Select the policy you want to bind to the policy label, or select New Policy to create a new policy and follow the instructions in To create and configure a policy by using the GUI. The policy that you selected or created is inserted into the list of globally bound Web App Firewall policies.

6. Make any additional adjustments.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the Configure Web App Firewall Policy dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

7. Repeat steps 5 through 7 to bind any additional Web App Firewall policies you want to the policy label.

8. Click Create or OK, and then click Close. A message appears in the status bar, stating that you have successfully created or modified the policy label.

Copied!
Failed!

Policies

April 23, 2019

The Web App Firewall uses two types of policies: firewall policies and auditing policies. Firewall policies control which traffic is sent to the Web App Firewall. Auditing policies control the log server to which Web App Firewall logs are sent.

Firewall policies can be complex because the policy rule can consist of multiple expressions in the Citrix ADC expressions language, which is a full-fledged object oriented programming language capable of defining with extreme precision exactly which connections to filter. Because firewall policies operate within the context of the Web App Firewall, they must meet certain criteria that are connected to how the Web App Firewall functions and what traffic is appropriately filtered by it. As long as you keep these criteria in mind, however, firewall policies are similar to policies for other Citrix ADC features. The instructions here do not attempt to cover all aspects of writing firewall policies, but only provide an introduction to policies and cover those criteria that are unique to the Web App Firewall.

Auditing policies are simple because the policy rule is always ns_true. You need only specify the log server that you want to send logs to, the logging levels that you want to use, and a few other criteria.
that are explained in detail.

**Web App Firewall Policies**

February 12, 2020

A firewall policy is a rule associated with a profile. The rule is an expression or group of expressions that define the types of request/response pairs that the Web App Firewall is to filter by applying the profile. Firewall policy expressions are written in the Citrix ADC expressions language, an object-oriented programming language with special features to support specific Citrix ADC functions. The profile is the set of actions that the Web App Firewall is to use to filter request/response pairs that match the rule.

Firewall policies enable you to assign different filtering rules to different types of web content. Not all web content is alike. A simple web site that uses no complex scripting and accesses and handles no private data might require only the level of protection provided by a profile created with basic defaults. Web content that contains JavaScript-enhanced web forms or accesses an SQL database probably requires more tailored protection. You can create a different profile to filter that content and create a separate firewall policy that can determine which requests are attempting to access that content. You then associate the policy expression with a profile you created and globally bind the policy to put it into effect.

The Web App Firewall processes only HTTP connections, and therefore uses a subset of the overall Citrix ADC expressions language. The information here is limited to topics and examples that are likely to be useful when configuring the Web App Firewall. Following are links to additional information and procedures for firewall policies:

- For procedures that explain how to create and configure a policy, see *Creating and Configuring Web App Firewall Policies*.
- For a procedure that explains in detail how to create a policy rule (expression), see *To create or configure an Web App Firewall rule (expression)*.
- For a procedure that explains how to use the Add Expression dialog box to create a policy rule, see *To add a firewall rule (expression) by using the Add Expression dialog box*.
- For a procedure that explains how to view the current bindings for a policy, see *Viewing a Firewall Policy's Bindings*.
- For procedures that explain how to bind an Web App Firewall policy, see *Binding Web App Firewall Policies*. 
• For detailed information about the Citrix ADC expressions language, see Policies and Expressions.

Note
Web App Firewall evaluates the policies based on the configured priority and goto expressions. At the end of the policy evaluation, the last policy that evaluates to true is used and the security configuration of the corresponding profile is invoked for processing the request.

For example, Consider a scenario where there are 2 policies.

• Policy_1 is a generic policy with Expression=ns_true and has a corresponding profile_1 which is a basic profile. The priority is set to 100.
• Policy_2 is more specific with Expression=HTTP.REQ.URL.CONTAINS(“XYZ”) and has a corresponding profile_2 which is an advance profile. The GoTo Expression is set to NEXT and the priority is set to 95 which is a higher priority compared to Policy_1.

In this scenario, if the target string “XYZ” is detected in the URL of the processed request, Policy_2 match is triggered as it has a higher priority even though Policy_1 is also a match. However, as per the GoTo expression configuration of Policy_2, the policy evaluation continues and the next policy Policy_1 is also processed. At the end of the policy evaluation, Policy_1 evaluates as true and the basic security checks configured in Profile_1 are invoked.

If the Policy_2 is modified and the GoTo Expression is changed from NEXT to END, the processed request that has the target string “XYZ”, triggers the Policy_2 match due to priority consideration and as per the GoTo expression configuration, the policy evaluation ends at this point. Policy_2 evaluates as true and the advanced security checks configured in Profile_2 are invoked.

NEXT
END

Policy evaluation is completed in one pass. Once the policy evaluation is completed for the request and the corresponding profile actions are invoked, the request does not go through another round of policy evaluation.

Creating and configuring Web App Firewall policies

February 12, 2020

A firewall policy consists of two elements: a rule, and an associated profile. The rule selects the HTTP traffic that matches the criteria that you set, and sends that traffic to the Web App Firewall for filtering.
The profile contains the filtering criteria that the Web App Firewall uses.

The policy rule consists of one or more expressions in the Citrix ADC expressions language. The Citrix ADC expressions syntax is a powerful, object-oriented programming language that enables you to precisely designate the traffic that you want to process with a specific profile. For users who are not completely familiar with the Citrix ADC expressions language syntax, or who prefer to configure their Citrix ADC appliance by using a web-based interface, the GUI provides two tools: the Prefix menu and the Add Expression dialog box. Both help you to write expressions that select exactly the traffic that you want to process. Experienced users who are thoroughly familiar with the syntax may prefer to use the Citrix ADC command line to configure their Citrix ADC appliances.

**Note:** In addition to the default expressions syntax, for backward compatibility the Citrix ADC operating system supports the Citrix ADC classic expressions syntax on Citrix ADC Classic and nCore appliances and virtual appliances. Classic expressions are not supported on Citrix ADC Cluster appliances and virtual appliances. Current Citrix ADC users who want to migrate existing configurations to the Citrix ADC Cluster must migrate any policies that contain classic expressions to the default expressions syntax.

For detailed information about the Citrix ADC expressions languages, see Policies and Expressions.

You can create a firewall policy by using the GUI or the Citrix ADC command line.

**To create and configure a policy by using the command line interface**

At the command prompt, type the following commands:

- **add appfw policy <name><rule> <profileName>**
- **save ns config**

**Example**

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
1 add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

**To create and configure a policy by using the GUI**

2. In the details pane, do one of the following:
To create a new firewall policy, click **Add**. The **Create Web App Firewall Policy** is displayed.

To edit an existing firewall policy, select the policy, and then click **Edit**. The **CreateWebAppFirewallPolicy** or **ConfigureWebAppFirewallPolicy** is displayed.

3. If you are creating a new firewall policy, in the **CreateWebAppFirewallPolicy** dialog box, **Policy Name text box**, type a name for your new policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

   If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.

4. Select the profile that you want to associate with this policy from the **Profile drop-down list**. You can create a new profile to associate with your policy by clicking **New**, and you can modify an existing profile by clicking **Modify**.

5. In the **Expression text area**, create a rule for your policy.

   • You can type a rule directly into the text area.

   • You can click **Prefix** to select the first term for your rule, and follow the prompts. See [To Create an Web App Firewall Rule (Expression)](/en-us/netscaler/ns-gen-Citrix ADC11-wrapper-con/ns-gen-appsec-wrapper-10-con/appfw-wrapper-con-10/appfw-policies-con/appfw-policies-firewall-tsk/appfw-policies-firewall-configuring-tsk.html) for a complete description of this process.

   • You can click **Add** to open the Add Expression dialog box, and use it to construct the rule. See [The Add Expression Dialog Box](/en-us/netscaler/ns-gen-Citrix ADC11-wrapper-con/ns-gen-appsec-wrapper-10-con/appfw-wrapper-con-10/appfw-policies-con/appfw-policies-firewall-tsk/appfw-policies-firewall-configuring-tsk.html) for a complete description of this process.

6. Click **Create** or **OK**, and then click **Close**.

**To create or configure an Web App Firewall rule (expression)**

The policy rule, also called the **expression**, defines the web traffic that the Web App Firewall filters by using the profile associated with the policy. Like other Citrix ADC policy rules (or **expressions**), Web App Firewall rules use Citrix ADC expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the **Web App Firewall** wizard or the Citrix ADC GUI to create your policy rule:
If you are configuring a policy in the Web App Firewall wizard, in the navigation pane, click Web App Firewall, then in the details pane click Web App Firewall Wizard, and then navigate to the Specify Rule screen.

If you are configuring a policy manually, in the navigation pane, expand Web App Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, the Create Web App Firewall Profile dialog box, or the Configure Web App Firewall Profile dialog box, click Prefix, and then choose the prefix for your expression from the drop-down list. Your choices are:

- **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
- **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
- **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
- **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

After you choose a prefix, the Web App Firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The Web App Firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADDRER(""), type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

Following are some examples of expressions for specific purposes.

- **Specific web host.** To match traffic from a particular web host:

  
  ```
  HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
  ```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
For shopping.example.com, substitute the name of the web host that you want to match.

- **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

```plaintext
1 HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
```

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

- **Specific type of content: GIF images.** To match GIF format images:

```plaintext
1 HTTP.REQ.URL.ENDSWITH(".png")
```

To match other format images, substitute another string in place of .png.

- **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

```plaintext
1 HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
```

To match all JavaScripts with .js extensions:

```plaintext
1 HTTP.REQ.URL.ENDSWITH(".js")
```

For more information about creating policy expressions, see “Policies and Expressions.”

**Note:** If you use the command line to configure a policy, remember to escape any double quotation marks within Citrix ADC expressions. For example, the following expression is correct if entered in the GUI:

```plaintext
1 HTTP.REQ HEADER("Host").EQ("shopping.example.com")
```

If entered at the command line, however, you must type this instead:

```plaintext
1 HTTP.REQ HEADER("Host").EQ("shopping.example.com")
```

---

**To add a firewall rule (expression) by using the Add Expression dialog box**

The Add Expression dialog box (also referred to as the Expression Editor) helps users who are not familiar with the Citrix ADC expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the Web App Firewall wizard or the Citrix ADC GUI:
• If you are configuring a policy in the Web App Firewall wizard, in the navigation pane, click Web App Firewall, then in the details pane click Web App Firewall Wizard, and then navigate to the Specify Rule screen.
• If you are configuring a policy manually, in the navigation pane, expand Web App Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, in the Create Web App Firewall Profile dialog box, or in the Configure Web App Firewall Profile dialog box, click Add.

3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
   • HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
   • SYS. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   • CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   • SERVER. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the Web App Firewall treats requests and associated responses as a single unit and filters both, you do not need to specify responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.

5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.

7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

Binding Web App Firewall policies

February 12, 2020

After you have configured your Web App Firewall policies, you bind them to Global or a bind point to put them into effect. After binding, any request or response that matches an Web App Firewall policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the Citrix ADC OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the Web App Firewall feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you configure the Web App Firewall to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you configure the Web App Firewall to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you bind your policies.

For more information about binding policies on the Citrix ADC appliance, see “Policies and Expressions.”

To bind an Web App Firewall policy by using the command line interface

At the command prompt, type the following commands:

- `bind appfw global <policyName>
- `bind appfw profile <profile_name> -crossSiteScripting data

Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
1  bind appfw global pl-blog 10
2  save ns config
```

Configure log expressions

The log expression support for binding Web App Firewall is added to log HTTP header information when a violations occurs.
Log expression is binded at the Application profile, and binding contains the expression that needs to be evaluated and sent to logging frameworks when violation occurs.

The Web App Firewall violation log record with http header information is recorded. You can specify a custom log expression and it helps in analysis and diagnosis when violations are generated for the current flow (request/response).

Example configuration

```
1 bind appfw profile <profile> -logexpression <string> <expression>
2 add policy expression headers "\" HEADERS(100):\"+HTTP.REQ.FULL_HEADER"
3 add policy expression body_100 "\"BODY:\"+HTTP.REQ.BODY(100)"
4 bind appfw profile test -logExpression log_body body_100
5 bind appfw profile test -logExpression log_body body_100
6 bind appfw profile test -logExpression "\"URL:\"+HTTP.REQ.URL\" IP:\"+CLIENT.IP.SRC"
```

Example logs

```
1 Dec 8 16:55:33 <local0.info> 10.87.222.145 CEF:0|Citrix|NetScaler|NS12.1|APPFW|APPFW_LOGEXPRESSION|6|src=10.217.222.128 spt=26409 method=POST request=http://10.217.222.44/test/credit.html msg= HEADERS(100):POST /test/credit.html HTTP/1.1 M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8z x/1.2.3 M Host: 10.217.222.44 M Accept: /M Content-Length: 33 M Content-Type: application/x-www-form-urlencoded M cn1=58 cn2=174 cs1=test cs2=PPE1 cs4=ALERT cs5=2017 act=not blocked

4 Other violation logs
```
To bind an Web App Firewall policy by using the GUI

1. Do one of the following:
   - Navigate to Security > Web App Firewall, and in the details pane, click Web App Firewall policy manager.
   - Navigate to Security > Web App Firewall > Policies > Firewall Policies, and in the details pane, click Policy Manager.
2. In the Web App Firewall Policy Manager dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
   - Override Global. Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance, and are applied before any other policies.
   - LB Virtual Server. Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
   - CS Virtual Server. Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.

Note

1. Only auditlog support is available. Support for logstream and visibility in security insight would be added in future release versions.
2. If auditlogs are generated, then only 1024 bytes of data can be generated per log message.
3. If log streaming is used, then the limits are based on maximum supported size of log stream/ipfix protocol size limitations. Maximum support size for log stream is larger than 1024 bytes.
• **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the Citrix ADC appliance.

• **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.

• **None.** Do not bind the policy to any bind point.

3. Click **Continue.** A list of existing Web App Firewall policies appears.

4. Select the policy you want to bind by clicking it.

5. Make any additional adjustments to the binding.

   • To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.

   • To modify the policy expression, double click that field to open the **Configure Web App Firewall Policy** dialog box, where you can edit the policy expression.

   • To set the Goto Expression, double click **field** in the Goto Expression column heading to display the drop-down list, where you can choose an expression.

   • To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

6. Repeat steps 3 through 6 to add any additional Web App Firewall policies you want to globally bind.

7. Click **OK.** A message appears in the status bar, stating that the policy has been successfully bound.

**Viewing a policy bindings**

April 23, 2019

You can quickly check to determine what bindings are in place for any firewall policy by viewing the bindings in the GUI.

**To view bindings for an Web App Firewall policy**

1. Navigate to **Security > Application Firewall > Policies > Firewall Policies**

2. In the details pane, select the policy that you want to check, and then click **Show Bindings.** The Binding Details for Policy: Policy message box is displayed, with a list of bindings for the selected policy.

3. Click **Close.**
Supplemental information about Web App Firewall policies

April 23, 2019

Following is supplemental information about particular aspects of Web App Firewall policies that system administrators who manage the Web App Firewall might need to know.

Correct but unexpected behavior

Web application security and modern web sites are complex. In a number of scenarios, a Citrix ADC policy might cause the Web App Firewall to behave differently in certain situations than a user who is familiar with policies would normally expect. Following are a number of cases where the Web App Firewall may behave in an unexpected fashion.

- Request with a missing HTTP Host header and an absolute URL. When a user sends a request, in the majority of cases the request URL is relative. That is, it takes as its starting point the Referer URL, the URL where the user’s browser is located when it sends the request. If a request is sent without a Host header, and with a relative URL, the request is normally blocked both because it violates the HTTP specification and because a request that fails to specify the host could under some circumstances constitute an attack. If a request is sent with an absolute URL, however, even if the Host header is missing, the request bypasses the Web App Firewall and is forwarded to the web server. Although such a request violates the HTTP specification, it poses no possible threat because an absolute URL contains the host.

Auditing policies

February 12, 2020

Auditing policies determine the messages generated and logged during a Web App Firewall session. The messages are logged in SYSLOG format to the local NSLOG server or to an external logging server. Different types of messages are logged based on the level of logging selected.
To create an auditing policy, you must first create either an NSLOG server or a SYSLOG server. And then you create the policy and specify log type and the server to which logs are sent.

**To create an auditing server by using the command line interface**

You can create two different types of auditing server: an NSLOG server or a SYSLOG server. The command names are different, but the parameters for the commands are the same.

To create an auditing server, at the command prompt, type the following commands:

- `add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]
- `save ns config`

**Example**

The following example creates a syslog server named syslog1 at IP 10.124.67.91, with log levels of emergency, critical, and warning, log facility set to LOCAL1, that logs all TCP connections:

```
1 add audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning -logFacility LOCAL1 -tcp ALL
2 save ns config
```

**To modify or remove an auditing server by using the command line interface**

- To modify an auditing server, type the `set audit <type>` command, the name of the auditing server, and the parameters to be changed, with their new values.
- To remove an auditing server, type the `rm audit <type>` command and the name of the auditing server.

**Example**

The following example modifies the syslog server named syslog1 to add errors and alerts to the log level:
To create or configure an auditing server by using the GUI

1. Navigate to **Security > Citrix Web App Firewall > Policies > Auditing > Nslog**.
2. In the Nslog Auditing page, click **Servers** tab.
3. Do one of the following:
   - To add a new auditing server, click **Add**.
   - To modify an existing auditing server, select the server, and then click **Edit**.
4. In the **Create Auditing Server** page, set the following parameters:
   - Name
   - Server Type
   - IP Address
   - Port
   - Log Levels
   - Log Facility
   - Date Format
   - Time Zone
   - TCP Logging
   - ACL Logging
   - User Configurable Log Messages
   - AppFlow Logging
   - Large Scale NAT Logging
   - ALG messages logging
   - Subscriber logging
   - SSL Interception
   - URL Filtering
   - Content Inspection Logging
5. Click **Create** and **Close**.

To create an auditing policy by using the command line interface

You can create an NSLOG policy or a SYSLOG policy. The type of policy must match the type of server. The command names for the two types of policy are different, but the parameters for the commands are the same.

At the command prompt, type the following commands:

- `add audit syslogPolicy <name> <-rule > <action>`
- `save ns config`

**Example**

The following example creates a policy named syslogP1 that logs Web App Firewall traffic to a syslog server named syslog1.

```
add audit syslogPolicy syslogP1 rule "ns_true"action syslog1
save ns config
```

To configure an auditing policy by using the command line interface

At the command prompt, type the following commands:

- `set audit syslogPolicy <name> [-rule <expression>] [-action <string>]`
- `save ns config`

**Example**

The following example modifies the policy named syslogP1 to log Web App Firewall traffic to a syslog server named syslog2.

```
set audit syslogPolicy syslogP1 rule "ns_true"action syslog2
save ns config
```

To configure an auditing policy by using the GUI

1. Navigate to **Security > Citrix Web App Firewall > Policies**.
2. In the details pane, click **Audit Nslog Policy**.
3. In the Nslog Auditing page, click **Policies** tab and do one of the following:
   - To add a new policy, click **Add**.
   - To modify an existing policy, select the policy, and then click **Edit**.
4. In the **Create Auditing Nslog Policy** page, set the following parameters:

- Name
- Auditing Type
- Expression Type
- Server

5. Click **Create**.

---

**Imports**

April 23, 2019

Several Web App Firewall features make use of external files that you upload to the Web App Firewall when configuring it. Using the GUI, you manage those files in the Imports pane, which has four tabs corresponding to the four types of files you can import: HTML error objects, XML error objects, XML schemas, and Web Services Description Language (WSDL) files. Using the Citrix ADC command line, you can import these types of files, but you cannot export them.
**HTML error object**

When a user’s connection to an HTML or Web 2.0 page is blocked, or a user asks for a non-existent HTML or Web 2.0 page, the Web App Firewall sends an HTML-based error response to the user’s browser. When configuring which error response the Web App Firewall should use, you have two choices:

- You can configure a redirect URL, which can be hosted on any Web server to which users also have access. For example, if you have a custom error page on your Web server, 404.html, you can configure the Web App Firewall to redirect users to that page when a connection is blocked.
- You can configure an HTML error object, which is an HTML-based Web page that is hosted on the Web App Firewall itself. If you choose this option, you must upload the HTML error object to the Web App Firewall. You do that in the Imports pane, on the HTML Error Object tab.

The error object must be a standard HTML file that contains no non-HTML syntax except for Web App Firewall error object customization variables. It cannot contain any CGI scripts, server-parsed code, or PHP code. The customization variables enable you to embed troubleshooting information in the error object that the user receives when a request is blocked. While most requests that the Web App Firewall blocks are illegitimate, even a properly configured Web App Firewall can occasionally block legitimate requests, especially when you first deploy it or after you make significant changes to your protected Web sites. By embedding information in the error page, you provide the user with the information that he or she needs to give to the technical support person so that any issues can be fixed.

The Web App Firewall error page customization variables are:

- `${NS_TRANSACTION_ID}`. The transaction ID that the Web App Firewall assigned to this transaction.
- `${NS_APPFW_SESSION_ID}`. The Web App Firewall session ID.
- `${NS_APPFW_VIOLATION_CATEGORY}`. The specific Web App Firewall security check or rule that was violated.
- `${NS_APPFW_VIOLATION_LOG}`. The detailed error message associated with the violation.
- `${COOKIE <CookieName>}`. The contents of the specified cookie. For `<CookieName>`, substitute the name of the specific cookie that you want to display on the error page. If you have multiple cookies whose contents you want to display for troubleshooting, you can use multiple instances of this customization variable, each with the appropriate cookie name.

**Note:** If you have blocking enabled for the Cookie Consistency Check, any blocked cookies are not displayed on the error page because the Web App Firewall blocks them.

To use these variables, you embed them in the HTML or XML of the error page object as if they were an ordinary text string. When the error object is displayed to the user, for each customization variable the Web App Firewall substitutes the information to which the variable refers. An example HTML error page that uses custom variables is shown below.
<html>
<head>
<title>Page Not Accessible</title>
</head>
<body>
<h1>Page Not Accessible</h1>
<p>The page that you accessed is not available. You can:</p>
<ul>
<li>return to the home page</li>
<li>re-establish your session, and try again, or</li>
<li>report this incident to the help desk via email or by calling</li>
</ul>
<p>If you contact the help desk, please provide the following information:</p>
<table cellpadding=8 width=80%>
<tr><th align=right width=30%>Transaction ID:</th><td align=left valign=top width=70%>${NS_TRANSACTION_ID}</td></tr>
<tr><th align=right width=30%>Session ID:</th><td align=left valign=top width=70%>${NS_APPFW_SESSION_ID}</td></tr>
<tr><th align=right width=30%>Violation Category:</th><td align=left valign=top width=70%>${NS_APPFW_VIOLATION_CATEGORY}</td></tr>
<tr><th align=right width=30%>Violation Log:</th><td align=left valign=top width=70%>${NS_APPFW_VIOLATION_LOG}</td></tr>
<tr><th align=right width=30%>Cookie Name:</th><td align=left valign=top width=70%>${COOKIE(cookieName)}</td></tr>
</table>
</body>
</html>

To use this error page, copy it into a text or HTML editor. Substitute the appropriate local information for the following variables, which are enclosed in square brackets to distinguish them from the Citrix ADC variables. (Leave those unchanged.):

- [homePage]. The URL for your web site’s home page.
- [helpDeskEmailAddress]. The email address that you want users to use to report blocking incidents.
- [helpDeskPhoneNumber]. The phone number that you want users to call to report blocking incidents.
- [cookieName]. The name of the cookie whose contents you want to display on the error page.

**XML error object**

When a user’s connection to an XML page is blocked, or a user asks for a nonexistent XML application, the Web App Firewall sends an XML-based error response to the user’s browser. You configure the error response by uploading an XML-based error page to the Web App Firewall in the Imports Pane,
on the XML Error Object tab. All XML error responses are hosted on the Web App Firewall. You cannot configure a redirect URL for XML applications.

Note:
You can use the same customization variables in an XML error object as in an HTML error object.

**XML Schema**

When the Web App Firewall performs a validation check on a user’s request for an XML or Web 2.0 application, it can validate the request against the XML schema or design type document (DTD) for that application and reject any request that does not follow the schema or DTD. Both an XML schema and a DTD are standard XML configuration files that describe the structure of a specific type of XML document.

**WSDL**

When the Web App Firewall performs a validation check on a user’s request for an XML SOAP-based web service, it can validate the request against the web services type definition (WSDL) file for that web service. A WSDL file is a standard XML SOAP configuration file that defines the elements of a specific XML SOAP web service.

**Importing and exporting files**

February 12, 2020

You can import HTML or XML error objects, XML schemas, DTDs, and WSDLs to the Web App Firewall by using the GUI or the command line. You can edit any of these files in a web-based text area after importing them, to make small changes directly on the Citrix ADC instead of having to make them on your computer and then reimport them. Finally, you can export any of these files to your computer, or delete any of these files, by using the GUI.

Note:
You cannot delete or export an imported file by using the command line.
To import a file by using the command line interface

At the command prompt, type the following commands:

- import appfw htmlerrorpage <src> <name>
- <save> ns config

Example

The following example imports an HTML error object from a file named error.html and assigns it the name HTMLError.

```plaintext
1 import htmlerrorpage error.html HTMLError
2 save ns config
```

To import a file by using the GUI

Before you attempt to import an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the Citrix ADC can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot import the file or object.

1. Navigate to Security > Application Firewall > Imports.
2. Navigate to Application Firewall > Imports.
3. In the Application Firewall Imports pane, select the tab for the type of file you want to import, and then click Add.

   The tabs are HTML Error Page, XML Error Page, XML Schema or WSDL. The upload process is identical on all four tabs from the user point of view.

4. Fill in the dialog fields.

   - **Name**—A name for the imported object.
   - **Import From**—Choose the location of the HTML file, XML file, XML schema or WSDL that you want to import in the drop-down list:
     - **URL**: A web URL on a website accessible to the appliance.
     - **File**: A file on a local or networked hard disk or other storage device.
     - **Text**: Type or paste the text of the custom response directly into a text field in the GUI.

   The third text box changes to the appropriate value. The three possible values are provided below.

   - **URL**—Type the URL into the text box.
• **File**—Type the path and filename to the HTML file directly, or click Browse and browse to the HTML file.

• **Text**—The third field is removed, leaving a blank space.

5. Click **Continue**. The File Contents dialog is displayed. If you chose URL or File, the File Contents text box contains the HTML file that you specified. If you chose Text, the File Contents text box is empty.

6. If you chose Text, type or copy and paste the custom response HTML that you want to import.

7. Click **Done**.

8. To delete an object, select the object, and then click **Delete**.

---

### To export a file by using the GUI

Before you attempt to export an XML schema, DTD, or WSDL file, or an HTML or XML error object, verify that the Web App Firewall appliance can access the computer where the file is to be saved. Otherwise, you cannot export the file.

1. Navigate to **Security > Web App Firewall > Imports**.

2. In the **Web App Firewall Imports** pane, select the tab for the type of file you want to export.

   The export process is identical on all four tabs from the user point of view.

3. Select the file that you want to export.

4. Expand the Action drop-down list, and select **Export**.

5. In the dialog box, choose **Save File** and click **OK**.

6. In the **Browse** dialog box, navigate to the local file system and directory where you want to save the exported file, and click **Save**.

---

### To edit an HTML or XML Error Object in the GUI

You edit the text of HTML and XML error objects in the GUI without exporting and then reimporting them.

1. Navigate to **Security > Application Firewall > Imports**, and then select the tab for the type of file that you want to modify.

2. Navigate to **Application Firewall > Imports**, and then select the tab for the type of file that you want to modify.
3. Select the file that you want to modify, and then click **Edit**.

The text of the HTML or XML error object is displayed in a browser text area. You can modify the text by using the standard browser-based editing tools and methods for your browser.

Note: The edit window is designed to allow you to make minor changes to your HTML or XML error object. To make extensive changes, you may prefer to export the error object to your local computer and use standard HTML or XML web page editing tools.

4. Click **OK**, and then click **Close**.

---

**Global configuration**

April 23, 2019

The Web App Firewall global configuration affects all profiles and policies. The Global Configuration items are:

- **Engine Settings.** A collection of global settings—session cookie name, session time-out, maximum session lifetime, logging header name, undefined profile, default profile, and import size limit—that pertain to all connections that the Web App Firewall processes, rather than to a specific subset of connections.

- **Confidential Fields.** A set of form fields in web forms that contain sensitive information that should not be logged to the Web App Firewall logs. Form fields such as password fields on a login page or credit card information on a shopping cart checkout form are normally designated as confidential fields.

- **Field Types.** The list of web form field types used by the Field Formats security check. Each of these field types is defined by a PCRE-compliant regular expression that defines the type of data and the minimum/maximum length of data that should be allowed in that type of form field.

- **XML Content Types.** The list of content types recognized as XML and subjected to XML-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

- **JSON Content Types.** The list of content types recognized as JSON and subjected to JSON-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.
Engine settings

April 8, 2020

The engine settings affect all requests and responses that the Citrix Web App Firewall processes. Following are the settings:

- **Cookie name**—The name of the cookie that stores the Citrix ADC session ID.
- **Session timeout**—The maximum inactive period allowed. If a user session shows no activity for this length of time, the session is terminated and the user is required to reestablish it by visiting a designated start page.
- **Cookie post-encrypts prefix**—The string that precedes the encrypted portion of any encrypted cookies.
- **Maximum session lifetime**—The maximum amount of time, in seconds, that a session is allowed to remain live. After this period is reached, the session is terminated and the user is required to reestablish it by visiting a designated start page. This setting cannot be less than the session timeout. To disable this setting, so that there is no maximum session lifetime, set the value to zero (0).
- **Logging header name**—The name of the HTTP header that holds the Client IP, for logging.
- **Undefined profile**—The profile applied when the corresponding policy action evaluates as undefined.
- **Default profile**—The profile applied to connections that do not match a policy.
- **Import size limit**—The maximum byte count of all files imported to the appliance, including signatures, WSDLs, schemas, HTML, and XML error pages. During an import, if the size of the imported object causes the cumulative count of all imported files to exceed the configured limit, the import operation fails. And the appliance displays the following error message: “ERROR: Import failed - exceeding the configured total size limit on the imported objects”.
- **Learn message rate limit**—The maximum number of requests and responses per second that the learning engine is to process. Any additional requests or responses over this limit are not sent to the learning engine.
- **Entity decoding**—Decode HTML entities when running Web App Firewall checks.
- **Log malformed request**—Enable logging of malformed HTTP requests.
- **Use configurable secret key**—Use a configurable secret key for Web App Firewall operations. This secret key is used for signing and verifying data. When “useConfigurableSecretKey” is turned ON, you must use the key enabled in the “set ns encryptionParams” parameter.
- **Reset learned data**—Remove all learned data from the Web App Firewall. Restarts the learning process by collecting fresh data.

Two settings, **Reset Learned Data** and **Signatures Auto-Update**, are found in different places depending on whether you use the command interface or the Citrix ADC GUI to configure your Citrix Web App Fire-
When using the command interface, you configure Reset Learned Data by using the reset appfw learning data command. This takes no parameters and has no other functions. You can configure the signature auto-update in the set appfw settings command. The -signatureAutoUpdate parameter enables or disables auto-updating of the signatures, and -signatureUrl configures the URL which hosts the updated signatures file.

When using the Citrix ADC GUI, you configure Reset Learned Data in Security > **Citrix Web App Firewall** > Engine Settings. The **Reset Learned Data** option is at the bottom of the dialog box. You configure Signatures Auto-Update for each set of signatures in Security > Citrix Web App Firewall > Signatures, by selecting the signatures file, clicking the right mouse button and selecting Auto Update Settings.

Normally, the default values for the Web App Firewall settings are correct. If the default settings cause a conflict with other servers or cause premature disconnection of your users, however, you have to modify them.

The Web App Firewall session limit is configurable using the following command:

```
1 > set appfw settings -sessionLimit 500000
2
3 Done
4
5 Default value:100000 Max value:500000 per PE
```

**To configure engine settings by using the command line interface**

At the command prompt, type the following commands:

- `set appfw settings [-sessionCookieName <name>] [-sessionTimeout <positiveInteger>] [-sessionLifetime <positiveInteger>] [-clientIPLoggingHeader <headerName>] [-undefaction <profileName>] [-defaultProfile <profileName>] [-importSizeLimit <positiveInteger>] [-logMalformedReq (ON | OFF)] [-signatureAutoUpdate (ON | OFF)] [-signatureUrl <expression>] [-cookiePostEncryptPrefix <string>] [-entityDecoding (ON | OFF)] [-useConfigurableSecretKey (ON | OFF)] [-learnRateLimit <positiveInteger>]`

- `save ns config`

**Example**

```
1 set appfw settings -sessionCookieName citrix-appfw-id -sessionTimeout 3600
```
To configure engine settings by using the Citrix ADC GUI

1. Navigate to Security > Citrix Web App Firewall
2. In the details pane, click Change Engine Settings under Settings.
3. In the Web App Firewall Engine Settings dialog box, set the following parameters:
   - Cookie Name
   - Session Timeout
   - Cookie Post Encrypt Prefix
   - Maximum Session Lifetime
   - Logging Header Name
   - Undefined Profile
   - Default Profile
   - Import Size Limit
   - Learn Messages Rate Limit
   - Entity Decoding
   - Log Malformed Request
   - Use Secret Key
   - Learn Message Rate Limit
   - Signatures Auto Update
4. Click OK.
You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the Citrix ADC logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the web site is configured to save such data, normally in a secure database.
Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

**Important:**

In the following two cases, the Confidential Field designation does not function as expected:

- If a Web form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the Citrix ADC logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the Web App Firewall masks a fifteen-character string with the letter “x,” instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your Web App Firewall to treat a web-form field on a protected web site as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

**To add a confidential field by using the command line interface**

At the command prompt, type the following commands:

```
• add appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX )]
  [-comment "<string>"] [-state ( ENABLED | DISABLED )]
• save ns config
```

**Example**

The following example adds all web form fields whose names begin withPassword to the confidential fields list.
To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- set appfw confidField <fieldName> <url> [-isRegex (REGEX | NOTREGEX)] [-comment "<string>"] [-state (ENABLED | DISABLED)]
- ‘save ns config’

Example

The following example modifies the confidential field designation to add a comment.

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- rm appfw confidField <fieldName> <url>
- save ns config

To configure a confidential field by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Confidential Fields.
3. In the Manage Confidential Fields dialog box, do one of the following:
   - To add a new form field to the list, click Add.
   - To change an existing confidential field designation, select the field, and then click Edit.
   - The Web App Firewall Confidential Fields dialog box appears.
Note:
If you select an existing confidential field designation and then click Add, the Create Confidential Form Field dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.

4. In the dialog box, fill out the elements. They are:
   - **Enabled check box.** Select or clear to enable/disable this confidential field designation.
   - **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **FieldName.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
   - **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
   - **Comments.** Enter a comment. Optional.

5. Click Create or OK.

6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.

7. When you have finished adding, modifying, and removing confidential field designations, click Close.

Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_` (Applies confidential-field status to all field names that begin with the “passwd_” string.)

```
^((\d*[0-9a-zA-Z_]*\[0-9A-Fa-f]\[0-9A-Fa-f\])\?passwd_ (Applies confidential-field status to all field names that begin with the string passwd_, or that contain the string -passwd_ after another string that might contain non-ASCII special characters.)
```

- Following are some regular expressions that define specific URL types that you might find useful. Sub-
Constitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you could use the following regular expression:

```
https://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*+)/logon[.]pl?
```

- If the web form appears on multiple web pages on the web host www.example-español.com, which contains the n-tilde (ñ) special character, you could use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:

```
https://www[.]example-esp\xC3\xB1ol[.]com/([0-9A-Za-z][0-9A-Za-z_-]*+)/logon[.]pl?
```

- If the web form containing query.pl appears on multiple web pages on different hosts within the example.com domain, you could use the following regular expression:

```
https://([0-9A-Za-z][0-9A-Za-z_-]*[.]*)example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*+)/logon[.]pl?
```

- If the web form containing query.pl appears on multiple web pages on different hosts in different domains, you could use the following regular expression:

```
https://([0-9A-Za-z][0-9A-Za-z_-]*[.]*)([0-9A-Za-z][0-9A-Za-z_-]*[.])*[.]a-z{2,6}
/(\[0-9A-Za-z][0-9A-Za-z_-]*\]*/\*)logon[.]pl?
```

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you could use the following regular expression:

```
https://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*+)/logon[.]pl?
```

**Field types**

February 12, 2020
A field type is a PCRE-format regular expression that defines a particular data format and minimum/maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The Web App Firewall comes with several default field types, which are:

- **integer.** A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).
- **alpha.** A string of any length consisting of letters only.
- **alphanum.** A string of any length consisting of letters and/or numbers.
- **nohtml.** A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.
- **any.** Anything at all.

**Important:**

Assigning the any field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected web sites and applications in that form field. You should use the any type sparingly, if you use it at all.

You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

**To add a field type by using the command line interface**

At the command prompt, type the following commands:

- `add appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

**Example**

The following example adds a field type named SSN that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```
1  add appfw fieldType SSN "^[1-9][0-9]{2,2}-[0-9]{3}$"{ 
2     2,2 }
3    -[0-9] 
4     
```
To modify a field type by using the command line interface

At the command prompt, type the following commands:

- `set appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

Example

The following example modifies the field type to add a comment.

```
set appfw fieldType SSN "^[1-9][0-9]{2,2} -[0-9]{4,4} $" 1 -comment "US Social Security Number"
```

To remove a field type by using the command line interface

At the command prompt, type the following commands:

- `>rm appfw fieldType <name>`
- `save ns config`

To configure a field type by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Field Types.
3. In the Manage Field Types dialog box, do one of the following:
• To add a new field type to the list, click **Add**.
• To change an existing field type, select the field type, and then click **Edit**.

The **Configure Field Type** dialog box appears.

**Note:**

If you select an existing field type designation and then click **Add**, the dialog box displays the information for that field type. You can modify that information to create your new field type.

4. In the dialog box, fill out the elements. They are:

• Name
• Regular Expression
• Priority
• Comment

5. Click **Create** or **OK**.

6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click **Remove** to remove it, and then click **OK** to confirm your choice.

7. When you have finished adding, modifying, and removing field types, click **Close**.

**Examples**

Following are some regular expressions for field types that you might find useful:

```
^[1-9][0-9]{2,2} -[0-9}{4,4} $ U.S. Social Security numbers
^\[A-C]\[0-9]{7,7} $ California driver's license numbers
^+[0-9]{1,3} [0-9()-]{1,40} $ International phone numbers with country codes
^\[0-9]{4,4} $ U.S. ZIP code numbers
^\[0-9A-Za-z][0-9A-Za-z.]+\{1,4}\$ Email addresses
```

XMLEntityTypes

April 23, 2019

© 1999-2020 Citrix Systems, Inc. All rights reserved.
By default, the Web App Firewall treats files that follow certain naming conventions as XML. You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the Web App Firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

**To add an XML content type pattern by using the command line interface**

At the command prompt, type the following commands:

- `add appfw XMLContentType <XMLContentTypevalue> [-isRegex ( REGEX | NOTREGEX )]
- `save ns config`

**Example**

The following example adds the pattern `.*xml` to the XML Content Types list and designates it as a regular expression.

```bash
add appfw XMLContentType ".*xml" -isRegex REGEX
```

**To remove an XML content type pattern by using the command line interface**

At the command prompt, type the following commands:

- `rm appfw XMLContentType <XMLContentTypevalue>
- `save ns config`

**To configure the XML content type list by using the GUI**

1. Navigate to **Security > Web App Firewall**.
2. In the details pane, under **Settings**, click **Manage XML Content Types**.
3. In the **Manage XML Content Types** dialog box, do one of the following:
   - To add a new XML content type, click Add.
   - To modify an existing XML content type, select that type and then click Edit.

The Configure Web App Firewall XML Content Type dialog appears. Note: If you select an
existing XML content type pattern and then click Add, the dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.

4. In the dialog box, fill out the elements. They are:
   - **IsRegex**. Select or clear to enable PCRE-format regular expressions in the form field name.
   - **XML Content Type** Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.

5. Click **Create**.

6. To remove an XML content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.

7. When you have finished adding and removing XML content type patterns, click **Close**.

**JSON content types**

April 23, 2019

By default, the Web App Firewall treats files with the content type “application/json” as JSON files. The default setting enables the Web App Firewall to recognize JSON content in requests and responses, and to handle that content appropriately.

You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the Web App Firewall recognizes all JSON content on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

**To add a JSON content type pattern by using the command line interface**

At the command prompt, type the following commands:

- `add appfw JSONContentType <JSONContentTypevalue> [-isRegex ( REGEX | NOTREGEX ) ]`
- `save ns config`
**Example**

The following example adds the pattern `.*\json` to the JSON Content Types list and designates it as a regular expression.

```
1 add appfw JSONContentType ".*\json" -isRegex REGEX
```

**To configure the JSON content type list by using the GUI**

1. Navigate to **Security > Application Firewall**.
2. In the details pane, under **Settings**, click **Manage JSON Content Types**.
3. In the Manage JSON Content Types dialog box, do one of the following:
   - To add a new JSON content type, click **Add**.
   - To modify an existing JSON content type, select that type and then click **Edit**.
     The Configure Web App Firewall JSON Content Type dialog appears.
     Note: If you select an existing JSON content type pattern and then click Add, the dialog box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.
4. In the dialog box, fill out the elements. They are:
   - **IsRegex**. Select or clear to enable PCRE-format regular expressions in the form field name.
   - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.
5. Click **Create** or **OK**.
6. To remove a JSON content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click **Close**.

**Statistics and reports**

February 12, 2020

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the Web App Firewall.
**The Web App Firewall statistics**

When you enable the statistics action for Web App Firewall signatures or security checks, the Web App Firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the Monitoring tab of the main logon page of your Web App Firewall appliance by selecting one of the following choices in the Select Group list box:

- **Web App Firewall.** A summary of all statistics information gathered by your Web App Firewall appliance for all profiles.
- **Web App Firewall (per profile).** The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your Web App Firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check, to diagnose the issue, and then take corrective action.

**The Web App Firewall Reports**

The Web App Firewall reports provide information about your Web App Firewall configuration and how it is handling traffic for your protected web sites.

**The PCI DSS report**

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of twelve security criteria that most credit card companies require businesses who accept online payments via credit and debit cards to meet. These criteria are designed to prevent identity theft, hacking, and other types of fraud. If an internet service provider or online merchant does not meet the PCI DSS criteria, that ISP or merchant risks losing authorization to accept credit card payments through its web site.

ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which Web App Firewall settings are relevant to PCI DSS, how they should be configured, and (most important) whether your current Web App Firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your Web App Firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the Web App Firewall so that your protected web site(s) will be in compliance with that criterion.
The PCI DSS report is located under System > Reports. To generate the report as an Adobe PDF file, click Generate PCI DSS Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

Note: To view this and other reports, you must have the Adobe Reader program installed on your computer.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the Web App Firewall is licensed and enabled on your Citrix ADC appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the Web App Firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your Web App Firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is currently in compliance and, if it is not, how to bring it into compliance.
- **Configuration.** Data for individual profiles, which you access either by clicking Web App Firewall Configuration at the top of the report, or directly from the Reports pane. The Web App Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary omitted, and is described below.

**The Web App Firewall configuration report**

The Web App Firewall Configuration report is located under System > Reports. To display it, click Generate Web App Firewall Configuration Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

The Web App Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **Web App Firewall Policies.** A table that lists your current Web App Firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.
- **Web App Firewall Profiles.** A table that lists your current Web App Firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click Download All Profiles. You display the report page for each individual profile by selecting that profile in the table.
at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click Download Current Profile at the top of the page. To return to the Profiles Summary page, click Web App Firewall Profiles. To go back to the main page, click Home. You can refresh the PCI DSS report at any time by clicking Refresh in the upper right corner of the browser. You should refresh the report if you make changes to your configuration.

Web App Firewall logs

July 8, 2020

The Web App Firewall generated log messages can be quite useful for keeping track of the configurational changes, Web App Firewall policy invocations, and security check violations.

When the log action is enabled for security checks or signatures, the resulting log messages provide information about the requests and responses that the Web App Firewall has observed while protecting your web sites and applications. The most important information is the action taken by the Web App Firewall when a signature or a security check violation was observed. For some security checks, the log message can provide additional useful information, such as the location and the detected pattern that triggered the violation. You can deploy security checks in non-block mode and monitor the logs to determine whether the transactions that are triggering security violations are valid transactions (false positives). If they are, you can either remove, or reconfigure the signature or security checks, deploy relaxations, or take other appropriate measures to mitigate the false positives before you enable blocking for that signature or security check. An excessive increase in the number of violation messages in logs can indicate a surge in malicious requests. This can alert you that your application might be under attack to exploit a specific vulnerability that is detected and thwarted by Web App Firewall protections.

Citrix ADC (Native) format logs

The Web App Firewall uses the Citrix ADC format logs (also called native format logs) by default. These logs have the same format as those generated by other Citrix ADC features. Each log contains the following fields:

• Timestamp. Date and time when the connection occurred.
• Severity. Severity level of the log.
Citrix ADC 13.0

- Module. Citrix ADC module that generated the log entry.
- Event Type. Type of event, such as signature violation or security check violation.
- Event ID. ID assigned to the event.
- Client IP. IP address of the user whose connection was logged.
- Transaction ID. ID assigned to the transaction that caused the log.
- Session ID. ID assigned to the user session that caused the log.
- Message. The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search for any of these fields, or any combination of information from different fields. Your selection is limited only by the capabilities of the tools you use to view the logs. You can observe the Web App Firewall log messages in the GUI by accessing the Citrix ADC syslog viewer, or you can manually connect to the Citrix ADC appliance and access logs from the command line interface, or you can drop into shell and tail the logs directly from the /var/log/ folder.

Example of a Native Format Log message

```
Jun 22 19:14:37 <local0.info> 10.217.31.98 06/22/2015:19:14:37 GMT ns 0-PPE-1 :
  default APPFW APPFW_XSS 60 0 : 10.217.253.62 616-PPE1 y/3 upt2K8ySWWId3Kavbxyni7Rw0000

  field text_area="Bad tag: script" <blocked>
```

**Common Event Format (CEF) Logs**

The Web App Firewall also supports CEF logs. CEF is an open log management standard that improves the interoperability of security-related information from different security and network devices and applications. CEF enables customers to use a common event log format so that data can easily be collected and aggregated for analysis by an enterprise management system. The log message is broken into different fields so that you can easily parse the message and write scripts to identify important information.

**Analyzing the CEF Log Message**

In addition to date, timestamp, client IP, log format, appliance, company, build version, module, and...
security check information, Web App Firewall CEF Log messages include the following details:

- src – source IP address
- spt – source port number
- request – request URL
- act – action (e.g. blocked, transformed)
- msg – message (Message regarding the observed security check violation)
- cn1 – event ID
- cn2 – HTTP Transaction ID
- cs1 – profile name
- cs2 – PPE ID (e.g. PPE1)
- cs3 – Session ID
- cs4 – Severity (e.g. INFO, ALERT)
- cs5 – event year
- cs6 - Signature Violation Category
- method – Method (e.g. GET/POST)

For example, consider the following CEF format log message, which was generated when a Start URL violation was triggered:

```
1 Jun 12 23:37:17 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0
2 |APPFW|APPFW_STARTURL|6|src=10.217.253.62 spt=47606 method=GET
3 request=http://aaron.stratum8.net/FFC/login.html msg=Disallow Illegal URL.
4 cn1=1340 cn2=653 cs1=pr_ffc cs2=PPE1 cs3=EsdGd3VD00aaURLcZnj05Y6D0mE0002 cs4=
5 ALERT cs5=2015 act=blocked
```

The above message can be broken down into different components. Refer to the CEP log components table.

Example of a request check violation in CEF log format: request is not blocked

```
1 Jun 13 00:21:28 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW

```

Logging geolocation in the Web App Firewall violation messages

Geolocation, which identifies the geographic location from which requests originate, can help you configure the Web App Firewall for the optimal level of security. To bypass security implementations such as rate limiting, which rely on the IP addresses of the clients, malware or rogue computers can keep changing the source IP address in requests. Identifying the specific region from where requests are coming can help determine whether the requests are from a valid user or a device attempting to launch cyberattacks. For example, if an excessively large number of requests are received from a specific area, it is easy to determine whether they are being sent by users or a rogue machine. Geolocation analysis of the received traffic can be very useful in deflecting attacks such as denial of service (DoS) attacks.

The Web App Firewall offers you the convenience of using the built-in Citrix ADC database for identifying the locations corresponding to the IP addresses from which malicious requests are originating. You can then enforce a higher level of security for requests from those locations. Citrix default syntax
(PI) expressions give you the flexibility to configure location based policies that can be used in conjunction with the built-in location database to customize firewall protection, bolstering your defense against coordinated attacks launched from rogue clients in a specific region.

You can use the Citrix ADC built-in database, or you can use any other database. If the database does not have any location information for the particular client IP address, the CEF log shows geolocation as an Unknown geolocation.

**Note:** Geolocation logging uses the Common Event Format (CEF). By default, CEF logging and GeoLocationLogging are OFF. You must explicitly enable both parameters.

Example of a CEF log message showing geolocation information

```
1   June 8 00:21:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW
3   spt=18655 method=GET request=http://aaron.stratum8.net/FFC/login.html
4   msg=Disallow Illegal URL. cn1=77 cn2=1547 cs1=test_pr_adv cs2=PPE1
5   cs3=KDynjg1pbFtfhC/nt0rBU1o/Tyg0001 cs4=ALERT cs5=2015 act=not blocked
```

Example of a log message showing geolocation= Unknown

```
1   June 9 23:50:53 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|
2   APPFW|APPFW_STARTURL|6|src=10.217.30.251 geolocation=Unknown spt=5086
3   method=GET request=http://aaron.stratum8.net/FFC/login.html msg=Disallow Illegal URL.
4   cn1=74 cn2=1576 cs1=test_pr_adv cs2=PPE2 cs3=PyR0eOEM4gf6GJiTyauHByL88E0002
5   cs4=ALERT cs5=2015 act=not blocked
```

**Using the command line to configure the log action and other log parameters**

To configure the log action for a security checks of a profile by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> SecurityCheckAction ([log] | [none])`
- `unset appfw profile <name> SecurityCheckAction`

**Examples**

```
set appfw profile pr_ffc StartURLAction log
unset appfw profile pr_ffc StartURLAction
```
To configure CEF logging by using the command line

The CEF logging is disabled by default. At the command prompt, type one of the following commands to change or display the current setting:

- `set appfw settings CEFLogging on`
- `unset appfw settings CEFLogging`
- `sh appfw settings | grep CEFLogging`

To configure the logging of the credit card numbers by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> -doSecureCreditCardLogging ([ON] | [OFF])`
- `unset appfw profile <name> -doSecureCreditCardLogging`

To configure Geolocation logging by using the command line

1. Use the set command to enable GeoLocationLogging. You can enable the CEF logging at the same time. Use the unset command to disable geolocation logging. The show command shows the current settings of all the Web App Firewall parameters, unless you include the grep command to show the setting for a specific parameter.

   - `set appfw settings GeoLocationLogging ON [CEFLogging ON]`
   - `unset appfw settings GeoLocationLogging`
   - `sh appfw settings | grep GeoLocationLogging`

2. Specify the database

   `add locationfile /var/netscaler/inbuilt_db/Citrix_netscaler_InBuilt_GeoIP_DB.csv`
   or
   `add locationfile <path to database file>`

Customizing Web App Firewall Logs

Default format (Pi) expressions give you the flexibility to customize the information included in the logs. You have the option to include the specific data that you want to capture in the Web App Firewall generated log messages. For example, if you are using AAA-TM authentication along with the Web App Firewall security checks, and would like to know the accessed URL that triggered the security check violation, the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request, you can use the following commands to specify customized log messages that include all the data:

```
1 > sh version
```
Configuring Syslog policy to segregate Web App Firewall logs

The Web App Firewall offers you an option to isolate and redirect the Web App Firewall security log messages to a different log file. This might be desirable if the Web App Firewall is generating a large number of logs, making it difficult to view other Citrix ADC log messages. You can also use this option when you are interested only in viewing the Web App Firewall log messages and do not want to see the other log messages.

To redirect the Web App Firewall logs to a different log file, configure a syslog action to send the Web App Firewall logs to a different log facility. You can use this action when configuring the syslog policy, and bind it globally for use by Web App Firewall.

Example:

1. Switch to the shell and use an editor such as vi to edit the /etc/syslog.conf file. Add a new entry to use local2.* to send logs to a separate file as shown in the following example:

    ```
    local2.* /var/log/ns.log.appfw
    ```

2. Restart the syslog process. You can use the grep command to identify the syslog process ID (PID), as shown in the following example:

    ```
    root@ns## ***ps -A | grep syslog**
    1063 ?? Ss 0:03.00 /usr/sbin/syslogd -b 127.0.0.1 -n -v -v -8 -C
    root@ns## ***kill -HUP** 1063
    ```

3. From the command line interface, configure the syslog action and policy. Bind it as a global Web App Firewall policy.
> add audit syslogAction sysact 1.1.1.1 -logLevel ALL -logFacility LOCAL2
> add audit syslogPolicy syspol1 ns_true sysact1
> bind appfw global syspol1 100

1. All Web App Firewall security check violations will now be redirected to the /var/log/ns.log.appfw file. You can tail this file to view the Web App Firewall violations that are getting triggered during the processing of the ongoing traffic.

root@ns## tail -f ns.log.appfw

Warning: If you have configured the syslog policy to redirect the logs to a different log facility, the Web App Firewall log messages no longer appear in the /var/log/ns.log file.

**Viewing the Web App Firewall Logs**

You can view the logs by using the syslog viewer, or by logging onto the Citrix ADC appliance, opening a UNIX shell, and using the UNIX text editor of your choice.

To access the log messages by using the command line

Switch to the shell and tail the ns.log in the /var/log/ folder to access the log messages pertaining to the Web App Firewall security check violations:

- Shell
  - tail -f /var/log/ns.log

You can use the vi editor, or any Unix text editor or text search tool, to view and filter the logs for specific entries. For example, you can use grep command to access the log messages pertaining to the Credit Card violations:

- tail -f /var/log/ns.log | grep SAFECOMMERCE

To access the log messages by using the GUI

The Citrix GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- To view log messages for a specific security check of a profile, navigate to **Web App Firewall > Profiles**, select the target profile, and click Security Checks. Highlight the row for the target security check and click Logs. When you access the logs directly from the selected security check of the profile, it filters out the log messages and displays only the logs pertaining to the violations for the selected security check. Syslog viewer can display Web App Firewall logs in the Native format as well as the CEF format. However, in order for the syslog viewer to filter out the target profile specific log messages, the logs must be in the CEF log format when accessed from the profile.
• You can also access the Syslog Viewer by navigating to **Citrix ADC > System > Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all Web App Firewall security check violation logs for all profiles. This is useful for debugging when multiple security check violations might be triggered during request processing.

• Navigate to **Web App Firewall > policies > Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all security check violation logs for all profiles.

The HTML based Syslog Viewer provides the following filter options for selecting only the log messages that are of interest to you:

• **File**—The current /var/log/ns.log file is selected by default, and the corresponding messages appear in the Syslog Viewer. A list of other log files in the /var/log directory are available in a compressed .gz format. To download and un-compress an archived log file, just select the log file from the dropdown option. The log messages pertaining to the selected file are then displayed in the syslog viewer. To refresh the display, click the Refresh icon (a circle of two arrows).

• **Module list box**—You can select the Citrix ADC module whose logs you want to view. You can set it to APPFW for Web App Firewall logs.

• **Event Type list box**—This box contains a set of check boxes for selecting the type of event you are interested in. For example, to view the log messages pertaining to the signature violations, you can select the **APPFW_SIGNATURE_MATCH** check box. Similarly, you can select a check box to enable the specific security check that is of interest to you. You can select multiple options.

• **Severity**—You can select a specific severity level to show just the logs for that severity level. Leave all the check boxes blank if you want to see all logs.

To access the Web App Firewall security check violation log messages for a specific security check, filter by selecting **APPFW** in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the **APPFW_FIELDFORMAT** check box and click the Apply button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer. Similarly, if you select the **APPFW_SQL** and **APPFW_STARTURL** check boxes and click the **Apply** button, only log messages pertaining to these two security check violations will appear in the syslog viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **EventType**, **EventID**, **ClientIP**, **TransactionID**, and so on appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

**Click to Deploy**: This functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. If
the relaxation rule can be deployed for a log message, a check box appears at the right edge of the Syslog Viewer box in the row. Select the check box, and then select an option from the Action list to deploy the relaxation rule.

**Edit & Deploy**, **Deploy**, and **Deploy All** are available as Action options. For example, you can select an individual log message to edit and deploy. You can also select the check boxes for multiple log messages from one or more security checks and use the Deploy or Deploy All option. Click to Deploy functionality is currently supported for the following security checks:

- StartURL
- URL Buffer overflow
- SQL Injection
- XSS
- Field consistency
- Cookie consistency

To use Click to Deploy functionality in the GUI

1. In the **Syslog Viewer**, select **APPFW** in the **Module** options.
2. Select the security check for which to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the **Action** drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

**Note:**

SQL Injection and XSS rules that are deployed by using Click **Deploy** option do not include the fine grain relaxation recommendations.

**Highlights**

- **CEF Log Format support**—The CEF log format option provides a convenient option to monitor, parse, and analyze the Web App Firewall log messages to identify attacks, fine tune configured settings to decrease false positives, and gather statistics.
- **Click to Deploy**—The Syslog viewer provides an option to filter, evaluate, and deploy relaxation rules for single or multiple security check violations from one convenient location.
- **Option to customize log message**—You can use advanced PI expressions to customize log messages and include the data you want to see in the logs.
- **Segregate Web App Firewall specific logs**—You have an option to filter and redirect application-firewall specific logs to a separate log file.
- **Remote Logging**—You can redirect the log messages to a remote syslog server.
• **Geolocation Logging**—You can configure the Web App Firewall to include the geolocation of the area from where the request is received. A built-in geolocation database is available, but you have the option to use an external geolocation database. The Citrix ADC appliance supports both IPv4 and IPv6 static geolocation databases.

• **Information rich log message**—Following are some examples of the type of information that can be included in the logs, depending on the configuration:
  - An Web App Firewall policy was triggered.
  - A security check violation was triggered.
  - A request was considered to be malformed.
  - A request or the response was blocked or not blocked.
  - Request data (such as SQL or XSS special characters) or response data (such as Credit card numbers or safe object strings) was transformed.
  - The number of credit cards in the response exceeded the configured limit.
  - The credit card number and type.
  - The log strings configured in the signature rules, and the signature ID.
  - Geolocation information about the source of the request.
  - Masked (X’d out) user input for protected confidential fields.

**Mask sensitive data using regex pattern**

The REGEX_REPLACE advanced policy (PI) function in a log expression (bound to a Web Application Firewall (WAF) profile) enables you to mask sensitive data in WAF logs. You can use the option to mask data using a regex pattern and provide a character or a string pattern to mask the data. Also, you can configure the PI function to replace the first occurrence or all occurrences of the regex pattern.

By default the Citrix GUI interface provides the following mask:

- SSN
- Credit Card
- Password
- Username

**Mask sensitive data in Web Application Firewall logs**

You can mask sensitive data in WAF logs by configuring the REGEX_REPLACE advanced policy expression in the log expression bound to a WAF profile.

To mask sensitive data, you must complete the following steps:

1. Add a Web Application Firewall profile
2. Bind a log expression to the WAF profile
Add a Web Application Firewall profile

At the command prompt, type:

`add appfw profile <name>`

**Example:**

Add `appfw profile testprofile1`

Bind a log expression with the Web Application Firewall profile

At the command prompt, type:

`bind appfw profile <name> -logExpression <string> <expression> -comment <string>`

**Example:**

`bind appfw profile testProfile -logExpression "MaskSSN" HTTP.REQ.BODY (10000).REGEX_REPLACE(re!\b\d{ 3 } -\d{ 2 } -\d{ 4 } \b!, "xxx", ALL)" -comment "SSN Masked"`

Mask sensitive data in Web Application Firewall logs by using Citrix ADC GUI

1. On the navigation pane, expand **Security > Citrix Web App Firewall > Profiles**.
2. On the **Profiles** page, click **Edit**.
3. On the **Citrix Web App Firewall Profile** page, navigate to **Advanced Settings** section and click **Extended Logging**.

![Citrix Web App Firewall Profile](image)

4. In the **Extended Logging** section, click **Add**.
5. On the Create Citrix Web App Firewall Extended Log Binding page, set the following parameters:

   a) Name. Name of the log expression.
   b) Enabled. Select this option to mask sensitive data.
   c) Log mask. Select the data to be masked.
   d) Expression. Enter the advanced policy expression that enables you to mask sensitive data in WAF logs.
   e) Comments. Brief description about the masking sensitive data.

6. Click Create and Close.

PCRE character encoding format

April 20, 2020

The **Citrix ADC operating system supports direct** entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your Web App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

Many character types require encoding using a PCRE regular expression if you include them in your Web App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The Citrix ADC appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the Web App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This charac-
ter set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.

- **Chinese Traditional (Big5).** The Web App Firewall supports all characters in the Big5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The Web App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The Web App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

- **Korean (EUC-KR).** The Web App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The Web App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The Web App Firewall supports certain more characters in the UTF-8 character set, including those used in modern Russian.

When configuring the Web App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which is assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the Web App Firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in a Web App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

**Note:**

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s
UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as `\x20` to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the Web App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.
  
  **Actual URL:** `http://www.josénuñez.com`  
  **Encoded URL:** `http://www\[.\]jos\[\xC3\xA9nu\[\xC3\xB1ez\[.\]com$`  
- Another URL containing extended ASCII characters.
  
  **Actual URL:** `http://www.example.de/trömsso.html`  
  **Encoded URL:** `http://www\.example\.de/tr\xC3\xB6msso\.html$`  
- A form field name containing extended ASCII characters.
  
  **Actual Name:** `nome_do_usuário`  
  **Encoded Name:** `\"nome_do_usu\xC3\xA1rio\"$`  
- A safe object expression containing extended ASCII characters.
  
  **Unencoded Expression:** `[A-Z]\{3,6\}[1-9][0-9]\{6,6\}`  
  **Encoded Expression:** `[A-Z]\{3,6\}[\xC2][a-zA-Z]\{1-9\}[0-9]\{0-9\}[6,6]`  

You can find several tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful website that contains this information is available in the following table.

`http://www.utf8-chartable.de/unicode-utf8-table.pl`

For the characters in the table on this website to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of webpages are correct.

**Whitehat WASC signature types for WAF use**

April 23, 2019

The Citrix Web Web App Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web Web
App Firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

**WASC 1.0 signature types**

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

**WASC 2.0 signature types**

- Abuse of Functionality
- Brute Force
- Content Spoofing
- Denial of Service
- Directory Indexing
- Information Leakage
- Insufficient Anti-automation
- Insufficient Authentication
- Insufficient Authorization
- Insufficient Session Expiration
- LDAP Injection
- Session Fixation

**Best Practices**

- Autocomplete Attribute
- Insufficient Cookie Access Control
- Insufficient Password Strength
- Invalid HTTP Method Usage
- Non-HttpOnly Session Cookie
- Persistent Session Cookie
- Personally Identifiable Information
- Secured Cachable HTTP Messages
- Unsecured Session Cookie
Streaming support for request processing

April 20, 2020

Citrix Web App Firewall supports request side streaming to provide a significant performance boost. Instead of buffering a request, the appliance examines the incoming traffic for security violation such as SQL, cross-site scripting, field consistency, field formats. When the appliance completes processing data for a field, the request is forwarded to the back-end server while the appliance continues to evaluate other fields. This data processing significantly improves the processing time in handling forms have many fields.

**Note:**

Citrix Web App Firewall supports a maximum post size of 20 MB without streaming. For better resource utilization, Citrix recommends you to enable streaming only for payloads greater than 20 MB. Also, the back-end server must accept the chunked requests if streaming is enabled.

Although the streaming process is transparent to the users, minor configuration adjustments are required due to the following changes:

**RegEx Pattern Match:** RegEx pattern match is now restricted to 4K for contiguous character string match.

**FieldNameMatch:** Web App Firewall learning engine can only distinguish the first 128 bytes of the name. If a form has multiple fields with names that have identical string match for the first 128 bytes, the learning engine does not distinguish them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Removal of white spaces, percent decoding, unicode decoding, and charset conversion are done during canonicalization to provide security check inspection. The 128 byte limit is applicable for canonicalized representation of the field name in UTF-8 character format. The ASCII characters are 1 byte in length but the UTF-8 representation of the characters in some international languages might range from 1 byte to 4 bytes. If each character in a name takes 4 bytes for converting to UTF-8 format, only first 32 characters in the name might be distinguished by the learned rule.

**Field Consistency Check:** When you enable Field Consistency, all the forms in the session are stored based on the “as_fid” tag inserted by the Web App Firewall without considering the “action_url.”

- **Mandatory Form tagging for Form Field consistency:** When the field consistency check is enabled, the form tag must be enabled also. The Field Consistency protection might not work if form tagging is turned off.
• **Sessionless Form Field Consistency:** The Web App Firewall no longer carries out the “GET” to “POST” conversion of forms when sessionless field consistency parameter is enabled. The form tag is required for sessionless field consistency also.

• **Tampering of as_fid:** If a form is submitted after tampering as_fid, it triggers field consistency violation even if no field was tampered. In non-streaming requests, this was allowed because the forms can be validated using the “action_url” stored in the session.

**Signatures:** The signatures now have the following specifications:

• **Location:** It is now a mandatory requirement that location must be specified for each pattern. All patterns in the rule **MUST** have a `<Location>` tag.

• **Fast Match:** All signature rules must have a fast match pattern. If there is no fast match pattern, an attempt is made to select one if possible. Fast match is a literal string but some PCRE’s can be used for fast match if they contain a usable literal string.

• **Deprecated Locations:** Following locations are no longer supported in signature rules.
  - HTTP_ANY
  - HTTP_RAW_COOKIE
  - HTTP_RAW_HEADER
  - HTTP_RAW_RESP_HEADER
  - HTTP_RAW_SET_COOKIE

**XSS/SQL Transform:** Raw data is used for transformation because the SQL special characters such as single quote('), backslash (), and semicolon (;)), and cross-site scripting tags are same and do not require canonicalization of data. Representation of special characters such as HTML entity encoding, percent encoding, or ASCII are evaluated for transform operation.

The Web App Firewall no longer inspects both the attribute name and value for the cross-site scripting transform operation. Now only cross-site scripting attribute names are transformed when streaming is engaged.

**Processing XSS Tags:** As part of the streaming changes in NetScaler 10.5.e build and later, the processing of the cross-site scripting tags has changed. In earlier releases, presence of either open bracket (<), or close bracket (>), or both open and close brackets (<> was flagged as cross-site scripting Violation. The behavior has changed in 10.5.e build onwards. Presence of only the open bracket character (<), or only the close bracket character (>) is no longer considered as an attack. This is when an open bracket character (<) is followed by a close bracket character (>), the Cross-site scripting attack gets flagged. Both characters must be present in the right order (< followed by >) to trigger Cross-site scripting violation.

**Note:**

**Change in SQL violation log Message:** As part of the streaming changes in 10.5.e build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for...
contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input are separated by many bytes. The appliance has a track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message includes SQL keyword, SQL special character, or both the SQL keyword and the SQL special character. The rest of the input is no longer included in the log message, as shown in the following example:

**Example:**

In 10.5, when the Web App Firewall detects the SQL violation, the entire input string might be included in the following log message:

SQL Keyword check failed for field `text="select a name from testbed1;\((\);"">blocked`

In 11.0, we log only the field name, keyword, and special character (if applicable) in the following log message.

SQL Keyword check failed for field `text="select()"">blocked`

This change is applicable to requests that contain `application/x-www-form-urlencoded`, or `multipart/form-data`, or `text/x-gwt-rpc` content-types. Log messages generated during processing of JSON or XML payloads are not affected in this change.

**RAW POST Body:** The security check inspections are always done on RAW POST body.

**Form ID:** The Web App Firewall inserted “as_fid” tag, which is a computed hash of the form is longer unique for the user session. It is an identical value for a specific form irrespective of the user or the session.

**Charset:** If a request does not have a charset, the default charset specified in the application profile is used when processing the request.

**Counters:**

Counters with prefix “se_” and “appfwreq_” are added to track the streaming engine and streaming engine request counters.

```
nscconsmsg -d statswt0 -g se_err_
nscconsmsg -d statswt0 -g se_tot_
nscconsmsg -d statswt0 -g se_cur_
nscconsmsg -d statswt0 -g appfwreq_err_
nscconsmsg -d statswt0 -g appfwreq_tot_
nscconsmsg -d statswt0 -g appfwreq_cur_
```

_err counters: indicate the rare event which should have succeeded but failed due to either memory allocation problem or some other resource crunch.
_tot counters: ever increasing counters.

_cur counters: counters indicating current values that keep changing based on usage from current transactions.

**Tips:**

- The Web App Firewall security checks must work the same as before.
- There is no set ordering for the processing of the security checks.
- The response side processing is not affected and remains unchanged.
- Streaming is not engaged if CVPN is used.

**Important:**

**Calculating the Cookie length:** In release 10.5.e in addition to 11.0 release (in builds before 65.x), Web App Firewall way of processing the cookie header was changed. The appliance evaluated the cookie individually, and if the length of a cookie in the cookie header exceeded the configured length, the Buffer Overflow violation was triggered. As a result, requests blocked in NetScaler 10.5 version or earlier releases might be allowed. The length of the entire cookie header is not calculated for determining the cookie length. In some situations, the total cookie size might be larger than the accepted value, and the server might respond with “400 Bad Request”.

**Note:**
The change has been reverted. The behavior in NetScaler version 10.5.e to version 59.13xx.e and its subsequent builds is similar to the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

Copied!
Failed!

**Trace HTML requests with security logs**

April 20, 2020

**Note:**
This feature is available in Citrix ADC release 10.5.e.

Troubleshooting requires analysis of data received in the client request and can be challenging. Especially if there is heavy traffic flowing through the appliance. Diagnosing issues might affect the functionality or application security might require a quick response.
The Citrix ADC has an option to isolate traffic for a Web App Firewall profile and collect nstrace for the HTML requests. The nstrace collected in –appfw mode will include details of the entire request including the Web App Firewall generated log messages. You can use “Follow TCP stream” in the trace to view the details of the individual transaction including headers, payload, as well as the corresponding log message, together in the same screen.

This gives you a comprehensive overview regarding your traffic. Having a detailed view of the request, payload, and associated log records can be very useful to analyze security check violation. You can easily identify the pattern that is triggering the violation. If the pattern should be allowed, you can take a decision to modify the configuration and/or add a relaxation rule.

**Benefits**

1. **Isolate traffic for specific profile**: This enhancement is useful when you isolate traffic for only one profile or specific transactions of a profile for troubleshooting. You no longer have to skim through the entire data collected in the trace or need special filters to isolate requests interest you which can be tedious with heavy traffic. You now have the option to view only the data that you are interested in.

2. **Collect data for specific requests**: The trace can be collected for a specified duration. You can collect trace for only a couple of requests to isolate, analyze, and debug specific transactions if needed.

3. **Identify resets or aborts**: Unexpected closing of connections are not easily visible. The trace collected in –appfw mode captures a reset or an abort, triggered by the Web App Firewall. This allows a quicker isolation of issue when you do not see a security check violation message. Malformed requests or other non-RFC compliant requests terminated by Web App Firewall will now be easier to identify.

4. **View decrypted SSL traffic**: HTTPS traffic is captured in plain text to allow for easier troubleshooting.

5. **Provides comprehensive view**: Allows you to look at the entire request at the packet level, check the payload, look at the logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.

6. **Modify configuration**: The debugging can provide useful information to decide if the observed behavior is the correct behavior or the configuration should be modified.

7. ** Expedite response time**: Faster debugging on target traffic can improve the response time to provide explanations and/or root cause analysis by Citrix engineering and support team.

Please see any task topic in eDocs for documenting tasks. Manual Configuration by using the command line interface
To configure debug tracing for a profile by using the command line interface

Step 1. Enable ns trace.

You can use the show command to verify the configured setting.

- `set appfw profile <profile> -trace ON`

Step 2. Collect trace. You can continue to use all the options which are applicable for the nstrace command.

- `start nstrace -mode APPFW`

Step 3. Stop trace.

- `stop nstrace`

**Location of the trace:** The nstrace is stored in a time-stamped folder which is created in the /var/nstrace directory and can be viewed using wireshark. You can tail the /var/log/ns.log to see the log messages providing details regarding the location of the new trace.

**Tips:**

- When –appfw mode option is used, the nstrace will only collect the data for the profile(s) for which “trace” was enabled.
- Enabling trace on the profile will not automatically start collecting the traces till you explicitly execute the “start nstrace” command to collect the trace.
- Although, enabling trace on a profile may not have any adverse effect on the performance of the Web App Firewall but you may want to enable this feature only for the duration for which you want to collect the data. It is recommended that you turn the –trace flag off after you have collected the trace. This will prevent the risk of inadvertently getting data from profiles for which you had enabled this flag in the past.
- The block or log action must be enabled for the security check for the transaction record to be included in the nstrace.
- Resets and aborts will be logged independently of security checks actions when trace is “On” for the profile(s).
- This feature is only applicable for troubleshooting the requests received from the client. The traces in –appfw mode do not include the responses received from the server.
- You can continue to use all the options which are applicable for the nstrace command. For example,

  `start nstrace -tcpdump enabled -size 0 -mode appFW`

- If a request triggers multiple violations, the nstrace for that record will include all the corresponding log messages.
• CEF log message format is supported for this functionality.

• Signature violations triggering block and/or log action for request side checks will also be included in the trace.

• Only HTML (non-XML) requests are collected in the trace.

Example of a Log record in the trace:

![Log record example]

Copied!
Failed!

Web App Firewall support for cluster configurations

April 17, 2020

Note:

Citrix Web App Firewall for striped and partially striped configurations was introduced in Citrix ADC 11.0 version.

A cluster is a group of Citrix ADC appliances configured and managed as a single system. Each appliance in the cluster is called a node. Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations. The Web App Firewall is fully supported in all configurations.

The two main advantages of striped and partially striped virtual server support in cluster configurations are the following:
1. Session failover support—striped and partially striped virtual server configurations support session failover. The advanced Web App Firewall security features, such as Start URL closure and the Form Field Consistency check, maintain, and use sessions during transaction processing. In a high availability configuration, or in a spotted cluster configuration, when the node that is processing the Web App Firewall traffic fails, all the session information is lost and the user has to re-establish the session. In striped virtual server configurations, user sessions are replicated across multiple nodes. If a node goes down, a node running the replica becomes the owner. Session information is maintained without any visible impact to the user.

2. Scalability—Any node in the cluster can process the traffic. Multiple nodes of the cluster can process the incoming requests served by the striped virtual server. This improves the Web App Firewall’s ability to handle multiple simultaneous requests, thereby improving the overall performance.

Security checks and signature protections can be deployed without the need for any additional cluster-specific Web App Firewall configuration. You can do the usual Web App Firewall configuration on the configuration coordinator (CCO) node for propagation to all the nodes.

**Note:**

The session information is replicated across multiple nodes, but not across all the nodes in the striped configuration. Therefore, failover support accommodates a limited number of simultaneous failures. If multiple nodes fail simultaneously, the Web App Firewall might lose the session information if a failure occurs before the session is replicated on another node.

**Highlights**

- Web App Firewall offers scalability, high throughput, and session failover support in cluster deployments.
- All Web App Firewall security checks and signature protections are supported in all cluster configurations.
- Character-maps are not yet supported for a cluster. The learning engine recommends Field-Types in learned rules for the Field Format security check.
- Stats and learned rules are aggregated from all the nodes in a cluster.
- Distributed Hash Table (DHT) provides the caching of the session and offers the ability to replicate session information across multiple nodes. When a request comes to the virtual server, the Citrix ADC appliance creates Web App Firewall sessions in the DHT, and can also retrieve the session information from the DHT.
- Clustering is licensed with the advanced and premium licenses. This feature is not available with the Standard license.
Debugging and troubleshooting

April 23, 2019

Refer to the following troubleshooting and debugging information related to each of the Web App Firewall functionality:

- Application Firewall - High CPU
- Memory
- Large File Upload Failure
- Learning
- Signatures
- Trace log
- Miscellaneous

High CPU

February 12, 2020

Following are some of the functionality and high CPU related debugging issues encountered and the best practices to follow when working with Web App Firewall:

**Check Policy hits, Bindings, Network configuration, Web App Firewall configuration:**

- Identify misconfiguration
- Identify `vserver` that is serving the affected traffic

**Inspect logs in the following log files for security violations and recent configuration changes:**

- `/var/log/ns.log`
- `/var/nslog/import.log`
- `/var/nslog/aslearn.log`
- `tail -f /var/log/ns.log | grep APPFW_SIGNATURE_MATCH`

Example:

```
1 Jun 13 01:11:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW| APPFW_SIGNATURE_MATCH|6|src=10.217.253.62 spt=61141 method =GET request= http://aaron.stratum8.net/FFC/wwwboard/passwd.txt msg=Signature violation rule ID 807: web-cgi /wwwboard/passwd.txt access
```
Isolate the traffic that is effected:

- Isolate the profile
- Isolate the security check
- Isolate the URL, vserver and traffic parameters

Conditional profile level trace helps identify the traffic and violation records:

- set appfw profile <profile> -trace ON
- start nstrace -mode APPFW -size 0
- stop nstrace

Note: Ensure that the trace is collected with -size 0 option.

Check appfw, dht, IP reputation activity counters:

- nsconmsg -g as_ -g appfwreq_ -g iprep -d current

Monitor window size for resets in connection:

Appfw sets the window size to 9845 when Citrix ADC resets the connection due to an invalid http message.

Examples:

- Malformed request received - connection reset
- High CPU related issues
- Check data sheets for system limits
- Inspect for cpu usage, appfw, DHT and memory related activity. Monitor appfw sessions
- nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -g mem_AS_OBJ -g mem_AS_COMPONENT -d current

Monitor memory allocated and freed from Web App Firewall components and objects during the target time period. It helps in isolating the protection leading to high CPU usage.

- Profiler output
- Observe logs

Isolate appfw check leading to high CPU:

- startURLClosure
- Formfiledconsistency
- CSRF
- Cookie protections
- Referer header check
**Memory**

February 12, 2020

Following are some of the best practices to follow when encountered with Web App Firewall usage memory related issues:

**nsconmsg command usage:**

- Look for global memory statistics to ascertain that there is enough memory in the system and there are no memory allocation failures by executing the following command:
  
  ```bash
  * *- nsconmsg -d memstats
  ```

- Observe current allocated and maximum memory limits for appsecure, IP reputation, cache and compression by executing the following command:
  
  ```bash
  nsconmsg -d memstats | egrep -i APPSECURE|IPREP|CACHE|CMP
  ```

- Check appfw, DHT, IP reputation activity counters by executing the following command:
  
  ```bash
  nsconmsg -g as -g appfwreq -g iprep -d current
  ```

- Check all Web App Firewall error counters by executing the following command:
  
  ```bash
  nsconmsg -g as -g appfwreq -g iprep -d stats | grep err
  ```

- Check all system error counters by executing the following command:
  
  ```bash
  nsconmsg -g err -d current
  ```

- Inspect for CPU, APPFWREQ, AS and DHT counters by executing the following command:
  
  ```bash
  nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -d current
  ```

- Check the configured Cache memory by executing the following command:
  
  ```bash
  show cacheparameter
  ```

- Check the configured memory by executing the following command:
  
  ```bash
  nsconmsg -d memstats | egrep -i CACHE
  ```

- Identify distribution of memory in Web App Firewall components and objects:
**Display AS_OBJ memory:**

```bash
nsconmsg -K newnslog -d stats | grep AS_OBJ | egrep -v AppFW_cpu0|total | sort -k3
```

**Display AS_COMPONENT memory:**

```bash
nsconmsg -K newnslog -d stats | grep AS_COMPONENT | egrep -v AppFW_cpu0|total | sort -k3
```

Check for number of alive sessions by executing the following command:

**Monitor/plot active session counts:**

```bash
nsconmsg -g as_alive_sessions -d current
```

**Monitor/plot total allocated, free, updated sessions:**

- ```bash
  nsconmsg -g as_tot_alloc_sessions -g as_tot_free_sessions -d current
  ```
- ```bash
  nsconmsg -g as_tot_update_sessions -d current
  ```

If required, reduce session timeout to ensure that session limits are not used by executing the following command:

```bash
set appfwsettings -sessionTimeout <300>
```

If required, set maximum lifetime of session by executing the following command:

```bash
set appfwsettings -sessionLifetime <7200>
```

**Checking allocated and used memory**

To check the total allocated memory and used memory:

- Use the `nsconmsg -d memstats` command. Observe the `MEM_APPSECURE` field.
- Use the `stat appfw` command to obtain memory consumption information.

Web App Firewall does not automatically delete the logs after certain period of time or size.

- **All AppFw logs are archived in the */var/log/ns.log* file. The *ns.log* file performs the rollover task.**

For more information, refer to the following link: [http://support.citrix.com/article/CTX121898](http://support.citrix.com/article/CTX121898)

**Increasing Web App Firewall memory:**

- There is no CLI option to increase Web App Firewall memory. Web App Firewall memory is platform-specific.
- You may use the `nsapimgr` option to increase memory but it is not recommended.
The max allowed memory for Web App Firewall is determined by the platform and disabling IC does not impact memory allocation.

Large file upload failures

May 18, 2020

When you encounter large file upload failures, ensure that you check the following:

- Misconfigured application firewall postbody limit
- Enabled file upload scanning leading to increased processing time.
- Hitting system limits.

For payloads greater than 20 MB, Citrix recommends you to enable streaming on the application firewall profile. Also, you must ensure the back-end server supports chunked requests before enabling streaming.

Since release 11.0, the streaming flag can be enabled on per profile basis to avoid buffering by executing the following command:

```
set appfw profile <profile name> -streaming on
```

Learning

February 12, 2020

Following are some of the best practices recommended when encountered with Learning functionality issues:

**Aslearn process:**

- Verify that the process aslearn is running.
- Check top command output
- Check output of ps command by executing the following command:
  
  ```
  ps -ax | grep aslearn | grep -v "grep"
  ```
Identify recent configuration commands executed prior to the observed problem by verifying the `ns.log` file:

```
/var/log/ns.log
```

Inspect aslearn logs to check for aslearn messages:

```
/var/log/aslearn.log
```

Isolate the profile and security check that is effected

Identify the GUI and CLI command which is failing by executing the following command:

```
show appfw learningdata <profileName> <securityCheck>
```

**Examples:**

- `show learningdata test_profile starturl`
- `show learningdata test_profile crosssiteScripting`
- `show learningdata test_profile sqlInjection`
- `show learningdata test_profile csRFTag`
- `show learningdata test_profile fieldformat`
- `show learningdata test_profile fieldconsistency`

Perform integrity check of sqlite from bsd shell prompt:

```
nsshell ## sqlite3 /var/ns/log/asl/<profile_name_in_lowercase>.db 'pragma integrity_check;
```

**Examples:**

```
1 root@ns# sqlite3 /var/nslog/asl/tsk0247284.db 'pragma integrity_check;'
2 ok
```

Deploy or remove rules to start learning again:

- If 2000 learn items (per protection) are reached, you cannot start learning any more for that protection
- If 20 MB size is reached for the database, stop learning for all protections
- Restart aslearn process

```
*/netscaler/aslearn -start -f/netscaler/aslearn.conf*
```
Citrix ADC 13.0

- Check the space in the /var folder by executing the following:
  
  `du -h /var`

- Check the learning threshold limits by executing the following command:
  
  `show appfwlearningsettings <profile_name> <securityCheck>`

- Collect learned data by executing the following command:
  
  `export appfwlearningdata <profile_name> <securityCheck>`

- Ascertain that learned data is uploaded in the collector.

**Signatures**

March 12, 2020

**Getting started with signatures**

To add signature:

1. Select the **Default**-signature and click **add** to make a copy.
2. Give a meaningful name. The new sig object is added as a User-Defined object.
3. Enable the target rules that are pertinent to your specific need.
   - The rules are disabled by default.
   - more rules require more processing
4. Configure the actions:
   - Block and Log actions are enabled by default. Stats is another option
5. Set the signature to be used by your profile.

**Tips for Using Signatures**

- Optimize the processing overhead by enabling only those signatures that are applicable for protecting your application.
- Every pattern in the rule must match to trigger a signature match.
• You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks.

• You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.

• Add multiple security check conditions to create your own customized check.

**Best Practices for Using Signatures**

Following are some of the best practices you can follow when encountered with issues related to Signatures:

• Verify that the import command has succeeded on primary as well as secondary.

• Verify that CLI and GUI outputs are consistent.

• Check ns.log to identify any errors during signature import and auto update.

• Check if the DNS name server is configured properly.

• Check schema version incompatibility.

• Check if the device is unable to access the Signature Update URL hosted on AWS for auto-update.

• Check for the version mismatch between Default signature and user-added ones.

• Check for version mismatch between signature objects on the primary and secondary nodes.

• Monitor for High CPU Utilization (disable auto-update to rule out issue with signature update).

Failed!

**Trace Log**

March 12, 2020

To record trace logs:

1. Enable tracing for the profile. You can use the show command to verify the configured setting.

   ```
   set appfw profile <profile> -trace ON
   ```

1. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.

   ```
   start nstrace -mode APPFW
   ```
1. Stop collecting the trace

```bash
stop nstrace
```

Location of the trace: The nstrace is stored in a time-stamped folder which is created in the `/var/nstrace` directory and can be viewed using wireshark. You can tail the `/var/log/ns.log` file to see the log messages providing details regarding the location of the new trace.

Advantages of trace logs:

- Isolate traffic for specific profile
- Collect data for specific requests
- Identify resets or aborts
- View decrypted SSL traffic: HTTPS traffic is captured in plain text to allow for easier troubleshooting.
- Provides comprehensive view: Allows you to look at the entire request at the packet level, check the payload, view logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.
- Expedite response time: Faster debugging on target traffic to do root cause analysis.

## Miscellaneous

February 12, 2020

Following are the resolutions for some of the issues that you might encounter when using Web App Firewall.

- Web App Firewall sets window size to 9845 when resetting connection for invalid http messages.
  - Malformed request received - connection reset [Client/Server sending invalid content-length header]
  - Unknown content-type in request headers
- System Limit: the application appears frozen
  - Occurs when maximum session limit is reached. (100K)
  - Less system memory for operation.
    - IP Reputation feature not working
      - The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.
• Unexpected Web App Firewall violations being triggered
  – Session timeout has a default value of 900 seconds. If session timeout is set to a low value,
    browser may trigger false positives for checks which rely on sessionization (e.g. CSRF, FFC).
    Check for session timeout and look at the session ID (cs3 in CEF logs). If the sessionID is
    different, the session timeout could be the reason.
  – If form is dynamically generated by javascript, it may trigger false FFC violations.

• Empty field name in FFC violation logs (prior to 11.0 release)
  This may be seen in scenarios where we come across a form field which is not in the forms in
  our session.
  Scenarios where this may occur:
  – The session has timed out from when the form was sent to the client and when it was received.
  – The form was generated on the client side using a java script.

Signature alert Articles

June 25, 2019

Citrix Web Application Firewall (WAF) announces signature updates that you can download and apply on your appliance. When you detect a security attack, you will receive an email notification about the new signature update. You can download the signature and apply it on your appliance.

How to receive signature alert notification

September 16, 2019

This article explains how to configure signature alert settings to receive email notifications for new signature updates.

Summary

Network administrators would like to receive an email notification for new Web Application Firewall signature updates and notification.
Problem

A Network administrator who wants to be notified when a new signature is available for the Web Application Firewall can elect to be notified by email. The administrator will receive an email notification when new signatures are available to be downloaded.

Network administrators to receive email notification for new signature updates.

Solution

To receive email notification for new signature updates, follow the steps given below:

2. In the Alert Settings section, enable the Notify me through email option.
3. Select Add Products to view the product catalog.
4. Click Application Firewall and then click the Signatures check box.
5. Click Save Settings.
1. In the **Alert Settings** section, enable the **Notify me through email** option.
2. Select **Add Products** to view the product catalog.
3. Click **Application Firewall** and then click the **Signatures** check box.
4. Click **Save Settings**.

**Signature update version 27**

November 18, 2019
New signatures rules are generated for the vulnerabilities identified in version 27. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

**Signature version**

Signature version 27 applicable to NetScaler VPX 11.1, NetScaler 12.0, and Citrix ADC 12.1 platforms.

**Common Vulnerability Entry (CVE) insight**

Following is a list of signature rules, CVE IDs, and its description.

<table>
<thead>

### Signature update version 28

November 18, 2019

New signatures rules are generated for the vulnerabilities identified in version 28. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

### Signature version

Signature version 28 applicable to NetScaler VPX 11.1, NetScaler 12.0, and Citrix ADC 12.1 and Citrix ADM 13.0 platforms.

### Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

**Signature update version 29**

November 18, 2019

New signatures rules are generated for the vulnerabilities identified in version 29. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

**Signature version**

Signature version 29 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

**Note:**

- Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

**Common Vulnerability Entry (CVE) insight**

Following is a list of signature rules, CVE IDs, and its description.
**Signature update version 30**

February 12, 2020

New signatures rules are generated for the vulnerabilities identified in version 30. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

**Signature version**

Signature version 30 applicable to NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, and Citrix ADC 13.0 platforms.

**Note**

Enabling Post body and Response body signature rules may affect Citrix ADC CPU.

**Common Vulnerability Entry (CVE) insight**

Signature update version 37

February 12, 2020

New signatures rules are generated for the vulnerabilities identified in version 37. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 37 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

<table>

New signatures rules are generated for the vulnerabilities identified for the week 2020-01-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

**Signature update version 40**

February 12, 2020

New signatures rules are generated for the vulnerabilities identified for the week 2020-01-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

**Signature version**

Signature version 40 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.
**Note:**
The signature update version 40 includes a fix for the incorrect signature rule 1861. Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Signature update version 41

February 12, 2020

New signatures rules are generated for the vulnerabilities identified for the week 2020-02-04. You can download and configure these signature rules to protect your appliance from security vulnerable attacks. The signature update includes the signature ID, signature version, and list of CVEs addressed.

Signature version

Signature version 41 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

Note:
The signature update version 41 includes a fix for the incorrect signature rule 1861. Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

**Signature update for May 2020**

June 4, 2020

New signatures rules are generated for the vulnerabilities identified in the week 2020-05-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

**Signature version**

Signature version 45 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

**Note:**

Enabling Post body and Response body signature rules might affect Citrix ADC CPU. According to the latest Snort release, the signature rules with ID 1258, 1306, 2520, 2661, 5695, 10996, 11817, 12056, 15471, 17049 and 21634 have been removed.

**Signature update for July 2020**

July 7, 2020

New signatures rules are generated for the vulnerabilities identified in the week 2020-07-01. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

**Signature version**

Signature version 48 applicable for NetScaler VPX 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0 platforms.

**Note:**

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

</table>
Sometimes the incoming web traffic is comprised of bots and most organizations suffer from bot attacks. Web and mobile applications are significant revenue drivers for business and most companies are under the threat of advanced cyberattacks, such as bots.

A bot is a software program that automatically performs certain actions repeatedly at a much faster rate than a human. Bots can interact with webpages, submit forms, execute actions, scan texts, or download content. They can access videos, post comments, and tweet on social media platforms. Some bots, known as chatbots, can hold basic conversations with human users.

A bot that performs a helpful service, such as customer service, automated chat, and search engine crawlers are good bots. At the same time, a bot that can scrape or download content from a website, steal user credentials, spam content, and perform other kinds of cyberattacks are bad bots.

With a good number of bad bots performing malicious tasks, it is essential to manage bot traffic and protect your web applications from bot attacks. By using Citrix bot management, you can detect the incoming bot traffic and mitigate bot attacks to protect your web applications.

Citrix bot management helps identify bad bots and protect your appliance from advanced security attacks. It detects good and bad bots and identifies if incoming traffic is a bot attack. By using bot management, you can mitigate attacks and protect your web applications.

Citrix ADC bot management provides the following benefits:

- **Defend against bots, scripts, and toolkits.** Provides real-time threat mitigation using static signature based defense and device fingerprinting.
- **Neutralize automated basic and advanced attacks.** Prevents attacks, such as App layer DDoS, password spraying, password stuffing, price scrapers, and content scrapers.
- **Protect your APIs and investments.** Protects your APIs from unwarranted misuse and protects infrastructure investments from automated traffic.

Some use cases where you can benefit by using the Citrix bot management system are:

- **Brute force login.** A government web portal is constantly under attack by bots attempting to brute force user logins. The organization discovered the attack by looking through web logs and seeing specific users being hit over and over again with rapid login attempts and passwords incrementing using a dictionary attack approach. By law, they must protect themselves and their users. By deploying the Citrix bot management, they can stop brute force login using device fingerprinting and rate limiting techniques.

- **Block bad bots and device fingerprint unknown bots.** A web entity gets 100,000 visitors each day. They have to upgrade the underlying footprint and they are spending a fortune. In a recent audit, the team discovered that 40 percent of the traffic came from bots, scraping content, picking news, checking user profiles, and more. They want to block this traffic to protect their
users and reduce their hosting costs. Using bot management, they can block known bad bots, and fingerprint unknown bots that are hammering their site. By blocking these bots, they can reduce bot traffic by 90 percent.

What does Citrix bot management do

The Citrix bot management helps organizations protect their web applications and public assets from advanced security attacks. When an incoming traffic is bot, the bot management system detects the bot type, assigns an action, and generates bot insights, as shown in the following diagram.

![Bot Management Diagram](image)

How does Citrix ADC bot management work

The following diagram shows how the Citrix ADC bot management works. The process involves six detection techniques that help in detecting the incoming traffic as a good or a bad bot. Good bots are allowed, bad bots are dropped, and undetected bots are rate limited.

1. The process starts by enabling bot management feature on the appliance.
2. When a client sends a request, the appliance evaluates the traffic using bot policy rules. If the incoming request is identified as a bot, the appliance applies a bot detection profile.
3. You must bind the default or custom bot signature file to the bot detection profile. The bot signature file has a list of bot signature rules for identifying the incoming bot type.
4. The bot detection rules are available under six detection categories in the signature file. The categories are white list, black list, static signature, IP reputation, device fingerprint, and rate limiting. Based on the bot traffic, the system applies a detection rule to the traffic.
5. If the incoming bot traffic matches an entry in the bot white list, the system bypasses other detection techniques and the associated action logs the data.
6. If the incoming bot traffic matches an entry in the bot black list, the detection stops and the request is dropped.
7. If the incoming bot traffic matches an entry in the IP Reputation list, the request is redirected, logged, or dropped depending on the configured action.
8. If the request matches the rate limiting detection category, the request is dropped, logged, or redirected depending on the configured action.
9. If the request behavior relates to any anomaly (bad bot) and if it matches the evaluation of device fingerprint detection technique, then the associated action drops, redirects, or logs the data.
10. After detecting the bot type, based on the action triggered, you can view bot insights on the Citrix ADM server.

**Bot Detection**

August 31, 2020

The Citrix ADC bot management system uses six different techniques to detect the incoming bot traffic. The techniques are used as detection rules to detect the bot type. The techniques are bot allow list, bot block list, IP reputation, device fingerprinting, rate limiting, bot trap, TPS, and CAPTCHA.

**Note:**

- Bot management supports a maximum of 32 configuration entities for block list, allow list, and rate limiting techniques.

**Bot white list.** A customized list of IP addresses, subnets, and policy expressions that can be bypassed as an allowed list.

**Bot black list.** A customized list of IP addresses, subnets, and policy expressions that has to be blocked from accessing your web applications.

**IP reputation.** This rule detects if the incoming bot traffic is from a malicious IP address.

**Device fingerprinting.** This rule detects if the incoming bot traffic has device fingerprint ID in the incoming request header and browser attributes of an incoming client bot traffic.

**Limitation:**

1. Java Script must be enabled in the client browser.
2. Does not support in headless browsers.
3. Does not work for XML responses.

**Rate limiting.** This rule rate limits multiple requests coming from the same client.
**Bot trap.** Detects and blocks automated bots by advertising a trap URL in the client response. The URL appears invisible and not accessible if the client is a human user. The detection technique is effective in blocking attacks from automated bots.

**TPS.** Detects incoming traffic as bots if the maximum number of requests and percentage increase in requests exceeds the configured time interval.

**CAPTCHA.** This rule uses a CAPTCHA for mitigating bot attacks. A CAPTCHA is a challenge-response validation to determine if the incoming traffic is from a human user or an automated bot. The validation helps block automated bots that cause security violations to web applications. You can configure CAPTCHA as a bot action in IP reputation and device fingerprint detection techniques.

Now, let us see how you can configure each technique to detect and manage your bot traffic.

**How to upgrade to Citrix ADC CLI-based bot management configuration**

You must complete the following steps to upgrade your appliance to Citrix ADC CLI-based bot management configuration:

1. Backup existing Bot signatures
   
   At the command prompt, type:
   
   ```
   create system backup [fileName] -comment <string>
   ```
   
   1. Unset Bot signature from Bot profiles
   
   At the command prompt, type:
   
   ```
   unset bot profile <profile_name> -signature
   ```
   
   1. Remove Bot signature file
   
   At the command prompt, type:
   
   ```
   rm bot signature <signature_file_name>
   ```
   
   1. Save configuration
   
   At the command prompt, type:
   
   ```
   save ns config
   ```
   
   Save configuration
   
   ```
   save ns config
   ```

**Configure Citrix ADC CLI-based bot management**

The bot management configuration enables you to bind one or more bot detection techniques to a specific bot profile. You begin the process by enabling bot management feature on your appliance.
Once you enable, you import the bot signature file into the appliance. After import, you must create a bot profile. You then create a bot policy with bot profile bound to it for evaluating the incoming traffic as bot and bind the policy globally or to a virtual server.

Note:
If you are upgrading your appliance from an older version, you must first manually convert the existing bot management configuration to Citrix ADC CLI based bot management configuration. For more information, see Upgrade your appliance to Citrix ADC CLI based bot management configuration topic.

You must complete the following steps to configure Citrix ADC-based bot management:

1. Enable bot management
2. Import bot signature
3. Add bot profile
4. Bind bot profile
5. Add bot policy
6. Bind bot policy
7. Configure bot settings

Enable bot management

Before you can begin, ensure that the Bot Management feature is enabled on the appliance. If you have a new Citrix ADC or VPX, you must enable the feature before you configure it. If you are upgrading a Citrix ADC or VPX appliance from an earlier version of the Citrix ADC software version to the current version, you must need to enable the feature before you configure it. At the command prompt, type:

```
enable ns feature Bot
```

Import bot signature

You must import the default signature bot file and bind it to the bot profile. At the command prompt, type:

```
import bot signature [<src>] <name> [-comment <string>] [-overwrite]
```

Where,

- **src**: Local path to and name of, or URL (protocol, host, path, and file name) for, the file in which to store the imported signature file. Note: The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access. Maximum Length: 2047
- **name**: Name to assign to the bot signature file object on the Citrix ADC. This is a mandatory argument. Maximum Length: 31
comment. Any comments to preserve information about the signature file object. Maximum Length: 255.
overwrite. Overwrites the existing file.
Note: Use the overwrite option to update the content in the signature file. Alternately, use the update bot signature <name> command to update the signature file on the Citrix ADC appliance.

Example

import bot signature http://www.example.com/signature.json signaturefile - comment commentsforbot - overwrite

Note: You can use the overwrite option to update the content in the signature file. Also, you can use the update bot signature <name> command to update the signature file in the Citrix ADC appliance.

Add bot profile

A bot profile is a collection of profile settings to configure bot management on the appliance. You can configure the settings to perform bot detection.

At the command prompt, type:

add bot profile <name> [-signature <string>] [-errorURL <string>] [-trapURL <string>] [-comment <string>] [-whiteList ( ON | OFF )] [-blackList ( ON | OFF )] [-rateLimit ( ON | OFF )] [-deviceFingerprint ( ON | OFF )] [-deviceFingerprintAction ( none | log | drop | redirect | reset | mitigation )] [-ipReputation ( ON | OFF )] [-trap ( ON | OFF )] [-trapAction ( none | log | drop | redirect | reset )] [-tps ( ON | OFF )]

Example:

add bot profile profile1 -signature signature -errorURL http://www.example.com/error.html -trapURL /trap.html -whitelist ON -blacklist ON -ratelimit ON -deviceFingerprint ON -deviceFingerprintAction drop -ipReputation ON -trap ON

Bind bot profile

After you create a bot profile, you must bind the bot detection mechanism to the profile.

At the command prompt, type:
bind bot profile <name> ([-blackList [ -type ( IPv4 | Subnet | Expression ) ] [-enabled (ON | OFF)] [-value <string>] [-action (log | drop | reset)] [-logMessage <string>] [-comment <string>]]) (-whiteList [ -type ( IPv4 | Subnet | Expression ) ] [-enabled (ON | OFF)] [-value <string>] [-log (ON | OFF)] [-logMessage <string>] [-comment <string>])) (-rateLimit [-type (session | SOURCE_IP | url)] [-enabled (ON | OFF)] [-url <string>] [-cookieName <string>] [-rate <positive_integer>] [-timeslice <positive_integer>] [-action (none | log | drop | redirect | reset)] [-logMessage <string>] [-comment <string>]) (-ipReputation [-category <ipReputationCategory>] [-enabled (ON | OFF)] [-action (none | log | drop | redirect | reset | mitigation)] [-logMessage <string>] [-comment <string>]) (-captchaResource [-url <string>] [-enabled (ON | OFF)] [-waitTime <positive_integer>] [-gracePeriod <positive_integer>] [-mutePeriod <positive_integer>] [-requestLengthLimit <positive_integer>] [-retryAttempts <positive_integer>] [-action (none | log | drop | redirect | reset)] [-logMessage <string>] [-comment <string>]) (-tps [-type (SOURCE_IP | GeoLocation | REQUEST_URL | Host)] [-threshold <positive_integer>] [-percentage <positive_integer>] [-action (none | log | drop | redirect | reset | mitigation)] [-logMessage <string>] [-comment <string>])

Example:
The following example is for binding IP reputation detection technique to a specific bot profile.

bind bot profile profile5 -ipReputation -category BOTNET -enabled ON -action drop -logMessage message

Add bot policy

You must add the bot policy for evaluating bot traffic.

At the command prompt, type:

add bot policy <name> -rule <expression> -profileName <string> [-undefAction <string>] [-comment <string>] [-logAction <string>]

Where,

Name. Name for the bot policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore characters. Can be changed after the bot policy is added.

Rule. Expression that the policy uses to determine whether to apply bot profile on the specified request. This is a mandatory argument. Maximum Length: 1499
profileName. Name of the bot profile to apply if the request matches this bot policy. This is a mandatory argument. Maximum Length: 127

undefAction. Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition. Maximum Length: 127

Comment. Any type of information about this bot policy. Maximum Length: 255

logAction. Name of the messagelog action to use for requests that match this policy. Maximum Length: 127

Example:

```
add bot policy pol1 -rule "HTTP.REQ.HEADER("header")\.CONTAINS("custom")" -profileName profile1 -undefAction drop -comment commentforbotpolicy -logAction log1
```

**Bind bot policy global**

At the command prompt, type:

```
bind bot global -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-type ( REQ OVERRIDE | REQ DEFAULT )] [-invoke (-labelType ( vserver | policylabel )-labelName <string>)]
```

Example:

```
bind bot global -policyName pol1 -priority 100 -gotoPriorityExpression NEXT -type REQ_OVERRIDE
```

**Bind bot policy to a virtual server**

At the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@ [-weight <positive_integer>] )| (<serviceGroupName>@ | (-policyName <string>@ [-priority <positive_integer>] [-gotoPriorityExpression <expression>]) [-type ( REQUEST | RESPONSE )] [-invoke (<labelType> <labelName>)] )| -analyticsProfile <string>@)
```

Example:

```
bind lb vserver lb-server1 -policyName pol1 -priority 100 -gotoPriorityExpression NEXT -type REQ_OVERRIDE
```
Configure bot settings

You can customize the default settings if necessary.
At the command prompt, type:

```
set bot settings [-defaultProfile <string>] [-javaScriptName <string>]
[-sessionTimeout <positive_integer>] [-sessionCookieName <string>]
[-dfpRequestLimit <positive_integer>] [-signatureAutoUpdate (ON | OFF)]
[-signatureUrl <URL>] [-proxyServer <ip_addr|ipv6_addr|*>]
[-proxyPort <port|*>]
```

Where,

defaultProfile. Profile to use when a connection does not match any policy. Default setting is "", which sends unmatched connections back to the Citrix ADC without attempting to filter them further. Maximum Length: 31

javaScriptName. Name of the JavaScript that the BotNet feature uses in response. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-) and underscore (_) symbols. The following requirement applies only to the Citrix ADC CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my cookie name” or ‘my cookie name’). Maximum Length: 31

sessionTimeout. Timeout, in seconds, after which a user session is terminated. Minimum value: 1, Maximum value: 65535

sessionCookieName. Name of the SessionCookie that the BotNet feature uses it for tracking. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-) and underscore (_) symbols. The following requirement applies only to the Citrix ADC CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my cookie name” or ‘my cookie name’). Maximum Length: 31

dfpRequestLimit. Number of requests to allow without bot session cookie if device fingerprint is enabled Minimum value: 1, Maximum Value: 4294967295

signatureAutoUpdate. Flag used to enable/disable bot auto update signatures.
Possible values: ON, OFF
Default value: OFF

signatureUrl. URL to download the bot signature mapping file from server. Default value: https://nsbotsignatures.s3.amazonaws.com/BotSignatureMapping.json. Maximum Length: 2047

ProxyServer. Proxy Server IP to get updated signatures from AWS.
proxyPort. Proxy Server Port to get updated signatures from AWS. Default value: 8080

Example:
set bot settings -defaultProfile profile1 -javaScriptName json.js -sessionTimeout 1000 -sessionCookieName session

Configuring bot management by using Citrix ADC GUI

You can configure Citrix ADC bot management by first enabling the feature on the appliance. Once you enable, you can create a bot policy to evaluate the incoming traffic as bot and send the traffic to the bot profile. Then, you create a bot profile and then bind the profile to a bot signature. As an alternative, you can also clone the default bot signature file and use the signature file to configure the detection techniques. After creating the signature file, you can import it into the bot profile. All these steps are performed in the below sequence:

1. Enable bot management feature
2. Configure bot management settings
3. Clone Citrix bot default signature
4. Import Citrix bot signature
5. Configure bot signature settings
6. Create bot profile
7. Create bot policy

Enable bot management feature

Follow the steps given below to enable bot management:

1. On the navigation pane, expand System and then click Settings.
2. On the **Configure Advanced Features** page, select the **Bot Management** check box.

3. Click **OK**, and then click **Close**.

---

**Configure bot management settings for device fingerprint technique**

Follow the steps given below to configure device fingerprint technique:

1. Navigate to **Security > Citrix Bot Management**.

2. In the details pane, under **Settings** click **Change Citrix Bot Management Settings**.

3. In the **Configure Citrix Bot Management Settings**, set the following parameters.
   a) Default Profile. Select a bot profile.
b) JavaScript Name. Name of the JavaScript file that bot management uses in its response to the client.
c) Session Timeout. Timeout in seconds after which the user session is terminated.
d) Session Cookie. Name of the session cookie that the bot management system uses for tracking.
e) Device Fingerprint Request Limit. Number of requests to allow without a bot session cookie, if device fingerprint is enabled

Configure Citrix Bot Management Settings

4. Click OK.

Clone bot signature file

Follow the steps given below to clone bot signature file:

2. In Citrix Bot Management Signatures page, select the default bot signatures record and click Clone.
3. In the Clone Bot Signature page, enter a name and edit the signature data.
4. Click **Create**.

   ![Citrix Bot Management Signatures](image)

**Import bot signature file**

If you have your own signature file, then you can import it as a file, text, or URL. Perform the following steps to import the bot signature file:

1. Navigate to **Security > Citrix Bot Management** and **Signatures**.
2. On the **Citrix Bot Management Signatures** page, import the file as URL, File, or text.
3. Click **Continue**.

   ![Import Citrix Bot Management Signature](image)

4. On the Import Citrix Bot Management Signature page, set the following parameters.
   a) **Name**: Name of the bot signature file.
   b) **Comment**: Brief description about the imported file.
   c) **Overwrite**: Select the check box to allow overwriting of data during file update.
   d) **Signature Data**: Modify signature parameters
5. Click **Done**.
Configure bot allow list by using Citrix ADC GUI

This detection technique enables you to bypass URLs that you configure an allowed listed one. Follow the steps below to configure an allow list URL:

3. On the Citrix Bot Management Profile page, go to Signature Settings section and click White List.
4. In the White List section, set the following parameters:
   a) Enabled. Select the check box to validate the allow list URLs as part of the detection process.
   b) Configure Types. Configure a allow list URL. The URL is bypassed during bot detection. Click Add to add a URL to the bot allow list.
   c) In the Configure Citrix Bot Management Profile Whitelist Binding page, set the following parameters:
      i. Type. URL type can be an IPv4 address, subnet IP address or an IP address matching a policy expression.
      ii. Enabled. Select the check box to validate the URL.
      iii. Value. URL address.
iv. Log. Select the check box to store log entries.

vi. Comments. Brief description about the allow list URL.

vii. Click OK.

Configure Citrix Bot Management Profile Whitelist Binding

- **Type**: IPv4
- **Value**: 1.1.1.1
- **Log**: Enabled
- **Log Message**: Log if bot is detected by bot whitelist
- **Comments**: bot whitelist detection

5. Click Update.

6. Click Done.

Configure bot block list by using Citrix ADC GUI

This detection technique enables you to drop the URLs that you configure as block listed one. Follow the steps below to configure a block list URL.

1. Navigate to **Security > Citrix Bot Management** and **Profiles**.

2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **Black List**.

4. In the **Black List** section, set the following parameters:
   
   a) **Enabled**. Select the check box to validate block list URLs as part of the detection process.
   
   b) **Configure Types**. Configure a URL to be part of the bot block list detection process. These URLs are dropped during bot detection. Click Add to add a URL to the bot block list.
   
   c) In the **Configure Citrix Bot Management Profile Blacklist Binding** page, set the following parameters.
      
      i. **Type**. URL type can be an IPv4 address, subnet IP address, or IP address.
      
      ii. **Enabled**. Select the check box to validate the URL.
      
      iii. **Value**. URL address.
      
      iv. **Log**. Select the check box to store log entries.
      
      v. **Log Message**. Brief description of the login.
      
      vi. **Comments**. Brief description about the block list URL.
      
      vii. Click **OK**.

5. Click **Update**.

6. Click **Done**.
Configure IP reputation by using Citrix ADC GUI

This configuration is a pre-requisite for the bot IP reputation feature. The detection technique enables you to identify if there is any malicious activity from an incoming IP address. As part of the configuration, we set different malicious bot categories and associate a bot action to each of it. Follow the steps below to configure IP reputation technique.

2. On the Citrix Bot Management Profiles page, select a signature file and click Edit.
3. On the Citrix Bot Management Profile page, go to Signature Settings section and click IP Reputation.
4. On the IP Reputation section, set the following parameters:
   a) Enabled. Select the check box to validate incoming bot traffic as part of the detection process.
   b) Configure Categories. You can use IP reputation technique for incoming bot traffic under different categories. Based on the configured category, you can drop or redirect the bot traffic. Click Add to configure a malicious bot category.
   c) In the Configure Citrix Bot Management Profile IP Reputation Binding page, set the following parameters:
      i. Category. Select a malicious bot category from the list. Associate a bot action based on category.
      ii. Enabled. Select the check box to validate the IP reputation signature detection.
      iii. Bot action. Based on the configured category, you can assign no action, drop, redirect, mitigation, or CAPTCHA action.
      iv. Log. Select the check box to store log entries.
vi. Comments. Brief description about the bot category.

5. Click OK.

6. Click Update.

7. Click Done.

Configure bot rate limit by using Citrix ADC GUI

This detection technique enables you to block bots based on the number of requests received within a predefined time from a client IP address, a session, or a configured resource (for example, from a URL). Follow the steps below to configure rate limit technique.

2. On the Citrix Bot Management Profiles page, select a signature file and click Edit.

3. On the Citrix Bot Management Profile page, go to Signature Settings section and click Rate Limit.

4. On the Rate Limit section, set the following parameters:
   a) Enabled. Select the check box to validate the incoming bot traffic as part of the detection process.
   b) Session. Rate limit requests based on a session. Click Add to configure rate limit requests based on a session.
   c) In the Configure Citrix Bot Management Signature Rate Limit page, set the following parameters.
      i. Category. Select a malicious bot category from the list. Associate an action based on the category.
ii. Enabled. Select the check box to validate the incoming bot traffic.

iii. Bot action. Choose a bot action for the selected category.

iv. Log. Select the check box to store log entries.

vi. Comments. Brief description about the bot category.

vii. Click **OK**.

5. Click **Update**.

6. Click **Done**.
Configure device fingerprinting by using Citrix ADC GUI

This detection technique sends a java script challenge to the client and extracts the device information. Based on device information, the technique drops or bypasses the bot traffic. Follow the steps to configure the detection technique.

1. Navigate to **Security > Citrix Bot Management** and **Profiles**.

2. On the **Citrix Bot Management Profiles** page, select a signature file and click **Edit**.

3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **Device Fingerprint**.

4. In the **Device Fingerprint** section, set the following parameters:
   
   a) **Enabled**. Set this option to enable the rule.
   b) **Configuration**. For the given device fingerprint, assign no action, drop, or redirect, mitigation, or CAPTCHA action.
   c) **Log**. Select the check box to store log entries.

5. Click **Update**.

6. Click **Done**.
Bot trap technique advertises a trap URL in the client response. The URL appears invisible and not accessible if the client is a human user. However, if the client is an automated bot, the URL is accessible and when accessed, the attacker is categorized as bot and any subsequent request from the bot is blocked. The trap technique is effective in blocking attacks from bots.

**Note:**

The default trap URL is a static one. However, the Citrix ADC bot management allows you to configure a customized trap URL in the bot management profile. This is done to strengthen the bot detection technique and make it harder for attackers to find the trap URL.

To complete bot trap technique, you must complete the following steps.

1. Enable bot trap URL
2. Configure bot trap URL in bot profile

**Enable bot trap URL**

Before you can begin, you must ensure the Bot trap URL feature is enabled on the appliance. At the command prompt, type:

```
enable ns feature Bot
```

**Configure bot trap URL by using Citrix ADC GUI**

Follow the steps given below to set the bot trap URL:

2. In the Citrix Bot Management Profiles page, click Edit to configure the bot trap URL settings.

3. In the Create Citrix Bot Management Profile page, set the following parameters.
   1. Trap URL. Type the URL that you want to confirm as the bot trap URL.

4. In the Signature Settings section, click Bot Trap.

5. In the Bot Trap section, set the following parameters:
   a) Enabled. Select the check box to enable bot trap detection.
   b) In the Configure section, set the following parameters.
      i. Action. Action to be taken for bot detected by bot trap access.
      ii. Log. Enable or disable logging for bot trap binding.
6. Click **Update** and **Done**.

**Configure CAPTCHA for IP reputation and device fingerprint detection**

CAPTCHA is an acronym that stands for “Completely Automated Public Turing test to tell Computers and Humans Apart”. CAPTCHA is designed to test if an incoming traffic is from a human user or an automated bot. CAPTCHA helps to block automated bots that cause security violations to web applications. In Citrix ADC appliance, CAPTCHA uses the challenge-response module to identify if the incoming traffic is from a human user and not an automated bot.

**Configure bot static signature by using Citrix ADC GUI**

This detection technique enables you to identify the user agent info from the browser details. Based on user agent information, the bot is identified as a bad or a good bot and then you assign a bot action to it. Follow the steps below to configure static signature technique.

**How CAPTCHA works in Citrix ADC bot management**

In Citrix ADC bot management, CAPTCHA validation is configured as a policy action to be run after bot policy is evaluated. The CAPTCHA action is available only for IP reputation and device fingerprint detection techniques. Following are the steps to understand how CAPTCHA works:

1. If a security violation is observed during IP reputation or device fingerprint bot detection, the ADC appliance sends a CAPTCHA challenge.
2. The client sends the CAPTCHA response.
3. The appliance validates the CAPTCHA response and if the CAPTCHA is valid, the request is allowed and it is forwarded to the back-end server.
4. If the CAPTCHA response is invalid, the appliance sends a new CAPTCHA challenge until the maximum number of attempts is reached.
5. If the CAPTCHA response is invalid even after the maximum number of attempts, the appliance drops or redirects the request to the configured error URL.
6. If you have configured log action, then the appliance stores the request details in the ns.log file.

**Configure CAPTCHA settings by using the Citrix ADC GUI**

The bot management CAPTCHA action is supported only for IP reputation and device fingerprint detection techniques. Follow the steps below to configure the CAPTCHA settings.

1. Navigate to **Security > Citrix Bot Management and Profiles**.
2. On the **Citrix Bot Management Profiles** page, select a profile and click **Edit**.
3. On the **Citrix Bot Management Profile** page, go to **Signature Settings** section and click **CAPTCHA**.
4. In **CAPTCHA Settings** section, click **Add to configure CAPTCHA** settings to the profile:
5. In the **Configure Citrix Bot Management CAPTCHA** page, set the following parameters.
   a) **URL**. Bot URL for which the CAPTCHA action is applied during IP reputation and device fingerprint detection techniques.
   b) **Enabled**. Set this option to enable CAPTCHA support.
   c) **Grace time**. Duration until when no new CAPTCHA challenge is sent after current valid CAPTCHA response is received.
   d) **Wait time**. Duration taken for the ADC appliance to wait until the client sends the CAPTCHA response.
   e) **Mute Period**. Duration for which the client which sent an incorrect CAPTCHA response must wait until allowed to try next. During this mute period, the ADC appliance does not allow any requests. Range: 60–900 seconds, Recommended: 300 seconds.
   f) **Request Length limit**. Length of the request for which the CAPTCHA challenge is sent to the client. If the length is greater than the threshold value, the request is dropped. Default value is 10–3000 bytes.
   g) **Retry Attempts**. Number of attempts the client is allowed to retry to solve the CAPTCHA challenge. Range: 1–10, Recommended: 5.
   h) **No Action/Drop/Redirect action to be taken if the client fails the CAPTCHA validation**.
   i) **Log**. Set this option to store request information from the client when response CAPTCHA fails. The data is store in ns.log file.
   j) **Comment**. A brief description about the CAPTCHA configuration.
6. Click **OK** and **Done**.

Configure Citrix Bot Management Captcha

<table>
<thead>
<tr>
<th>Parameter</th>

</tbody>
</table>

Comment: CAPTCHA action support

8. On the Citrix Bot Management Signatures page, select a signature file and click **Edit**.
9. On the Citrix Bot Management Signature page, go to **Signature Settings** section and click **Bot Signatures**.
10. In the **Bot Signatures** section, set the following parameters:
11. Configure **Static Signatures**. Select a bot static signature record and click Edit to assign a bot action to it.
12. Click **OK**.
13. Click **Update Signature**.
14. Click **Done**.
Auto update for bot signatures

The bot static signature technique uses a signature lookup table with a list of good bots and bad bots. The bots are categorized based on user-agent string and domain names. If the user-agent string and domain name in incoming bot traffic matches a value in the lookup table, a configured bot action is applied.

The bot signature updates are hosted on the AWS cloud and the signature lookup table communicates with AWS database for signature updates. The auto signature update scheduler runs every 1-hour to check the AWS database and updates the signature table in ADC appliance.

The signature auto update URL to configure is, `https://nsbotsignatures.s3.amazonaws.com/BotSignatureMapping.json`

Note:

You can also configure a proxy server and periodically update signatures from AWS cloud to ADC appliance through proxy. For proxy configuration, you must set the proxy IP address and port address in the bot settings.

How bot signature auto update works

The following diagram shows how the bot signatures are retrieved from AWS cloud, updated on Citrix ADC, and viewed on Citrix ADM for signature update summary.
The bot signature auto-update scheduler does the following:

1. Retrieves the mapping file from the AWS URI.
2. Checks the latest signatures in the mapping file with the existing signatures in ADC appliance.
3. Downloads the new signatures from AWS and verifies the signature integrity.
4. Updates the existing bot signatures with the new signatures in the bot signature file.
5. Generates an SNMP alert and sends the signature update summary to Citrix ADM.

**Configure bot signature auto update**

For configuring bot signature auto update, complete the following steps:

**Enable bot signature auto update**

You must enable the auto update option in the bot settings on the ADC appliance.

At the command prompt, type:

```
set bot settings -signatureAutoUpdate ON
```

**Configure proxy server settings (optional)**

If you are accessing the AWS signature database through a proxy server, you must configure the proxy server and port.

```
set bot settings -proxyserver -proxyport
```

**Example:**

```
set bot settings -proxy server 1.1.1.1 -proxyport 1356
```

**Configure bot signature auto update using the Citrix ADC GUI**

Complete the following steps to configure bot signature auto update:

1. Navigate to **Security > Citrix Bot Management.**
2. In the details pane, under Settings click Change Citrix Bot Management Settings.

3. In the Configure Citrix Bot Management Settings, select the Auto Update Signature check box.

4. Click OK and Close.

Create bot management profile

A bot profile is a collection of bot management settings that are used for detecting the bot type. In a profile, you determine how the Web App Firewall applies each of its filters (or checks) to bot traffic to your websites, and responses from them.

Follow the steps given below to configure the bot profile:

2. In the details pane, click Add.

3. In the Create Citrix Bot Management Profile page, set the following parameters.
   
   a) Name. Bot profile name.
   
   b) Signature. Name of the bot signature file.
   
   c) Error URL. URL for redirects.
d) Comment. Brief description about the profile.

4. Click **Create** and **Close**.

---

**Create Citrix Bot Management Profile**

- **Name**: bot-profile
- **Signature**: 
- **Error URL**: http://error.com
- **Comment**: configuration for bot profile

---

Create bot policy

The bot policy controls the traffic going to the bot management system and also to control the bot logs sent to the auditlog server. Follow the procedure to configure the bot policy.

1. Navigate to **Security > Citrix Bot Management > Bot Policies**.
2. In the details pane, click **Add**.
3. In the **Create Citrix Bot Management Policy** page, set the following parameters.
   a) Name. Name of the Bot policy.
   b) Expression. Type the policy expression or rule directly in the text area.
   c) Bot Profile. Bot profile to apply the bot policy.
   d) Undefined Action. Select an action that you prefer to assign.
   e) Comment. Brief description about the policy.
   f) Log Action. Audit log message action for logging bot traffic. For more information about audit log action, see Audit logging topic.
4. Click **Create** and **Close**.
Bot Transactions Per second (TPS)

The Transactions Per Second (TPS) bot technique detects incoming traffic as a bot if the number of requests per second (RPS) and percentage increase in RPS exceeds the configured threshold value. The detection technique protects your web applications from automated bots that can cause web scraping activities, brute forcing login, and other malicious attacks.

**Note:**

The bot technique detects an incoming traffic as bot only if both the parameters are configured and if both values increase beyond threshold limit.
Let us consider a scenario, where the appliance receives many requests coming from a specific URL and you want the Citrix ADC bot management to detect if there is a bot attack. The TPS detection technique examines the number of requests (configured value) coming from the URL within 1 second and the percentage increase (configured value) in the number of requests received within 30 minutes. If the values exceed the threshold limit, the traffic is considered as bot and the appliance runs the configured action.

**Configure bot transactions per second (TPS) technique**

To configure TPS, you must complete the following steps:

1. Enable bot TPS
2. Bind TPS settings to bot management profile

**Bind TPS settings to bot management profile**

Once you enable the bot TPS feature, you must bind the TPS settings to the bot management profile.

At the command prompt, type:

```bash
bind bot profile <name>... (-tps [-type (SourceIP | GeoLocation | RequestURL | Host)] [-threshold <positive_integer>] [-percentage <positive_integer>] [-action (none | log | drop | redirect | reset | mitigation)] [-logMessage <string>])
```

**Example:**

```bash
bind bot profile profile1 -tps -type RequestURL -threshold 1 -percentage 100000 -action drop -logMessage log
```

**Enable bot transaction per second (TPS)**

Before you can begin, you must ensure the Bot TPS feature is enabled on the appliance. At the command prompt, type:

```bash
set bot profile profile1 -enableTPS ON
```

**Configure bot transactions per second (TPS) by using the Citrix ADC GUI**

Follow the steps given below to complete the configuration:

1. Navigate to **Security > Citrix Bot Management > Profiles**.
2. In the **Citrix Bot Management Profiles** page, select a profile and click **Edit**.
3. In the **Create Citrix Bot Management Profile** page, click **TPS** under **Signature Settings** section.
4. In the TPS section, enable the feature and click **Add**.

5. In **Configure Citrix Bot Management Profile TPS Binding** page, set the following parameters.
   a) **Type.** Input types allowed by TPS detection technique. Possible values: SOURCE IP, GEOLOCATION, HOST, URL.
      SOURCE_IP – TPS based on client IP address.
      GEOLOCATION – TPS based on the client's geographic location.
      HOST - TPS based on client requests forwarded to a specific back-end server IP address.
      URL – TPS based on client requests coming from a specific URL.
   b) **Fixed Threshold.** Maximum number of requests allowed from a TPS input type within 1 second time interval.
   c) **Percentage Threshold.** Maximum percentage increase in requests from a TPS input type within 30 minute time interval.
   d) **Action.** Action to be taken for bot detected by TPS binding.
   e) **Log.** Enable or disable logging for TPS binding.
   f) **Log Message.** Message to log for bot detected by TPS binding. Maximum Length: 255.
   g) **Comments.** A brief description about the TPS configuration. Maximum Length: 255

6. Click **OK** and then **Close**.
Following are some of the troubleshooting scenarios covered in Citrix ADC bot management.

1. How to handle false positive cases?

You can use the bot white list functionality to manage false positive cases and these transactions can be bypassed.

2. How to find more details about bad bot traffic?

You can use the auditlogging functionality to get details about the traffic classified as bad bots. For information about classified category of bad bots.

3. Why should you change the default signature name?

You can change the default signature name if there are conflicts detected at the end point resources served by Citrix ADC appliance.
Bot Management

April 7, 2020

1. What is Citrix ADC bot management?
   Citrix ADC bot management detects and distinguishes traffic from good bots, bad bots, and human clients. The bot management functionality protects your web applications by dropping connections from bad bots.

2. Why should Citrix ADC manage bots for your web application?
   Malicious bots constitute 30% of your internet traffic. Malicious bots impact web applications in various ways such as initiating a DoS attack, spamming email addresses, slowing down application using downloader programs, downloading the content from websites and so forth. In addition, bots can easily bypass some of the well known detection mechanisms leading to loss of data, revenue, and reputation to your organization.

3. What are the techniques used for detecting an incoming bot?
   Citrix ADC bot management uses bot signatures, IP reputation, rate limiting, and device fingerprinting techniques detection techniques. In addition, you can configure a customized blacklist on Citrix ADC GUI to categorize organization specific bad bots.

4. What is a bot signature file and its purpose?
   The bot signature file contains the footprint of known good and bad bots. The signature file can be updated periodically to include the latest bot signatures for better bot protection.

5. What type of Citrix ADC license must I purchase?
   Bot management is available with ADC Platinum license.

6. Where can I find bot logs for troubleshooting?
   Citrix ADC audit logs provide detected bot details. For more information, see Audit Logging topic.

7. Is there an auto update functionality for bot signature files?
   Currently, Citrix ADC does not support auto update functionality.

8. Is there a pre-requisite for using bot IP reputation technique?
   Enable IP reputation feature before enabling and configuring the IP reputation in bot profile.
Cache Redirection

April 23, 2019

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a Citrix ADC appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The Citrix ADC appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A Citrix ADC appliance configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the Citrix ADC appliance resides directly in front of the clients. In a server-side deployment, the Citrix ADC appliance is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache redirection policies

April 23, 2019

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the Citrix ADC appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The appliance provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.
Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

Built-in cache redirection policies

July 27, 2020

The Citrix ADC appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use two types of appliance expressions languages, classic and default syntax. For more information about these languages, see Policies and expressions.

Built-in classic cache redirection policies

Built-in cache redirection policies based on classic expressions are called classic cache redirection policies. For a complete description of classic expressions and how to configure them, see Policies and Expressions.

The classic cache redirection policies evaluate basic characteristics of traffic and other data. For example, classic cache redirection policies can determine whether an HTTP request or response contains a particular type of header or URL.

The Citrix ADC appliance provides the following built-in classic cache redirection policies:

<table>
<thead>
<tr>
<th>Built-In Policy Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bypass-non-get</td>
<td>Bypass the cache if the request uses an HTTP method other than GET.</td>
</tr>
<tr>
<td>bypass-cache-control</td>
<td>Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.</td>
</tr>
</tbody>
</table>
### Built-In Policy Name | Description
---|---
bypass-dynamic-url | Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/.
bypass-urltokens | Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.
bypass-cookie | Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg.

---

### Built-in default syntax cache redirection policies

Built-in cache redirection policies based on default syntax expressions are called default syntax cache redirection policies. For a complete description of default syntax expressions and how to configure them, see Policies and Expressions.

In addition to the same types of evaluations done by classic cache redirection policies, default syntax cache redirection policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, directing the request to either cache or origin server).

Citrix ADC appliances provide the following two built-in actions for the default syntax cache redirection policies:

- CACHE
- ORIGIN

As implied by their names, they direct the request to the cache server or the origin server, respectively.

**Note:** If you are using the built-in default syntax cache redirection policy, you cannot modify the action.

The Citrix ADC appliance provides the following built-in default syntax cache redirection policies:

### Built-In Policy Name | Description
---|---
bypass-non-get_adv | Bypass the cache if the request uses an HTTP method other than GET.
<table>
<thead>
<tr>
<th>Built-In Policy Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bypass-cache-control_adv</td>
<td>Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.</td>
</tr>
<tr>
<td>bypass-dynamic-url_adv</td>
<td>Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/.</td>
</tr>
<tr>
<td>bypass-urltokens_adv</td>
<td>Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.</td>
</tr>
<tr>
<td>bypass-cookie_adv</td>
<td>Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg.</td>
</tr>
</tbody>
</table>

**Display the built-in cache redirection policies**

You can display the available cache redirection policies by using the command line interface or the configuration utility.

**Display the built-in cache redirection policies by using the CLI**

At the command prompt, type:

```bash
show cr policy [<policyName>]
```

**Example:**

```
1 > show cr policy
2 1) Cache-By-Pass RULE: NS_NON_GET Policy:bypass-non-get
3 2) Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE || NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA) Policy:bypass-cache-control
4 3) Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE || NS_EXT_CFM || NS_EXT_EX || NS_EXT_SHTML || NS_EXT_HTX) || (NS_URL_PATH_CGIBIN || NS_URL_PATH_EXEC || NS_URL_PATH_BIN)
```

Display the built-in cache redirection policies by using the GUI

2. Select one of the configured policies to view details.

Configure a cache redirection policy

March 11, 2020

A cache redirection policy includes one or more expressions (also called rules). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the Citrix ADC appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the classic policy format are called classic cache redirection policies. Each such policy has a name and includes a classic expression or a set of classic expressions that are combined by using logical operators.

For classic cache redirection policies, you do not explicitly configure actions for the policies. By default, the Citrix ADC appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the newer policy format are called Advanced redirection policies. Such policy has a name and includes a default syntax expression, or a set of default syntax expressions that are combined by using logical operators, and the following built-in actions:

- CACHE
- ORIGIN

For more information about classic expressions and default syntax expressions, see Policies and Expressions.
Add a cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

```
1 - add cr policy <policyName> -rule "expression"
2 - show cr policy [policyName]
```

Examples:

Policy with a simple expression:

```
1 > add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
2 Done
3 > show cr policy Policy-CRD-1
4   Cache-By-Pass RULE: REQ.HTTP.URL != '/*.jpeg' Policy:Policy-CRD-1
5 Done
```

Policy with a compound expression:

```
1 > add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi || REQ.HTTP.URL != /*.png)"
2 Done
3 > show cr policy Policy-CRD-2
4   Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == '/*.cgi' || REQ.HTTP.URL != '/*.png') Policy:Policy-CRD-2
5 Done
```

Policy that evaluates a header:

```
1 > add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
2 Done
3 > show cr policy Policy-CRD-3
4   Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS HEADER Policy:Policy-CRD-3
5 Done
```

Add a default syntax cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:
1 - add cr policy <policyName> **-rule** <expression> [-action<string>] [-logAction<string>]

2 - show cr policy [<policyName>]

Examples:

Policy with a simple expression:

```
1 > add cr policy crpol1 -rule !(HTTP.REQ.URL.ENDORWSITH(".jpeg")) -action origin
2    Done
3 > show cr policy crpol1
4    Policy: crpol1 Rule: !(HTTP.REQ.URL.ENDORWSITH(".jpeg")) Action: ORIGIN
5    Done
```

Policy with a compound expression:

```
1 > add cr policy crpol11 -rule "http.req.method.eq(post) && (HTTP.REQ.
   URL.ENDORWSITH(".png") || HTTP.REQ.URL.ENDORWSITH(".cgi"))" -action cache
2    Done
3 > show cr policy crpol11
4    Policy: crpol11   Rule: http.req.method.eq(post) && (HTTP.REQ.
       URL.ENDORWSITH(".png") || HTTP.REQ.URL.ENDORWSITH(".cgi"))
       Action: CACHE
5    Done
```

Policy that evaluates a header:

```
1 > add cr policy crpol12 -rule http.req.header("If-Modified-Since").exists -action origin
2    Done
3 > show cr policy crpol12
4    Policy: crpol12   Rule: http.req.header("If-Modified-Since").exists   Action: ORIGIN
5    Done
```

Modify or remove a cache redirection policy by using the CLI

- To modify a cache redirection policy, use the set cr policy command, which is just like add cr policy command, except that you enter the name of an existing policy.
To remove a policy, use the `rm cr policy` command, which accepts only the `<name>` argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see `Unbind a policy from a cache redirection virtual server`.

**Configure a cache redirection policy with a simple expression by using the GUI**

2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:

   - Expression Type-General
   - Flow Type-REQ
   - Protocol-HTTP
   - Qualifier-URL
   - Operator- !=
   - Value* - /*.jpeg

   The simple expression in the following example checks for an If-Modified-Since header in a request:

   - Expression Type - General
   - Flow Type - REQ
   - Protocol - HTTP
   - Qualifier - HEADER
   - Operator - EXISTS
   - Header Name - If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.

**Configure a cache redirection policy with a compound expression by using the GUI**

2. In the details pane, click Add.
3. In the Name text box, enter a name for the policy.
The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:

- **Match Any Expression.** The policy matches the traffic if one or more individual expressions match the traffic.

- **Match All Expressions.** The policy matches the traffic only if every individual expression matches the traffic.

- **Tabular Expressions.** Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:
  - The AND [ && ] operator, to require that, to match the policy, a request must match both the current expression and the following expression.
  - The OR [ ] operator, to require that, to match the policy, a request must match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

- The BEGIN SUBGROUP [+ ( ] operator, which tells the Citrix ADC appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -( .)
- The END SUBGROUP [+ ) ] operator, which tells the Citrix ADC appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .

- **Advanced Free-Form.** Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the Citrix ADC classic expressions lan-
guage.

For more information about creating classic expressions in the Advanced Free-Form text area, see Configuring Classic Policies and Expressions.

**Caution:** If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.

5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

You should leave the expression type set to General for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

- **REQ.** Configures the Citrix ADC appliance to examine incoming connections, or requests.
- **RES.** Configures the appliance to examine outgoing connections, or responses.

7. In the Protocol drop-down list, choose a protocol for your expression.

The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose **REQ** or **RES** in the previous drop-down list, either all four or only three of the following choices are available:

- **HTTP.** Configures the appliance to examine the HTTP header.
- **SSL.** Configures the appliance to examine the SSL client certificate. Available only if you chose **REQ** (requests) in the previous drop-down list.
- **TCP.** Configures the appliance to examine the TCP header.
- **IP.** Configures the appliance to examine the source or destination IP address.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Qualifier</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP</td>
<td>METHOD</td>
<td>HTTP method used in the request.</td>
</tr>
<tr>
<td>-</td>
<td>URL</td>
<td>Contents of the URL header.</td>
</tr>
<tr>
<td>-</td>
<td>URLTOKENS</td>
<td>URL tokens in the HTTP header.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Qualifier</td>
<td>Definition</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>-</td>
<td>VERSION</td>
<td>HTTP version of the connection.</td>
</tr>
<tr>
<td>-</td>
<td>HEADER</td>
<td>Header portion of the HTTP request.</td>
</tr>
<tr>
<td>-</td>
<td>URLLEN</td>
<td>Length of the contents of the URL header.</td>
</tr>
<tr>
<td>-</td>
<td>URLQUERY</td>
<td>Query portion of the contents of the URL header.</td>
</tr>
<tr>
<td>-</td>
<td>URLQUERYLEN</td>
<td>Length of the query portion of the URL header.</td>
</tr>
<tr>
<td>SSL</td>
<td>CLIENT.CERT</td>
<td>SSL client certificate as a whole.</td>
</tr>
<tr>
<td>-</td>
<td>CLIENT.CERT.SUBJECT</td>
<td>Contents of the client certificate subject field.</td>
</tr>
<tr>
<td>-</td>
<td>CLIENT.CERT.ISSUER</td>
<td>Client certificate issuer.</td>
</tr>
<tr>
<td>-</td>
<td>CLIENT.CERT.SIGALGO</td>
<td>Signature algorithm used in the client certificate.</td>
</tr>
<tr>
<td>-</td>
<td>CLIENT.CERT.VERSION</td>
<td>Client certificate version.</td>
</tr>
<tr>
<td>-</td>
<td>CLIENT.CERT.VALIDFROM</td>
<td>Date from which the client certificate is valid. (The start date.)</td>
</tr>
<tr>
<td>-</td>

9. Choose the operator for your expression from the Operator drop-down list.

Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

- `==` . Matches the following text string exactly.
- `!=` . Does not match the following text string.
- `>` . Is greater than the following integer.
- `CONTAINS` . Contains the following text string.
- `CONTENTS` . The contents of the designated header, URL, or URL query.
- `EXISTS` . The specified header or query exists.
- `NOTCONTAINS` . Does not contain the following text string.
- `NOTEXISTS` . The specified header or query does not exist.

If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.

For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.

12. Click OK to add your expression to the Expression list.

13. Repeat steps 4 through 11 to create additional expressions.

14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

Cache redirection configurations

April 23, 2019

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent.** A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the Citrix ADC appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.

- **Forward proxy.** A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.

- **Reverse proxy.** Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

Configure transparent redirection

February 12, 2020

When you configure transparent cache redirection, the Citrix ADC appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the Citrix ADC appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the request does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see [Direct policy hits to the cache instead of the origin](#).

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this
virtual server can receive traffic coming to the appliance on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

Enable cache redirection and load balancing

April 23, 2019

The appliance cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

Enable cache redirection and load balancing by using the CLI

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

1 - enable ns feature cr lb
2 - show ns feature

Example:

1 > enable ns feature cr lb
Done
3 > show ns feature

<table>
<thead>
<tr>

</tbody>
</table>
Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
   a) In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
   a) In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.

Configure edge mode

April 23, 2019

When deployed at the edge of a network, the Citrix ADC appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns on the collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

Enable edge mode by using the CLI

At the command prompt, type the following commands to enable edge mode and verify the setting:

```
1 - enable ns mode Edge
2 - show ns mode
```
Example:

```
1  > enable ns mode edge
2      Done
3
4  > show ns mode
5
6          Mode       Acronym      Status
7              -------     -------     ------
8          ...
9          ...
10         ...
11  6)    MAC-based forwarding   MBF          ON
12  7)    Edge configuration    Edge         ON
13  8)    Use Subnet IP        USNIP        OFF
14          ...
15          ...
16          ...
17  16)   Bridge BPDUs         BridgeBPDUs    OFF
18      Done
```

Enable edge mode by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configure a cache redirection virtual server

April 23, 2019

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.
A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the appliance represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

**add a cache redirection virtual server in transparent mode by using the cli**

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

```
add cr vserver <name> <serviceType> [IPAddress <port>] [-cacheType <cacheType>] [-redirect <redirect>]
```

```
show cr vserver [/<name>]
```

**Example:**

```
add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect POLICY
```

```
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: RULE Cache: TRANSPARENT
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
```

**Modify or remove a cache redirection virtual server by using the CLI**

- To modify a virtual server, use the `set cr vserver` command, which is just like using the `add cr vserver` command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the `rm cr vserver` command, which accepts only the `<name>` argument.

**Add a cache redirection virtual server in transparent mode by using the GUI**

2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters as shown:
   • Name*—name
   • Port*—port
   *A required parameter

4. In the Protocol drop-down list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.

5. Click the Advanced tab.

6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.

7. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.

8. Select the new cache redirection virtual server to display the details of its configuration.

**Bind policies to the cache redirection virtual server**

April 23, 2019

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

**Bind policies to a cache redirection virtual server by using the CLI**

At the command prompt, type:

```
1 - bind cr vserver <name> -policyName <string>
2 - show cr vserver [<name>]
```

**Example:**

```
1 > bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
2 Done
3 > bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
4 Done
5 > bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
```
Bind a user-defined policy to a cache redirection virtual server by using the GUI

2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Copied!
Failed!

Unbind a policy from a cache redirection virtual server

April 23, 2019

When you unbind a policy from the cache redirection virtual server, the Citrix ADC appliance no longer applies the policy when evaluating client requests.
Unbind a policy from a cache redirection virtual server by using the command CLI

At the command prompt, type:

```
1 - unbind cr vserver <name> -policyName <string>
2 - show cr vserver [<name>]
```

Example:

```
1 unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
2 > show cr vserver Vserver-CR-1
  Vserver-CR-1 (:80) - HTTP  Type: CONTENT
  State: UP  ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default:  Content Precedence: RULE  Cache:
            TRANSPARENT
  On Policy Match: ORIGIN  L2Conn: OFF  OriginUSIP: OFF
  Redirect: POLICY  Reuse: ON  Via: ON  ARP: OFF
1) Cache bypass  Policy: bypass-cache-control
13 Done
```

Unbind a user-defined policy from a cache redirection virtual server by using the GUI

2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

Create a load balancing virtual server

February 12, 2020

The cache redirection virtual server on the Citrix ADC appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.
Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see Load Balancing.

**Create a load balancing virtual server by using the CLI**

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

```
1 - add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
2 - show lb vserver [<name>]
```

**Example:**

```
1 > add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
2 Done
3 > show lb vserver Vserver-LB-CR
   Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
   State: DOWN
   Last state change was at Fri Jul 2 08:47:52 2010
   Time since last state change: 0 days, 00:00:08.470
   Effective State: DOWN
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Port Rewrite : DISABLED
   No. of Bound Services : 0 (Total) 0 (Active)
   Configured Method: LEASTCONNECTION
   Mode: IP
   Persistence: NONE
   Vserver IP and Port insertion: OFF
   Push: DISABLED  Push VsServer:
   Push Multi Clients: NO
   Push Label Rule: none
3 Done
```

**Create a load balancing virtual server by using the GUI**

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name*-name
   - IP Address*-IPAddress
   - Port*-port
   *A required parameter

4. In the Protocol list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.

5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

Configure an HTTP service

April 23, 2019

On the Citrix ADC appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

Configure an HTTP service by using the CLI

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

```
1  - add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
2  - show service [<name>]
```

Example:

```
1 > add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
2  Done
```
Modify or remove a service by using the CLI

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.
- To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

Add an HTTP service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
Bind/unbind a service to/from a load balancing virtual server

April 23, 2019

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

Bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

1 - bind lb vserver <name> <serviceName>
2 - show lb vserver [ <name> ]

Example:

1 > bind lb vserver vserver-LB-CR service-HTTP-1
2  Done
3 > show lb vserver Vserver-LB-CR
4 Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
5 State: DOWN
6 Last state change was at Fri Jul 2 08:47:52 2010
7 Time since last state change: 0 days, 00:42:25.610
8 Effective State: DOWN
9 Client Idle Timeout: 180 sec
10 Down state flush: ENABLED
11 Disable Primary Vserver On Down : DISABLED
12 Port Rewrite : DISABLED
13 No. of Bound Services : 1 (Total) 0 (Active)
14 Configured Method: LEASTCONNECTION
Unbind a service from a load balancing virtual server by using the CLI

To unbind a service, use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/unbind a service from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Enable the use the proxy port setting for transparent caching

April 23, 2019

If the use source IP (USIP) option is disabled on a cache service configured on the Citrix ADC appliance, the appliance forwards client requests to the cache service by using an appliance-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client’s IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client’s source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.
For more information about configuring the Use Proxy Port option globally or on a service, see Configuring the Source Port for Server-Side Connections.

Assign a port range to the Citrix ADC appliance

April 23, 2019

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other Citrix ADC appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the Citrix ADC appliance. This allotment enables network devices to unambiguously identify the Citrix ADC appliance that sent the request.

Assign a source port range to a Citrix ADC appliance by using the CLI

At the command prompt, type:

```sh
set ns param -crPortRange <startPortNumber-endPortNumber>
```

Assign a source port range to a Citrix ADC appliance by using the appliance GUI

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Enable load balancing virtual servers to redirect requests to cache

April 23, 2019
If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a Citrix ADC appliance at the edge of its network and all traffic flows through the appliance.

**Enable load balancing virtual servers to redirect requests to the cache by using the CLI**

At the command prompt, type:

```
1 - set lb vserver <name> [-cacheable ( YES | NO)]
2 - show lb vserver [<name>]
```

**Example:**

```
1 set lb vserver Vserver-LB-CR - cacheable YES
> show lb vserver Vserver-LB-CR
  Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul  2 08:47:52 2010
  Time since last state change: 0 days, 01:05:51.510
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 1 (Total) 0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Cacheable: YES  PQ: OFF SC: OFF
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none
1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
Done
```
For transparent cache redirection, the appliance intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server. When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

**Turn off caching for a load balancing virtual server by using the CLI**

To turn off caching for a load balancing virtual, use the unset lb vserver command instead of set lb vserver. Specify a value of NO value for the `cacheable` parameter.

**Enable or disable load balancing virtual servers to redirect requests to the cache by using the GUI**

2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

**Configure forward proxy redirection**

February 12, 2020

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the Citrix ADC appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the appliance is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the appliance compares the request with a policy for caching. If the request is not cacheable, the appliance queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the appliance forwards the request to a load balancing virtual server for the cache.

The appliance relies on a host domain name or IP address in the request’s HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.
Typically, the Citrix ADC appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the appliance. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a forward proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see Configure a cache redirection policy.

Create a DNS service

April 23, 2019

A DNS service is a representation, on the Citrix ADC appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

Create a DNS service by using the CLI

At the command line, type the following commands to create a DNS service and verify the configuration:

© 1999-2020 Citrix Systems, Inc. All rights reserved.
1. Navigate to Traffic Management > Load Balancing > Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters as shown:

   • Service Name*—name
   • Server*—IP
   • Port*—port
Create a DNS load balancing virtual server

April 23, 2019

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

Create a DNS load balancing virtual server by using the CLI

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

1. `add lb vserver <name> <serviceType>`
2. `show lb vserver [<name>]`

Example:

```
1 > add lb vserver Vserver-DNS-1 DNS
2   Done
3 > show lb vserver Vserver-DNS-1
4   Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5   State: DOWN
6   Last state change was at Fri Jul  2 10:32:28 2010
7   Time since last state change: 0 days, 00:00:08.10
8   Effective State: DOWN ARP:DISABLED
9   Client Idle Timeout: 120 sec
10  Down state flush: ENABLED
11  Disable Primary Vserver On Down : DISABLED
12  No. of Bound Services : 0 (Total)   0 (Active)
13  Configured Method: LEASTCONNECTION
14  Mode: IP
15  Persistence: NONE
16   Done
```
Create a DNS load balancing virtual server by using the GUI

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, DNS).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

Bind the DNS service to the load balancing virtual server by using the CLI

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

```
1 - bind lb vserver <name> <serviceName>
2 - show lb vserver <name>
```

Example:

```
1 > bind lb vserver Vserver-DNS-1 Service-DNS-1
2   Done
3 > show lb vserver Vserver-DNS-1
4   Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5   State: DOWN
6   Last state change was at Fri Jul 2 10:32:28 2010
7   Time since last state change: 0 days, 00:12:16.80
8   Effective State: DOWN ARP:DISABLED
9   Client Idle Timeout: 120 sec
10  Down state flush: ENABLED
11  Disable Primary Vserver On Down : DISABLED
12  No. of Bound Services : 1 (Total) 0 (Active)
```
Unbind a DNS service from the load balancing virtual server by using the CLI

Use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/Unbind a DNS service to/from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configure a client web browser to use a forward proxy

April 23, 2019

When you configure the Citrix ADC appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.
Configure reverse proxy redirection

April 23, 2019

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the appliance receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before it is sent to the backend server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a reverse proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type REVERSE.
For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

**Configure mapping policies**

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).
- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).
- Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

**Configure a mapping policy for reverse proxy mode by using the CLI**

At the command prompt, type the following command to add a policy map and verify the configuration:

```
1 - add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]
2 - show policy map [<mapPolicyName>]
```
Example:
The following command maps a domain in a client request to a target domain:

```
> add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
Done
> show policy map myMappingPolicy
1) Name: myMappingPolicy
  Source Domain: www.mycompany.com    Source Url:
  Target Domain: www.myrealcompany.com    Target Url:
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
Done
> show policy map myOtherMappingPolicy
1) Name: myOtherMappingPolicy
  Target Domain: www.myrealcompany.com    Target Url: /realnews.html
```

Configure a mapping policy for reverse proxy mode by using the GUI

2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:
   - Name*- mapPolicyName
   - Source Domain*-sd
   - Target Domain*-td
   - Source URL-su
   - Target URL-tu
   *A required parameter
4. Click Create, and then click Close. The Map pane displays the new mapping policy.
Bind the mapping policy to the cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

```
1 - bind cr vserver <name> -policyName <string> [<targetVserver>]
2 - show cr vserver <name>
```

Example:

```
1 > bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
   Done
2 > show cr vserver Vserver-CRD-3
   Vserver-CRD-3 (10.102.29.50:88) - HTTP Type: CONTENT
   State: UP
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Default: Vserver-LB-CR Content Precedence: RULE Cache: REVERSE
   On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
   Redirect: POLICY Reuse: ON Via: ON ARP: OFF
1) Policy: Target: Vserver-LB-CR Priority: 0 Hits: 0
1) Map: myMappingPolicy Target: Vserver-LB-CR
   Done
```

Bind the mapping policy to the cache redirection virtual server by using the GUI

2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.
3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.
4. In the Policy Name column, select the policy from drop down list.
5. In the Target column, click the down arrow, and then select the vserver from drop down list.
6. Click OK.

Copied!

Selective cache redirection

April 23, 2019

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the Citrix ADC appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The appliance first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the appliance evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the Citrix ADC appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the appliance sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the appliance, which is configured as a Layer 4 switch that receives traffic on port 80.

The appliance can direct requests for images (for example, .png and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

**Note:** The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an
associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

Enable content switching

April 23, 2019

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the appliance, you must enable content switching.

Enable content switching by using the CLI

At the command prompt, type:

1 - enable ns feature CS
2
3 - show ns feature

Example:

1 > enable ns feature cs
2 Done
3 > show ns feature

5
6 Feature Acronym Status
7 ------- ------- -----
8 1) Web Logging WL ON
9 2) Surge Protection SP ON
10 3) Load Balancing LB ON
11 4) Content Switching CS ON
12 5) Cache Redirection CR ON
13 ...
14 ...
15 23) HTML Injection HTMLInjection ON
16 24) appliance Push push OFF
17 Done
Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configure a load balancing virtual server for the cache

April 23, 2019

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a transparent proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

Configure a cache redirection policy for a specific type of content

To identify requests that contain a .png or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the Citrix ADC appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do not have “.png” or “.jpeg” extensions.
To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in Configure a cache redirection policy.

Configure policies for content switching

June 26, 2019

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .png and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see Content switching.

You must first create the content switching policy and then bind it to the cache redirection virtual server.

Create a content switching policy by using the command CLI

At the command line, type:

```
1 - add cs policy <policyName> [-url <string> | -rule <expression>]
2 - show cs policy [<policyName>]
```

Examples:

```
1 > add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
  Done
2 > show cs policy Policy-CS-JPEG
    Rule: REQ.HTTP.URL == '/*.jpeg'
    Policy: Policy-CS-JPEG
    Hits: 0
  Done
7 >
8
```
Create a URL-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, /sports).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

Create a rule-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.

5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.

The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression’s effect.

6. Enter your policy expressions.

   For information about using the advanced syntax, see Configure advanced policy expression: Get started.

7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

### Bind the content switching policy to a cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

```
1 - bind cs vserver <name> <targetVserver> [-policyName <string>]
2 - show cs vserver [<name>]
```

**Example:**

```
1 > bind cs vserver Vserver-CR-1 lbcachejpeg -policyName Policy-CS-JPEG
   Done
2 > bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
   Done
3 > show cs vserver Vserver-CR-1
   Vserver-CR-1 (10.102.29.60:80) - HTTP  Type: CONTENT
   State: UP
   Last state change was at Fri Jul  2 12:53:45 2010
   Time since last state change: 0 days, 00:00:58.920
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Port Rewrite : DISABLED
   State Update: DISABLED
   Default: Content Precedence: RULE
   Done
```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Cacheable: YES
Vserver IP and Port insertion: OFF
Case Sensitivity: ON
Push: DISABLED  Push VServer: 
Push Label Rule: none

1) Policy: Policy-CS-JPEG  Target: lbcachejpeg  Priority: 0
   Hits: 0
2) Policy: Policy-CS-GIF  Target: lbcachegif  Priority: 0
   Hits: 0

Done

Bind the content switching policy to a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.
4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.
5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click OK.

Configure precedence for policy evaluation

April 23, 2019

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.
Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

Configure precedence for policy evaluation by using the CLI

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

1. `set cr vserver <name> [-precedence (RULE | URL)]`
2. `show cr vserver <name>`

Example:

```
1 > set cr vserver Vserver-CRD-1 -precedence URL
2   Done
3 > show cr vserver Vserver-CRD-1
4   Vserver-CRD-1 (*:80) - HTTP   Type: CONTENT
5   State: UP  ARP:DISABLED
6   Client Idle Timeout: 180 sec
7   Down state flush: ENABLED
8   Disable Primary Vserver On Down : DISABLED
9   Default:     Content Precedence: URL Cache: TRANSPARENT
10  On Policy Match: ORIGIN L2Conn: OFF  OriginUSIP: OFF
11  Redirect: POLICY    Reuse: ON   Via: ON ARP: OFF
12
13  1)     Cache bypass    Policy: bypass-cache-control
14  2)     Cache bypass    Policy: Policy-CRD
15   Done
16 >
```

Configure precedence for policy evaluation by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administer a cache redirection virtual server

April 23, 2019

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

View cache redirection virtual server statistics

April 23, 2019

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

View statistics for a cache redirection virtual server by using the CLI

At the command prompt, type:

```
stat cr vserver [name]
```

Example:

```
1 > stat cr vserver Vserver-CRD-1
2
3 Vserver Summary
```
### View statistics for a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

### View the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.
4. Click Applet Client or Web Start Client next to Statistical Utility.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

Enable or disable a cache redirection virtual server

April 23, 2019

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the Citrix ADC appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

Enable or disable a cache redirection virtual server by using the CLI

At the command line, type one of the following commands:

1 - enable cr vserver <name>
2 - show cr vserver <name>
3 - disable cr vserver <name>
4 - show cr vserver <name>

Examples:

1 > enable cr vserver Vserver-CRD-1
     Done
3 > show cr vserver Vserver-CRD-1
   Vserver-CRD-1 (*:80) - HTTP       Type: CONTENT
   State: UP   ARP:DISABLED
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Default:     Content Precedence: URL Cache: TRANSPARENT
   On Policy Match: ORIGIN L2Conn: OFF    OriginUSIP: OFF
   Redirect: POLICY        Reuse: ON      Via: ON ARP: OFF

13 1)   Cache bypass Policy: bypass-cache-control
14 2)   Cache bypass Policy: Policy-CRD
16 >
18 > disable cr vserver Vserver-CRD-1
19 Done
Enable or disable a cache redirection virtual server by using the GUI

2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, Vserver-CRD-1), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Direct policy hits to the cache instead of the origin

April 23, 2019

By default, when a request matches a policy, the Citrix ADC appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the onPolicyMatch parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:
1. CACHE - Directs all matching requests to the cache.
2. ORIGIN - Directs all matching requests to the origin server.

Note: For this option to work, you must select the cacheredirection type as POLICY.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

Change the destination for a policy hit to the origin or the cache by using the CLI

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

1 - set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]
2 - show cr vserver <name>

Example:

```
1 > set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
Done
3 > show cr vserver Vserver-CRD-1
4 Vserver-CRD-1 (:80) - HTTP Type: CONTENT
5 State: UP ARP:DISABLED
6 Client Idle Timeout: 180 sec
7 Down state flush: ENABLED
8 Disable Primary Vserver On Down : DISABLED
9 Default: Content Precedence: URL Cache: TRANSPARENT
10 On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
11 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
12
13 1) Cache bypass Policy: bypass-cache-control
14 2) Cache bypass Policy: Policy-CRD
15 Done
```

Change the destination for a policy hit to the origin or the cache by using the GUI

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select CACHE or ORIGIN from the Redirect To drop-down list.
5. Click OK.
Back up a cache redirection virtual server

April 23, 2019

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

Specify a backup cache redirection virtual server by using the CLI

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

1. `set cr vserver <name> [-backupVServer <string>]`
2. `show cr vserver <name>`

Example:

```
1) > set cr vserver Vserver-CRD-1 -backupVServer Vserver-CRD-2
2) Done
3) > show cr vserver Vserver-CRD-1
   Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
   State: UP ARP:DISABLED
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down: DISABLED
   Default: Content Precedence: URL Cache: TRANSPARENT
   On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
   Redirect: POLICY Reuse: ON Via: ON ARP: OFF
   Backup: Vserver-CRD-2

14) 1) Cache bypass Policy: bypass-cache-control
15) 2) Cache bypass Policy: Policy-CRD
16) Done
```
Specify a backup cache redirection virtual server by using the GUI

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

Manage client connections for a virtual server

April 23, 2019

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- Configure client timeout
- Insert Via headers in the requests
- Reuse TCP connections
- Configure delayed connection cleanup
Configure client timeout

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the Citrix ADC appliance closes any idle client connections. The default value is 180 sec for HTTP/SSL-based services and 9000 sec for TCP-based services.

Configure client timeout by using the CLI

At the command prompt, type the following commands to configure client timeout and verify the configuration:

1. `set cr vs <name> [-cltTimeout <secs>]`
2. `show cr vs <name>`

Example:

1. `> set cr vs Vserver-CRD-1 -cltTimeout 6000`
2. Done
3. `> show cr vs Vserver-CRD-1`
4. Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
5. State: UP ARP:DISABLED
6. Client Idle Timeout: 6000 sec
7. Down state flush: ENABLED
8. Disable Primary Vserver On Down: DISABLED
11. Redirect: POLICY Reuse: ON Via: ON ARP: OFF
13. 1) Cache bypass Policy: bypass-cache-control
14. 2) Cache bypass Policy: Policy-CRD
15. Done

Configure client timeout by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

**Insert Via headers in the requests**

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF
Default value: ON

**Enable or disable Via-header insertion in client requests by using the CLI**

At the command prompt, type:

```
1 - set cr vserver <name> [-via (ON|OFF)]
2 - show cr vserver <name>
```

**Example:**

```
1 > set cr vserver Vserver-CRD-1 -via ON
2   Done
3 > show cr vserver Vserver-CRD-1
4   Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
5   State: UP  ARP:DISABLED
6   Client Idle Timeout: 6000 sec
7   Down state flush: ENABLED
8   Disable Primary Vserver On Down : DISABLED
9   Default:  Content Precedence: URL Cache: TRANSPARENT
10  On Policy Match: CACHE  L2Conn: OFF  OriginUSIP: OFF
11  Redirect: POLICY  Reuse: ON  Via: ON ARP: OFF
12  Backup: Vserver-CRD-2
13
14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16   Done
17 >
```
Enable or disable Via-header insertion in client requests by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.

Reuse TCP connections

You can configure the Citrix ADC appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the appliance. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF
Default value: ON

Enable or disable the reuse of TCP connections by using the CLI

At the command prompt, type:

```
1 - set cr vserver <name> [-reuse (ON|OFF)]
2 - show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -reuse ON
2 Done
3 > show cr vserver Vserver-CRD-1
4 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
5 State: UP ARP:DISABLED
6 Client Idle Timeout: 6000 sec
7 Down state flush: ENABLED
8 Disable Primary Vserver On Down : DISABLED
9 Default: Content Precedence: URL Cache: TRANSPARENT
10 On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
11 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
12 Backup: Vserver-CRD-2
```
Enable or disable the reuse of TCP connections by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

Configure delayed connection cleanup

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Enable of disable the down state flush option by using the CLI

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

```
1 -> set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
2 -> show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
2 Done
3 > show cr vserver Vserver-CRD-1
4 Vserver-CRD-1 (*:80) - HTTP       Type: CONTENT
5 State: UP  ARP:DISABLED
6 Client Idle Timeout: 6000 sec
```
Enable or disable the reuse of TCP connections by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

Enable external TCP health check for UDP virtual servers

March 20, 2020

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

The Citrix ADC appliance supports external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the cache redirection virtual server and the configured port. The TCP listener reflects the status of the virtual server.
To enable external TCP health check for UDP virtual servers by using CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```bash
add cr vserver <name> <serviceType> -tcpProbePort <tcpProbePort>
```

Example:

```bash
add cr vserver Vserver-CR-1 HTTP -tcpProbePort 80
```

To enable external TCP health check for UDP virtual servers by using GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers, and then create a virtual server.
2. Click Add to create a virtual server.
3. In the Basic Settings pane, add the port number in the TCP Probe Port field.
4. Click OK.

N-Tier cache redirection

April 23, 2019

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the Citrix ADC appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the Citrix ADC appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called n-tier cache redirection.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a Citrix ADC appliance have to be fully transparent. However, if you configure transparent cache redirection, with the Citrix ADC appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such
as routers, cache servers, origin servers, and other Citrix ADC appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

**How N-tier cache redirection is implemented**

To solve the problem, appliance n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier Citrix ADC appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier Citrix ADC appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the appliance from which it received the request and send the response to the same appliance.

The lower-tier Citrix ADC appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the appliance to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier appliance, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier Citrix ADC appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier Citrix ADC appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier Citrix ADC appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination appliance from the source port range.

**Setup necessary for configuring N-Tier CRD**

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier Citrix ADC appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination port.
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier Citrix ADC appliances.

- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier appliance and bind all the services to the virtual server.

For each lower-tier Citrix ADC appliance,

- Configure the cache redirection port range on the appliance. Assign an exclusive range to each lower-tier appliance.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this appliance. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
  - Add a source IP expression to include the client IP in the header.
  - Enable the Use Port Range option.

**How N-tier cache redirection works during a cache hit**

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit
Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

**Traffic flow**

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the appliance in the upper tier.
6. The router forwards the response to Client A.

**How N-tier cache redirection works during a cache bypass**

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass

Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

**Traffic flow**

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier appliance, L1NS2.
5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the appliance in the upper tier.
7. The router forwards the response to Client A.

**How N-tier cache redirection works during a cache miss**

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss

Two Citrix ADC appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four Citrix ADC appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request,
which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.
4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the appliance in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier appliance, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.

Configure the upper-tier Citrix ADC appliances

February 12, 2020

Configure each of the upper-tier Citrix ADC appliances as follows.

Configure an upper-tier appliance for n-tier cache redirection by using the command CLI

At the command prompt, type the following commands:

- add service \<name\>@ \<serviceIP\> \<serviceType\> \<port\>
  Run this command for each service to be added.

- add lb vserver \<name\>@ ANY \* \<port\> -persistenceType \<persistenceMethod\> -lbMethod \<lbMethod\> -m MAC -sessionless ENABLED -cltTimeout \<client\>\_Timeout\_Value\>
• `bind lb vserver <name>@<serviceName>`
  Run this command for each service to be bound.

• `enable ns mode l3`

• `add ns pbr <name> <action> -srcPort <sourcePortNumber> -destPort <startPortNumber-endPortNumber> -nexthop <serviceIpAddress> -protocol TCP`

• `apply ns pbrs`
  Run this command after adding all the necessary PBRs.

**Configure an upper-tier appliance for n-tier cache redirection by using the GUI**

1. Enable L3 mode:
   a) In the navigation pane, click System, and then click Settings.
   b) In the Settings group, click the Configure modes link.
   c) Select the Layer 3 Mode (IP Forwarding) check box.
   d) Click OK.

2. Configure policy-based routing (PBR):
   a) Navigate to System > Network > PBRs.
   b) In the Policy-Based Routing (PBRs) pane, click Add.
   c) Type a name for the PBR.
   d) Select the action as Allow.
   e) In the Next Hop box, type the IP address of the service, which represents a lower-tier appliance.
   f) Select TCP from the Protocol drop-down list.
   g) Type the source port and the range of the destination port corresponding to the lower-tier appliance being added.
   h) Click Create.
   i) In the details pane, select the PBR and click Apply.
   j) Repeat Step (i) to Step (vii) for each lower-tier appliance.

3. Create a service for each lower-tier appliance:
   a) Navigate to Traffic Management > Load Balancing > Services.
   b) In the details pane, click Add.
   c) Specify the name, protocol, IP address, and port. The protocol should be ANY.
   d) Click Create.

4. Configure a load balancing virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Servers.
   b) In the details pane, click Add.
Configure the lower-tier Citrix ADC appliances

Configure each of the lower-tier Citrix ADC appliances as follows.

**Configure a lower-tier appliance for n-tier cache redirection by using the CLI**

At the command prompt, type the following commands:

- `add service <name>@<cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP"-cachetype transparent`
  Repeat for each cache server.
- `add lb vserver <name>@<serviceType> -m MAC`
- `bind lb vserver <name>@<cacheServiceName>`
  Repeat for each cache server.
- `add cr vserver <name> <serviceType> * <port> -srcIPExpr "HTTP.REQ.HEADER("ClientIP")"-originusip ON -usePortRange ON`
- `set ns param-crPortRange <startPortNumber>-<endPortNumber>`

**Configure a lower-tier appliance for n-tier cache redirection by using the GUI**

1. Create a service for each cache server. To create a service:
   a) Navigate to Traffic Management > Load Balancing > Services.
   b) In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
c) In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
d) In the Cache Type box, select Transparent Cache.
e) Click Create.

2. Configure a load balancing virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
c) In the Services tab, select the services that represent the cache servers.
d) In the Advanced tab, for Redirection Mode, select MAC Based.
e) Click Create.

3. Configure a cache redirection virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
c) For Cache Type, select Transparent.
d) On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER(“ClientIP”).
e) Click Create.

4. Assign a source port range for the appliance:
   a) In the navigation pane, click System, and then click Settings.
b) In the Settings group, click the Change global system settings link.
c) In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
d) Click OK.

---

**Translate destination IP address of a request to origin IP address**

February 12, 2020

You can configure the forward proxy cache redirection virtual server on the Citrix ADC appliance to translate the destination IP address of the request landing on the cache redirection virtual server to the origin server IP address. This translation occurs irrespective of whether the request is sent to the cached servers or the origin server.

Previously, forward proxy cache redirection virtual server in service provider environment could not
be effectively used to send traffic across firewall because of the limitations in cache redirection using content switching policies. The cache redirection virtual server did not translate the origin IP address into the destination IP when the packet was sent to cache. The destination IP address was that of the origin server only when the requests were served from cached server.

**Note:** Translation of destination IP address of a request to origin IP address is not supported for a transparent cache redirection virtual server. For a transparent cache redirection virtual server, this option must be set to OFF.

**Use case**

In a deployment that has Citrix ADC appliance configured for forward proxy cache redirection, firewall, and reused client IP addresses, firewall cannot distinguish/use the reused IP addresses. Therefore, these reused IP addresses must be translated to different IP addresses. To translate the reused IP addresses, the Citrix ADC appliance must perform the following:

1. Query a DNS load balancing virtual server for resolution of the destination.
2. Update the origin IP address and port number in the destination.
3. Send the request back to the firewall.

Consider the following deployment that has a Citrix ADC appliance configured for forward proxy cache redirection, firewall, two routers (Router 1 and Router 2). Network traffic flows to Internet 1 through Router 1 and to Internet 2 through Router 2 respectively.
In this example, input requests from clients come from two different VLANs, VLAN11 or VLAN12. The client IP address (10.0.0.0) is reused. Based on the cache redirection and content switching policies, the request can go directly to the origin server or to the firewall.

- If the request has to bypass the firewall and go to the internet, then based on the input request VLAN, either Router 1 or Router 2 is selected and the request is sent to Internet 1 or Internet 2.
- If the request has to go through the firewall, then the source IP of the request must be translated to specific IP address. The translated IP address can be used to identify the VLAN through which request has come. For example, if the input request is coming from VLAN11, then the source IP address is translated to 11.x.x.x. If the request is coming from VLAN12, then the source IP address is translated to 12.x.x.x.

After the firewall processes the request, the request is sent back to the appliance. Using the combination of listen policy and net profiles, the appliance then translates the source IP address back to the original IP address and sends the request to Router 1 or Router 2 based on the input VLAN ID.

**Note:** The mode of the load balancing virtual server that is bound to the cache must always be set to MAC mode. Though IP mode for this feature is not blocked, setting to IP mode leads to unexpected
behavior.

To translate the destination IP address and port number of the request to origin IP address by using the CLI

At the command prompt, type;

```
set cr vserver <vsname> -useoriginIpPortForCache <YES|NO>
```

Example:

```
set cr vserver cvsrv1 -useoriginIpPortForCache YES
```

When useoriginIpPortForCache is set to Yes and if the request must be served from the cached servers, then the request’s destination IP is translated to the origin server IP address.

**Note:** If useoriginIpPortForCache is enabled, always set the load balancing virtual server that is bound to the cache to MAC mode.

To translate the destination IP address and port of the request to origin IP address by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers and click Add.
2. Specify the details of the cache redirection virtual server.
3. Select Use Origin IP Port for cache to enable translation of the destination IP address of the request to origin IP address.
4. Click OK.

Clustering

July 29, 2019

**Note**
This feature is available with a Citrix ADC Advanced or premium edition license.
A Citrix ADC cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a node. The cluster can have one appliance or as many as 32 Citrix ADC nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must add the appliances as cluster nodes, set up communication between the nodes, set up links to the client and server networks, configure the appliances, and configure the distribution of client and server traffic.

**Prerequisites for cluster nodes**

March 11, 2020

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Citrix ADC appliances that are to be added to a cluster must satisfy the following criteria:

- All appliances must have the same software version and build.
- All appliances must be of the same platform type. This means that a cluster must have either all hardware appliances (MPX) or virtual appliances (VPX) or SDX Citrix ADC instances.

**Note:**

- For a cluster of hardware appliances (MPX), the appliances must be of the same model type.
- For the formation of the heterogeneous cluster, all appliances must be of MPX platform type.
- For a cluster of virtual appliances (VPX), the appliances must be deployed on the following hypervisors: XenServer, Hyper-V, VMware ESX, and KVM.
- Clusters of SDX Citrix ADC instances are supported in NetScaler 10.1 and later releases. To create a cluster of SDX Citrix ADC instances, see Set up a cluster of Citrix NetScaler instances.
- Jumbo frames are supported on a Citrix ADC cluster that is made up of Citrix ADC SDX instances.
- You can create L3 clusters of SDX instances.

- (For releases prior to NetScaler 11.0) All appliances must be on the same network. In NetScaler 11.0 and later releases, appliances can belong to different networks.
- All appliances must have the same licenses. Also, depending on the Citrix ADC version, there are some additional aspects to address:

  - For releases prior to NetScaler 10.5 Build 52.x:
    * A separate cluster license file is required. This file must be copied to the /nsconfig/license/ directory of the configuration coordinator.
    * Because of the separate cluster license file, the cluster feature is available irrespective of the Citrix ADC license.
  - For releases after NetScaler 10.5 Build 52.x:
    * No separate cluster license is required.
    * Cluster is licensed with the Advanced and Premium licenses. Cluster is not available for Standard license.

- Be initially configured and connected to a common client-side and server-side network.

**Note**

For a cluster of virtual appliances, that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.
Cluster overview

April 23, 2019

A Citrix ADC cluster is formed by grouping Citrix ADC appliances together. Based on the network location of the Citrix ADC appliances that you intend adding to the cluster, you must be aware of the following cluster setups:

**Note**

Unless specified otherwise, cluster features and configurations are the same for L2 and L3 clusters.

- **L2 cluster**: In this cluster deployment, all cluster nodes belong to the same network.

- **L3 cluster (also referred to as ‘cluster in INC mode’)**: In this cluster deployment, cluster nodes can belong to different networks. The cluster nodes from a specific network must be grouped into nodegroups that include only nodes from that network. From the following figure, we see that nodes n1, n2, n3 are in the same network and are grouped into Nodegroup1.

  Similarly, the case for nodes n4 and n5, that are grouped in Nodegroup2. In the third network, there are two nodegroups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.

  **Note**

  Supported from NetScaler 11.0 onwards.
Synchronization across cluster nodes

February 12, 2020

All configurations on a Citrix ADC cluster are performed on the cluster IP address, which is the management address of the cluster. This cluster IP address is owned by a cluster node that is referred to as the cluster configuration coordinator as shown in the following figure:
The configurations that are available on the configuration coordinator are automatically propagated to the other cluster nodes and therefore all cluster nodes have the same configurations.

- Citrix ADC allows only a few configurations to be performed on individual cluster nodes through their NSIP address. In these cases, you must ensure configuration consistency manually across all nodes in the cluster. These configurations are not propagated across the other cluster nodes. For more information on operations supported on each cluster nodes, see Operations Supported on Individual Cluster Nodes.
- The following commands when executed on the cluster IP address are not propagated to other cluster nodes:
  - `shutdown`. Shuts down only the configuration coordinator.
  - `reboot`. Reboots only the configuration coordinator.
  - `rm cluster instance`. Removes the cluster instance from the node that you are executing the command on.
- For a command to propagate to other cluster nodes:
  - The quorum must be configured on cluster instance.
  - The majority of the cluster quorum with \((n/2 + 1)\) of the cluster nodes must be active for the cluster to be operational.
  - A cluster can run with a minimum number of nodes when majority rule \((n/2 + 1)\) is relaxed.

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the cluster configuration coordinator are synchronized to the newly added cluster node. When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the configuration coordinator. If there is a mismatch in configurations, the node is synchronized by using one of the following:

- **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the configuration coordinator are applied to the node that is rejoining the clus-
The node remains operationally unavailable for the duration of the synchronization.

- **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

**Note**

You can also manually synchronize the configurations and files. For more information, see [Synchronizing Cluster Configurations](#) and [Synchronizing Cluster Files](#).

---

# Striped, partially striped, and spotted configurations

May 20, 2020

By virtue of command propagation, all nodes in a cluster have the same configurations. However, you might want some configurations to be available only on certain cluster nodes. While you cannot restrict the nodes on which the configurations are available, you can specify the nodes on which the configurations are active.

For example, you can:

- define a SNIP address to be active on only one node, or
- define a SNIP address to be active on all nodes, or
- define a VIP address to be active on only one node, or
- define a VIP address to be active on all nodes, or
- define a VIP address to be active only on two nodes of a 3-node cluster

Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations.

Figure 1. Three-node cluster with striped, partially striped, and spotted configurations
The following table provides more details on the types of configurations:

<table>
<thead>
<tr>
<th>Configuration Type</th>
<th>Active on</th>
<th>Applicable to</th>
<th>Configurations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Striped configuration</td>
<td>All the cluster nodes</td>
<td>All entries</td>
<td>No specific configuration required to make an entity striped. By default, all entities defined on a cluster IP address are striped on all the cluster nodes.</td>
</tr>
<tr>
<td>Partially striped configuration</td>
<td>A subset of cluster nodes</td>
<td>Refer Cluster Node groups.</td>
<td>Bind the entities that you want to be partially striped, to a node group. The configuration is active only on the cluster nodes that belong to the node group.</td>
</tr>
</tbody>
</table>

**Legend**
- Striped
- Spotted
- Partially striped

**NetScaler Cluster**

<table>
<thead>
<tr>
<th>Node Group (NG0)</th>
<th>Node Group (NG1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NS0</td>
<td>NS1</td>
</tr>
<tr>
<td>VIP: 10.102.29.75</td>
<td>VIP: 10.102.29.69</td>
</tr>
<tr>
<td>SNIP: 10.102.29.101</td>
<td>VIP: 10.102.29.106</td>
</tr>
<tr>
<td>VIP: 10.102.29.77</td>
<td>VIP: 10.102.29.69</td>
</tr>
</tbody>
</table>
Spotted configuration can be defined using one of two approaches.

**SNIP address** When creating the SNIP address, specify the node on which you want the SNIP address to be active, as the owner node.

**Example**, add ns ip 10.102.29.106 255.255.255.0 -type SNIP -ownerNode 2 (assuming node NS2 ID is 2). **Note**: You cannot change the ownership of a spotted SNIP address at run time. To change the ownership, you must first delete the SNIP address and add it again by specifying the new owner.

**Entities that can be bound to a node group**. By binding the entity to a single-member node group.

---

**Note**

When you disable USIP, Citrix recommends you to use spotted SNIP addresses. You can use
striped SNIP addresses only if there is a shortage of IP addresses. The use of striped IP addresses can result in ARP flux issues if no spotted IP addresses are present in the same subnet for ARP resolution.

When you enable USIP, Citrix recommends you to use striped SNIP addresses as a gateway for server initiated traffic.

**ARP owner support for striped IP**

In a cluster setup, you can configure a specific node to respond to the ARP request for a striped IP. The configured node responds to the ARP traffic.

A new parameter “arpOwner” is introduced in the “add, set, and unset ip” commands.

To enable the ARP owner on a node by using the CLI.

At the command prompt, type:

```
add ns ip <ip_address> -arpOwner <node_id>
```

**Note**
The ARP owner parameter is supported only in L2 cluster.

**Neighbor discovery owner support for striped IPv6 address**

In a cluster setup, you can configure a specific node as neighbor discovery (ND) owner for the striped IPv6 address to determine the link-layer address. A client sends a Neighbor Solicitation (NS) message to all the nodes in the cluster setup. The ND owner responds with a Neighbor Advertisement (NA) message with the link-layer address for the striped IPv6 address, and serves traffic.

**To enable ND owner on a node by using the CLI**

At the command prompt, type:

```
1 add ns ip6 <IPv6Address> -ndOwner <node id>
2 set ns ip6 <IPv6Address> -ndOwner <node id>
```

**Example:**

```
1 add ns ip6 2001::21/64 -ndOwner 1
2 set ns ip6 2001::21/64 -ndOwner 1
```
Citrix ADC 13.0

To enable ND owner on a node by using the GUI

1. Navigate to System > Network > IPs.
2. In the IPs page, go to the IPv6s tab and click Add.
3. In the Create IPv6 page, select one of the node IDs listed in NdOwner in Cluster drop-down menu.

Note
The ND owner parameter is supported only in L2 cluster.

Communication in a cluster setup

April 23, 2019

The interfaces of Citrix ADC appliances that are added to a cluster, are prefixed with a node ID. This helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u, where c is the controller number and u is the unit number, now becomes n/c/u, where n is the node ID. For example, in the following figure, interface 1/2 of node n1 is represented as 0/1/2, interface 1/1 of node n2 is represented as 1/1/1, and interface 1/4 of node n3 is represented as 2/1/4.

Figure 1. Interface naming convention in a cluster

*Server communication-*
The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the server data plane.

*Client communication-* The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
• **Inter-node communication** - The cluster nodes can also communicate with each other. The manner in which they communicate depends on whether the node exists on the same network or across networks.

  - Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:
    * Node to Node Messaging (NNM)
    * Steered traffic
    * Configuration propagation and synchronization

  - Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: `0x02 0x00 0x6F <cluster_id> <node_id> <reserved>`, where `cluster_id` is the cluster instance ID, `node_id` is the node number of the Citrix ADC appliance that are added to a cluster.

The following figures shows the communication interfaces in L2 clusters and L3 clusters.

Figure 2. Cluster communication interfaces - L2 cluster
Figure 3. Cluster communication interfaces - L3 cluster
Traffic distribution in a cluster setup

February 18, 2020

In a cluster setup, external networks view the collection of Citrix ADC appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the flow receiver.

Note
For an L3 cluster (nodes across different networks), only ECMP traffic distribution can be used.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor.
processor over the backplane (if the flow receiver and the flow processor are on the same network) or through the tunnel (if the flow receiver and the flow processor are on different networks).

**Note**
- The flow receiver and flow processor must be nodes capable of serving traffic.
- From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see Disabling Steering on the Cluster Backplane.

Figure 1. Traffic distribution in a cluster

The above figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects
The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped or partially striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

In an asymmetric cluster topology (all cluster nodes are not connected to the external switch), you must use linksets either exclusively or combined with ECMP or cluster link aggregation. For more information, see Using Linksets.

**Cluster nodegroups**

February 12, 2020

**Note**

Nodegroups are supported from NetScaler 10.1 onwards.

As the name indicates, a cluster nodegroup is a group of cluster nodes.

Figure 1. Citrix ADC cluster with nodegroups

The above figure shows a cluster which has nodegroups NG1 and NG2 that include 3 cluster nodes each. The cluster also has 3 nodes that are not part of any nodegroup.

A nodegroup can be configured for the following:
• To define spotted and partially striped configurations. For more information, see Nodegroups for Spotted and Partially-Striped Configurations.
• To configure redundancy of nodegroups. For more information, see Configuring Redundancy for Nodegroups.
  Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.
• To define an L3 cluster (also called a cluster in INC mode). In an L3 cluster, cluster nodes can be from different networks. You must group nodes that belong to a network in a single nodegroup. For example, if n1, n2, n3 are in network1 and n4, n5, n6 are in network2, then NG1 must include nodes of network1 and NG2 must include nodes of network2. For setting up an L3 cluster, see Creating a Citrix ADC Cluster.

  Note
  • Supported from NetScaler 11 onwards.
  • The above functions of a nodegroup are mutually exclusive. This means that a nodegroup can provide only one of the above mentioned functionality.

Cluster and node states

July 8, 2020

For a cluster to be functional, a majority of the nodes (n/2 + 1) must be operationally active (operational state is ACTIVE). Check table below.

  Important
  From NetScaler release 10.5, you can configure the cluster to be functional even when the majority criteria is not satisfied. This configuration must be performed when creating a cluster.

For more information on states of a cluster node, refer to States of a cluster node.

Routing in a cluster

February 12, 2020
Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

- All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.
- Routes are limited to the maximum number of ECMP routes supported by the upstream router.
- Node-specific routing configurations must be performed by using the owner-node argument as follows:

```
1 router ospf
2   owner-node 0
3   ospf router-id 97.131.0.1
4   exit-owner-node
5 !
```

The following command displays the consolidated cluster configuration for all nodes in VTYSH.
```
show cluster-config
```

The following command displays the cluster status on each node.
```
show cluser node
```

**IPv4 routing in L2 cluster**

The following section contains sample configurations that help you to configure IPv4 OSPF and BGP routing in L2 cluster.

**Adding spotted SNIP address and enabling dynamic routing**

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP addresses are added and dynamic routing is enabled on these SNIP addresses.

```
1   en ns fea ospf bgp
2   add vlan 10
3   add ns ip 10.10.10.1 255.255.255.0 -dynamicrouting enabled -ownernode 1
4   add ns ip 10.10.10.2 255.255.255.0 -dynamicrouting enabled -ownernode 2
5   add ns ip 10.10.10.3 255.255.255.0 -dynamicrouting enabled -ownernode 3
6   bind vlan 10 -ipaddress 10.10.10.1 255.255.255.0
```

**VTYSH IPv4 OSPF configuration**

For configuring IPv4 OSPF in L2 cluster, you must
Set the priority to zero.
Configure the Router-id as a spotted configuration.

Note
The OSPF configuration guidelines for L2 cluster are applicable for OSPFv3 also.

In the following sample configuration IPv4 OSPF is configured.

```
interface vlan10
  IP OSPF PRIORITY 0
!
  router ospf
    owner-node 1
      ospf router-id 97.131.0.1
    exit-owner-node
    owner-node 2
      ospf router-id 97.131.0.2
    exit-owner-node
    owner-node 3
      ospf router-id 97.131.0.3
    exit-owner-node
  network 10.10.10.0/24 area 0
  redistribute kernel
!
```

VTYSH IPv4 BGP configuration

In the following VTYSH sample configuration, IPv4 BGP is configured.

```
router bgp 100
  neighbor 10.10.10.10 remote-as 200
  owner-node 1
  neighbor 10.10.10.10 update-source 10.10.10.1
  exit-owner-node
  owner-node 2
  neighbor 10.10.10.10 update-source 10.10.10.2
  exit-owner-node
  owner-node 3
  neighbor 10.10.10.10 update-source 10.10.10.3
  exit-owner-node
  redistribute kernel
!
```
IPv6 routing in L2 cluster

The following section contains sample configurations that help you to configure IPv6 OSPF and BGP routing in L2 cluster.

Enable IPv6 routing

Before configuring IPv6 routing in a L2 cluster, you must enable the IPv6 feature.

To enable IPv6 routing by using the CLI,

At the command prompt, type:

```
• enable ns fea ipv6pt
```

Adding spotted SNIP6 address and enabling dynamic routing

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP6 addresses are added and dynamic routing is enabled on these SNIP6 addresses.

```
1 add ns ip6 3ffa::1/64 -dynamicrout enabled -ownerinode 1
2 add ns ip6 3ffa::2/64 -dynamicrout enabled -ownerinode 2
3 add ns ip6 3ffa::3/64 -dynamicrout enabled -ownerinode 3
4 add vlan 10
5 bind vlan 10 -ipaddress 3ffa::1/64
```

VTYSH IPv6 BGP configuration

In the following VTYSH sample configuration, IPv6 BGP is configured.

```
1 router bgp 100
2 neighbor 3ffa::10 remote-as 200
3 owner-node 1
4 neighbor 3ffa::10 update-source 3ffa::1
5 exit-owner-node
6 owner-node-2
7 neighbor 3ffa::10 update-source 3ffa::2
```
Install IPv6 learned routes

The Citrix ADC cluster can use routes learned by various routing protocols after you install the routes in the Citrix ADC cluster routing table.

To install IPv6 learned routes to the internal routing table by using the CLI:

At the command prompt, type:

- `ns route-install ipv6 bgp`
- `ns route-install ipv6 ospf`
- `ns route-install default`

**Note**

- If you have to exchange IPv4 routes on a IPv6 neighbor, you must remove the `no neighbor 3ffe::10 activate` VTSH command from the earlier configuration.
- The `update-source` VTSH command must be used for each owner node to specify right IPv6 source IP while connecting to BGP peer as given in BPG IPv4 configuration.

Routing in a L3 cluster

The routing in L3 cluster works only when the following configurations are done on the Citrix ADC appliance.

- Enable the dynamic routing for a VLAN.

  ```
  set vlan <id> -dynamicrouting enabled
  ```

- To reach all cluster nodes, the VIP, CLIP, and Citrix ADC IP (NSIP) must be advertised by routing protocols along with `set vlan` command.
**Deployment scenario for BGP in L3 cluster**

Consider an example where all the cluster nodes are grouped in AS 100 network, and the upstream routers are in different AS 200.

The following figure depicts the AS 100 and AS 200 deployment in a cluster setup.

In this deployment, CLIP advertises CCO to upstream routers. Some cluster nodes drop the advertised traffic, as AS loop is detected.

To overcome the issue, configure the following command in vtysh BGP router mode for each neighbor.

At the VTYSH command prompt, type:

```
neighbor <peer_ip> allowas-in 1
```

As a best practice, Citrix recommends you to configure any one of the following:

- Configure route-maps to learn only desired networks such as; default route, Citrix ADC IP (NSIP), and NSIP subnets on cluster nodes.

- Configure upstream routes to advertise only desired networks such as; CLIP and Citrix ADC IP (NSIP) in cluster.

`Failed!`
IP addressing for a cluster

March 31, 2020

In addition to the standard types of Citrix ADC-owned IP addresses—Citrix ADC NSIP, Virtual IP (VIP), and Subnet IP (SNIP)—a clustered Citrix ADC appliance can have a cluster management IP (CLIP) address. It can also have striped and spotted IP addresses.

- **CLIP address.** An IP address owned by the cluster coordinator node (CCO). The CLIP address can float between different nodes in a cluster setup. If the CLIP is moved to a different node of the cluster, that node becomes the CCO. The CCO is the Citrix ADC appliance that is responsible for management tasks in the cluster. A network administrator uses the CLIP address to connect to the cluster to perform configuration and management tasks, such as accessing unified GUI, reporting, tracing packet flow, and collecting logs. You can add multiple CLIP addresses in a cluster on the same or different networks. Only configurations performed on the CCO through the cluster IP address are propagated to other nodes in the cluster.

- **Striped IP address.** A logical IP address available on all nodes of the cluster, it can be either a VIP or SNIP address.

- **Spotted IP address.** A logical IP (preferably SNIP address) is available only on one node. A spotted IP address has visibility on only that node. To minimize traffic-steering overhead, Citrix recommends that you use spotted SNIP address for backend communication with the server.

For example, in a four-node cluster group, you must configure each node with a spotted SNIP address. For more information on how to configure a spotted IP configuration, see Striped, Partially Striped, and Spotted Configurations.

You can define a SNIP address to be active on only one node, or active on all nodes. If a virtual IP address and Subnet IP address are available only on a specific node, it is of spotted configuration or if the Subnet IP address and Virtual server IP address are available on all nodes, it is defined as striped configuration.

**Note**

In a four-node cluster setup, you must configure a spotted SNIP address on each node. For more information about configuring a spotted IP configuration, see Striped, Partially Striped, and Spotted Configurations.

In an L3 cluster setup, only spotted SNIP configuration is supported, as shown in the following table.

<table>
<thead>
<tr>
<th>IP Address</th>
<th>NSIP</th>
<th>VIP</th>
<th>SNIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spotted</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>

Configuring layer 3 clustering

February 18, 2020

Understanding L3 Cluster

The demand to expand the high availability deployment and increase the scalability of the client traffic across different networks guided to establish L3 cluster. The L3 cluster lets you to group Citrix ADC appliances across individual subnets (L2 cluster).

L3 cluster is also referred to as “cluster in Independent Network Configuration (INC) mode”. In L3 cluster deployment, the cluster nodes in the same network are grouped together to form a Nodegroup. L3 cluster uses GRE tunneling to steer the packets across networks. The heartbeat messages across L3 clusters will be routed.

This document includes the following details:

- Architecture
- Example

Architecture

The L3 cluster architecture comprises of the following components:

- **Nodegroup.** The cluster nodes from each network (n1, n2) and (n3, n4), as depicted in below figure, are grouped together to form a Nodegroup. These Nodegroups are terminated to the layer 3 switch on either side of the network.
  - The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
The cluster communicates with the server through the physical connections between the cluster node and the server side connecting device. The logical grouping of these physical connections is called the server data plane.

- **Backplane Switch.** Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch.

- **GRE Tunnel.** The packets between nodes in a L3 cluster are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. The steering mechanism will change for nodes belonging to different network. The packets are steered through a GRE tunnel to the node on the other subnet, instead of rewriting the MAC.

**Example**

Consider an example of an L3 cluster deployment consisting of the following:

- Three Citrix ADC appliances (n1, n2, and n3) nodes are grouped together into Nodegroup1.
- Similarly, the nodes n4 and n5 are grouped in Nodegroup2. In the third network, there are two nodegroups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.
- The Citrix ADC appliances that belong to the same network are combined together to form a Nodegroup.

**Points to Consider before Configuring L3 Cluster**

Consider the following points before configuring L3 cluster on a Citrix ADC appliance:

- The backplane is not mandatory while configuring L3 subnets. If the backplane is not specified, the node will not go to backplane fail state.

  **Note**

  If you have some cluster nodes in the L2 network, it is mandatory to enable steering on the cluster backplane, else the nodes will go to backplane fail state.

- The external traffic distribution in L3 cluster supports only Equal Cost Multiple Path (ECMP).

- The following parameters are processed when steering is disabled is an L3 cluster deployment:
  - ICMP errors
  - Fragmentation
  - Striped SNIPs or MIPs
• The entities (route, route6, pbr, and pbr6) can be bound to configuration nodegroup.

• VLAN, RNAT, and IP tunnel cannot be bound to a config nodegroup.

• Config nodegroup should always have property STRICT “YES”.

• The cluster nodes should not be added to a config nodegroup via “add cluster node” command.

• The “clear config extended” command will not clear the entities (route, route6, pbr, pb6, rnat, IP tunnel, ip6tunnel). These entities should be cleared when an “add cluster instance –INC enabled” command is configured.

**Configuring L3 Cluster**

In an L3 cluster configuration, the cluster command has different attributes to configure that is based on nodes, and nodegroups. The L3 cluster configuration also includes an IPv6 profile apart from IPv4 profiles.

Configuring L3 cluster on a Citrix ADC appliance consists of the following tasks:

• Create a cluster instance
• Create a nodegroup in L3 cluster
• Add a Citrix ADC appliance to the cluster and group with nodegroup
• Add cluster IP address to the node
• Enable the cluster instance
• Save the configuration
• Add a new node to an existing nodegroup
• Create a new nodegroup in L3 cluster
• Group new nodes to the newly created nodegroup
• Join the node to the cluster

**Configuring the following by Using the Command Line**

• To create a cluster instance by using the Citrix ADC CLI

```plaintext
add cluster instance <clid> -inc <ENABLED> -processLocal <ENABLED>
```

• To create a nodegroup in L3 cluster

```plaintext
add cluster nodegroup <ng>
```

• To add a Citrix ADC appliance to the cluster and to associate with nodegroup
```plaintext
add cluster node <nodeid> <nodeip> -nodegroup <ng>

• To add the cluster IP address on this node
  add ns ip <IPAddress> <netmask> -type clip

• Enable the cluster instance
  enable cluster instance <clId>

• Save the configuration
  save ns config

• Warm reboot the appliance
  reboot -warm

• To add a new node to an existing nodegroup
  add cluster node <nodeid> <nodeip> -nodegroup <ng>

• To create a new nodegroup in L3 cluster
  add cluster nodegroup <ng>

• To group new nodes to the newly created nodegroup
  add cluster node <nodeid> <nodeip> -nodegroup <ng>

• To join the node to the cluster

  1. join cluster - clip \<ip\>_addr\> -password \<password\>
  2. add cluster instance 1 - inc ENABLED - processLocal ENABLED
  3. Done

Note
The “inc” parameter should be ENABLED for an L3 cluster.

  1. > add cluster nodegroup ng1
  2. Done
  3. > add cluster node 0 1.1.1.1 -state ACTIVE -nodegroup ng1
  4. Done
  5. > add ns ip 1.1.1.100 255.255.255.255 -type clip
```

© 1999-2020 Citrix Systems, Inc. All rights reserved.
Advertising Cluster IP address of a Layer 3 Cluster

You must configure the cluster IP address to be advertised to the upstream router to make the cluster configuration accessible from any subnet. The cluster IP address is advertised as a kernel route by the dynamic routing protocols configured on a node.

Advertising the cluster IP address consists of the following tasks:

- **Enable the host route option of the cluster IP address.** The host route option pushes the cluster IP address to ZebOS routing table for kernel route redistribution through dynamic routing protocols.

- **Configuring a dynamic routing protocol on a node.** A dynamic routing protocol advertises the cluster IP address to the upstream router. For more information on configuring a dynamic routing protocol, see Configuring Dynamic Routes.
To enable the host route option of the cluster IP Address by using the Citrix ADC CLI

At the command prompt, type:

```bash
1 - add nsip \<IPAddress\> \<netmask\> -**hostRoute ENABLED**
2 - **show nsip** \<IPAddress\>
3
4 > add ns ip 10.102.29.60 255.255.255.255 -hostRoute ENABLED
5
6  Done
```

**Spotted, partially striped configurations on L3 cluster**

The spotted and partially striped configurations on L3 cluster slightly differs from L2 cluster. The configuration might differ from node to node as the nodes reside on different subnets. The network configurations can be node specific in L3 cluster, hence you have to configure the spotted or partially striped configurations based on the below-mentioned parameters.

To configure spotted, partially striped configurations on a Citrix ADC appliance over L3 cluster perform the following tasks:

- Add a cluster ownergroup to an IPv4 static routing table
- Add a cluster ownergroup to an IPv6 static routing table
- Add a cluster ownergroup to an IPv4 policy based routing (PBR)
- Add a cluster ownergroup to an IPv6 PBR
- Add a VLAN
- Bind a VLAN to a specific ownergroup of cluster nodegroup

**Configuring the following by Using the Command Line**

- To add a cluster ownergroup to an IPv4 static route table of the Citrix ADC appliance
  ```bash
  add route <network> <netmask> <gateway> -ownergroup <ng>
  ```

- To add a cluster ownergroup to an IPv6 static route table of the Citrix ADC appliance
  ```bash
  add route6 <network> -ownergroup <ng>
  ```

- To add a cluster ownergroup to an IPv4 PBR
  ```bash
  add pbr <name> <action> -ownergroup <ng>
  ```

- To add a cluster ownergroup to an IPv6 PBR
  ```bash
  add pbr6 <name> <action> -ownergroup <ng>
  ```
• To add a VLAN

    add vlan <id>

• To bind a VLAN to a specific ownergroup of cluster nodegroup

    bind vlan \<id\> -ifnum -\[IPAddress \<ip\>_addr | ipv6\<ipaddr \>\] -\[-ownergroup \<ng\>\]

The following commands are sample examples of spotted and partially striped configurations which can be configured by using the Citrix ADC CLI.

    > add route 10.102.29.0 255.255.255.0 10.102.29.2 -ownergroup ng2
    Done

    > add route6 fe80::9404:60ff:fedd:a464/64 -ownergroup ng1
    Done

    > add pbr pbr1 allow -ownergroup ng1
    Done

    > add pbr6 pbr2 allow -ownergroup ng2
    Done

    > add vlan 2
    Done

    > bind vlan 2 -ifnum 1/2 -\[IPAddress 10.102.29.80 | fe80::9404:60ff:fedd:a464/64 -ownergroup ng1
    Done

**Configure nodegroup**

In an L3 cluster, to replicate the same set of configurations on more than one nodegroup, the following commands are used:

**Configuring the following by Using the Command Line**

• To add an IPv4 static route to the routing table of the Citrix ADC appliance
add route <network> <netmask> <gateway> -ownerGroup <ng>

Sample Configuration

```
1 add route 0 0 10.102.53.1 -ownerGroup ng1
2 add route 0 0 10.102.53.1 -ownerGroup ng2
```

To support the above configuration, a new nodegroup 'all' has to be defined and you have to configure the following commands:

Configuring the following by Using the Command Line

- To add a new nodegroup to cluster with strict parameter
  
  add cluster nodegroup \<name\> -strict \<YES | NO\>

- To bind a cluster node or an entity to the given nodegroup
  
  bind cluster nodegroup \<name\> -node \<nodeid\>

- To add IPv4 static route to all ownergroup
  
  add route <network> <netmask> <gateway> -ownerGroup <ng>

Sample configuration:

```
1 add cluster nodegroup all -strict YES
2 bind cluster nodegroup all -node 1
3 bind cluster nodegroup all -node 2
4 add route 0 0 10.102.53.1 -ownerGroup all
```

Setting up a Citrix ADC cluster

February 18, 2020
Citrix ADC appliances that you want to add to the cluster must satisfy the criteria specified in Prerequisites for Cluster Nodes. Before actually setting up a cluster, you must be aware of cluster basics. For information, see Cluster Overview.

Forming a cluster requires you to set up inter-node communication, create the cluster (by adding the first Citrix ADC appliance), and then add the other cluster nodes. Each of these steps is explained with relevant details in subsequent topics.

**Note**

While there are some differences in setting up an L2 and L3 cluster, there are many similarities too. The subsequent topics explain the setup for both cluster types while highlighting the configurations that are specific to L3 clusters.

**Setting up inter-node communication**

**July 28, 2020**

The nodes in a cluster setup communicate with one another using the following inter-node communication mechanisms:

- Nodes that are within the network (same subnet) communicate with each other through the cluster backplane. The backplane must be explicitly set up. The following are the detailed steps.
- Across networks, steering of packets is done through a GRE tunnel and other node-to-node communication is routed across nodes as required.

**Important**

- From Release 11.0 all builds, a cluster can include nodes from different networks.
- From Release 13.0 build 58.3, GRE steering is supported on Fortville NICs in an L3 cluster.

**To set up the cluster backplane, do the following for every node**

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.
Important points to note when setting up the cluster backplane

- Do not use the appliance’s management interface (0/x) as the backplane interface. In a cluster, the interface 0/1/x is read as:
  
  0 -> node ID 0  
  1/x -> Citrix ADC interface

- Do not use the backplane interfaces for the client or server data planes.

- Configure a link aggregate (LA) channel to optimize the throughput of the cluster backplane.

- In a two-node cluster, where the backplane is connected back-to-back, the cluster is operationally DOWN under any of the following conditions:
  - One of the nodes is rebooted.
  - Backplane interface of one of the nodes is disabled.

Therefore, Citrix recommends that you dedicate a separate switch for the backplane, so that the other cluster node and traffic are not impacted. You cannot scale out the cluster with a back-to-back link. You might encounter a downtime in the production environment when you scale out the cluster nodes.

- Backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN.

- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.

- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.

- The state of MAC spoofing on the different virtualization platforms can affect the steering mechanism on the cluster backplane. Therefore, make sure the appropriate state is configured:
  - XenServer - Disable MAC spoofing
  - Hyper-V - Enable MAC spoofing
  - VMware ESX - Enable MAC spoofing (also make sure “Forged Transmits” is enabled)

- The MTU for the cluster backplane is automatically updated. However, if jumbo frames are configured on the cluster, the MTU of the cluster backplane must be explicitly configured. The value must be set to 78 + X, where X is the maximum MTU of the client and server data planes. For example, if the MTU of a server data plane is 7500 and of the client data plane is 8922. The MTU of a cluster backplane must be set to 78 + 8922 = 9000. To set this MTU, use the following command:

  > set interface <backplane_interface> -mtu <value>

- The MTU for the interfaces of the backplane switch must be specified to be greater than or equal to 1,578 bytes. It is applicable if the cluster has features like MBF, L2 policies, ACLs, routing in
UDP based tunnel support for L2 and L3 cluster

Starting from Citrix ADC release 13.0 build 36.x, Citrix ADC L2 and L3 cluster can steer the traffic using UDP based tunneling. It is defined for the inter-node communications of two nodes in a cluster. By using the “tunnelmode” parameter, you can set GRE or UDP tunnel mode from the add and set cluster node command.

In an L3 cluster deployment, packets between Citrix ADC nodes are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. When this exchange occurs over the internet, in the absence of an IPsec tunnel, the NSIPs is exposed on the internet, and might result in security issues.

Important
Citrix recommends customers to establish their own IPsec solution when using a L3 cluster.

The following table helps you to categorize the tunnel support based on different deployments.

<table>
<thead>
<tr>
<th>Steering Types</th>
<th>AWS</th>
<th>Microsoft Azure</th>
<th>On-premises</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
<tr>
<td>GRE tunnel</td>
<td>Supported</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
<tr>
<td>UDP tunnel</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

Important
In a L3 cluster, the tunnel mode is set to GRE by default.

Configuring UDP based tunnel

You can add a cluster node by setting the parameters of node ID and mention the state. Configure the backplane by providing the interface name, and select the tunnel mode of your choice (GRE or UDP).

CLI procedures

To enable the UDP tunnel mode by using the CLI.

At the command prompt, type:

```
• add cluster node <nodeId>@ [-state <state>] [-backplane <interface_name>] [-tunnelmode <tunnelmode>]
```
• `set cluster node <nodeId>@ [-state <state>] [-tunnelmode <tunnelmode>]`

**Note**
Possible values for tunnel mode are NONE, GRE, UDP.

**Example**
• `add cluster node 1 -state ACTIVE -backplane 1/1/1 -tunnelmode UDP`
• `set cluster node 1 -state ACTIVE -tunnelmode UDP`

**GUI procedures**

To enable the UDP tunnel mode by using the GUI.

1. Navigate to **System > Cluster > Nodes**.
2. In the **Cluster Nodes** page, click **Add**.
3. In the **Create Cluster Node**, set the **Tunnel Mode** parameter to UDP and click **Create**.
4. Click **Close**.
Creating a Citrix ADC cluster

May 28, 2020

To create a cluster, start by taking one of the Citrix ADC appliances that you want to add to the cluster. On this node, you must create the cluster instance and define the cluster IP address. This node is the first cluster node and is called the cluster configuration coordinator. All configurations that are performed on the cluster IP address are stored on this node and then propagated to the other cluster nodes.

The responsibility of configuration coordination in a cluster is not fixed to a specific node. It can change over time depending on the following factors:

- The priority of the node. The node with the highest priority (lowest priority number) is made the configuration coordinator. Therefore, if a node with a priority number lower than that of the existing configuration coordinator is added, the new node takes over as the configuration coordinator.
  
  Note
  Node priority can be configured from NetScaler 10.1 onwards.

- If the current configuration coordinator goes down. The node with the next lowest priority number takes over as the configuration coordinator. If the priority is not set or if there are multiple nodes with the lowest priority number, the configuration coordinator is selected from one of the available nodes.

  Note
  The configurations of the appliance (including SNIP addresses and VLANs) are cleared by implicitly executing the `clear ns config extended` command. However, the default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster. For an L3 cluster (cluster nodes on different networks), networking configurations are not cleared from the appliance.

  Important
  HA Monitor (HAMON) on a cluster setup is used to monitor the health of an interface on each node. The HAMON parameter must be enabled on each node to monitor the state of the interface. If the
operational state of the HAMON enabled interface goes down due to any reason, the respective cluster node is marked as unhealthy (NOT UP) and that node cannot serve traffic.

To create a cluster by using the command line interface

1. Log on to an appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.

2. Add a cluster instance.

   add cluster instance <clId> -quorumType <NONE | MAJORITY> -inc <ENABLED | DISABLED> -backplanebasedview <ENABLED | DISABLED>

   **Note**
   - The cluster instance ID must be unique within a LAN.
   - The -quorumType parameter must be set to MAJORITY and not NONE in the following scenarios:
     - Topologies which do not have redundant links between cluster nodes. These topologies might be prone to network partition due to a single point of failure.
     - During any cluster operations such as node addition or removal.
   - For an L3 cluster, make sure the -inc parameter is set to ENABLED. The -inc parameter must be disabled for an L2 cluster.
   - When the -backplanebasedview parameter is enabled, the operational view (set of nodes that serve traffic) is decided based on heartbeats received only on the backplane interface. By default, this parameter is disabled. When this parameter is disabled, a node does not depend on the heartbeat reception only on the backplane.

3. [Only for an L3 cluster] Create a nodegroup. In the next step, the newly added cluster node must be associated with this node group.

   **Note**
   This nodegroup includes all or a subset of the Citrix ADC appliances that belong to the same network.

   add cluster nodegroup <name>

4. Add the Citrix ADC appliance to the cluster.

   add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name> -nodegroup <name>

   **Note** For an L3 cluster:
   - The nodegroup parameter must be set to the name of the nodegroup that is created.
• The backplane parameter is mandatory for nodes that are associated with a node-group that has more than one node, so that the nodes within the network can communicate with each other.

Example:

Adding a node for an L2 cluster (all cluster nodes are in the same network).

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
```

Adding a node for an L3 cluster which includes a single node from each network. Here, you do not have to set the backplane.

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -nodegroup ng1
```

Adding a node for an L3 cluster which includes multiple nodes from each network. Here, you have to set the backplane so that nodes within a network can communicate with each other.

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1 -nodegroup ng1
```

5. Add the cluster IP address (for example, 10.102.29.61) on this node.

```
add ns ip <IPAddress> <netmask> -type clip
```

**Example**

```
1 > add ns ip 10.102.29.61 255.255.255.255 -type clip
```

6. Enable the cluster instance.

```
enable cluster instance <clId>
```

7. Save the configuration.

```
save ns config
```

8. Warm reboot the appliance.

```
reboot -warm
```

Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

9. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see Change an RPC node password.
To create a cluster by using the configuration utility

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to System > Cluster.
3. In the details pane, click the Manage Cluster link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create.
6. In the Configure cluster instance dialog box, select the Enable cluster instance check box.
7. In the Cluster Nodes pane, select the node and click Open.
8. In the Configure Cluster Node dialog box, set the State.
9. Click OK, and then click Save.
10. Warm reboot the appliance.
11. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see Change an RPC node password.

Strict mode support for sync status of the cluster

You can now configure a cluster node to view errors when applying the configuration. A new parameter, “syncStatusStrictMode” is introduced in both add and set cluster instance command to track the status of each node in a cluster. By default, the “syncStatusStrictMode” parameter is disabled.

To enable the strict mode by using the CLI

At the command prompt, type:

```
set cluster instance <clID> [-syncStatusStrictMode (ENABLED | DISABLED)]
```

Example:

```
set cluster instance 1 -syncStatusStrictMode ENABLED
```

To view the status of strict mode by using the CLI

```
>show cluster instance 1
1) Cluster ID: 1
   Dead Interval: 3 secs
   Hello Interval: 200 ms
   Preemption: DISABLED
```

**Adding a node to the cluster**

**July 27, 2020**

You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When a NetScaler appliance is added to the cluster, the configurations from that appliance are cleared (by internally executing the clear ns config -extended command). The SNIP addresses, MTU settings of the backplane...
interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

The cluster configurations are then synchronized on this node. There can be an intermittent drop in traffic while the synchronization is in progress.

**Important**

Before you add a NetScaler appliance to a cluster:

- Set up the backplane interface for the node. Check preceding topic.
- Check if the licenses that are available on the appliance match those available on the configuration coordinator. The appliance is added only if the licenses match.
- If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
- Citrix recommends that you add the node as a passive node. Then, after joining the node to the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses, has L3 VLAN binding, or has static routes.
- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

**To add a node to the cluster by using the command line interface**

**Note**

When you add a node to a Cluster setup, if the node has a default static route, it gets added to the cluster coordinator node (CCO). If this default static route points to an incorrect gateway, it might result in downtime of the services. Hence, verify the default static route of the new node, before adding it to the cluster setup.

1. Log on to the cluster IP address, at the command prompt, do the following:

   - Add the appliance (for example, 10.102.29.70) to the cluster.

**Note**

For an L3 cluster:

- The nodegroup parameter must be set to a nodegroup that has nodes of the same network.
- If this node belongs to the same network as the first node that was added, then configure the nodegroup that was used for that node.
- If this node belongs to a different network, then create a nodegroup and bind this node.
to the nodegroup.

- The backplane parameter is mandatory for nodes that are associated with a node-
group that has more than one node, so that the nodes within the network can com-
municate with each other.

1. add cluster node <nodeId> <IPAddress> -state <state> -backplane <
   interface_name> -nodegroup <name>

   Example:

   add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1

   - Save the configuration.

   1 save ns config

2. Log on to the newly added node (for example, 10.102.29.70) and join the node to the cluster.

   1 join cluster -clip <ip_addr> -password <password>

   Example:

   join cluster -clip 10.102.29.61 -password nsroot

3. Perform the following configurations:

   - If the node is added to a cluster that has only spotted IPs, the configurations are synchro-
nized before the spotted IP addresses are assigned to that node. In such cases, L3 VLAN
   bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings.
   - Define the required spotted configurations.
   - Set the MTU for the backplane interface.

4. Save the configuration.

   1 save ns config

5. Warm reboot the appliance.

   1 reboot -warm

6. After the node is UP and sync is successful, change RPC credentials for the node from the cluster
   IP address. For more information about changing an RPC node password, see Change an RPC
   node password.

   1 set rpcNode <node-NSIP> -password <passwd>
To add a node to the cluster by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click Add to add the new node (for example, 10.102.29.70).
4. In the Create Cluster Node dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create. When prompted to perform a warm reboot, click Yes.
6. After the node is UP and sync is successful, change RPC credentials for the node from the cluster IP address. For more information about changing an RPC node password, see Change an RPC node password.
7. Navigate to System > Cluster > Nodes > Edit.
8. Modify the State to ACTIVE and confirm.

To join a previously added node to the cluster by using the configuration utility

If you have used the command line to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

Note

When a node joins the cluster, it takes over its share of traffic from the cluster and hence an existing connection can get terminated.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the nsroot password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **OK**.

Viewing the details of a cluster

April 23, 2019

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

**To view details of a cluster instance by using the command line interface**

Log on to the cluster IP address and, at the command prompt, type:

```
1   show cluster instance <clId>
```

**Note**

When executed from the NSIP address of a cluster node that is not the configuration coordinator, this command displays the status of the cluster on this node.

**To view details of a cluster node by using the command line interface**

Log on to the cluster IP address and, at the command prompt, type:

```
1   show cluster node <nodeId>
```

**To view details of a cluster instance by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Get Started**, click the **Manage Cluster** link to view the details of the cluster.
To view details of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, click the node for which you want to view the details.

Distributing traffic across cluster nodes

February 12, 2020

After you have created the Citrix ADC cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

Policy-based backplane steering

The policy-based backplane steering (PBS) is a mechanism in cluster deployment, which steers the traffic across cluster nodes based on the hash method defined for the flow. The flow is defined by a combination of L2 and L3 parameters similar to Access Control List (ACL).

The PBS supports both IPv4 and IPv6 traffic. In case of IPv6 deployments, the steering is supported by an extra option \[ dfdprefix <positive_integer> \]. This provides the flexibility to choose the same flow processor for the same IP prefix. The prefix option is supported for source IP or destination IP hash methods only.

Note

If the PBS mechanism is not used to steer the traffic, the traffic is steered through the default method.

To support this feature, new attributes are introduced in existing ACL commands.

To configure the new ACL attributes, at the Citrix ADC command prompt, type the following commands:
**CLI commands for IPv4**

- `add ns acl <aclname> <aclaction> [-type (classic | dfd)] [-dfdhash <dfdhash>]`
- `set ns acl <aclname> <aclaction> [-dfdhash <dfdhash>]`
- `show ns acl [<aclname>] [-type (classic | DFD)]`
- `apply ns acls [-type (classic | DFD)]`
- `clear ns acls [-type (classic | DFD)]`
- `renumber ns acls [-type (classic | DFD)]`

**CLI commands for IPv6**

- `add ns acl6 <acl6name> <acl6action> [-type (classic | dfd)][-dfdhash <dfdhash>][-dfdprefix <positive_integer>]
- `set ns acl6 <acl6name> <acl6action> [-dfdhash <dfdhash>][-dfdprefix <positive_integer>]
- `show ns acl6 [<acl6name>] [-type (classic | DFD)]`
- `apply ns acls6 [-type (classic | DFD)]`
- `clear ns acls6 [-type (classic | DFD)]`
- `renumber ns acls6 [-type (classic | DFD)]`

The following are the different types of hash methods that you can specify to steer the packet to the flow processor:

- SIP-SPORT-DIP-DPORT
- SIP
- DIP
- SIP-DIP
- SIP-SPORT

**Using Equal Cost Multiple Path (ECMP)**

February 18, 2020

By using the Equal Cost Multiple Path (ECMP) mechanism on a cluster deployment, active cluster nodes advertise the virtual server IP addresses. The cluster node which receives the advertised traffic...
Citrix ADC 13.0

steers the traffic to the node that must process the traffic. There can be redundant steering in spotted and partially striped virtual servers. Therefore, from NetScaler 11 onwards, spotted and partially striped virtual server IP addresses advertise the owner nodes, which reduce the redundant steering.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see Configuring Dynamic Routes. For more information on routing in a cluster, see Routing in a Cluster.

To use ECMP, you must first perform the following:

- Enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address.
- Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN.
- Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the vtysh shell.

Perform similar configurations on the cluster IP address and on the external connecting device.

Note

- Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
- ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers do not have associated VIP addresses.

Figure 1. ECMP topology
When you use ECMP mechanism for traffic distribution on a cluster deployment, the active cluster nodes advertise the virtual server IP addresses to the upstream router. The ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2. The traffic flow in the Figure 1 is described as follows:

1. The client sends a request to the VIP hosted on cluster.
2. The upstream router, based on the learned routes of the VIP, forwards the packet to any one of the nodes. Let’s say NS1. The node NS1 is the flow receiver.
3. The flow receiver (NS1) determines the node that must process the traffic, which is called the flow processor. For example, Node NS2 is the flow processor.
4. The flow receiver (NS1) with SNIP1 (97.131.0.2) steers the request to the flow processor (NS2) with SNIP2 (97.131.0.3).
5. The flow processor (NS2) establishes a connection with the server.
6. The server processes the request and sends the response to the SNIP address that sent the request to the server.

Notes:

- Only ACTIVE nodes advertise VIP routes.
- INACTIVE nodes do not advertise VIP routes.
- All ACTIVE nodes advertise striped VIPs.
Only ACTIVE owner nodes advertise spotted or partially striped VIPs.

To configure ECMP on the cluster by using the command line interface

1. Log on to the cluster IP address.
2. Enable the routing protocol.

   ```
   enable ns feature <feature>
   ```

   **Example:** To enable the OSPF routing protocol.

   ```
   enable ns feature ospf
   ```

3. Add a VLAN.

   ```
   add vlan <id>
   ```

   **Example**

   ```
   add vlan 97
   ```

4. Bind the interfaces of the cluster nodes to the VLAN.

   ```
   bind vlan <id> -ifnum <interface_name>
   ```

   **Example**

   ```
   bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2
   ```

5. Add a spotted SNIP address for each node and enable dynamic routing on it.

   ```
   add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -dynamicRouting ENABLED
   ```

   **Example**

   ```
   1 add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting ENABLED -type SNIP
   2 add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting ENABLED -type SNIP
   3 add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting ENABLED -type SNIP
   ```
6. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

```
bind vlan <id> -IPAddress <SNIP> <netmask>
```

**Example**

```
bind vlan 97 -ipAddress 97.131.0.1 255.0.0.0
```

**Note**

You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3–6.

7. Configure the routing protocol on ZebOS using vtysh shell.

**Example:**

To configure an OSPF routing protocol on node IDs 0, 1, and 2.

```
vtysh
! interface vlan97 !
router ospf owner-node 0
ospf router-id 97.131.0.1 exit-owner-node
owner-node 1 ospf router-id 97.131.0.2
exit-owner-node
owner-node 2
ospf router-id 97.131.0.3 exit-owner-node redistribute kernel network 97.0.0.0/8 area 0 !
```

**Note**

For VIP addresses to be advertised, RHI setting is done by using the vserverRHILevel parameter as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -vserverRHILevel <vserverRHILevel>
```

For OSPF specific RHI settings, there are more settings that can be done as follows:

```
add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType ( TYPE1 | TYPE5 ) -ospfArea <positive_integer>
```

Use the add ns ip6 command to perform the preceding commands on IPv6 addresses.
8. Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
1 //For OSPF (IPv4 addresses) Global config: Configure terminal feature ospf Interface config: Configure terminal
   interface Vlan10 no shutdown ip address 97.131.0.5/8
   Configure terminal router ospf 1 network 97.0.0.0/8 area 0.0.0.0
2 3 //For OSPFv3 (IPv6 addresses) Global config: Configure terminal feature ospfv3 Configure terminal interface Vlan10 no shutdown ipv6 address use-link-local-only ipv6 router ospfv3 1 area 0.0.0.0 Configure terminal router ospfv3 1
```

**Router monitoring cluster nodes in ECMP deployment**

In a cluster setup, on an owner node that has a spotted SNIP address configuration, you can now disable the ownerDownResponse option. By default, the option is enabled, allowing the node to respond to an ICMP/ARP/ICMP6/ND6 request coming from the upstream router. You can now disable this option to allow the router to monitor if a cluster node is active or inactive. When the router sends a request, if the option is disabled, it identifies the owner node to be inactive and unavailable for traffic distribution.

**To configure ECMP for static routes traffic distribution by using the command line interface**

```
1 add ns ip <ipaddress> <netmask> -ownernode <node-id> -ownerDownResponse disable
```

Copied!
Failed!

**Use Case: ECMP with BGP routing**

April 23, 2019

To configure ECMP with BGP routing protocol, perform the following steps:

1. Log on to the cluster IP address.
2. Enable BGP routing protocol.
3. Add VLAN and bind the required interfaces.

```
1 > enable ns feature bgp
```

```
2 > add vlan 985
3 > bind vlan 985 -ifnum 0/0/1 1/0/1
```

4. Add the spotted IP address and bind them to the VLAN.

```
1 > add ns ip 10.100.26.14 255.255.255.0 -ownerNode 1 -
   dynamicRouting ENABLED
2 > add ns ip 10.100.26.15 255.255.255.0 -ownerNode 2 -
   dynamicRouting ENABLED
3 > bind vlan 985 -ipAddress 10.100.26.10 255.255.255.0
```

5. Configure BGP routing protocol on ZebOS using vtysh shell.

```
1 > vtysh conf t router bgp 65535 neighbor 10.100.26.1 remote-as
   65535
```

6. Configure BGP on the external switch. The following sample configurations are provided for
   the Cisco® Nexus 7000 C7010 Release 5.2(l) switch. Similar configurations must be performed
   on other switches.

```
1 > router bgp 65535 no synchronization
2 bgp log-neighbor-changes neighbor 10.100.26.14 remote-as 65535
   neighbor 10.100.26.15 remote-as 65535 no auto-summary
3 dont-capability-negotiate
dont-capability-negotiate
5 no dynamic-capability
```

**Configuration of cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol**

March 27, 2020

With ECMP over a cluster setup, a Citrix ADC appliance is able to handle the traffic through a routing
protocol. The ECMP mechanism helps in advertising the virtual server IP addresses through all active
cluster nodes.
To use ECMP, you must first enable the BGP protocol on the cluster IP address. Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN. Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the vtysh shell.

Use Case: Cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol

Consider an example of a cluster deployment with Cisco Nexus 7000 switch:

- Two Citrix ADC appliances (Node 1 and Node 2), connected to the Nexus switch (upstream).
- Two Cisco Nexus 7000 switch.
- Client and server (drawing HTTP traffic through the Nexus switch). With Hot Standby Router Protocol (HSRP) enabled on the client-side.

Prerequisites

Consider the following points before configuring cluster nodes on a Citrix ADC appliance.

1. All appliances must be of the same platform type.
2. Border Gateway Protocol (BGP) must be enabled on the cluster nodes.
Configuring by using the command line on Citrix ADC appliance

1. Log on to an appliance (for example, appliance with NSIP address 1.1.1.1)

2. To add a cluster node.

   ```
   add cluster node 0 1.1.1.2 - state ACTIVE - backplane 0/10/8
   ```

3. To add the cluster IP address

   ```
   add ns ip 1.1.1.10 255.255.255.254 - type clip
   ```

4. Save the configuration

   ```
   save ns config
   ```

5. Warm reboot the appliance

   ```
   reboot -warm
   ```

6. To add node 1 using CLIP

   ```
   add cluster node 1 2.2.2.2 - state ACTIVE - backplane 1/10/8
   ```

7. To join a node to the cluster

   ```
   join cluster - clip 1.1.1.10 - password nsroot
   ```

8. Perform the following configuration on CLIP

   - `enable ns feature bgp ospf DYNAMICROUTING`
   - `add ns ip 11.1.1.3 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
   - `add ns ip 11.1.1.7 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
   - `add ns ip 11.1.1.5 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`
   - `add ns ip 11.1.1.9 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

- `feature ospf`
On the Cisco Nexus router (11.1.1.6/31 and 11.1.1.8/31), you must perform the following configurations by using the command line:

- feature ospf
- feature bgp
- feature interface-vlan
- feature hsrp

```bash
> interface vlan100
  no shutdown
  ip address 50.1.1.1/8
  hsrp 50
  ip 50.50.50.50

> interface Ethernet 4/15
  ip address 11.1.1.2/31
  no shutdown

> interface Ethernet 4/22
  switchport
  switchport access vlan 100
```

```bash
> interface vlan100
  no shutdown
  no ip redirects
  ip address 50.1.1.2/8
  hsrp 50
  ip 50.50.50.50

> interface Ethernet 4/13
  ip address 11.1.1.6/31
  no shutdown

> interface Ethernet 4/15
  ip address 11.1.1.8/31
```
For BGP protocol, you must perform the following configurations on CLIP of Citrix ADC appliance:

```
> vtysh
ns# router bgp 1
redistribute kernel
owner-node 0
neighbor 11.1.1.2 remote-as 2
neighbor 11.1.1.2 as-origination-interval 1
neighbor 11.1.1.2 advertisement-interval 0
neighbor 11.1.1.6 remote-as 2
neighbor 11.1.1.6 as-origination-interval 1
neighbor 11.1.1.6 advertisement-interval 0
owner-node 1
neighbor 11.1.1.4 remote-as 2
neighbor 11.1.1.4 as-origination-interval 1
neighbor 11.1.1.4 advertisement-interval 0
neighbor 11.1.1.8 remote-as 2
neighbor 11.1.1.8 as-origination-interval 1
neighbor 11.1.1.8 advertisement-interval 0
exit-owner-node
```

Perform the following configurations on Cisco Nexus router (11.1.1.3 and 11.1.1.5)

```
> ip access-list acl1
10 permit ip 50.0.0.0/8 any
route-map test permit
match ip address acl1
router bgp 2
address-family ipv4 unicast
redistribute direct route-map test
maximum-paths 2
neighbor 11.1.1.3 remote-as 1
address-family ipv4 unicast
neighbor 11.1.1.5 remote-as 1
address-family ipv4 unicast
```

Perform the following configurations on Cisco Nexus router (11.1.1.7 and 11.1.1.9)

```
> ip access-list acl1
```
For OSPF protocol, you must perform the following configurations on CLIP of Citrix ADC appliance:

```
> vtysh
ns# router ospf 1
redistribute kernel
owner-node 0
  network 15.1.1.2/31 area 0
  network 15.1.1.6/31 area 0
exit-owner-node

owner-node 1
  network 15.1.1.4/31 area 0
  network 15.1.1.8/31 area 0
exit-owner-node

route-map map2 permit 1
set metric 10
```

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

```
> route-map- map2 permit 1
  set metric 10

interface Ethernet4/15
  ip address 15.1.1.2/31
  ip router ospf 1 area 0.0.0.0
  no shutdown

interface Ethernet4/19
  ip address 15.1.1.4/31
  ip router ospf 1 area 0.0.0.0
  no shutdown
```
router ospf 1
router-id 1.1.1.1
redistribute direct route-map map2

On the Cisco Nexus router (11.1.1.7/31 and 11.1.1.9/31), you must perform the following configurations by using the command line:

```bash
> route-map- map2 permit 1
  set metric 10

interface Ethernet4/13
  ip address 15.1.1.6/31
  ip router ospf 1 area 0.0.0.0
  no shutdown

interface Ethernet4/15
  ip address 15.1.1.8/31
  ip router ospf 1 area 0.0.0.0
  no shutdown

router ospf 1
  router-id 1.1.1.2
  redistribute direct route-map map2
```

Using cluster link aggregation

February 12, 2020

Cluster link aggregation, as the name suggests, is a group of interfaces of cluster nodes. It is an extension of Citrix ADC link aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster. For more information about link aggregation, see Configuring Link Aggregation.

**Important**

- Cluster link aggregation is supported for a cluster of hardware (MPX) appliances.
- Cluster link aggregation is supported for a cluster of virtual (VPX) appliances that are de-
ployed on ESX and KVM hypervisors, with the following restrictions:

- Dedicated interfaces need to be used. This means that the interfaces must not be shared with other virtual machines.

- If the cluster link aggregation member interfaces are manually disabled or if cluster link aggregation itself is manually disabled, then interface power down capability is achieved only by LACP timeout mechanism.

- Jumbo MTU is not supported on LACP cluster link aggregation.

**Note:** Cluster link aggregation is not supported on VPX appliances that are deployed on XenServer, AWS, and Hyper-V.

- Starting from 12.0 release, cluster link aggregation is supported on Citrix ADC SDX appliances.

- The number of interfaces that can be bound to cluster LA is 16 (from each node), and the maximum number of interfaces in cluster LA can be \((16 \times n)\), where \(n\) is the number of nodes in a cluster. The total number of interfaces in cluster LA depends on the number of interfaces for every port channel on upstream switch.

- If a Citrix ADC appliance uses Intel Fortville interfaces, the switchover of a Citrix ADC cluster node to passive mode might cause a few seconds of outage with CLAG. The issue occurs because LACP is enabled for CLAG to function properly, and the outage time depends on NIC LACP timers.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

Figure 1. Cluster Link Aggregation topology
A cluster LA channel has the following attributes:

- Each channel has a unique MAC agreed upon by cluster nodes.
- The channel can bind both local and remote nodes’ interfaces.
- A maximum of four cluster LA channels are supported in a cluster.
- Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.
- Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore looses management access.

Figure 2. Traffic distribution flow using cluster LA
Start

Client: Sends request

Switch: Receives a ARP request

Switch: Forwards the ARP request to one of the cluster nodes (based on switch logic)

Cluster node: Receives the ARP request and responds with the CLAG MAC (global MAC known to all cluster nodes), and sends the ARP response

Flow Receiver: Receives client traffic

IP Striped?

No

Flow receiver is the node that must process the traffic. (Flow receiver = Flow processor). No steering required.

Stop

Yes

Flow receiver: Determines the flow processor and steers traffic to that node
Backup and restore support of cluster LA on Citrix ADC MPX

You can now backup and restore the cluster setup of LA on Citrix ADC MPX. The cluster LA MAC address is independent of the physical interface MAC address of the cluster nodes, and can change after backup and restore process. The cluster LA can serve the traffic after cluster restore process is complete. For more information about backup and restore, see Backup and restore of cluster setup.

Static cluster link aggregation

April 23, 2019

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

To configure a static cluster LA channel by using the command line interface

1. Log on to the cluster IP address.

   Note
   Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch will forward traffic to the cluster even though the cluster LA channel is not configured. This can lead to loss of traffic.

2. Create a cluster LA channel.

   ```
   add channel <id> -speed <speed>
   ```

   Example

   ```
   add channel CLA/1 -speed 1000
   ```

   Note
   You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the <speed> attribute in the cluster LA channel are added to the active distribution list.
3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.

```
bind channel <id> <ifnum>
```

**Example**

```
bind channel CLA/1 0/1/2 1/1/2 2/1/2
```

4. Verify the configurations.

```
show channel <id>
```

**Example**

```
show channel CLA/1
```

**Note**

You can bind the cluster LA channel to a VLAN by using the bind vlan command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
Global config:
Configure terminal

Interface level config:

interface Ethernet2/47
switchport
switchport access vlan 10
channel-group 7 mode on
no shutdown

interface Ethernet2/48
switchport
switchport access vlan 10
channel-group 7 mode on
no shutdown
```

*Failed!*
Dynamic cluster link aggregation

February 18, 2020

Dynamic cluster LA channel uses Link Aggregation Control Protocol (LACP).

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

Points to remember:

- Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).
  
  Note
  
  Make sure the LACP mode is not set as PASSIVE on both the Citrix ADC cluster and the external connecting device.

- Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, CLA/2 channel is created.

- Specify the LAG type as Cluster.

To configure a dynamic cluster LA channel by using the command line interface

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lacpMode <lacpMode> -lacpKey <positive_integer> -lagType CLUSTER
```

Example:

To configure a cluster LA channel CLA/1 of 3 interfaces.

```
1 > set interface 0/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
2 > set interface 1/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
3 > set interface 2/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
```

Note

Optionally, you can enable Link Redundancy in a Cluster with LACP.
Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
1 Global config:
2 Configure terminal
3 feature lacp
4 Interface level config:

6    interface Ethernet2/47
7    switchport
8    switchport access vlan 10
9    channel-group 7 mode active
10   no shutdown
11
12    interface Ethernet2/48
13    switchport
14    switchport access vlan 10
15    channel-group 7 mode active
16   no shutdown
```

**Link redundancy in a cluster with LACP**

February 12, 2020

A Citrix ADC cluster provides link redundancy for LACP to ensure that all nodes have the same partner key.

To understand the need for link redundancy, let us consider the example of the following cluster setup along with the accompanying cases (with attention to case 3):
In this setup, interfaces I1, I2, I3 and I4 are bound to LACP channel with KEY 5. On the partner side, I1 and I2 are connected to Switch 1 to form a single LA channel with KEY 1. Similarly, I3 and I4 are connected to Switch 2 to form a single LA channel with KEY 2.

Now let us consider the following cases to understand the need for link redundancy:

- **Case 1: Switch 1 is up and Switch 2 is down**

  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key2 and would start receiving LACPDUs from Key1. On both the nodes, cluster LA is connected to KEY 1 and I1 and I2 will be UP and channel on both the nodes would be UP.

- **Case 2: Switch1 goes down and Switch2 becomes UP**

  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key1 and would start receiving LACPDUs from Key2. On both the nodes, cluster LA is connected to Key2 and I3 and I4 will be UP and channel on both the nodes would be UP.

- **Case 3: Both Switch1 and Switch2 are UP**

  In this case, it is possible that cluster LA on node1 chooses Key1 as its partner and cluster LA on node2 chooses Key2 as its partner. This means that I1 on node1 and I4 on node2 are receiving traffic which is undesirable. This can happen because the LACP state machine is node-level and chooses its partners on first-come first-serve basis.

  To solve these concerns, link redundancy of dynamic cluster LA is supported. To configure link redundancy on a channel or interface, you must enable it and optionally specify the threshold throughput as follows:

  ```
  set channel CLA/1 -linkRedundancy ON -lrMinThroughput <positive_integer>
  ```
The throughput of the partner channels is checked against the configured threshold throughput. The partner channel that satisfies the threshold throughput is selected in first-in-first-out (FIFO) manner. If none of the partner channel meets the threshold, or if threshold throughput is not configured, the partner channel with the maximum number of links is selected.

**Note**
The threshold throughput can be configured from NetScaler 11 onwards.

---

**Managing the Citrix ADC cluster**

April 23, 2019

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform cluster tasks such as configuring nodegroups, disabling nodes of a cluster, discovering Citrix ADC appliances, viewing statistics, synchronizing cluster configurations, cluster files, and the time across the nodes, and upgrading or downgrading the software of cluster nodes.

---

**Configuring linksets**

June 2, 2020

Linksets must be used when some cluster nodes are not physically connected to the external network. In such a cluster topology, the unconnected cluster nodes use the interfaces specified in the linkset to communicate with the external network through the cluster backplane. Linksets are typically used in scenarios when the connecting devices have insufficient ports to connect the cluster nodes.

**Note**
Linksets are a mandatory configuration in the following scenarios:
- For deployments that require MAC-Based Forwarding (MBF).
- For “-m MAC” mode that is enabled at the virtual server along with MBF mode enabled globally.
To improve the manageability of ACL and L2 policies involving interfaces. You define a linkset of the interfaces and add ACL and L2 policies based on linksets.

Linksets must be configured only through the cluster IP address.

For example, consider a three node cluster where the upstream switch has only two ports available. Using linksets, you can connect two nodes to the switch and leave the third node unconnected. In the following figure, a linkset (LS/1) is formed by binding the interfaces 0/1/2 and 1/1/2. NS2 is the unconnected node of the cluster.

Figure 1. Linksets topology

The linkset informs NS2 that it can use interfaces 0/1/2 and 1/1/2 to communicate with the network devices. All traffic to and from NS2 is now routed through interfaces 0/1/2 or 1/1/2.

Figure 2. Traffic distribution flow using linksets
Start

Client: Sends request

Switch: Receives a ARP request

Switch: Broadcasts the ARP request on the interfaces of the connected nodes

Cluster: Determines the ARP owner and sends the ARP response

Switch: Forwards the client request to the ARP owner (the ARP owner becomes the flow receiver for all client traffic destined for that VIP address)

Flow receiver: Determines the flow processor and steers traffic to that node

Stop
To configure a linkset by using the command line interface

1. Log on to the cluster IP address.

2. Create a linkset.

   ```
   add linkset <id>
   ```

   **Example**

   ```
   add linkset LS/1
   ```

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.

   ```
   bind linkset <id> -ifnum <interface_name> ...
   ```

   **Example**

   ```
   bind linkset LS/1 -ifnum 0/1/2 1/1/2
   ```

4. Verify the linkset configurations.

   ```
   show linkset <id>
   ```

   **Example**

   ```
   show linkset LS/1
   ```

   **Note**

   You can bind the linkset to a VLAN by using the “bind vlan” command. The interfaces of the linkset are automatically bound to the VLAN.

To configure a linkset by using the configuration utility

1. Log on to the cluster IP address.

2. Navigate to **System > Network > Linksets**.

3. In the details pane, click **Add**.

4. In the **Create Linkset** dialog box:
   - Specify the name of the linkset by setting the Linkset parameter.
   - Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.

5. Click **Create**, and then click **Close**.

Nodegroups for spotted and partially-striped configurations

February 12, 2020

By virtue of the default cluster behavior, all configurations performed on the cluster IP address are available on all nodes of the cluster. However, there might be cases where you need some configurations to be available only on specific cluster nodes.

You can achieve this requirement by defining a nodegroup that includes the specific cluster nodes, and then binding the configuration to that nodegroup. This ensures that the configuration is active only on those cluster nodes. These configurations are called partially-striped or spotted (if active only one a single node). For more information, see Striped, Partially Striped, and Spotted Configurations.

For example, consider a cluster with three nodes. You create a nodegroup NG0 that includes node n1 and another nodegroup NG1 that includes n2 and n3. Bind load balancing virtual servers .77 to NG0 and load balancing virtual server .69 to NG1.

This means that virtual server .77 will be active only on n1 and consequently only n1 will receive traffic that is directed to .77. Similarly, virtual server .69 will be active only on nodes n2 and n3 and consequently only n2 and n3 will receive traffic that is directed to .69.

Figure 1. Citrix ADC cluster with nodegroups configured for spotted and partial-striped configurations

The entities or configurations that you can bind to a nodegroup are:

- Load balancing, content switching, cache redirection, authentication, authorization, and auditing virtual servers

  Note

  FTP load balancing virtual servers cannot be bound to nodegroups.

- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)

- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)

- Limit identifiers and stream identifiers
Behavior of nodegroups

April 23, 2019

Due to the interoperability of nodegroups with different Citrix ADC features and entities, there are some behavioral aspects to be noted. Nodes in a nodegroup can also be backed up. Read on for more information.

General behavior of a cluster nodegroup

- A nodegroup that has entities bound to it cannot be removed.
- A cluster node that belongs to a nodegroup with entities bound to it, cannot be removed.
- A cluster instance that has nodegroups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity that is not part of the nodegroup. If you need to do so, first remove the dependency. Then, add both the entities to the nodegroup and reassociate the entities.

Examples:

- Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a nodegroup, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the nodegroup, and then configure VS2 as the backup for VS1.
- Assume you have a content switching virtual server, CSV1, whose target load balancing virtual server is LBVS1. To add CSV1 to a nodegroup, first remove LBVS1 as the target. Then, bind each server individually to the nodegroup, and then configure LBVS1 as the target.
- Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the nodegroup, and then reassociate the virtual servers.

- You cannot bind an entity to a nodegroup that has no nodes and that has the strict option enabled. Consequently, you cannot unbind the last node of a nodegroup that has entities bound to it and that has the strict option enabled.
- The strict option cannot be modified for a nodegroup that has no nodes but has entities bound to it.
**Backing up nodes in a nodegroup**

By default, a nodegroup is designed to provide back up nodes for members of a nodegroup. If a nodegroup member goes down, a cluster node that is not a member of the nodegroup dynamically replaces the failed node. This node is called the replacement node.

**Note**
For a single-member nodegroup, a backup node is automatically preselected when an entity is bound to the nodegroup.

When the original member of the nodegroup comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the Citrix ADC allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do this, you must enable the strict option. In this scenario, when a nodegroup member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the nodegroup when it comes up. This option ensures that entities bound to a nodegroup are active only on nodegroup members.

**Note**
The strict and sticky option can be set only when creating a nodegroup.

**Configuring nodegroups for spotted and partially-striped configurations**

February 18, 2020

To configure a nodegroup for spotted and partially-striped configurations you must first create a nodegroup and then bind the required nodes to the nodegroup. You must then associate the required entities to that nodegroup. The entities that are bound to the nodegroup will be:

- **Spotted** - If bound to a nodegroup that has a single node.
- **Partially Striped** - If bound to a nodegroup that has more than one node.

**Some points to remember:**
- GSLB is supported on a cluster only when GSLB sites are bound to nodegroups that have a single cluster node. For more information, see [Setting Up GSLB in a Cluster](#).
• Citrix Gateway is supported on a cluster only when the VPN virtual servers are bound to node-
groups that have a single cluster node. The sticky option must be enabled on the nodegroup.
• For versions prior to NetScaler 11, application firewall is supported only on individual cluster
nodes (spotted configuration). Application firewall profiles can be associated only with virtual
servers that are bound to nodegroups that have a single cluster node. This means that applica-
tion You are not allowed to do the following:
  – Bind application firewall profiles to striped or partially striped virtual servers.
  – Bind the policy to a global bind point or to user-defined policy labels.
  – Unbind, from a nodegroup, a virtual server that has application firewall profiles.
• NetScaler 11 introduced application firewall support for striped and partially-striped configura-
tions. For more information, see Application Firewall Support for Cluster Configurations.

Check Citrix ADC Features Supported in a Cluster to see the NetScaler versions from which GSLB, Citrix
Gateway, and application firewall are supported in a cluster.

To configure a nodegroup by using the command line interface

1. Log on to the cluster IP address.
2. Create a nodegroup. Type:

   add cluster nodegroup <name> -strict (YES | NO)

   Example

   1 add cluster nodegroup NG0 -strict YES

3. Bind the required nodes to the nodegroup. Type the following command for each member of
   the nodegroup:

   bind cluster nodegroup <name> -node <nodeId>

   Example

   To bind nodes with IDs 1, 5, and 6.

   1 > bind cluster nodegroup NG0 -node 1
   2 > bind cluster nodegroup NG0 -node 5
   3 > bind cluster nodegroup NG0 -node 6

4. Bind the entity to the nodegroup. Type the following command once for every entity that you
   want to bind:

   bind cluster nodegroup <name> (-vServer <string> | -identifierName <
   string> | -gslbSite <string> -service <string>)
To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1:

```
1 > bind cluster nodegroup NG0 -vServer VS1
2 > bind cluster nodegroup NG0 -vServer VS2
3 > bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the nodegroup. Type:

```
show cluster nodegroup <name>
```

Example

```
1 > show cluster nodegroup NG0
```

**To configure a nodegroup by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Node Groups**.
3. In the details pane, click **Add**.
4. In the **Create Node Group** dialog box, configure the nodegroup:
   a) Under **Cluster Nodes**, click the **Add** button.
      - The Available list displays the nodes that you can bind to the nodegroup and the Configured list displays the nodes that are bound to the nodegroup.
      - Click the + sign in the Available list to bind the node. Similarly, click the - sign in the Configured list to unbind the node.
   b) Under **Virtual Servers**, select the tab corresponding to the type of virtual server that you want to bind to the nodegroup. Click the **Add** button.
      - The Available list displays the virtual servers that you can bind to the nodegroup and the Configured list displays the virtual servers that are bound to the nodegroup.
      - Click the + sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.
Configuring redundancy for nodegroups

April 23, 2019

Note
Supported from NetScaler 10.5 Build 52.1115.e onwards.

Nodegroups can be configured such that when one nodegroup goes down, another nodegroup can take over and process traffic. For example, when a nodegroup NG1 goes down, NG2 takes over.

Note
This functionality can be used to configure datacenter redundancy where each nodegroup is configured as a datacenter.

To achieve this use case, cluster nodes must be logically grouped into nodegroups, where some nodegroups must be configured as ACTIVE and others as SPARE. The active nodegroup with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active nodegroup goes down, the node count of this nodegroup is compared with the node count of the other active nodegroups in order of their priority. If a nodegroup has a higher or equal node count, that nodegroup is made operationally active. Else, the spare nodegroups are checked.

Note
- Only one state-specific nodegroup can be active at a given point in time.
- A cluster node inherits the state of the nodegroup. So, if a node with “SPARE” state is added to nodegroup with state as “ACTIVE”, the node automatically behaves as an active node.
- The preemption parameter that is defined for the cluster instance decides whether the initial active nodegroup will take control when the it comes up again.
- A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a nodegroup setup that has nodegroup redundancy defined. NG1 is initially the active nodegroup. When it loses one of the nodes, the spare nodegroup (NG3) with the highest priority starts serving traffic.

Figure 1. Citrix ADC cluster with nodegroup redundancy configured
Configuring redundancy for nodegroups

1. Log on to the cluster IP address.

2. Create the active nodegroup and bind the required cluster nodes.

   1 > add cluster nodegroup NG1 -state ACTIVE
   2 > bind cluster nodegroup NG1 -node n1
   3 > bind cluster nodegroup NG1 -node n2
   4 > bind cluster nodegroup NG1 -node n3

3. Create the spare nodegroup and bind the requisite nodes.

   1 > add cluster nodegroup NG2 -state SPARE -priority 20
   2 > bind cluster nodegroup NG2 -node n4
   3 > bind cluster nodegroup NG2 -node n5
   4 > bind cluster nodegroup NG2 -node n6

4. Create another spare nodegroup and bind the requisite nodes.

   1 > add cluster nodegroup NG3 -state SPARE -priority 10
   2 > bind cluster nodegroup NG3 -node n7

Disabling steering on the cluster backplane

April 23, 2019

**Note**
Supported from NetScaler 11 onwards.

The default behavior of a Citrix ADC cluster is to direct the traffic that it receives (flow receiver) to another node (flow processor) that must then process the traffic. This process of directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

If required, you can disable steering so that the process becomes local to the flow receiver and therefore makes the flow receiver as the flow processor. Such a configuration setup can come handy when you have a high latency link.

**Note**
This configuration is applicable only for striped virtual servers.

- For partially striped virtual servers, if the flow receiver is a non-owner node, the traffic is steered to a owner node. If however, the flow receiver is a owner node, then steering is disabled.
- For spotted virtual servers, flow receiver is the flow processor, and hence there is no need for steering.

Some points to remember when disabling the steering mechanism:

- Striped SNIPs are not supported as steering is disabled.
- MPTCP and FTP does not work.
- L2 mode must be disabled.
- If USIP is enabled, traffic may not reach back to the same node as the steering is disabled.
- Traffic that is directed to the cluster IP address is steered to the configuration coordinator.
- When a node joins or leaves a cluster, it is possible that more than 1/N connections will be affected. This is due to the fact that a change in the nodes available, may cause the routes to be rehashed. As a result, the traffic will be routed to another node and due to the non-availability of steering, the traffic will not be processed.
Steering can be disabled at the individual virtual server level or at the global level. The global configuration takes precedence over the virtual server setting.

- Disabling backplane steering for all striped virtual servers
  Configured at cluster instance level. Traffic meant for any striped virtual server will not be steered on cluster backplane.
  
  ```
  add cluster instance \<clId\> -processLocal ENABLED
  ```

- Disabling backplane steering for a specific striped virtual server
  Configured on a striped virtual server. Traffic meant for the virtual server will not be steered on cluster backplane.
  
  ```
  add lb vserver <name> <serviceType> -processLocal ENABLED
  ```

Synchronizing cluster configurations

April 23, 2019

Citrix ADC configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is executed through the cluster IP address.

Additionally, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

To synchronize cluster configurations by using the command line interface

At the command prompt of the appliance on which you want to synchronize the configurations, type:

```
1 force cluster sync
```

To synchronize cluster configurations by using the configuration utility

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Force cluster sync.
4. Click **OK**.

### Synchronizing time across cluster nodes

April 23, 2019

The cluster uses Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

**To enable/disable PTP by using the command line interface**

At the command prompt of the cluster IP address, type:

```
set ptp -state disable
```

**To enable/disable PTP by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click **Configure PTP Settings**.
4. In the **Enable/Disable PTP** dialog box, select whether you want to enable or disable PTP.
5. Click **OK**.

### Synchronizing cluster files

February 12, 2020
The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Additionally, you can manually synchronize the cluster files.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netscaler/htmlinjection/ens/
- /nsconfig/monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netscaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmtpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

**Tip**

Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. You must execute the “sync cluster files” command from the cluster IP address before executing a command.
To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

1 sync cluster files <mode>

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Synchronize cluster files.
4. In the Synchronize cluster files dialog box, select the files to be synchronized in the Mode drop-down box.
5. Click OK.

Viewing the statistics of a cluster

April 23, 2019

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

1 stat cluster instance <clId>

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

1 stat cluster node <nodeid>
Note
When executed from the cluster IP address, this command displays the cluster level statistics. However, when executed from the NSIP address of a cluster node, the command displays node level statistics.

To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, in the center of the page, click Statistics.

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, select a node and click Statistics to view the statistics of the node. To view the statistics of all the nodes, click Statistics without selecting a specific node.

Discovering Citrix ADC appliances

April 23, 2019

You can discover the appliances present in the same subnet as the current node. The required discovered appliances can then be selectively added to the cluster. This operation can be performed to either create a new cluster or to add nodes to an existing cluster.

Note
- The discover operation can be performed only through the configuration utility.
- This operation cannot discover Citrix ADC appliances from different networks.
- When performing this operation to add nodes to an existing cluster, the L3 VLAN configurations will be cleared from the node. You must make sure to define these configurations once the appliance is added to the cluster.
To discover appliances by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, at the bottom of the page, click Discover NetScalers.
4. In the Discover NetScalers dialog box, set the following parameters:
   - **IP address range** - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
   - **Backplane interface** - Specify the interfaces to be used as the backplane interface. This is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click OK.
6. Select the appliances that you want to add to the cluster.
7. Click OK.

Disabling a cluster node

February 18, 2020

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see Synchronization across cluster nodes.

A disabled node cannot serve traffic and all existing connections on this node are terminated.

**Note**

If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You must manually synchronize the configurations as described in Synchronizing Cluster Configurations.

To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:
To disable the cluster, run the `disable cluster instance <clId>` command on the cluster IP address.

**Note**
To disable the cluster, run the `disable cluster instance` command on the cluster IP address.

**To disable a cluster node by using the configuration utility**

1. On the node that you want to disable, navigate to **System > Cluster**, and click **Manage Cluster**.
2. In the **Configure cluster instance** dialog box, unselect the **Enable cluster instance** check box.

**Note**
To disable the cluster instance on all the nodes, perform the above procedure on the cluster IP address.

**Removing a cluster node**

April 23, 2019

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally executing the clear ns config -extended command). The SNIP addresses, MTU settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

**Note**
- If the deleted node was the cluster configuration coordinator, another node is automatically selected as the cluster configuration coordinator, and the cluster IP address is assigned to that node. All the current cluster IP address sessions will be invalid and you will have to start a new session.
- To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP address(es) are deleted.
- When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.
To remove a cluster node by using the command line interface

For NetScaler 10.1 and later versions

Logon to the cluster IP address and at the command prompt, type:

```
rm cluster node <nodeId>
```

Note
If the cluster IP address is unreachable from the node, execute the `rm cluster instance` command on the NSIP address of that node itself.

For NetScaler 10

1. Log on to the node that you want to remove from the cluster and remove the reference to the cluster instance.

```
rm cluster instance <clId>
save ns config
```

2. Log on to the cluster IP address and remove the node from which you removed the cluster instance.

```
rm cluster node <nodeId>
save ns config
```

Make sure you do not run the `rm cluster node` command from the local node as this results in inconsistent configurations between the configuration coordinator and the node.

To remove a cluster node by using the configuration utility

On the cluster IP address, navigate to `System > Cluster > Nodes`, select the node you want to remove and click `Remove`.

Copied!
Failed!
Removing a node from a cluster deployed using cluster link aggregation

February 18, 2020

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see Using Cluster Link Aggregation.

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.

   set cluster node <nodeId> -state PASSIVE

3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.

   Note
   You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.

4. Remove the node from the cluster.

   rm cluster node <nodeId>

Copied!
Failed!

Detecting jumbo probe on a cluster

February 12, 2020

If a Jumbo frame is enabled on a Cluster interface, the backplane interface should be large enough to support the all packets in the Jumbo frame. This is achieved by setting the Maximum Transmission Unit (MTU) of the backplane as:
Backplane_MTU = maximum (all cluster interface MTU’s) + 78

To verify the above configuration, you must send a jumbo probe (of the above computational size) to all peer nodes of a Cluster setup. If the probe does not succeed, the appliance displays a warning message in the output of the “show cluster instance” command.

In the command interface mode, type the following command:

```
> show cluster instance

Cluster ID: 1
Dead Interval: 3 secs
Hello Interval: 200 msecs
Preemption: DISABLED
Propagation: ENABLED
Quorum Type: MAJORITY
INC State: DISABLED
Process Local: DISABLED
Cluster Status: ENABLED (admin), ENABLED (operational), UP
```

**Warning**

The MTU for a backplane interface must be large enough to handle all packets in the frame. It must be equal to $\text{MTU}_{\text{VAL}}$. If the recommended value is not user configurable, you must review the MTU value of jumbo interfaces.

**Route monitoring for dynamic routes in cluster**

February 12, 2020

You can use a route monitor to make a Cluster node dependent on the internal routing table whether
it contains or does not contain dynamically learnt route. In a Cluster system, a route monitor on each node checks the internal routing table to ensure there is a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

In a cluster deployment, if the client-side or server side-link of a node goes down, traffic is steered to this node through the peer nodes for processing. The steering of traffic is implemented by configuring dynamic routing and adding static ARP entries, pointing to the special MAC address of each node, on all the nodes. If there are a large number of nodes in a cluster deployment, adding and managing static ARP entries with special MAC addresses on all the nodes is a cumbersome task. Now, nodes implicitly use special MAC addresses for steering packets. Therefore, static ARP entries pointing to special MAC addresses are no longer required to be added to the cluster nodes.

To bind a cluster node using the command line interface

At the command prompt, type:

```
1 bind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [netmask<]]
2 unbind cluster node <nodeId> (-routeMonitor <ip_addr|ipv6_addr|*> [netmask<])
```

Consider a scenario where Node 1 is bound to route monitor 1.1.1.0 255.255.255.0. When a dynamic route fails, Node 1 become INACTIVE. Health status is available in the Show Cluster Node command by node id as show below.

```
1 Node ID: 1
2 IP: 10.102.169.96
3 Backplane: 1/1/2
4 Health: NOT UP
5 Reason(s): Route Monitor(s) of the node have failed
6 Route Monitor - Network: 1.1.1.0 Netmask: 255.255.255.0 State: DOWN
```

Monitoring cluster setup using SNMP MIB with SNMP link

February 12, 2020
SNMP mib is device specific information that has been configured on the SNMP agent for the purpose of identifying a Citrix ADC appliance, such as appliance name, administrator, location. In a cluster setup, you can now configure the SNMP MIB in any node by including the “ownerNode” parameter in the set snmp mib command. Without this parameter, the set snmp mib command applies only to the Cluster Coordinator (CCO) node.

To display the MIB configuration for a cluster node other than the CCO, include the “ownerNode” parameter in the show snmp mib command

**Configuring SNMP MIB on CLIP**

To configure and view MIB configuration on CLIP by using the command line interface.

```
1 set snmp mib [-contact <string>] [-name <string>] [-location <string>]
2   [-customID <string>] [-ownerNode <positive_integer>]
3 # Done
4 show snmp mib [-ownerNode <positive_integer>]
5
6 > set mib -contact John -name NS59 -location San Jose -customID 123 -
7   ownerNode 3
8 # Done
9 > sh mib -ownerNode 3
10 # ---------------------------
11   Cluster Node ID: 3
12 # ---------------------------
13   NetScaler system MIB:
14   sysDescr:  NetScaler NS11.1: Build 46.4.a.nc, Date: Jun 7
15     2016, 10:27:29
16   sysUpTime:  124300
17   sysObjectID: .1.3.6.1.4.1.5951.1.1
18   sysContact:  John
19   sysName:  NS59
20   sysLocation:  San Jose
21   sysServices:  72
22   Custom ID: 123
23 # Done
24
25 > unset mib -contact -name -location -customID -ownerNode 3
26 # Done
27 > sh mib -ownerNode 3
28 # ---------------------------
29   Cluster Node ID: 3
30 # ---------------------------
31   NetScaler system MIB:
```
Monitoring command propagation failures in a cluster deployment

May 20, 2019

In a cluster deployment of NetScaler appliances, you can use the new command “show prop status” for faster monitoring and troubleshooting of issues related to command-propagation failure on non-CCO nodes. This command displays up to 20 of the most recent command propagation failures on all non-CCO nodes. You can use either the NetScaler appliance command line or the NetScaler GUI to perform this operation after accessing them through the CLIP address or through the NSIP address of any node in the cluster deployment.

Graceful shutdown of nodes

May 8, 2020

In a cluster setup, some of the existing connections (1/Nth connections, where N is the cluster size) at the cluster level or specific virtual server level are lost. This behavior is observed if a node leaves or joins the system. To address the loss, you must gracefully handle the existing connections. Graceful handling is done by configuring “retain connections on cluster” option in the CLIP address and specifying timeout interval in the node’s NSIP.

Graceful handling of connections is applicable in two scenarios:
1. Cluster upgrade
2. New node addition

**Graceful handling of Nodes in cluster upgrade**

To upgrade a cluster, you must upgrade one node at a time. Before upgrading a node, you must set it to passive state and then set it to active state after the upgrade. To avoid terminating existing connections when upgrading the node, shut it down gracefully with a configured timeout interval. Otherwise, 1/Nth (where N is the cluster size) of the cluster’s connections are terminated.

**Note**

If existing sessions are not completed within the configured timeout interval, they get terminated after the grace time.

Following are the steps to gracefully handle nodes in a cluster upgrade scenario:

1. Consider a cluster setup of five nodes (n0, n1, n2, n3, n4).

2. Before you shut down a node, you must configure “retainConnectionsOnCluster” option to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

   **Example**

   On CLIP

   ```
   set cluster instance <clusterID> -retainConnectionsOnCluster YES
   OR
   set lb vserver <vserver name> -retainConnectionsOnCluster Yes
   ```

3. Now, log on to the NSIP address of node n3 and set the node n3 to PASSIVE with a timeout internal.

   **Example**

   ```
   set cluster node n3 -state PASSIVE -delay 60
   saveconfig
   ```

4. After the grace period expires, close all connections, shut down n3 and reboot the Citrix ADC appliance.

5. Upgrade the appliance. Then, with the CLI connected to the appliance’s NSIP address, set the node to ACTIVE.

   **Example**
set cluster node n3 -state ACTIVE
saveconfig

6. Repeat steps 4–6 for all nodes in the cluster.

7. After all nodes are upgraded and set to ACTIVE, reset the retainConnectionsOnCluster option from the CLIP address.

   **Example**
   ```
   set cluster instance <clusterID> -retainConnectionsOnCluster NO
   OR
   set lb vserver <vserver name> -retainConnectionsOnCluster NO
   saveconfig
   ```

   **Note**
   If there is a version mismatch when upgrading a cluster, cluster propagation is automatically disabled and no commands are allowed on the CLIP.

---

**Graceful handling of nodes during a new node addition**

The graceful handling of nodes describes how a new node can be added to the existing Citrix ADC cluster. Consider you have a Citrix ADC cluster that is already serving traffic. And you want to add an extra appliance as a node to the cluster without terminating its existing connections. To accomplish the preceding scenario, set the option to retain existing connections either at a Global level or at a specific virtual server level. Once done, save the configuration. Now set the option to retain connections to NO, to allow existing connections from other nodes to be reassigned to the new node.

Following are the steps to gracefully handle nodes if a node newly added:

1. You save the existing configuration that has “retainConnectionsOnCluster” option enabled to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.
   
   **On CLIP**
   ```
   1 set cluster instance x - retainConnectionsOnCluster YES
   ```
   OR
   ```
   1 set lb vserver xxxx - retainConnectionsOnCluster Yes
   ```

2. Add a node ‘n5’ to the cluster setup.
3. Disable “the retainConnectionOnCluster” option to “NO” for distributing existing connections from other nodes to the newly added node n5.

On CLIP

```
1 set cluster instance x - retainConnectionsOnCluster NO
```

OR

```
1 set lb vserver xxxx - retainConnectionsOnCluster NO
```

**Note**
The backplane steering depends on the type of traffic distribution mechanism (ECMP, CLAG, and USIP) on a cluster setup. The increase in backplane steering is based on the traffic type.

### Configuring graceful shutdown of nodes in a cluster

To configure graceful shutdown of nodes in a cluster, do the following:

1. Configure “retainConnectionsonCluster” option at Global (Cluster) level.
2. Configure “retainConnectionsonCluster” option at the virtual server level.
3. Set the node (leaving the system) to the passive state with a graceful timeout interval specified in the node's NSIP address.
4. Monitor the existing connections to make sure all transactions are completed within the grace period.

### To retain existing connections at the global (cluster) level by using the command line

You can retain existing connections either at a global level or at a specific virtual server level. This option is configured to retain all existing connections at the global level. By default, this option is disabled.

At the command prompt type:

```
1 - set cluster instance <clusterID> - retainConnectionsOnCluster YES
2
3 - set cluster instance 60 - retainConnectionsOnCluster YES
```
To retain existing connections of a specific virtual server in the cluster by using the command line

This option is configured to retain existing connections specific to a load balancing virtual server. To retain those connections, we enable this option at the virtual server level. By default, this option is disabled.

At the command prompt, type:

```
1 - set lb vserver <clusterID> -retainConnectionsOnCluster Yes
2
3 - set lb vserver v1 -retainConnectionsOnCluster Yes
```

To set a cluster node to passive state by using the command line

To set a cluster node to passive state with a graceful timeout interval. This setting is performed in the node’s NSIP as propagation is disabled during cluster upgrade.

At the command prompt, type:

```
1 - set cluster node <clusterID> -state passive
2
3 - priority <positive_integer>
4 -delay <mins>
5
6 - set cluster node 4 -state PASSIVE -delay 60
7
8 - set cluster instance 60 - retainConnectionsOnCluster YES
9 - set lb vserver v1 -retainConnectionsOnCluster Yes
10 - set cluster node 4 -state PASSIVE -delay 60
```

Note

You might observe the following behavior on a cluster node when it is set to passive with delay option configured from a CLIP:

- After the timeout, the node shows as passive from the NSIP of the node.
- The `show cluster instance` command on CLIP displays the node as active from the CLIP. Whereas the `show cluster node` command on the CLIP displays the node as passive.

To configure graceful shutdown of nodes by using the Citrix ADC GUI

1. Navigate to Configuration > System > Cluster and click Manage Cluster.
2. On the Manage Cluster page, select Retain Connections on Cluster option.
3. Click OK, and then click Done.

Graceful shutdown of services

April 23, 2019

Starting with NetScaler 12.1 build 49.xx, Citrix ADC clusters support graceful shutdown of services. To gracefully shutdown the services, you can perform one of the following tasks.

- Explicitly disable the service, and
  - Set a delay (in seconds).
  - Enable graceful shutdown.
- Add a TROFS code or string to the monitor.

For more details, see Graceful shutdown of services.

To configure graceful shutdown for a service by using the CLI

Disable with graceful option only:

At the command prompt, type:

```
1 disable service <name> [-graceFul (YES|NO)]
2
3 show service <name>
```

Example

```
1 disable service svc1 -graceFul YES
2 Done
3 sh service svc1
  svc1 (10.102.225.11:80) - HTTP
  State: GOING OUT OF SERVICE   Graceful (number of active clients: 1)
  Last state change was at Wed Jul 25 10:46:29 2018
  Time since last state change: 0 days, 00:00:02.680
  ..... ...
  ..... ...
```

Copied!

Traffic Domain: 0

1) Monitor Name: tcp-default
State: UP
    Weight: 1
    Passive: 0
Probes: 26 Failed [Total: 0
    Current: 0]
Last response: Success - TCP syn+ack received.
Response Time: 0.0 millisec

Disable with timeout and graceful option:

At the command prompt, type:

disable service <name> [<delay>] [-graceful (YES|NO)]
show service <name>

Example

disable service svc1 2000 -graceful YES
Done
> sh service svc1
    svc1 (10.102.225.11:80) - HTTP
    State: GOING OUT OF SERVICE (Graceful (number of active clients: 1), Out Of Service in 1998 seconds)
    Last state change was at Wed Jul 25 10:49:08 2018
    Time since last state change: 0 days, 00:00:01.710
    ...
    Traffic Domain: 0

1) Monitor Name: tcp-default
    State: UP
    Weight: 1

    Probes: 57 Failed [Total: 0
    Current: 0]
    Last response: Success - TCP syn+ack received.
    Response Time: 0.0 millisec
Done

Disable service group with timeout and graceful option:
At the command prompt, type:

```bash
1  disable serviceGroup <serviceGroupName>@ [<serverName>@ <port>] [-delay <secs>] [-graceFul ( YES | NO )]
2  Show service group <serviceGroupName>
```

Example:

```bash
1  disable servicegroup sg -delay 2000 -graceFul yes
2  sh servicegroup sg
3          sg = HTTP
4  State: DISABLED  Effective State: OUT OF SERVICE
5          SERVICE Monitor Threshold : 0
6          Max Conn: 0   Max Req: 0   Max Bandwidth: 0 kbits
7  Use Source IP: NO

15          Last state change was at Mon Aug 13 15:15:11 2018
16                   .......
17
18  2)  200.200.10.22:80 Server Name: server4
19          Server ID: None Weight: 1
20          State: GOING OUT OF SERVICE (learnt from node:2 ) Graceful (number of active clients: 7), Out Of Service in 1993 seconds
21          Last state change was at Mon Aug 13 15:15:11 2018
```

Note: CLIP displays the aggregated value of all active clients connections from all cluster nodes.
To configure graceful shutdown for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

To configure a TROFS code or string in a monitor by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2 add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
3 add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
```

To configure a TROFS code or string in a monitor by using the GUI

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following steps:
   - Select Type as HTTP, and specify a TROFS Code.
   - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

IPv6 ready logo support for clusters

February 12, 2020

You can test clustered appliances for IPv6 Ready Logo certification. Modified commands for testing IPv6 core protocols, such as for ND test cases, Router Solicitation processing, and sending route advertisement and router redirection messages are available in a clustered setup. Following are the IPv6 functionalities available for testing the IPv6 core protocols.

Following are the modified functionalities available to pass IPv6 core protocols, such as ND test cases, Router Solicitation processing and sending Route advertisement and router redirection messaging in IPv6readylogo phase2 test suite.

- Link Local SNIPs
- Address Resolution and Neighbor Unreachability
- Router and Prefix Discovery
Citrix ADC 13.0

- Router Redirection
- DoDAD

With these modified commands, the following configurations are supported in a clustered appliance.

**Supportable configurations for testing IPv6 core protocols**

For a clustered setup to pass IPv6 Ready Logo test cases, you can execute the following configurations on the Cluster Management IP address (CLIP).

- global IP6 configuration
- basic IPv6 configuration
- additional IPv6 configurations

**Global configuration**

A global IPv6 configuration enables you to set the global IPv6 parameters (such as relearning, routeRedirection, ndBasereachTime, nRetransmissionTime, natprefix, td, and doDAD) to run the basic IPv6 configuration.

At the command prompt, type the following:

```
set ipv6 [-ralearning ( ENABLED | DISABLED )] [-routerRedirection ( ENABLED | DISABLED )][-ndBasereachTime<positive_integer>][-ndRetransmissionTime <positive_integer>] [-natprefix <ipv6_addr>][-td<positive_integer>] [-doDAD ( ENABLED | DISABLED )]
```

**Basic IPv6 configuration**

The basic IPv6 configuration enables you to create an IPv6 address and bind to a VLAN interface. You must perform the following configurations to test the IPv6 core protocols.

To add a VLAN to the clustered setup by using the NetScaler command line

At the command prompt, type:

```
add vlan <id>
```

To add another VLAN to the clustered set up by using the NetScaler command line

At the command prompt, type:

```
add vlan <id>
```
To bind an interface to a VLAN by using the NetScaler command line

At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```

To bind an interface to a VLAN by using the NetScaler command line

This command adds the global prefix as on-link prefix into RA information for subsequent Router Advertisements. At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```

To add IPv6 SNIP address on a VLAN by using the NetScaler command line

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To add IPv6 address on VLAN by using the NetScaler command line

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|ipv6_addr>
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|ipv6_addr>
```

To display link local IPv6 address attached to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
sh VLAN
```

**Example 1**
add vlan 2
add vlan 3
bind vlan 2 -ifnum 1/2
bind vlan 3 -ifnum 1/3
add ip6 fe80::9404:60ff:fedd:a464/64 -vlan 2 -scope link-local -type SNIP
add ip6 fe80::c0ee:7bff:fedd:263/64 -vlan 3 -scope link-local -type SNIP
bind vlan 3 -ipAddress 3ffe:501:ffff:101:c0ee:7bff:fedd:263/64

Example 2

sh vlan
1) VLAN ID: 2 VLAN Alias Name:
   Interfaces : 1/6
   IPs :
      3ffe:501:ffff:100:2e0:edff:fe15:ea2a/64
3) VLAN ID: 3 VLAN Alias Name:
   Link-local IPv6 addr: fe80::9404:60ff:fedd:a464/64
   Interfaces : 1/5
   IPs :
      3ffe:501:ffff:101:2e0:edff:fe15:ea2b/64
Done

Additional IPv6 cluster configuration

To test IPv6 core protocols, you can use the following new or modified IPv6 configurations.

To set VLAN specific Router Advertisement parameters by using the NetScaler command line

At the command prompt, type:

set nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv ( YES | NO )] [-sendRouterAdv ( YES | NO )] [-srcLinkLayerAddrOption ( YES | NO )] [-onlyUnicastRtAdvResponse ( YES | NO )] [-managedAddrConfig ( YES | NO )] [-otherAddrConfig ( YES | NO )] [-currHopLimit < positive_integer>] [-maxRtAdvInterval < positive_integer>] [-minRtAdvInterval <positive_integer>] [-linkMTU <positive_integer>] [-reachableTime <positive_integer>] [-retransTime <positive_integer>] [-defaultLifeTime <integer>]
To set an on-link global prefix's configurable parameters by using the NetScaler command line

At the command prompt, type:

```
set onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )][-autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )][-decrementPrefixLifeTimes ( YES | NO )] [-prefixValideLifeTime < positive_integer>] [-prefixPreferredLifeTime <positive_integer>]
```

To add configurable parameters to an on-link global prefix by using the NetScaler command line

At the command prompt, type:

```
add onLinkIPv6Prefix <ipv6Prefix> [-onlinkPrefix ( YES | NO )][-autonomusPrefix ( YES | NO )] [-depricatePrefix ( YES | NO )][-decrementPrefixLifeTimes ( YES | NO )]-prefixValideLifeTime < positive_integer>][-prefixPreferredLifeTime <positive_integer>]
```

To set on-link link IPv6 prefix's configurable parameters by using the NetScaler command line

At the command prompt, type the following:

```
help set onLinkIPv6Prefix
```

To bind an on-link link IPv6 prefix's configurable parameters by using the NetScaler command line

At the command prompt, type:

```
help bind nd6RAvariables
```

To show nd6RAvariables by using the NetScaler command line

At the command prompt, type:

```
help sh nd6RAvariables
```

**Example**

```
> sh nd6RAvariables
1) Vlan : 1
2) SendAdvert YES : NO  CeaseAdv : NO  SourceLLAddress: 
3) UnicastOnly NO : NO  ManagedFlag : NO  OtherConfigFlag: 
```
Managing cluster heartbeat messages

February 12, 2020
Managing heartbeat messages in a cluster is similar to managing them in a high availability (HA) configuration. Nodes can send and receive heartbeat messages to and from each other on all interfaces that are enabled. To avoid increased traffic resulting from heartbeat messages, you can now disable the heartbeat option on node interfaces. However, the heartbeat option on the backplane interface cannot be disabled, because it is required for maintaining connectivity among the cluster nodes.

For more information about managing heart messages, see Managing High Availability Heartbeat Messages on a NetScaler Appliance.

To manage heartbeat messages on a node interface by using the Citrix ADC CLI

At the command prompt, type:

```
1 set interface <ID> [-HAHeartBeat (ON | OFF)]
2 Show interface <ID>
```

Configuring owner node response status

February 18, 2020

In a cluster setup, on a node has a spotted SNIP address, you can configure the ownerDownResponse option. By default, the option is enabled, allowing the spotted IP address to respond to PING or ARP requests (coming from the upstream router) when the node is inactive. If you disable the option, the IP address cannot respond to the router requests when the owner node is inactive.

To know how this feature is used for monitoring static routes in ECMP deployment, see Using Equal Cost Multiple Path (ECMP) topic.

To set owner node response status by using the Citrix ADC CLI

At the command prompt, type:

```
1 add ns ip <IPAddress> [-ownerNode <positive_integer>] [-ownerDownResponse (YES | NO)] [-td <positive_integer>]
```
Example

```
add ns ip 2.2.2.2 255.255.255.0 -ownernode 6 -ownerdownResponse YES
```

To set owner node response status by using the Citrix ADC GUI

1. Navigate to System > Network > IPs and click Add to create a spotted SNIP address.
2. On the Create IPAddress page, select or clear the ownerDownResponse check box.

To edit owner node response status by using the Citrix ADC GUI

Navigate to System > Network > IPs, select an IP address, and click Edit to select or clear the ownerDownResponse check box.

Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration

April 23, 2019

In a cluster set up with MSR option enabled on the route, only active nodes can probe to a static route and reach a network while inactive and spare nodes have no link to the route and cannot probe to it. You can now configure an inactive or spare node to send PING and ARP probe to IPv4 route and send ping6 and nd6 probe to IPv6 route. You can perform this only in a Spotted Cluster configuration in which the SNIP address is active and owned exclusively only by one node.

VRRP interface binding in a single node active cluster

February 12, 2020
When you migrate a high availability (HA) setup to a cluster setup, all configurations must be compatible and must be supportable in the cluster. To achieve this, you can now configure virtual router IDs (VRIDs and VRID6s) on a node interface.

Important: Currently, only a single-node active cluster system supports VRIDs and VRID6s.

For instructions for configuring VRIDs and VRID6s, see Configuring Virtual MAC Addresses.

To configure a virtual router ID on a single-node active cluster, add the VRID or VRID6 and bind it to the cluster-node interface.

To add a VRID by using the Citrix ADC CLI

At the command prompt, type:

```
add vrID <ID>
```

To bind a VRID to the cluster-node interface by using the Citrix ADC CLI

At the command prompt, type:

```
Bind vrid <ID> -ifnum <interface_name> | -trackifNum <interface_name>
```

To add a VRID6 by using the Citrix ADC CLI

At the command prompt, type:

```
add vrID6 <ID>
```

To bind a VRID6 to cluster node interface by using the Citrix ADC CLI

At the command prompt, type:

```
bind vrid6 <ID> -ifnum <interface_name> | -trackifNum <interface_name>
```

(Example)

```
Add vrID 100
Bind vrid 100 -ifnum 1/1 1/2
```

```
Add vrID6 100
Bind vrid6 100 -ifnum 1/1 1/2
```

Cluster setup and usage scenarios

August 14, 2019

This section explains some scenarios in which the Citrix ADC cluster can be set up, and configured for different features and network topologies. Provide feedback if you want any other scenarios to be documented.

Creating a two-node cluster

April 23, 2019

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of \((n/2 +1)\) nodes, where \(n\) is the number of cluster nodes, are able to serve traffic. If that formula were applied to a two-node cluster, the cluster would fail if one node went down \((n/2 +1=2)\).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You must add one node as the configuration coordinator and the other node as the other cluster node.

Note

Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA setup to a cluster setup

June 17, 2020

Migrating an existing high availability (HA) setup to a cluster setup requires you to first remove the Citrix ADC appliances from the HA setup and create a backup of the HA configuration file. You must then use the two appliances to create a cluster and upload the backed-up configuration file to the cluster.
Note

• Before uploading the backed-up HA configuration file to the cluster, you must modify it to make it cluster compatible. Refer to the relevant step of the procedure below.

• Use the `batch -f <backup_filename>` command to upload the backed-up configuration file.

The above approach is a very basic migration solution which results in downtime for the deployed application. As such, it must be used only in deployments where there is no consideration to application availability.

However, in most deployments, the availability of the application is of paramount importance. For such cases, you must use the approach where an HA setup can be migrated to a cluster setup without any resulting downtime. In this approach, an existing HA setup is migrated to a cluster setup by first removing the secondary appliance and using that appliance to create a single-node cluster. After the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster.

To convert a HA setup to cluster setup (without any downtime) by using the command line interface

Let us consider the example of a HA setup with primary appliance (NS1) - 10.102.97.131 and secondary appliance (NS2) - 10.102.97.132.

1. Make sure the configurations of the HA pair are stable.
2. Log on to any one of the HA appliances, go to the shell, and create a copy of the ns.conf file (for example, ns_backup.conf).
3. Log on to the secondary appliance, NS2, and clear the configurations. This operation removes NS2 from the HA setup and makes it a standalone appliance.

```
1 > clear ns config full
```

Note

• This step is required to make sure that NS2 does not start owning VIP addresses, now that it is a standalone appliance.

• At this stage, the primary appliance, NS1, is still active and continues to serve traffic.

4. Create a cluster on NS2 (now no longer a secondary appliance) and configure it as a PASSIVE node.

```
1 > add cluster instance 1
2
3 > add cluster node 0 10.102.97.132 -state PASSIVE -backplane 0/1/1
```
5. Modify the backed-up configuration file as follows:

- Remove the features that are not supported on a cluster. For the list of unsupported features, see Citrix ADC Features Supported by a Cluster. This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.

- Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

  **Example**

  ```
  > add vlan 10 -ifnum 0/1
  ```

  should be changed to

  ```
  > add vlan 10 -ifnum 0/0/1 1/0/1
  ```

- The backup configuration file can have SNIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

  **Example**

  ```
  > add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
  > add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
  ```

- Update the hostname to specify the owner node.

  **Example**

  ```
  > set ns hostname ns0 -ownerNode 0
  > set ns hostname ns1 -ownerNode 1
  ```

- Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs.)
6. On the cluster, do the following:
   - Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.
   - Apply configurations from the backed-up and modified configuration file to the configuration coordinator through the cluster IP address.
     
     ```
     1 > batch -f ns_backup.conf
     ```
   - Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

7. Switch the traffic from the HA setup to the cluster.
   - Log on to the primary appliance, NS1, and disable all the interfaces on it.
     
     ```
     1 > disable interface <interface_id>
     ```
   - Log on to the cluster IP address and configure NS2 as an ACTIVE node.
     
     ```
     1 > set cluster node 0 -state ACTIVE
     ```
   
   **Note**
   There might be a small amount (in the order of seconds) of downtime between disabling the interfaces and making the cluster node active.

8. Log on to the primary appliance, NS1, and remove it from the HA setup.
   - Clear all the configurations. This operation removes NS1 from the HA setup and makes it a standalone appliance.
     
     ```
     1 > clear ns config full
     ```
   - Enable all the interfaces.
     
     ```
     1 > enable interface <interface_id>
     ```

9. Add NS1 to the cluster.
   - Log on to the cluster IP address and add NS1 to the cluster.
     
     ```
     1 > add cluster node 1 10.102.97.131 -state PASSIVE -backplane 1/1/1
     ```
   - Log on to NS1 and join it to the cluster by sequentially executing the following commands:
     
     ```
     1 > join cluster -clip 10.102.97.133 -password nsroot
     ```
10. Log on to NS1 and perform the required topological and configuration changes.

11. Log on to the cluster IP address and set NS1 as an ACTIVE node.

```
1 > set cluster node 1 -state ACTIVE
```

Copied!

Failed!

### Transitioning between a L2 and L3 Cluster

**February 12, 2020**

**Note**

Supported from NetScaler 11 onwards.

An L2 cluster is one where all the nodes are from the same network and an L3 cluster is one that can include nodes from different networks. You can seamlessly transition from one type of cluster to the other without any downtime for the applications that are deployed on the Citrix ADC.

### Transitioning a cluster from L2 to L3

You can transition to an L3 cluster when you want the cluster to include nodes from other networks. On the cluster IP address, do the following:

1. Create a nodegroup.

   **Example**

   ```
   1 > add cluster nodegroup NG0
   ```

   This nodegroup is used in the next step to group all the nodes from the existing L2 cluster.

2. Transition the L2 cluster to an L3 cluster.

   **Example**

   ```
   1 > set cluster instance 1 -inc ENABLED -nodegroup NG0
   ```
This command achieves the dual purpose of transitioning to L3 cluster and also adding all the nodes of the L2 cluster to the nodegroup.

3. Now, you can add more nodes to the cluster as explained in Adding a Node to the Cluster.

**Transitioning a cluster from L3 to L2**

You can transition to an L2 cluster when you want to retain nodes that belong to a single network.

On the cluster IP address, do the following:

1. Remove the cluster nodes from the networks that you do not want to retain.
   ```
   Example
   1 > rm cluster node <nodeId>
   ```

2. Transition the L3 cluster to a L2 cluster.
   ```
   Example
   1 > set cluster instance 1 -inc DISABLED
   ```

   The cluster now includes nodes only of a single network.

*Copied!*

**Setting up GSLB in a cluster**

**February 12, 2020**

--- **Note**

Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

--- **Note**

If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. This happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than /var/netscaler/locdb/, you must manually synch the file to all the cluster nodes.
To set up GSLB in a cluster by using the command line interface:

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see GSLB Configuration Entities.

   ```
   add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr> -clip <ip_addr> <publicCLIP>
   ```

   **Note**
   When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address (needed only when the cluster is deployed behind a NAT device). While configuring a GSLB site, you must use the cluster IP address of the same site. These parameters are required to ensure the availability of the GSLB auto-sync functionality.

2. Create a cluster node group.

   ```
   add cluster nodegroup <name> [-sticky (YES | NO)]
   ```

   **Note**
   Enable the sticky option if you want to set up GSLB based on VPN users.

3. Bind a single cluster node to the node group.

   ```
   bind cluster nodegroup <name> -node <nodeId>
   ```

4. Bind the local GSLB site to the node group.

   ```
   bind cluster nodegroup <name> -gslbSite <string>
   ```

   **Note**
   Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

   **To bind the ADNS service:**

   ```
   bind cluster nodegroup <name> -service <string>
   ```

   **To bind the DNS load balancing virtual server:**

   ```
   bind cluster nodegroup <name> -vServer <string>
   ```

6. Bind the GSLB virtual server to the node group.

   ```
   bind cluster nodegroup <name> -vServer <string>
   ```

7. [Optional] To setup GSLB based on VPN users, bind the VPN virtual server to the GSLB node group.
bind cluster nodegroup <name> -vServer <string>

8. Verify the configurations.
    show gslb runningConfig

To set up GSLB in a cluster by using the graphical user interface:
Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.
    Navigate to Traffic Management > GSLB to perform the required configurations.
2. Create a node group and perform other node group related configurations.
    Navigate to System > Cluster > Node Groups to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the CLI procedure mentioned above.

Support for GSLB parent-child topology in a cluster

Starting with NetScaler 12.1 build 49.xx, GSLB parent-child topology is supported in cluster.
For more information about the parent-child topology, see Parent-child topology deployment using the MEP protocol.

To set up GSLB parent-child topology in a cluster by using the CLI

Parent site
Perform the following configuration:

1. Create a cluster node group.
    add cluster nodegroup <name>

    Example:
    add cluster nodegroup parentng

2. Bind a single cluster node to the node group.
    bind cluster nodegroup <name> -node <nodeId>

    Example:
    bind cluster nodegroup parentng -node n2
3. Bind the local GSLB site to the nodegroup.

   `bind cluster nodegroup <name> -gslbSite <string>`

   **Example:**
   
   `bind cluster nodegroup parentng -gslbSite site1`

4. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

   `bind cluster nodegroup <name> -service <string>`

   **Example:**
   
   `bind cluster nodegroup parentng -service ADNS`

5. Bind the GSLB virtual server to the node group.

   `bind cluster nodegroup <name> -vServer <string>`

   **Example:**
   
   `bind cluster nodegroup parentng -vServer gslbvs1`

**Child site**

Perform the following configuration:

1. Create a cluster node group.

   `add cluster nodegroup <name>`

   **Example:**
   
   `add cluster nodegroup childng`

2. Bind a single cluster node to the node group.

   `bind cluster nodegroup <name> -node <nodeId>`

   **Example:**
   
   `bind cluster nodegroup childng -node -n3`

3. Bind the local GSLB site to the nodegroup.

   `bind cluster nodegroup <name> -gslbSite <string>`

   **Example:**
   
   `bind cluster nodegroup childng -gslbSite site1`
**Note**
For parent and child sites to exchange aggregated statistics in metric-based load balancing methods, you must add local GSLB services on the child site. The metric-based load balancing methods are least connection, least bandwidth, and least packets.

**To set up GSLB parent-child topology in a cluster by using the GUI**

1. Configure the GSLB entities.
   Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group.
   Navigate to **System > Cluster > Node Groups** to perform the required configurations.

3. In the Node Group page, select the node group to which you want to bind a node, click **Edit** and perform the following tasks. You can also perform these tasks when adding a node group.
   - Bind a node to the node group.
     In Advance Settings, click **Cluster Nodes** and perform the following tasks:
       - In Cluster Nodes section, click **No Cluster Node**.
       - In Select Cluster Node, click **>** and select the node that you want to bind to the node group. You can also add a new cluster node.
   - Bind the local GSLB site to the node group.
     In Advance Settings, click **GSLB Sites** and perform the following tasks:
       - In GSLB Sites section, click **No GSLB Site**.
       - In Select GSLB Site, click **>** and select the GSLB site that you want to bind to the node group. You can also add a new GSLB site.
   - Bind the GSLB virtual server to the node group.
     In Advance Settings, click **Virtual Servers** and perform the following task:
       - In Virtual Servers pane, click **+**.
       - In Choose Virtual Server, select the server that you want to bind to the node group.
     - Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.
       In Advance Settings, click **Services** and perform the following tasks:
       - In Services section, click **No Service**.
       - In Select Service, select the service that you want to bind to the node group. You can also add a new service.
Using cache redirection in a cluster

February 12, 2020

Cache redirection in a cluster works in the same way as it does on a standalone Citrix ADC appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see Cache Redirection.

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests will be dropped.

- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode MBF command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 mode in a cluster setup

April 23, 2019

Note

Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.
Using cluster LA channel with linksets

April 23, 2019

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

Note

Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology
To configure cluster LA channel and linksets by using the Citrix ADC command line

1. Log on to the cluster IP address.

2. Bind the connected interfaces to a cluster LA channel.

   add channel CLA/1 -ifnum 0/1/2 1/1/2

3. Bind the cluster LA channel to the linkset.

   add linkset LS/1 -ifnum CLA/1

Failed!

Backplane on LA channel

June 25, 2020

In this deployment, LA channels are used for the cluster backplane.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.
   a) Log on to the first node that you want to add to the cluster and do the following:
b) Log on to the cluster IP address and do the following:

1 > add cluster node 1 10.102.29.70 -state ACTIVE
2 > add cluster node 2 10.102.29.80 -state ACTIVE

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:

a) Create the LA channels for nodes NS0 and NS1.

1 > add channel 0/LA/1 -ifnum 0/1/1 0/1/2
2 > add channel 1/LA/2 -ifnum 1/1/1 1/1/2

b) Configure the backplane for the cluster nodes.

1 > set cluster node 0 -backplane 0/LA/1
2 > set cluster node 1 -backplane 1/LA/2
3 > set cluster node 2 -backplane 2/1/1

Common interfaces for client and server and dedicated interfaces for backplane

April 23, 2019
This is a one-arm deployment of the Citrix ADC cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

**To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane**

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```bash
1> create cluster instance 1
2> add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
3> enable cluster instance 1
4> add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5> save ns config
6> reboot -warm
```

3. Log on to the cluster IP address and do the following:

```bash
1> add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
```
4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```bash
1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

   //For the backplane interfaces

   ```bash
   1 > add vlan 10
   2 > bind vlan 10 0/1/1 1/1/1 2/1/1
   ```

   //For the interfaces that are connected to the client and server networks.

   ```bash
   1 > add vlan 20
   2 > bind vlan 20 0/1/2 1/1/2 2/1/2
   ```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

   //For the backplane interfaces. Repeat for each interface…

   ```bash
   1 > interface Ethernet2/47
   2   switchport access vlan 100
   3   switchport mode access
   4   end
   ```

   //For the interfaces connected to the client and server networks. Repeat for each interface…

   ```bash
   1 > interface Ethernet2/47
   2   switchport access vlan 200
   3   switchport mode access
   4   end
   ```
Common switch for client, server, and backplane

April 23, 2019

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the Citrix ADC cluster.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
To deploy a cluster with a common switch for the client, server, and backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

2. Log on to the first node that you want to add to the cluster and do the following:

   ```
   1 > create cluster instance 1
   2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
   3 > enable cluster instance 1
   4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
   5 > save ns config
   6 > reboot -warm
   ```

3. Log on to the cluster IP address and do the following:

   ```
   1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
   2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
   ```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

   ```
   1 > join cluster -clip 10.102.29.61 -password nsroot
   2 > save ns config
   3 > reboot -warm
   ```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   //For the backplane interfaces

   ```
   1 > add vlan 10
   2 > bind vlan 10 0/1/1 1/1/1 2/1/1
   ```

   //For the client-side interfaces

   ```
   1 > add vlan 20
   2 > bind vlan 20 0/1/2 1/1/2 2/1/2
   ```

   //For the server-side interfaces

   ```
   1 > add vlan 30
   2 > bind vlan 30 0/1/3 1/1/3 2/1/3
   ```
2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

  //For the backplane interfaces. Repeat for each interface…

  1 > interface Ethernet2/47
  2   switchport access vlan 100
  3   switchport mode access
  4   end

  //For the client interfaces. Repeat for each interface…

  1 > interface Ethernet2/48
  2   switchport access vlan 200
  3   switchport mode access
  4   end

  //For the server interfaces. Repeat for each interface…

  1 > interface Ethernet2/49
  2   switchport access vlan 300
  3   switchport mode access
  4   end

Common switch for client and server and dedicated switch for backplane

February 12, 2020

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the Citrix ADC cluster. The cluster backplane uses a dedicated switch for inter-node communication.
To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
   - Log on to the first node that you want to add to the cluster and do the following:
Log on to the cluster IP address and do the following:

- Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   //For the backplane interfaces

   1 > add vlan 10
   2 > bind vlan 10 0/1/1 1/1/1 2/1/1

   //For the client-side interfaces

   1 > add vlan 20
   2 > bind vlan 20 0/1/2 1/1/2 2/1/2

   //For the server-side interfaces

   1 > add vlan 30
   2 > bind vlan 30 0/1/3 1/1/3 2/1/3

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(l) switch. Similar configurations must be performed on other switches.

   //For the backplane interfaces. Repeat for each interface...
//For the client interfaces. Repeat for each interface…

1 > interface Ethernet2/47
2 > switchport access vlan 100
3 > switchport mode access
4 > end

//For the server interfaces. Repeat for each interface…

1 > interface Ethernet2/48
2 > switchport access vlan 200
3 > switchport mode access
4 > end

**Different switch for every node**

April 23, 2019

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.
The cluster configurations will be the same as the other deployments scenarios. Most of the client-side configurations will be done on the client-side switches.

Sample cluster configurations

April 23, 2019

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.
   
   • Log on to first node.
   
   • Add the cluster instance.

   ```
   > add cluster instance 1
   ```

   • Add the first node to the cluster.
1. Add the cluster node.

   ```bash
   1 > add cluster node 0 10.102.33.184 -backplane 0/1/1
   ```

   - Enable the cluster instance.

   ```bash
   1 > enable cluster instance 1
   ```

   - Add the cluster IP address.

   ```bash
   1 > add ns ip 10.102.33.185 255.255.255.255 -type CLIP
   ```

   - Save the configurations.

   ```bash
   1 > save ns config
   ```

   - Warm reboot the appliance.

   ```bash
   1 > reboot -warm
   ```

2. Add the other three nodes to the cluster.

   - Log on to cluster IP address.
   - Add the second node to the cluster.

   ```bash
   1 > add cluster node 1 10.102.33.187 -backplane 1/1/1
   ```

   - Add the third node to the cluster.

   ```bash
   1 > add cluster node 2 10.102.33.188 -backplane 2/1/1
   ```

   - Add the fourth node to the cluster.

   ```bash
   1 > add cluster node 3 10.102.33.189 -backplane 3/1/1
   ```

3. Join the added nodes to the cluster. This step is not applicable for the first node.

   - Log on to each newly added node.
   - Join the node to the cluster.

   ```bash
   1 > join cluster -clip 10.102.33.185 -password nsroot
   ```

   - Save the configuration.

   ```bash
   1 > save ns config
   ```

   - Warm reboot the appliance.
4. Configure the Citrix ADC cluster through the cluster IP address.

// Enable load balancing feature

```bash
1 > enable ns feature lb
```

// Add a load balancing virtual server

```bash
1 > add lb vserver first_lbvserver http
2 ....
3 ....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

**ECMP**

- Log on to the cluster IP address.
- Enable the OSPF routing protocol.

```bash
1 > enable ns feature ospf
```

- Add a VLAN.

```bash
1 > add vlan 97
```

- Bind the interfaces of the cluster nodes to the VLAN.

```bash
1 > bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
```

- Add a spotted SNIP on each node and enable dynamic routing on it.

```bash
1 > add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -dynamicRouting ENABLED
2 > add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
3 > add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -dynamicRouting ENABLED
4 > add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -dynamicRouting ENABLED
```

- Bind one of the SNIP addresses to the VLAN.

```bash
1 > bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
```
• Configure the routing protocol on ZebOS by using vtysh shell.

**Static cluster LA**

- Log on to the cluster IP address.
- Add a cluster LA channel.

```
1 > add channel CLA/1 -speed 1000
```

- Bind the interfaces to the cluster LA channel.

```
1 > bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```

- Perform equivalent configuration on the switch.

**Dynamic cluster LA**

* Log on to the cluster IP address.
* Add the interfaces to the cluster LA channel.

```
1 > set interface 0/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
2 > set interface 1/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
3 > set interface 2/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
4 > set interface 3/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
```

* Perform equivalent configuration on the switch.

**Linksets.** Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

a) Log on to the cluster IP address.

b) Add a linkset.

```
1 > add linkset LS/1
```

c) Bind the connected interfaces to the linkset.

```
1 > bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6
```

6. Update the state of the cluster nodes to **ACTIVE**.
Using VRRP in a cluster setup

April 14, 2020

Virtual Router Redundancy Protocol (VRRP) is supported in a cluster setup for both IPv4 and IPv6. The two VRRP features supported in a cluster setup are Interface based VRRP and IP based VRRP.

**IP based VRRP**

In IP based VRRP, striped VIP addresses bound to the same VRID are configured on all nodes of a cluster setup. These VIP addresses are active on all the nodes.

One of the cluster nodes acts as the VRID owner and sends out the VRRP advertisement to other nodes. If there is failure of the VRID owner node, another node in the cluster assumes the ownership of the VRID and starts sending VRRP advertisements. You can also assign a specific cluster node as the owner of the VRID.

**Note**

Citrix recommends you to use IP based method for VRRP deployment in cluster.

**Configuring IP based VRRP for IPv4**

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address. The generic VMAC address is in the form of 00:00:5e:00:02:<VRID>.
- **(Optional) Assign a node as the owner of the virtual MAC address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC address. You can set the owner node using the `set vrID <id> -ownerNode <positive_interger>` command.
• **Bind the VRID to the VIP address of the nodes.** Bind the created VRID to the striped VIP address.

**To add a VRID by using the CLI**

At the command prompt, type:

```
1 - add vrid <ID> [-ownerNode <positive_integer>]
2 - show vrid <ID>
```

**To bind the VRID to VIP address by using the CLI**

At the command prompt, type:

```
• set ns ip <IPv4Address> -vrid <ID>
• show vrid <ID>
```

**To add a VRID by using the GUI**

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the Create **VMAC** page, specify a value in the **Virtual Router ID** field and then click **Create**.

**To bind the VRID to a VIP address by using the GUI**

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP configuration.

```
1 > add vrid 90
2  Done
3 > set ns ip 192.0.2.90 - vrid 90
4  Done
```

**Configuring IP based VRRP for IPv6**

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv6:

• **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:02:<VRID6>.
• **(Optional) Assign a node as the owner of the virtual MAC6 address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC6 address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC6 address.

• **Bind the VRID6 to the VIP6 address of the nodes.** Bind the created VRID6 to the striped VIP6 address.

**To add a VRID6 by using the CLI**

At the command prompt, type:

- `add vrid6 <ID> [-ownerNode <positive_integer>]`
- `show vrid6 <ID>`

**To bind the VRID6 to VIP6 address by using the CLI**

At the command prompt, type:

- `set ns ip6 <IPv6Address> -vrid6 <ID>`
- `show vrid6 <ID>`

**To add a VRID6 by using the GUI**

1. Navigate to **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field and then click **Create**.

**To bind the VRID6 to a VIP6 address by using the GUI**

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP6 configuration.

```
1 > add vrid6 90
2  Done
3 > set ns ip6 2001:db8::5001 -vrid6 90
4  Done
```
Interface based VRRP

In the interface based VRRP feature, the same virtual MAC address is configured on both the nodes of the cluster. This virtual MAC address is used in GARP advertisements and ARP responses for the IP addresses configured on a node. This feature is useful in an active-spare two-node cluster setup that has external devices/routers that do not accept GARP advertisements.

**Note**

The interface based VRRP feature is applicable only to a two-node cluster with one node in active state and the other node serving as a spare.

With the same virtual MAC address on both cluster nodes, when the active node goes down and the spare node takes over as active, the MAC address for the IP addresses on the new active node remain unchanged and the ARP tables on the external devices/routers do not need to be updated.

Configuring interface based VRRP for IPv4

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address.
- **Bind the VRID to node interfaces.** Bind the interfaces to the created VRID. The bound interfaces (in the current active node) use the virtual MAC address in GARP advertisements and ARP responses for its IPv4 addresses. You must associate the VRID to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

**To add a VRID by using the CLI**

At the command prompt, type:

```
1 - add vrid <ID>
2 - show vrid <ID>
```

**To bind the VRID to an interface by using the CLI**

At the command prompt, type:

```
1 - bind vrid <ID> -ifnum <interface_name>
2 - show vrid <ID>
```
To add a VRID and bind it to interfaces by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.

2. On the **Create virtual MAC** page, specify a value in the **Virtual Router ID** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 > add vrid 300
2  Done
3 > bind vrid 300 -ifnum 1/1/2 2/1/3
4  Done
```

Configuring interface based VRRP for IPv6

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:01:<VRID6>.
- **Bind the VRID6 to node interfaces.** Bind the interfaces to the created VRID6. The bound interfaces (in the current active node) use the virtual MAC6 address in GARP advertisements and ARP responses for its IPv6 addresses. You must associate the VRID6 to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

To add a VRID6 by using the CLI

At the command prompt, type:

```
1 - add vrid6 <ID>
2 - show vrid6 <ID>
```

To bind the VRID6 to an interface by using the CLI

At the command prompt, type:

- `bind vrid6 <ID> -ifnum <interface_name>`
- `show vrid6 <ID>`

To add a VRID6 and bind it to interfaces by using the GUI

1. Navigate **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the Create virtual MAC6 page, specify a value in the Virtual Router ID field, bind interfaces in the Associate Interfaces section, and then click Create.

```
1 > add vrid6 100
2 Done
3 > bind vrid6 100 -ifnum 0/1/1 1/1/2 2/1/3
4 Done
```

**Monitoring services in a cluster using path monitoring**

February 12, 2020

In a cluster setup, ownership for monitoring services is distributed among the nodes. Therefore, different nodes monitor different services. The node that monitors a service is called the service owner. Only the service owner probes the server to monitor the status of the services assigned to it. It further communicates the status of the services to all other nodes within the cluster. The drawback with distributed monitoring is that the network connectivity and link state between all nodes and the server is not determined. To overcome this drawback, you can use path monitoring.

Path monitoring checks the network connectivity and link state between a node and service provided by the server. A node sends ICMP pings to verify whether the server is reachable or not.

**How path monitoring works**

Consider an example of a Citrix ADC cluster consisting of three nodes N1, N2, and N3. N2 is the service owner that monitors the state of HTTP services (S1). It advertises the service state to other nodes in the cluster. Path monitoring is enabled on all nodes in the cluster, for all the services. Each node sends only an ICMP ping to the server. The service owner sends both the HTTP service request and an ICMP ping. Each node reports its path monitoring state to the service owner.
The following two parameters determine the service state of a node:

- \( S \) = service state advertised by the service owner
- \( P \) = path monitoring state of each node

Whether a node can reach a server or not, determines the path monitoring state for that node.

The following table shows the service state set based on the path monitoring state, when pathMonitorIndv parameter is enabled or disabled.

<table>
<thead>
<tr>
<th>Parameter Path monitoring state</th>
<th>Service state</th>
</tr>
</thead>
<tbody>
<tr>
<td>pathMonitorIndv = NO; This is the default configuration.</td>
<td>P1 = DOWN</td>
</tr>
<tr>
<td></td>
<td>P2 = UP</td>
</tr>
<tr>
<td></td>
<td>P3 = UP</td>
</tr>
<tr>
<td>pathMonitorIndv = YES</td>
<td>P1 = DOWN</td>
</tr>
<tr>
<td></td>
<td>P2 = UP</td>
</tr>
<tr>
<td></td>
<td>P3 = UP</td>
</tr>
</tbody>
</table>

In this example, the service owner decides the service state for all the nodes based on the node whose path monitoring state is set to DOWN. If the path monitoring state for any of the nodes is DOWN, then the service owner sets the service state for all the nodes as DOWN. The service state for all the nodes is set to UP only if the path monitoring state for each of the node is UP.

You can use path monitoring for individual nodes by enabling the pathMonitorIndv parameter. This parameter enables the service owner to set the service state for each node based on the path moni-
Citrix ADC 13.0

toring state of that respective node.

Note
If pathMonitorIndv parameter is set, some features like persistence might break.

Configuring path monitoring

Path monitoring is applicable for all the services and service groups. Path monitoring parameter is
disabled by default.

To enable path monitoring for services/service groups by using the CLI

At the command prompt, type:

1 add service <service name> <IP address> <service type> <port> [-pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]
2 add servicegroup <servicegroup name> <service type> [-pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]

Example:

1 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES
2 add servicegroup sg_1 HTTP -pathMonitor YES
3 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES -pathMonitorIndv YES
4 add servicegroup sg_1 HTTP -pathMonitor YES -pathMonitorIndv YES

You can also set the path monitoring parameter from the set command, as follows:

1 set service <service name> [-pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]
2 set servicegroup <servicegroup name> [-pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]

Example:

1 set service s1 -pathMonitor YES
2 set servicegroup sg_1 -pathMonitor YES
3 set service s1 -pathMonitorIndv YES
4 set servicegroup sg_1 -pathMonitorIndv NO
To enable path monitoring for services/service groups by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
   For service groups, navigate to Traffic Management > Load Balancing > Service Groups.
2. In the Services/Service Groups pane, select a service/service group from the list, and then double-click to open it.
3. On the Service Settings tab, click Edit.
4. Select Path Monitoring.
5. Select Individual Path Monitoring, if you want to apply it, and then click OK.

Note
You can enable Individual Path Monitoring only if you enable Path Monitoring.

Backup and restore of cluster setup

February 12, 2020

You can back up the current state of a Citrix ADC cluster node, and later use the backed-up files to restore the node to the same cluster state. As a precautionary measure, you must use this feature before performing an upgrade on the cluster nodes.

Backup a cluster Setup

Depending on the type of data to be backed up and the frequency at which you will create a backup, you can take a basic or a full backup.

- **Basic back up.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are listed in the table.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Sub-Directory or Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>/nsconfig/</td>
<td></td>
</tr>
</tbody>
</table>

- ns.conf
- ZebOS.conf

---

**Important**

The backup and restore does not work if CLAG is configured on a SDX cluster setup.

The backup is stored as a compressed TAR file in the /var/ns_sys_backup/ directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the rm system backup command to delete existing backup files so that you can create more backups.

When you perform back up operation on a CLIP of a cluster setup, back up files are created on each of the cluster nodes.

**How to backup a cluster setup**

To backup the cluster setup on CLIP by using Citrix ADC command line interface

**At the command prompt, do the following:**

- Save the configuration.

  ```
  save ns config
  ```

- Create the backup file (basic or full).

  ```
  create system backup ["<filename>"][-level (basic | full)][-comment < string>]
  ```

  **Example**

  ```
  create system backup cluster-backup-1 -level basic
  ```
After you run this command, back up TAR files are created on each of the cluster nodes with the specified file name. For example, CLUSTER-backup-1.tgz file is created on each of the cluster node.

Note
If the filename is not specified, back up TAR files are created on each of the cluster nodes with the following naming convention:

- backup_<level>_nsip_address of the cluster node _<date-timestamp >.tgz
- backup_<nsip_address of the cluster node _<date-timestamp >.tgz

For example, on a three node cluster setup,

- backup_<level>_nsip_address of the cluster node _<date-timestamp >.tgz is created on node0
- backup_<level>_nsip_address of the cluster node _<date-timestamp >.tgz is created on node1
- backup_<level>_nsip_address of the cluster node _<date-timestamp >.tgz is created on node2

- Verify the created backup files on CLIP.
  show system backup

Restore a cluster setup

When a cluster node becomes faulty, you can replace this node with a new node and set the new node for a cluster using a backup file of the faulty node.

For example, in a three-node cluster setup, if node1 becomes faulty, you can replace this faulty node with a new node as node1. Using the restore operation, you can restore one of the faulty node’s backup files on the new node.

Note
The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

How to restore a cluster node

To restore a cluster node by using Citrix ADC command line interface

At the command prompt, do the following:
• Obtain a list of the backup files available on CLIP.

  show system backup

• Copy the backup tar file to /var/ns_sys_backup directory of the cluster node, which is to be restored.

• Add the backup tar file to the cluster node memory by running the following command on the cluster node.

  add system backup <filename>

  **Example**

  add system backup CLUSTER-BACKUP-1.tgz

  **Note**

  The command must be run on the cluster node to be restored.

• Restore the cluster node by specifying the backup file.

  restore system backup <filename>

  **Example**

  restore system backup CLUSTER-BACKUP-1.tgz

  **Note**

  The command must be run on the cluster node to be restored.

• Reboot the cluster node.

  reboot

  **Note**

  The command must be run on the cluster node to be restored.

**Upgrading or downgrading the Citrix ADC cluster**

July 28, 2020

All the nodes of a Citrix ADC cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each Citrix ADC appliance of the cluster, one node at a time.
A node that is being upgraded or downgraded is not removed from the cluster. The node continues to be a part of the cluster and serves traffic uninterrupted, except for the down-time when the node reboots after it is upgraded or downgraded.

However, due to software version mismatch among the cluster nodes, configuration propagation is disabled on the cluster and is enabled only after all the cluster nodes are of the same version. Since configuration propagation is disabled during upgrading on downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time.

**Important**

In a cluster setup, a Citrix ADC appliance might crash, when:

- upgrading the setup from Citrix ADC 13.0 47.x or 13.0 52.x build to a later build, or
- upgrading the setup to Citrix ADC 13.0 47.x or 13.0 52.x build

Workaround: During the upgrade process, perform the following steps:

- Disable all cluster nodes and then upgrade each cluster node
- Enable all cluster nodes after all the nodes are upgraded

**Points to note before upgrading or downgrading the cluster**

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes, but make sure to perform the same configurations on all the nodes to maintain them in synch.
- You cannot execute the “start ntrace” command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes through their NSIP address.
- Owing to changes in cluster licensing that were made in NetScaler 10.5 Build 52.11 see Prerequisites for cluster nodes, look into the following:
  - If the cluster is setup in a build prior to NetScaler 10.5 Build 52.11, the cluster will work with the separate cluster license file. No changes are required.
  - If the cluster is setup in NetScaler 10.5 Build 52.11 or later releases and then downgraded to a build prior to NetScaler 10.5 Build 52.11, the downgraded cluster will not work as it now expects a separate cluster license file.
- While upgrading from any NetScaler 10.1 build to a later release, syncookie must be disabled on all TCP profiles (using the “set ns tcpProfile <name> -synCookie DISABLED” command) and after that a striped SNIP must be added on the CLIP subnet. Once upgraded, syncookie can be enabled again.
While upgrading the Citrix ADC appliance from a NetScaler 10.1 build to a NetScaler 10.5 build, do not execute the “show audit messages” command as this can cause the Citrix ADC appliance to become unresponsive.

NetScaler 10.5 54.x and 55.x builds are not suitable for cluster deployment. This is because, for services that need probing, SYN packets are processed locally (on the flow receiver) even though syncookie is disabled.

When a cluster is being upgraded, it is possible that the upgraded nodes have some additional features activated that are not available on the nodes that are not upgraded. This results in a license mismatch warning while the cluster is being upgraded. This warning will be automatically resolved when all the cluster nodes are upgraded.

**Important**

- Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
- Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnect of cluster IP sessions.

### To upgrade or downgrade the software of the cluster nodes

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.

2. Access each node through its NSIP address and perform the following:
   - Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see [Upgrade and downgrade a NetScaler appliance](#).
   - Save the configurations.
   - Reboot the appliance.

3. Repeat step 2 for each of the other cluster nodes.

---

**Operations supported on individual cluster nodes**

April 23, 2019
As a rule, Citrix ADC appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when executed from the NSIP address, are not propagated to other cluster nodes.

The operations are:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Command 1</th>
<th>Command 2</th>
<th>Action 1</th>
<th>Action 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster instance</td>
<td>set</td>
<td>rm</td>
<td>enable</td>
<td>disable</td>
</tr>
<tr>
<td>cluster node</td>
<td>set</td>
<td>rm</td>
<td></td>
<td></td>
</tr>
<tr>
<td>nstrace</td>
<td>start</td>
<td>show</td>
<td>stop</td>
<td></td>
</tr>
<tr>
<td>interface</td>
<td>set</td>
<td>enable</td>
<td>disable</td>
<td></td>
</tr>
<tr>
<td>route</td>
<td>add</td>
<td>rm</td>
<td>set</td>
<td>unset</td>
</tr>
<tr>
<td>arp</td>
<td>add</td>
<td>rm</td>
<td></td>
<td>send -all</td>
</tr>
</tbody>
</table>

- force cluster sync
- sync cluster files
- disable ntp sync
- save ns config
- reboot
Citrix ADC 13.0

- shutdown

For example, when you execute the command disable interface 1/1/1 from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

*Copied!*

*Failed!*

**Support for heterogeneous cluster**

February 12, 2020

Citrix ADC appliance now supports a heterogeneous cluster in a cluster deployment. A heterogeneous cluster spans nodes of different Citrix ADC hardware and you can have a combination of different platforms in the same cluster.

*Important*

The formation or supportability of a heterogeneous cluster is possible and limited only to MPX hardware platforms.

The supportability and formation of the heterogeneous cluster depend on certain Citrix ADC models. The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an equal number of packet engines.

<table>
<thead>
<tr>
<th>Number of Packet Engines</th>
<th>MPX Hardware Platforms</th>
<th>Supported MPX Hardware Platforms to form Heterogeneous Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>MPX 11500</td>
<td>MPX 14020</td>
</tr>
<tr>
<td>7</td>
<td>MPX 11515</td>
<td>MPX 14040</td>
</tr>
<tr>
<td>9</td>
<td>MPX 11530</td>
<td>MPX 14060</td>
</tr>
</tbody>
</table>

The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an unequal number of packet engines.

<table>
<thead>
<tr>
<th>Hardware Platforms</th>
<th>Supported Hardware Platforms to form Heterogeneous Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPX 150XX</td>
<td>MPX 140XX</td>
</tr>
</tbody>
</table>
For more information on how to form a heterogeneous cluster deployment of Citrix ADC MPX appliances with the different number of packet engines across different SSL chipsets, see the Heterogeneous cluster deployments section in SSL offloading configuration.

**Note**
Before release 13.0 build 47.x, if you run the “join cluster” command from the node that has an unequal number of packet engines, the following error message appears: “Mismatch in the number of active PPEs between CCO and local node”.

**Points to note**

1. The extra management CPU setting must be same on all the cluster nodes.
2. The newly added node must have the same capacity on the data planes and backplane, as that of existing cluster nodes.
3. If there are mixed platform devices supporting different ciphers, then the cluster would agree upon a common cipher list.

**FAQs**

June 17, 2020
A list of the frequently asked questions about clustering.

**How many Citrix ADC appliances can be included in a single Citrix ADC cluster?**

A Citrix ADC cluster can include one appliance or as many as 32 Citrix ADC nCore hardware or virtual appliances. Each of these nodes must satisfy the criteria specified in Prerequisites for Cluster Nodes.

**Can a Citrix ADC appliance be a part of multiple clusters?**

No. A Citrix ADC appliance can belong to can belong to one cluster only.
What is a cluster IP address? What is its subnet mask?

The cluster IP address is the management address of a Citrix ADC cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

How can I make a specific cluster node as the cluster configuration coordinator?

To manually set a specific node as the cluster configuration coordinator, you must set the priority of that node to the lowest numeric value (highest priority). To understand, let us consider a cluster with three nodes that have the following priorities:

n1 - 29, n2 - 30, n3 - 31

Here, n1 is the configuration coordinator. If you want to make n2 the configuration coordinator, you must set its priority to a value that is lower than n1, for example, 28. On saving the configuration, n2 becomes the configuration coordinator.

Note

n2 with its original priority value of 30 will also become the configuration coordinator when n1 goes down, as the node with the next lowest priority value is selected in the event that the configuration coordinator goes down.

Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?

When a Citrix ADC appliance is part of a cluster, you must be able to identify the node to which the interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

How can I set the hostname for a cluster node?

The hostname of a cluster node must be specified by executing the set ns hostname command through the cluster IP address. For example, to set the hostname of the cluster node with ID 2, the command is:

```bash
set ns hostname hostName1 -ownerNode 2
```
Can I automatically detect Citrix ADC appliances so that I can add them to a cluster?

Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see Discovering NetScaler Appliances.

Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive?

Yes. When any of these operations are performed on an active node of the cluster, the cluster will have one less node to serve traffic. Also, existing connections on this node are terminated.

I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single *.conf file for all the configurations.
2. Edit the configuration file to remove features that are not supported in a cluster environment.
3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.
4. Apply the configurations to the configuration coordinator node of the cluster by using the batch-command.

Can I migrate the configurations of a standalone Citrix ADC appliance or an HA setup to the clustered setup?

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the clear ns config command (with the extended option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.
2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.
3. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.
Are backplane interfaces part of the L3 VLANs?

Yes, by default, backplane interfaces have presence on all the L3 VLANs that are configured on the cluster.

How can I configure a cluster that includes nodes from different networks?

Note

Supported from NetScaler 11.0 onwards.

A cluster that includes nodes from different networks is called a L3 cluster (sometimes referred to as a cluster in INC mode). In an L3 cluster, all nodes that belong to a single network must be grouped together in a single nodegroup. Therefore, if a cluster includes two nodes each from three different networks, you will have to create 3 nodegroups (one for each network) and associate each of these nodegroups with the nodes that belong to that network. For configuration information, see the steps to setup a cluster.

How can I configure/un-configure the NSVLAN on a cluster?

Do either one of the following:

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to cluster.
- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

I have a cluster setup where some Citrix ADC nodes are not connected to the external network. Can the cluster still function normally?

Yes. The cluster supports a mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see Using Linksets.

How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup?

Deployments that use MBF must use linksets. For more information, see Using Linksets.
Can I execute commands from the NSIP address of a cluster node?

No. Access to individual cluster nodes through the NSIP addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can execute from the NSIP address of a cluster node. For more information, see Operations Supported on Individual Nodes.

Can I disable configuration propagation among cluster nodes?

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch error can automatically disable configuration propagation.

Can I change the NSIP address or change the NSVLAN of a Citrix ADC appliance when it is a part of the cluster?

No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

Does the Citrix ADC cluster support L2 and L3 VLANs?

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.

- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.
  - All nodes have an IP address on the same subnet as the one bound to the VLAN.
  - The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

When you add a new node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

How can I configure SNMP on a Citrix ADC cluster?

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a standalone appliance. The only difference is that SNMP on a cluster must be configured through the clus-
ter IP address. When generating hardware specific traps, two additional varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

**What details must I have available when I contact technical support for cluster-related issues?**

The Citrix ADC appliance provides a `show techsupport -scope cluster` command that extracts configuration data, statistical information, and logs of all the cluster nodes. You must run this command on the cluster IP address.

The output of this command is saved in a file named `collector_cluster_<nsip_CCO>_P_<date-timestamp>.tar.gz` which is available in the `/var/tmp/support/cluster/` directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

**Can I use striped IP addresses as the default gateway of servers?**

In case of cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a Citrix ADC-owned IP address). For example, in case of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

**Can I view routing configurations of a specific cluster node from the cluster IP address?**

Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the vtysh shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
1 \> vtysh
2 ns# owner-node 0 1
3 ns(node=0 1)# show cluster state
4 ns(node=0 1)# exit-cluster-node
5 ns#
```

**How can I specify the node for which I want to set the LACP system priority?**

*Note*

Supported from NetScaler 10.1 onwards.
In a cluster, you must set that node as the owner node by using the `set lacp` command.

**For example:** To set the LACP system priority for node with ID 2:

```
set lacp -sysPriority 5 -ownerNode 2
```

### How are IP tunnels configured in a cluster setup?

**Note**

Supported from NetScaler 10.1 onwards.

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP address.

### How can I add a failover interface set (FIS) on the nodes of a Citrix ADC cluster?

**Note**

Supported from NetScaler 10.5 onwards.

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added, using the command as follows:

```
add fis <name> -ownerNode <nodeId>
```

**Notes**

- The FIS name for each cluster node must be unique.
- A cluster LA channel can be added to a FIS. You must make sure that the cluster LA channel has a local interface as a member interface.

For more information on FIS, see [Configuring failover interface set](#).

### How are net profiles configured in a cluster setup?

**Note**

Supported from NetScaler 10.5 onwards.

You can bind spotted IP addresses to a net profile. This net profile can then be bound to spotted load balancing virtual server or service (that is defined using a nodegroup). The following recommendations must be followed, failing which, the net profile configurations are not honored and the USIP/US-NIP settings will be used:

**Note**

- If the `strict` parameter of the nodegroup is set to **Yes**, the net profile must contain a mini-
mum of one IP address from each nodegroup member.

- If the strict parameter of the nodegroup is set to No, the net profile must include at least one IP address from each of the cluster nodes.

**How can I configure WI on NS in a cluster setup?**

**Note**

Supported from NetScaler 11.0 Build 62.x onwards.

To use WI on NS on a cluster, you must do the following:

1. Make sure that the Java package and the WI package are present in the same directory on all the cluster nodes.
2. Create a load balancing virtual server that has persistency configured.
3. Create services with IP addresses as the NSIP address of each of the cluster nodes that you want to serve WI traffic. This step can only be configured using the Citrix ADC CLI.
4. Bind the services to the load balancing virtual server.

**Note**

If you are using WI on NS over a VPN connection, make sure that the load balancing virtual server is set as WIHOME.

**Can the cluster LA channel be used for management access?**

No. Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore loses management access.

**How cluster nodes communicate to each other and what are the different types of traffic that goes through backplane?**

A backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:

- Node to Node Messaging (NNM)
- Steered traffic
- Configuration propagation and synchronization

Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: 0x02 0x00 0x6F
<cluster_id> <node_id> <reserved>, where <cluster_id> is the cluster instance ID, <node_id> is the node number of the Citrix ADC appliance that are added to a cluster.

Note
The amount of traffic that is handled by a backplane will have negligible CPU overhead.

What gets routed over GRE tunnel for Layer 3 cluster?

Only steered data traffic goes over the GRE tunnel. The packets are steered through the GRE tunnel to the node on the other subnet.

How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed?

The NNM, heartbeat messages, and cluster protocol are non-steering traffic. These messages are not sent through the tunnel, but they are routed directly.

What are the MTU recommendations when Jumbo frames are enabled for layer 3 cluster tunneled traffic?

The following are the layer 3 cluster recommendations of Jumbo MTU over GRE tunnel:

- The Jumbo MTU can be configured among cluster nodes across the L3 path to accommodate GRE tunnel overhead.
- The fragmentation does not happen for full sized packets which need to be steered.
- Steering of traffic continues to work even if Jumbo frames are not allowed, but with more overhead due to fragmentation.

How the global hash key is generated and shared across all nodes?

The rsskey for a standalone appliance is generated at the boot time. In a cluster setup, the first node holds the rsskey of the cluster. Every new node joining to the cluster will synchronize the rsskey.

What is the need of “set rsskeytype –rsskey symmetric” command for *:**, USIP on, useproxyport off, topologies?

This is not specific to cluster, applies to a standalone appliance as well. With USIP ON, and use proxy port disabled, symmetric rsskey reduces both Core to Core (C2C) steering and node to node steering.
Troubleshooting the Citrix ADC cluster

April 23, 2019

If a failure occurs in a Citrix ADC cluster, the first step in troubleshooting is to get information on the cluster instance and the cluster nodes by running the show cluster instance <clId> and show cluster node <nodeId> commands respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.

- **Check the commands recently executed.** Run the history command to check the recent configurations performed on the cluster. You can also review the ns.conf file to verify the configurations that have been implemented.

- **Check the ns.log files.** Use the log files, available in the /var/log/ directory of each node, to identify the commands executed, status of commands, and the state changes.

- **Check the newnslog files.** Use the newnslog files, available in the /var/nslog/ directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple newnslog files as a single file, by copying the files to a single directory, and then running the following command:

```
nsconmsg -K newnslog-node<id> -K newnslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the show techsupport -scope cluster command to send the report to the technical support team.

Tracing the packets of a Citrix ADC cluster

April 9, 2020
The Citrix ADC operating system provides a utility called nstrace to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the nstrace utility are:

• Can be configured to trace packets selectively by using classic expressions and default expressions.
• Can capture the trace in multiple formats: nstrace format (.cap) and TCP dump format (.pcap).
• Can aggregate the trace files of all cluster nodes on the configuration coordinator.
• Can merge multiple trace files into a single trace file (only for .cap files).

You can use the nstrace utility from the Citrix ADC command line or the Citrix ADC shell.

To trace packets of a standalone appliance

Run the start nstrace command on the appliance. The command creates trace files in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>.cap.

You can view the status by executing the show nstrace command. You can stop tracing the packets by executing the stop nstrace command.

Note

You can also run the nstrace utility from the Citrix ADC shell by executing the nstrace.sh file. However, it is recommended that you use the nstrace utility through the Citrix ADC command line interface.

To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the start nstrace command on the cluster IP address. The command is propagated and executed on all the cluster nodes. The trace files are stored in individual cluster nodes in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form nstrace<id>_node<id>.cap.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the stop nstrace command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the /var/nstrace/<date-timestamp> directory as follows:
Merge multiple trace files

You can prepare a single file from the trace files (supported only for .cap files) obtained from the cluster nodes. The single trace files gives you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the Citrix ADC shell, type:

```
1 > nstracemerge.sh -srcdir <DIR> -dstdir <DIR> -filename <name> -filesize <num>
```

where,

- srcdir is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- dstdir is the directory where the merged trace file are created.
- filename is the name of the trace file that is created.
- filesize is the size of the trace file.
Examples

Following are some examples of using the nstrace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

  Using classic expressions:
  ```
  > start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF == 2/1/1"
  ```

  Using default expressions:
  ```
  > start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") && CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
  ```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not “s1”:

  Using classic expressions
  ```
  > start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 && SOURCEPORT > 80)"
  ```

  Using default expressions
  ```
  > start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (CONNECTION.SVCNAME.NE("s1") && CONNECTION.SRCPORT.GT(80))"
  ```

  Note
  For more information about filters used in nstrace, see nstrace.

Capturing SSL Session Keys During a Trace

When you run the “start nstrace” command, you can set the new “capsslkeys” parameter to capture the SSL master keys for all SSL sessions. If you include this parameter, a file named nstrace.sslkeys is generated along with the packet trace. This file can be imported into Wireshark to decrypt the SSL traffic in the corresponding trace file.

This functionality is similar to web browsers exporting session keys that can later be imported into Wireshark for decrypting SSL traffic.

Advantages of using SSL session keys

Following are the advantages of using SSL session keys:
1. Generates smaller trace files that do not include the extra packets created by the SSLPLAIN mode of capturing.
2. Provides the ability to view plaintext [SP(1] from the trace and choose whether to share the master keys file or protect sensitive data by not sharing it.

Limitations of using SSL session keys

Following are the limitations of using SSL session keys:

1. SSL sessions cannot be decrypted if initial packets of the session are not captured.
2. SSL sessions cannot be captured if the Federal Information Processing Standard (FIPS) mode is enabled.

To capture SSL session keys by using the command line interface (CLI)

At the command prompt, type the following commands to enable or disable SSL session keys in a trace file and verify trace operation.

```
1 > start nstrace -capsslkeys ENABLED
2 > show nstrace
3 Example
4 > start nstrace -capsslkeys ENABLED
5 > show nstrace
6   State:  RUNNING  Scope:  LOCAL  TraceLocation: 
       " /var/nstrace/04May2016_17_51_54/...
7   Nf:  24  Time:  3600  Size:  164
     Mode:  TXB  NEW_RX
8   Traceformat:  NSCAP  PerNIC:  DISABLED  FileName:  04
      May2016_17_51_54 Link:  DISABLED
9   Merge:  ONSTOP  Doruntimecleanup:  ENABLED  TraceBuffers:
      5000  SkipRPC:  DISABLED
10  SkipLocalSSH:  DISABLED  Capsslkeys:  ENABLED  InMemoryTrace:
     DISABLED
11  Done
```

To configure SSL session keys by using the Citrix ADC GUI

1. Navigate to Configuration > System > Diagnostics > Technical Support Tools and click Start new Trace to start tracing encrypted packets on an appliance.
2. On the Start Trace page, select the Capture SSL Master Keys check box.
3. Click OK and Done.
To import the SSL Master Keys into Wireshark

On the Wireshark GUI, navigate to Edit > Preferences > Protocols > SSL > (Pre)-Master-Secret log filename and specify the master key files obtained from the appliance.

Troubleshooting common issues

February 18, 2020

**While joining a node to the cluster, I get the following message, “ERROR: Invalid interface name/number.” What must I do to resolve this error?**

This error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance's management interface as the backplane interface, and that the <nodeld> bit of the interface is the same as the node's Id. For example, if the nodeld is 3, the backplane interface must be 3/<c>/<u>.

**While joining a node to the cluster, I get the following message, “ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster.” What must I do to resolve this error?**

This error occurs when you try to join a node without adding the node's NSIP to the cluster. To resolve this error, you must first add the node's NSIP address to the cluster by using the add cluster node command and then execute the join cluster command.

**While joining a node to the cluster, I get the following message, “ERROR: Connection refused.” What must I do to resolve this error?**

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.

- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a new cluster IP address and try re-joining the cluster.
While joining a node to the cluster, I get the following message, “ERROR: License mismatch between the configuration coordinator and the local node.” What must I do to resolve this error?

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

**From the command line:**
- `show ns hardware`
- `show ns license`

**From the shell:**
- `nsconmsg -g feature -d stats`
- `ls /nsconfig/license`
- View the contents of the `/var/log/license.log` file

What must I do when the configurations of a cluster node are not in sync with the cluster configurations?

In most cases, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by executing the `force cluster sync` command from the node that you want to synchronize. For more information, see [Synchronizing Cluster Configurations](#).

When configuring a cluster node, I get the following message, “ERROR: Session is read-only; connect to the cluster IP address to modify the configuration.”

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NSIP address of individual nodes are read-only.

**Why does the node state show “INACTIVE” when the node health shows “UP”?**

A healthy node can be in the INACTIVE state for a number of reasons. A scan of `ns.log` or error counters can help you determine the exact reason.
How can I resolve the health of a node when its health shows “NOT UP”?

Node health “Not UP” indicates that there are some issues with the node. To know the root cause, you must run the `show cluster node` command. This command displays the node properties and the reason for the node failure.

What must I do when the health of a node shows as “NOT UP” and the reason indicates that configuration commands have failed on a node?

This issue arises when some commands are not executed on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see Synchronizing Cluster Configurations.
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

When I run the `set vserver` command, I get the following message, “No such resource.” What must I do to resolve this issue?

The `set vserver` command is not supported in clustering. The `unset vserver`, `enable vserver`, `disable vserver`, and `rm vserver` commands are also not supported. However, the `show vserver` command is supported.

I cannot configure the cluster over a Telnet session. What must I do?

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?

When PTP packets are dropped due to backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.
   ```
   set ptp -state disable
   ```
2. Configure Network Time Protocol (NTP) for the cluster. For more information, see Setting up Clock Synchronization.

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by executing the following command at the shell prompt:

```
## ssh nsroot@<cluster IP address>
```

What must I do to recover a cluster node that has connectivity issues?

To recover a node that has connectivity issues:

1. Disable the cluster instance on that node (since you cannot execute commands from the NSIP of a cluster node).
2. Execute the commands required to recover the node.
3. Enable the cluster instance on that node.

Some nodes of the cluster have two default routes. How can I remove the second default route from the cluster node?

To delete the additional default route, do the following on each node that has the extra route:

1. Disable the cluster instance.
   ```
   disable cluster instance <clId>
   ```
2. Remove the route.
   ```
   rm route <network> <netmask> <gateway>
   ```
3. Enable the cluster instance.
   ```
   enable cluster instance <clId>
   ```

The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?

If RPC password of node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in rpc credentials and this could affect cluster
functionality. To solve this issue, use the set ns rpcNode command to update the password on the
NSIP of the node which has come online.

Content Switching

June 25, 2020

In today’s complex Web sites, you may want to present different content to different users. For exam-
ple, you may want to allow users from the IP range of a customer or partner to have access to a special
Web portal. You may want to present content relevant to a specific geographical area to users from
that area. You may want to present content in different languages to the speakers of those languages.
You may want to present content tailored to specific devices, such as smartphones, to those who use
the devices. The Citrix ADC content switching feature enables the appliance to distribute client re-
quests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to
meet your needs. This entails enabling the content switching feature, setting up load balancing for
the server or servers that host each version of the content that is being switched, creating a content
switching virtual server, creating policies to choose which requests are directed to which load bal-
ancing virtual server, and binding the policies to the content switching virtual server. You can then
customize the setup to meet your needs by setting precedence for your policies, protecting your setup
by configuring a backup virtual server, and improving the performance of your setup by redirecting
requests to a cache.

How Content Switching Works

Content Switching enables the Citrix ADC appliance to direct requests sent to the same Web host to dif-
ferent servers with different content. For example, you can configure the appliance to direct requests
for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for
static content to another server. You can configure the appliance to perform content switching based
on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers
with different content on the basis of various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client re-
quest for the type of device from which the request originated. Based on the device type, it
directs the request to a specific Web server. For example, if the request came from a cell phone,
the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.

- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client’s browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.

- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.

- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

**Figure 1. Content Switching Architecture**
A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a **content group** —a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using Citrix ADC classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the Citrix ADC appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see Configuring Default Syntax Policies.

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer, you must create a load balancing virtual server for it and bind its virtual server.
as a service to the content switching virtual server.

**Configuring Basic Content Switching**

June 25, 2020

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of websites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

**Note**

After creating a content group, you can modify its content switching virtual server to customize the configuration.

**Enabling content switching**

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.
To enable content switching by using the command line interface

At the command prompt, type the following commands to enable content switching and verify the configuration:

```
  1  enable ns feature CS
  2
  3  show ns feature
```

Example:

```
  1  > enable feature ContentSwitch
      Done
  2  > show feature
  3
  4
  5  Feature       Acronym  Status
      -------      -------  ------
  6  1)  Web Logging  WL      OFF
  7  2)  Surge Protection  SP      ON
  8  3)  Load Balancing  LB      ON
  9  4)  Content Switching  CS      ON
 10
 11
 12
 13
 14  22)  Responder  RESPONDER  ON
 15  23)  HTML Injection  HTMLInjection  ON
 16  24)  NetScaler Push  push      OFF
 17
```

To enable content switching by using the configuration utility

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select Content Switching.

The following figure illustrates the step wise configuration of Content Switching.
Creating content switching virtual servers

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

To create a virtual server by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <IPAddress> <port>
```

Example:

```
add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
```

To add a content switching virtual server by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and add a virtual server.
2. Specify a name for content switching virtual server.

   **Note**
   There is different Content Switching virtual server for each protocol. (For example, HTTP and SSL).
3. Populate the relevant fields and click OK.
### Content switching virtual server statistics

The content switching virtual server statistics display information such as vserver hits, request bytes, response bytes, total packets received, total packets sent, spillover threshold, spillover hits, current client established connections, and virtual server down backup hits, and so on.

The content switching virtual server statistics also display the summary details of the bound default load balancing virtual server.

### To view statistics of content switching virtual server by using the CLI

At the command prompt, type:

```
1 stat cs vserver <name>
```

**Example:**

```
1 stat cs vserver CS_stats
```

<table>
<thead>
<tr>
<th>Vserver Summary</th>
<th>IP</th>
<th>port</th>
<th>Protocol</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>CS_stats</td>
<td>1.1.1.1</td>
<td>80</td>
<td>HTTP</td>
<td>UP</td>
</tr>
</tbody>
</table>

**VServer Stats:**

- **Rate (/s)**
- **Total**

- Vserver hits: 0 / 0
- Requests: 0 / 0
- Responses: 0 / 0
- Request bytes: 0 / 0
- Response bytes: 0 / 0
- Total Packets rcvd: 0 / 0
- Total Packets sent: 0 / 0
- Current client connections: 0 / 0
- Current Client Est connections: 0 / 0
- Current server connections: 0 / 0
- Spill Over Threshold: 0 / 0
- Spill Over Hits: 0 / 0
- Labeled Connection: 0 / 0
- Push Labeled Connection: 0 / 0
- Deferred Request: 0 / 0
- Invalid Request/Response: 0 / 0
- Invalid Request/Response Dropped: 0 / 0
- Vserver Down Backup Hits: 0 / 0
- Current Multipath TCP sessions: 0 / 0
- Current Multipath TCP subflows: 0 / 0
- Apdex for client response times: 1.00 / 0
- Average client TTLB: 0 / 0

Done
To view statistics of content switching virtual server by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.

2. Select the virtual server and click Statistics.

Configuring a load balancing setup for content switching

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see How load balancing works. For detailed instructions on setting up a basic load balancing configuration, see Set up basic load balancing.
Configuring a content switching action

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Therefore, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

Note
You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server.

Configuring an action that specifies the name of the target load balancing virtual server

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface

At the command prompt, type:
To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

Configuring an action that specifies an expression for selecting the target at run time

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.
For example, if you are switching requests based on the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as mylb_. For example, load balancing virtual servers for HTML pages and PDF files can be named mylb_html and mylb_pdf, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is "mylb_"+HTTP.REQ.URL.SUFFIX. If the content switching virtual server receives a request for an HTML page, the expression returns mylb_html, and the request is switched to virtual server mylb_html.

To create a content switching action that specifies an expression, by using the command line interface

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

```
1 add cs action <name> -targetVserverExpr <expression>) [-comment <string >]
2 show cs action <name>
```

Example:

```
1 > add cs action mycsaction1 -targetvserverExpr ""mylb_" + HTTP.REQ.URL.SUFFIX"
2   Done
3 > show cs action mycsaction1
4   Name: mycsaction1
5   Target Vserver Expression: ""mylb_" + HTTP.REQ.URL.SUFFIX
6   Target LB Vserver: No_Target
7   ...
8   Done
9 >
```

To configure a content switching action that specifies an expression by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.
Configuring content switching policies

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using Citrix ADC classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The Citrix ADC appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.

- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.

- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

  **Note**

  A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

  If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about Citrix ADC classic policies and expressions, see Configuring Classic Policies and Expressions. For information about Default Syntax policies, see Configuring Default Syntax Expressions.

To create a content switching policy by using the command line interface

At the command prompt, type one of the following commands:

```
1  add cs policy <policyName> -domain <domain>
2  add cs policy <policyName> -url <URLValue>
```
add cs policy <policyName> -rule <RULEValue>
add cs policy <policyName> -rule <RULEValue> -action <actionName>

Example:
add cs policy Policy-CS-1 -url "http://example.com"
add cs policy Policy-CS-1 -domain "example.com"
add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ (10.217.84.0)"
add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009 Dec)"
add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1

To rename a content switching policy by using the command line interface

At the command prompt, type:
rename cs policy <policyName> <newName>

Example:
rename cs policy myCSPolicy myCSPolicy1

To rename a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, select a policy and, in the Action list, select Rename.

To create a content switching policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies, and click Add.
2. Populate the relevant fields and click Create.
Configuring content switching policy labels

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the Citrix ADC CLI or the configuration utility to configure content switching policy labels. In the Citrix ADC CLI, you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the Citrix ADC GUI, you perform both tasks in a single dialog box.

To create a content switching policy label by using the command line interface

At the command prompt, type:

```
add cs policylabel <labelName> <cspolicylabelTypetype>
```

Example:

```
add cs policylabel testpollab http
```

To rename a content switching policy label by using the command line interface

At the command prompt, type:

```
rename cs policylabel <labelName> <newName>
```
Example:

```
rename cs policylabel oldPolicyLabelName newPolicyLabelName
```

**To rename a content switching policy label by using the configuration utility**

Navigate to Traffic Management > Content Switching > Policy Labels, select a policy label and, in the Action list, select Rename.

**To bind a policy to a content switching policy label by using the command line interface**

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

```
bind cs policylabel <labelName> <policyName> <priority> [-targetVserver <string>] | [-gotoPriorityExpression <expression>] | [-invoke <labeltype> <labelName>] ]
```

```
show cs policylabel <labelName>
```

Example:

```
bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
```

```
show cs policylabel testpollab
```

```
Label Name: testpollab
Label Type: HTTP
Number of bound policies: 1
Number of times invoked: 0
Policy Name: test_Pol
Priority: 100
Target Virtual Server: LBVIP
```

**Note**

If a policy is configure with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configure with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.
To unbind a policy from a policy label by using the command line interface

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

1. `unbind cs policylabel <labelName> <policyName>`
2. `show cs policylabel <labelName>`

Example:

```
1. unbind cs policylabel testpollab test_Pol
2. show cs policylabel testpollab
   Label Name: testpollab
   Label Type: HTTP
   Number of bound policies: 0
   Number of times invoked: 0
```

To remove a policy label by using the command line interface

At the command prompt, type:

```
rm cs policylabel <labelName>
```

To manage a content switching policy label by using the configuration utility

Navigate to Traffic Management > Content Switching > Policy Labels, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

Binding Policies to a Content Switching Virtual Server

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

**Note**

If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see
Configuring a Content Switching Action section.

**To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the command line interface**

At the command prompt, type:

```
bind cs vserver <name>[<lbvserver<string> -targetLBVServer<string> -policyname <string> -priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type ( REQUEST | RESPONSE )] [-invoke (<labelType> <labelName>)]
```

**Example:**

```
bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT
3 bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression
4 'q.header("a") .count' -flowtype REQUEST -invoke policylabel label1
6 bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -priority 20
```

**Note**

The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

**To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, open a virtual server and, in the
Content Switching Policy Binding section, bind a policy to the virtual server, and specify a target load balancing virtual server.

**Configuring policy based logging for content switching**

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified
in the policy is performed, the Citrix ADC appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

**Note**

If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the Citrix ADC appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configuring the Citrix ADC appliance for audit logging. After you configure the audit message action, you specify the action in a content switching policy.

**To configure policy based logging for a content switching policy by using the command line interface**

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

```
set cs policy <policyName> -logAction <string>
show cs policy <policyName>
```

**Example:**

```
> set cs policy cspol1 -logAction csLogAction
Done
> show cs policy cspol1

Policy: cspol1  Rule: TRUE  Action: csact1
LogAction: csLogAction
Hits: 0

1) CS Vserver: csvs1
   Priority: 10
Done
> 
```
To configure policy based logging for a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, open a policy and, in the LogAction list, select a log action for the policy.

Verifying the configuration

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

Viewing the properties of content switching virtual servers

You can view the properties of content switching virtual servers that you have configured on the Citrix ADC appliance. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

Note

If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

```
1  show cs vserver
2
3  show cs vserver <name>
```
1. show cs vserver Vserver-CS-1
2. Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
3. State: UP
4. Last state change was at Thu Jun 30 10:48:59 2011
5. Time since last state change: 6 days, 20:03:00.760
6. Client Idle Timeout: 180 sec
7. Down state flush: ENABLED
8. Disable Primary Vserver On Down : DISABLED
9. Appflow logging: DISABLED
10. Port Rewrite : DISABLED
11. State Update: DISABLED
12. Default: Content Precedence: RULE
13. Vserver IP and Port insertion: OFF
14. Case Sensitivity: ON
15. Push: DISABLED Push VServer:
16. Push Label Rule: none
17. ...
18. 1) Policy : __ESNS_PREBODY_POLICY Priority: 0
19. 2) Policy : __ESNS_POSTBODY_POLICY Priority: 0
20. 1) Compression Policy Name: __ESNS_CMP_POLICY Priority: 2147483647
21. GotoPriority Expression: END
22. Flowtype: REQUEST
23. 2) Rewrite Policy Name: __ESNS_REWRITE_POLICY Priority: 2147483647
24. GotoPriority Expression: END
25. Flowtype: REQUEST
26. 3) Cache Policy Name: dfbx Priority: 10
27. GotoPriority Expression: END
28. Flowtype: REQUEST
29. 4) Responder Policy Name: __ESNS_RESPONDER_POLICY Priority: 2147483647
30. GotoPriority Expression: END
32. 2) Policy: plain Target: LBVIP1 Priority: 90 Hits: 0
33. 3) Policy: DispOrderTest2 Target: KerbAuthLBVS Priority: 91 Hits: 0
34. 4) Policy: test_Pol Target: LBVIP1 Priority: 92 Hits: 0
35. 5) Policy: PolicyNameTesting Target: LBVIP1 Priority: 100 Hits: 0
36. Done
Viewing content switching policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

```plaintext
1  show cs policy
2
3  show cs policy <PolicyName>
```
To view the properties of content switching policies by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, select a policy and, in the Action list, select Show Bindings.

Viewing a content switching virtual server configuration by using the visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

Note

The Visualizer requires a graphical interface, so it is available only through the configuration utility.

To view a content switching configuration by using the Visualizer in the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Content Switching Visualizer window, you can adjust the viewable area as follows:
   - Click the Zoom In and Zoom Out icons to increase or decrease the viewable area.
   - Click the Save Image icon to save the graph as an image file.
• In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.

4. To view configuration details for entities that are bound to this virtual server, you can do the following:
   • To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
   • To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   • To view the configuration details for a monitor, click the icon for the monitor, click the Related Tasks tab, and then click View Monitor.

5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click Statistics.

6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff.

7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.

8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.

   **Note**
   This option is available only on Citrix ADC nCore builds.

9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.

10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some
Customizing the Basic Content Switching Configuration

February 28, 2020

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.

Configuring Case Sensitivity for Policy Evaluation

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the Citrix ADC appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

To configure case sensitivity by using the command line interface

At the command prompt, type:

```plaintext
set cs vserver <name> -caseSensitive (ON|OFF)
```

Example:

```
set cs vserver Vserver-CS-1 -caseSensitive ON
```

To configure case sensitivity by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Case Sensitive.
Setting the Precedence for Policy Evaluation

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You need not configure precedence, the default precedence often works correctly.

You can configure either URL-based precedence or rule-based precedence in the following scenarios:

- One policy or set of policies must be applied first
- Another policy or set of policies is applied only if the first set does not match a request.

Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an “HTTP 404 Not Found” error message is sent to the client.

Note

You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.
**Precedence with Rule-Based Policies**

If you configure precedence based on rules, which is the default setting, the request is tested based on the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an “HTTP 404 Not Found” error message is sent to the client.

**To configure precedence by using the command line interface**

At the command prompt, type:

```
set cs vserver \<name\> -precedence ( RULE | URL )
```

**Example:**

```
set cs vserver Vserver-CS-1 -precedence RULE
```

**To configure precedence by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and then specify Precedence.

**Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers**

You can configure the Citrix ADC so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as *. As a result, the configuration size is also reduced.

**To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line**

At the command prompt, type:

```
add cs vserver \<name\> \<serviceType\> \<IPAddress\> Port *
```
**Example**

```
1 > add cs vserver cs1 HTTP 10.102.92.215 *
2   Done
3 > sh cs vserver cs1

     cs1 (10.102.92.215:*) - HTTP      Type: CONTENT
     State: UP
     Last state change was at Tue May 20 01:15:49 2014
     Time since last state change: 0 days, 00:00:03.270
     Client Idle Timeout: 180 sec
     Down state flush: ENABLED
     Disable Primary Vserver On Down : DISABLED
     Appflow logging: ENABLED
     Port Rewrite : DISABLED
     State Update: DISABLED
     Default:   Content Precedence: RULE
     Vserver IP and Port insertion: OFF
     L2Conn: OFF   Case Sensitivity: ON
     Authentication: OFF
     401 Based Authentication: OFF
     Push: DISABLED   Push VServer:
     Push Label Rule: none
     IcmpResponse: PASSIVE
     RHState: PASSIVE
     TD: 0
4   Done
```

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (*) to specify the port.

**Configuring per-VLAN Wildcarded Virtual Servers**

If you want to configure content switching for traffic on a specific VLAN, you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.
To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```
1 add cs vserver \<name\> \<serviceType\> IPAddress ‘* Port *’ -
listenpolicy \<expression\> \[-listenpriority \<positive\>_integer \>
```

Example:

```
1 add cs vserver Vserver-CS-vlan1 ANY * *
2 -listenpolicy ”CLIENT.VLAN.ID.EQ(2)” -listenpriority 10
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in Set up basic load balancing.

Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- `set cs vserver \<name\> -mssqlServerVersion \<mssqlServerVersion\>`
- `show cs vserver \<name\>`
Example

```
> set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2
Done
> show cs vserver myMSSQLcsvip myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type: CONTENT State: UP . . . . . . MSsql Server Version: 2008R2 . . . . . Done
```

To set the Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server, and specify the protocol as MYSQL.
2. In Advanced Settings, select MySQL, and specify the Server Version.

Enable external TCP health check for UDP virtual servers

In public clouds, you can use the Citrix ADC appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. To monitor the health of the UDP application, public clouds recommend adding a TCP-based endpoint to your service. The endpoint reflects the health of the UDP application.

The Citrix ADC appliance supports external TCP-based health check for a UDP virtual server. This feature introduces a TCP listener on the VIP of the content switching virtual server and the configured port. The TCP listener reflects the status of the virtual server.

To enable external TCP health check for UDP virtual servers by using CLI

At the command prompt, type the following command to enable an external TCP health check with the tcpProbePort option:

```
add cs vserver <name> <protocol> <IPAddress> <port> -tcpProbePort <tcpProbePort>
```

Example:

```
add cs vserver Vserver-CS-1 UDP 10.102.29.161 5002 -tcpProbePort 5000
```

To enable external TCP health check for UDP virtual servers by using GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, add the port number in the **TCP Probe Port** field.
4. Click **OK**.

### Content Switching for Diameter Protocol

April 23, 2019

For Diameter-protocol traffic, you can configure the Citrix ADC appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the Citrix ADC appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the Citrix ADC selects an appropriate load balancing server pool.
Sample Configuration

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

   ```
   1 add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
   2 add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
   3 add lb vserver vs_rx DIAMETER -persistenceType DIAMETER -persistavpno 263
   4 add lb vserver vs_cx DIAMETER -persistenceType DIAMETER -persistavpno 263
   5 bind lb vserver vs_rx svc_pcrf[1-3]
   6 bind lb vserver vs_cx svc_hss[1-3]
   ```

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

   ```
   1 add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
   2 add cs action cx_action -targetLBvserver vs_cx
   3 add cs action rx_action -targetLBvserver vs_rx
   4 add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ(16777216)" -action cx_action
   ```

CSCF=Call Session Control Function
HSS=Home Subscriber Server
PCRF=Policy and Charging Rules Function
Protecting the Content Switching Setup against Failure

February 12, 2020

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

Conﬁguring a Backup Virtual Server

If the primary content switching virtual server is marked DOWN or DISABLED, the Citrix ADC appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When conﬁguring the backup virtual server, you can specify the conﬁguration parameter Disable Primary When Down to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can conﬁgure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also conﬁgure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

Note

If a content switching virtual server is conﬁgured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the
redirect URL. The redirect is used when the primary and backup virtual servers are down.

To set up a backup content switching virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -backupVs<server <string> -disablePrimaryOnDown (ON |OFF)
```

Example

```
set cs vserver Vserver-CS-1 -backupVs Vserver-CS-2 -
   disablePrimaryOnDown ON
```

To set up a backup content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and specify a Backup Virtual Server.

Diverting Excess Traffic to a Backup Virtual Server

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:
To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and configure spillover.

Configuring a Redirection URL

You can configure a redirect URL to communicate the status of the Citrix ADC appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example www.example.com/ instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

Note

If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user’s browser.
To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -redirectURL \<URLValue\>
```

Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and specify a Redirect URL.

Configuring the State Update Option

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

When State Update is disabled:

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

When State Update is enabled:

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.
If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

To configure the state update option by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <ipAddress> <port> -stateUpdate ENABLED
```

Example

```
add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED
-cltTimeout 180
```

To configure the state update option by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Traffic Settings, and then select State Update.

flushing the surge queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the Citrix ADC appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client...
request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

**Note**

You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

### To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a
<serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.

- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>].
```

**Examples**

1. `flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80`
   The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10.

2. `flush ns surgeQ`
   The above command flushes all the surge queues on the appliance.

To flush a surge queue by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

*Failed!*

### Managing a Content Switching Setup

July 8, 2020

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.
**Unbinding Policies from the Content Switching Virtual Server**

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

**To unbind a policy from a content switching virtual server by using the command line interface**

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

*Example:*

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

**To unbind a policy from a content switching virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open the virtual server.
2. Click **Policies** section, select the policy, and click **Unbind**.

**Removing Content Switching Virtual Servers**

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the Citrix ADC appliance first unbinds all policies from the content switching virtual server, and then removes it.

**To remove a content switching virtual server by using the command line interface**

At the command prompt, type:

```
rm cs vserver <name>
```

*Example:*

```
rm cs vserver Vserver-CS-1
```

**To remove a content switching virtual server by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server, and click **Delete**.
Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `disable cs vserver <name>`
- `enable cs vserver <name>`

Example:

disable cs vserver Vserver-CS-1
enable cs vserver Vserver-CS-1

To disable or re-enable a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Enable or Disable.

Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the Citrix ADC configuration.

To rename a virtual server by using the command line interface

At the command prompt, type:

`rename cs vserver <name> <newName>`

Example:

`rename cs vserver Vserver-CS-1 Vserver-CS-2`

To rename a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Rename.
Managing Content Switching Policies

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

For more information, see Examples of URL-Based Policies pdf.

Note
You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

To modify, remove, or rename a policy by using the command line interface

At the command prompt, type one of the following commands:

- set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]
- rm cs policy <policyName>
- rename cs policy <policyName> <newPolicyName>

Example:

```
1  set cs policy Policy-CS-1 -domain "www.domainxyz.com"
2  
3  set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ (10.100.148.0)"
4  
5  set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
6  
7  set cs policy Policy-CS-1 -url /sports/*
8  
9  rename cs policy Policy-CS-1 Policy-CS-11
10  
11  rm cs policy Policy-CS-1
```

To modify, remove, or rename a policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. Select the policy, and either delete it, edit it or, in the Action list, click Rename.
Managing Client Connections

February 4, 2020

To ensure efficient management of client connections, you can configure the content switching virtual servers on the Citrix ADC appliance to use the following features:

- **Configuring the ICMP Response.** You can configure the Citrix ADC appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

  The following settings can be made on a virtual server:
  - When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, the Citrix ADC appliance always responds.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, the ADC appliance responds even if one virtual server is UP.
  - When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, ADC appliance responds even if one virtual server set to ACTIVE is UP.

Redirecting Client Requests to a Cache

The Citrix ADC cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the Citrix ADC appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see “Cache Redirection.

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cacheable <Value>
```

**Example**

```
set cs vserver Vserver-CS-1 -cacheable yes
```
To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Cacheable**.

### Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -downStateFlush \<Value\>
```

**Example**

```
set cs vserver Vserver-CS-1 -downStateFlush enabled
```

### Rewriting Ports and Protocols for Redirection

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the Citrix ADC appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.
To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -redirectPortRewrite \<Value\>
```

**Example**

```
set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
```

To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Rewrite.

**Inserting the IP Address and Port of a Virtual Server in the Request Header**

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the Citrix ADC appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

**Note**

This option is not supported for wildcarded virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -insertVserverIPPort \<vServerIPPORT\>
```

**Example**

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
```
To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in Virtual Server IP Port Insertion Value.

Setting a Time-out Value for Idle Client Connections

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the Citrix ADC appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -cltTimeout \<Value\>
```

Example

```
set cs vserver Vserver-CS-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and specify a Client Idle Time-Out value.

Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.
To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

1. `set cs vserver <name> -l2Conn (**ON** | **OFF**)
2. `show cs vserver <name>`

Example

```
1  > set cs vserver mycsvserver -l2Conn ON
2   Done
3  > show cs vserver mycsvserver
4  mycsvserver (192.0.2.56:80) - HTTP   Type: CONTENT
5     State: UP
6       . . .
7       . . .
8  L2Conn: ON  Case Sensitivity: ON
9       . . .
10      . . .
11   Done
12  >
```

To set the L2Conn option for a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Layer 2 Parameters.

Persistence support for content switching virtual server

February 12, 2020

Applications are moving from monolithic architectures toward microservices architecture. Different versions of the same application can co-exist in microservices architecture. Citrix ADC appliance must support continuous deployment of applications. This is usually achieved by platforms that perform
Canary deployments (such as Spinnaker). In a continuous deployment setup, a newer version of an application is deployed automatically and exposed to client traffic in stages until the application is stable to take complete traffic. Also, there must be uninterrupted services to the client.

The Citrix ADC content switching feature enables Citrix ADC the appliance to distribute client requests across multiple load balancing virtual servers based on the policies bound to the content switching virtual server.

For continuous deployments, content switching is used to select the load balancing virtual server serving various versions of an application.

In content switching, selection of load balancing virtual server for a specific application version changes at runtime because of the change in the content switching policies. During this transition, if some sessions are present with older versions of the application, such traffic must continue to be served by older versions only. To support this requirement, Citrix ADC appliance maintains persistence across multiple load balancing groups behind a content switching virtual server. Persistence for content switching virtual server enables seamless transition of clients from one version to another.

**Supported persistence types on content switching virtual server**

The following persistence types are supported on content switching virtual servers.

<table>
<thead>
<tr>
<th>Persistence type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source IP</td>
<td><strong>SOURCEIP</strong>. Connections from the same client IP address are parts of the same persistence session. For more details, see Source IP address persistence.</td>
</tr>
<tr>
<td>HTTP Cookie</td>
<td><strong>COOKIEINSERT</strong>. Connections that have the same HTTP Cookie header are parts of the same persistence session. The format of the cookie that the Citrix ADC appliance inserts is: NSC_&lt;vid_str of CSvserver&gt;=&lt;vid_str of Lbvserver&gt; where NSC_XXXX is the virtual server ID that is derived from the virtual server name. For more details, see HTTP cookie persistence.</td>
</tr>
</tbody>
</table>
SSL Session ID

Connections that have the same SSL Session ID are parts of the same persistence session. For more details, see SSL session ID persistence.

You can configure a timeout value for persistence that is based on HTTP cookies. If you set the timeout value to 0, the ADC appliance does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are valid only if the software is running.

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of memory on your Citrix ADC appliance. The following table shows which types of persistence fall into each category.

<table>
<thead>
<tr>
<th>Persistence type</th>
<th>Number of simultaneous persistent connections supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source IP, SSL Session ID</td>
<td>250,000</td>
</tr>
<tr>
<td>HTTP Cookie</td>
<td>Memory limit. In CookieInsert, if timeout is not 0, the number of connections is limited by memory.</td>
</tr>
</tbody>
</table>

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

<table>
<thead>
<tr>
<th>Persistence type</th>
<th>HTTP</th>
<th>HTTPS</th>
<th>TCP</th>
<th>UDP/IP</th>
<th>SSL_Bridge</th>
<th>SSL_TCP</th>
<th>RTSP</th>
<th>SIP_UDP</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOURCEIP</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>COOKIEINSERT</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>SSLSESSION</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Backup persistence support**

You can configure the content switching virtual server to use source IP persistence type as the backup persistence type when the cookie persistence type fails. This is useful for canary deployments in microservices architecture.

When the cookie persistence type fails, the appliance falls back to source IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.

You can also set a timeout value for backup persistence. Timeout is the time period for which a persistence session is in effect.

**How persistence on content switching virtual server works**

**Scenario 1: A content switching virtual server without persistence**

The following example illustrates the deployment of multiple versions of an application with a content switching virtual server without persistence.

When client C1 sends a request to the application, the request is sent to the content switching virtual server in the Citrix ADC appliance. The content switching virtual server evaluates the policy and forwards the request to the load balancing virtual server (LB1) that is serving version v1 of the application.
Consider a new version v2 of the application is deployed and has to be exposed to a subset of users. The new load balancing virtual server (LB2) serving the v2 version is bound to the content switching virtual server by appropriate content switching policy.

When client C1 sends a new request, the policy is evaluated again and the request is forwarded to the load balancing virtual server LB2. Thus, the transactions for stateful applications fail if multiple versions of the application are deployed.

**Scenario 2: Content switching virtual server with persistence**

The following example illustrates the deployment of multiple versions of the application with a content switching virtual server with persistence.
When client C1 sends a request to the application, the request is sent to the content switching virtual server in the Citrix ADC appliance. The content switching virtual server evaluates the policy, creates persistence session entry, and forwards the request to the load balancing virtual server LB1 that is serving version v1 of the application.

The same client C1 requests again for the application, and the request is sent to the content switching virtual server in the Citrix ADC appliance. A lookup for the persistence session is done, and the load balancing virtual server LB1 is taken from the existing persistence session and the request is forwarded to LB1. No breakage of existing transaction happens with this solution; thus, maintaining the stateful nature of the application.
Let’s consider a new client C2. The new request C2 is sent to the newer version of the application through policy evaluation as there is no existing persistence session for this client. This results in a successful rollout of the newer version of the application without breaking its statefulness.

Because of the persistence support, customers can deploy multiple content or different versions of the application seamlessly without impacting the existing transactions, specifically for stateful applications. This was not possible without persistence in picture.

**Configure persistence type on content switching virtual server by using the CLI**

At the command prompt, type:

```
set cs vserver <name> -PersistenceType <type> [-timeout <integer>]
```

**Example:**

```
set cs vserver Vserver-CS-1 -persistenceType SOURCEIP -timeout 60
```

**Configure persistence type on content switching virtual server by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers** and click **Add**.
2. In **Basic Settings**, configure the persistence details.
If the content switching feature does not work as expected after you have configured it, you can use some common tools to access Citrix ADC resources and diagnose the problem.

Resources for Troubleshooting Content Switching

For best results, use the following resources to troubleshoot a content switching issue on a Citrix ADC appliance:

- Configuration file
- Relevant newnslog file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and eDocs

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the Citrix ADC trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

Troubleshooting Content Switching Issues

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- Issue
  The content switching feature is not functioning.

- Resolution
  Check the configuration as follows:
  - Verify that the appliance is licensed for content switching.
  - Verify that the feature is enabled.
- From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

**Issue**

Client receives a 503 - Service Unavailable response.

**Resolution**

- Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
- From the configuration, verify the policies and URL being accessed by the client.
- Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy expression and update it if necessary.
- Verify the URL and HTTP request and response headers. To do so, record an HTTPHeader trace and, if necessary, record the packet traces on the appliance and the client.

**Issue**

Intermittently, the content switching feature is not working as expected.

**Resolution**

- Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the server(s).
- Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
- Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
- Run the following commands to verify the bindings and the values of the policy hit counters in the output of the commands:
  
  ```
  show cs vserver <CS VServer>
  show cs policy <CS Policy>
  stat cs vserver <CS VServer>
  ```

- Using iehttpheaders or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
- Check the release notes and Knowledge Center articles.
- If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.
The Citrix ADC DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a Citrix ADC appliance ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, usernames, character sets, and packet size.

You can either configure load balancing to switch requests based on load balancing algorithms or elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameters. You can further configure monitors to track the state of database servers.

Note: Citrix ADC DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

**How DataStream Works**

In DataStream, the ADC appliance is placed in-line between the application and/or Web servers and the database servers. On the appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. DataStream Entity Model
As shown in this figure, a DataStream configuration can consist of an optional content switching virtual server (CS), a load balancing setup consisting of load balancing virtual servers (LB1 and LB2) and services (Svc1, Svc2, Svc3, and Svc4), and content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the Citrix ADC appliance. The appliance, then, authenticates the clients using the database user credentials configured on the appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2), which, then, distributes the requests to the appropriate database servers (represented by services on the appliance) based on the load balancing algorithm. The Citrix ADC appliance uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the appliance, the clients (application or Web servers) send their requests to the IP address of a load balancing virtual server configured on the appliance. The Citrix ADC appliance authenticates the client by using the database user credentials configured on the appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database
switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

• User name
• Database name
• Packet size
• Character set

Configuring Database Users

February 13, 2020

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler appliance. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

Note
Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

```bash
add db user <username> -password <password>
```

Example:

```
1   add db user nsdbuser -password dd260427edf
```
To add a database user by using the configuration utility

Navigate to System > User Administration > Database Users, and configure a database user. If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the ADC appliance.

To reset the password of a database user by using the command line interface

At the command prompt, type

```
1 set db user <username> -password <password>
```

Example:

```
1 set db user nsdbuser -password dd260538abs
```

To reset the password of database users by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and enter new values for the password. If a database user no longer exists on the database server, you can remove the user from the ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

```
1 rm db user <username>
```

Example:

```
1 rm db user nsdbuser
```

To remove a database user by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and click Delete.

Copied!
Failed!
Configuring a Database Profile

April 23, 2019

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

To create a database profile by using the command line interface

At the command line, type the following commands to create a database profile and verify the configuration:

```bash
1 add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness ( YES | NO )] [-kcdAccount <string>]
2 3 show db dbProfile
```

Example:

```bash
1 > add dbProfile myDBProfile -interpretQuery YES -stickiness YES -
    kcdAccount mykcdacct
2   Done
3 > show dbProfile myDBProfile
4 Name: myDBProfile
5 Interpret Query: YES
6 Stickyness: YES
7 KCD Account: mykcdacct
8 Reference count: 0
9
10 Done
11 >
```

To create a database profile by using the configuration utility

Navigate to **System > Profiles** and, on the **Database Profiles** tab, configure a database profile.
To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

```bash
set (lb | cs) vserver <name> -dbProfileName <string>
```

To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Profiles and, in the DB Profile list, select a profile to bind to the virtual server. To create a new profile, click plus (+).

**Note:**

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The Citrix ADC appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.
Parameter values specific to DataStream

• Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

• Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

• Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

• MS SQL Server Version
