You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

! router bgp 234
network 1.1.1.1 255.255.255.0
route-map bgp-out2 permit 10
set metric 9900
set community 8602:300
Troubleshooting OSPF-Specific Issues

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. `show interface` from both nscli and VTYSH
2. `show ip ospf interface`
3. `show ip ospf neighbor detail`
4. `show ip route`
5. `show ip ospf route`
6. `show ip ospf database summary`
   a. If there are only few LSAs in the database, then enter `show ip ospf database router`, `show ip ospf database A. network`, `show ip ospf database external`, and other commands to get the full details of LSAs.
   b. If there are a large number of LSAs in the database, enter the `show ip ospf database self-originated` command.
7. `show ip ospf`
8. `show ns ip`. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:
   
   ```
gcore -s -c xyz.core /netscaler/ospfd <pid>
   ```

   **Note:** The `gcore` command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:
   
   ```
   ns(config)#log file /var/ospf.log
   ```

2. Enable debugging ospf events and log them by using the following command:
   
   ```
   ns(config)#log file /var/ospf.log
   ```

   Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).
Parameter Descriptions (of commands listed in the CLI procedure)

Internet Protocol version 6 (IPv6)

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services. You have to license the IPv6 feature before you can implement it.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

<table>
<thead>
<tr>
<th>IPv6 features</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)</td>
</tr>
<tr>
<td>Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)</td>
</tr>
<tr>
<td>Management Applications (ping6, telnet6, ssh6)</td>
</tr>
<tr>
<td>Static Routing and Dynamic routing (OSPF)</td>
</tr>
<tr>
<td>Port Based VLANs</td>
</tr>
<tr>
<td>Access Control Lists for IPv6 addresses (ACL6)</td>
</tr>
<tr>
<td>IPv6 Protocols (TCP6, UDP6, ICMP6)</td>
</tr>
<tr>
<td>Server Side Support (IPv6 addresses for vservers, services)</td>
</tr>
<tr>
<td>USIP (Use source IP) and DSR (Direct Server Return) for IPv6</td>
</tr>
<tr>
<td>SNMP and CVPN for IPv6</td>
</tr>
<tr>
<td>HA with native IPv6 node address</td>
</tr>
<tr>
<td>IPv6 addresses for MIPs</td>
</tr>
<tr>
<td>Path-MTU discovery for IPv6</td>
</tr>
</tbody>
</table>

The following table lists NetScaler components that support IPv6 addresses and provides references to the topics that document the components.

Table 2. NetScaler Components That Support IPv6 Addresses and the Corresponding Documentation

<table>
<thead>

</tr>
</tbody>
</table>

You can configure IPv6 support for the above features after implementing the IPv6 feature on your NetScaler appliance. You can configure both tagged and prefix-based VLANs for IPv6. You can also map IPv4 addresses to IPv6 addresses.
Implementing IPv6 Support

IPv6 support is a licensed feature, which you have to enable before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

"Warning: Feature(s) not enabled [IPv6PT]"

The following message appears if you attempt to run IPv6 commands without the appropriate license:

"ERROR: Feature(s) not licensed"

After licensing the feature, use either of the following procedures to enable or disable IPv6.

To enable or disable IPv6 by using the command line interface

At the command prompt, type one of the following commands:

- `enable ns feature ipv6pt`
- `disable ns feature ipv6pt`

To enable or disable IPv6 by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure Advanced Features.

2. Select or clear the IPv6 Protocol Translation option.

Parameter Descriptions (of commands listed in the CLI procedure)

**enable ns feature**

No parameters provided in this topic or the command has no parameters. [View description(s) in command reference Top](#)
Implementing IPv6 Support

disable ns feature

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
VLAN Support

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN.

For more information about ND6 and VLANs, see "Configuring Neighbor Discovery."

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.
Simple Deployment Scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

![IPv6 Sample Topology](image)

The following table summarizes the names and values of the entities that must be configured on the NetScaler.

**Table 1. Sample Values for Creating Entities**

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LB Vserver</td>
<td>VS1_IPv6</td>
<td>2002:::9</td>
</tr>
<tr>
<td>Services</td>
<td>SVC1</td>
<td>10.102.29.1</td>
</tr>
<tr>
<td></td>
<td>SVC2</td>
<td>10.102.29.2</td>
</tr>
</tbody>
</table>
To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

To create IPv4 services by using the command line interface

At the command prompt, type:
Simple Deployment Scenario

```
add service <Name> <IPAddress> <Protocol> <Port>
```

Example

```
add service SVC1 10.102.29.1 HTTP 80
add service SVC2 10.102.29.2 HTTP 80
```

To create IPv4 services by using the configuration utility

Navigate to Load Balancing > Services, click Add, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the command line interface

At the command prompt, type:

```
add lb vserver <Name> <IPAddress> <Protocol> <Port>
```

Example

```
add lb vserver VS1_IPv6 2002::9 HTTP 80
```
To create IPv6 vserver by using the configuration utility

1. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB vserver by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <service>
```

Example

```
bind lb vserver VS1_IPv6 SVC1
```

The vservers receive IPv6 packets and the NetScaler performs Protocol Translation (RFC 2765) before sending traffic to the IPv4-based services.

To bind a service to an LB vserver by using the configuration utility

1. Navigate to Load Balancing > Virtual Servers.

2. In the Load Balancing Virtual Servers page, select the vserver for which you want to bind the service (for example, VS1_IPv6).

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box corresponding to the service that you want to bind to the vserver (for example, SVC1).

5. Click OK.

6. Repeat Steps 1-4 to bind the service (for example, SVC2 to the vserver).
Parameter Descriptions (of commands listed in the CLI procedure)

add service
No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

add lb vserver
No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

bind lb vserver
No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
Host Header Modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

To change the IPv6 address in the host header to an IPv4 address by using the command line interface

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

Example

```
set ns ip6 2002::9 -map 200.200.200.200
```

To change the IPv6 address in the host header to an IPv4 address by using the configuration utility

1. Navigate to Network > IPs and, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Open.

2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Parameter Descriptions (of commands listed in the CLI procedure)

**set ns ip6**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
VIP Insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP and enable VIP insertion.

To configure a mapped IPv6 address by using the command line interface

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

Example

```
> set ns ip6 2002::9 -map 200.200.200.200
Done
```

To configure a mapped IPv6 address by using the configuration utility

1. Navigate to Network > IPs, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:9, and click Open.

2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Use either of the following procedures to enable insertion of an IPv4 VIP address and port number in the HTTP requests sent to the servers.

To enable VIP insertion by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -insertVserverIPPort <Value>
```

Example
VIP Insertion

> set lb vserver VS1_IPv6 -insertVserverIPPort ON
Done

To enable VIP insertion by using the configuration utility

1. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion drop-down list box, select VIPADDR.

2. In the Vserver IP Port Insertion text box, type the vip header.

Parameter Descriptions (of commands listed in the CLI procedure)

set ns ip6

set lb vserver
No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
Traffic Domains

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network.** Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.

- **Use of Duplicate entities on the NetScaler appliance.** Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.

  Note: Duplicate entities with same name is not supported.

- **Multitenancy.** Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANs configured on the appliance.

Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the **default traffic domain**, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see “Supported NetScaler Features in Traffic Domains.”
As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

The following table lists the settings used in the example.
How Traffic Domains Work

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Settings in traffic domain 1</td>
<td>VLANs bound to traffic domain 1</td>
<td>VLAN 2</td>
</tr>
<tr>
<td>Client connected to TD1</td>
<td>CL-TD1 (for reference purposes only)</td>
<td>IP address: 192.0.2.3</td>
</tr>
<tr>
<td>Load balancing virtual server in TD1</td>
<td>LBVS-TD1</td>
<td>IP address: 192.0.2.15</td>
</tr>
<tr>
<td>Service bound to virtual server LBVS-TD1</td>
<td>SVC1-TD1</td>
<td>IP address: 192.0.2.36</td>
</tr>
<tr>
<td>SNIP</td>
<td>SNIP-TD1 (for reference purposes only)</td>
<td>IP address: 192.0.2.27</td>
</tr>
<tr>
<td>Settings in traffic domain 2</td>
<td>VLAN bound to traffic domain 2</td>
<td>VLAN 3</td>
</tr>
<tr>
<td>Client connected to TD2</td>
<td>CL-TD2 (for reference purposes only)</td>
<td>IP address: 192.0.2.3</td>
</tr>
<tr>
<td>Load balancing virtual server in TD2</td>
<td>LBVS-TD2</td>
<td>IP address: 192.0.2.15</td>
</tr>
<tr>
<td>Service bound to virtual server LBVS-TD2</td>
<td>SVC3-TD2</td>
<td>IP address: 192.0.2.36</td>
</tr>
<tr>
<td>SNIP in TD2</td>
<td>SNIP-TD2 (for reference purposes only)</td>
<td>IP address: 192.0.2.29</td>
</tr>
</tbody>
</table>

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.15.

2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.

3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.15. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.15.

4. NS1 sends an ARP response with the MAC address of interface 1/1.

5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.

6. Client CL-TD1 sends a request to 192.0.2.15. The request is received by LBVS-TD1 on port 1/1 of NS1.

7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.

9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.15.

2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.

3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.15. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.15. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.

4. NS1 sends an ARP response with the MAC address of interface 1/3.

5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.

6. Client CL-TD2 sends a request to 192.0.2.15. The request is received by LBVS-TD2 on interface 1/3 of NS1.

7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.

8. S2 replies to SNIP 192.0.2.29 on NS1.

9. NS1 sends S2's reply to client CL-TD2.
Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

<table>
<thead>
<tr>
<th>Supported features in traffic domains</th>

<td></td>
</tr>
</tbody>
</table>

Any NetScaler feature not listed above is supported only in the default traffic domain. Traffic domains are not supported in a cluster configuration.
Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.

- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.

- **Create feature entities on the traffic domain.** Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled “How traffic domains work.”

The command line interface has two commands for these two tasks, but the configuration utility combines them in a single dialog box.

**To create a VLAN and bind interfaces to it by using the command line interface**

At the command prompt, type:

- `add vlan <id>`
- `bind vlan <id> -ifnum <slot/port>`
- `show vlan <id>`

**To create a traffic domain entity and bind VLANs to it by using the command line interface**

At the command prompt, type:
To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

To create a VLAN by using the configuration utility

Navigate to Network > VLANs, click Add, and set the parameters.

To create a traffic domain entity by using the configuration utility

Navigate to Network > Traffic Domains, click Add, and in the Create Traffic Domain dialog box, set the parameters.

To create a service by using the configuration utility

Navigate to Load Balancing > Services, click Add, and set the parameters.
To create a load balancing virtual server by using the configuration utility

Navigate to Load Balancing > Virtual Servers, click Add, and set the parameters.

Web Interface

The Web Interface on Citrix NetScaler appliances is based on Java Server Pages (JSP) technology and provides access to Citrix XenApp and Citrix XenDesktop applications. Users access resources through a standard Web browser or by using the Citrix XenApp plug-in.

The Web Interface runs as a service on port 8080 on the NetScaler appliance. To create Web Interface sites, Java is executed on Apache Tomcat Web server version 6.0.35 on the NetScaler appliance. The Web Interface sites provide user access to the XenApp and XenDesktop resources, which include applications, content, and desktops.

The Web Interface installation includes installing the Web Interface tar file and JRE tar file on the NetScaler appliance. To configure the Web Interface, you create a Web Interface site and bind one or more XenApp or XenDesktop farms to it.
How Web Interface Works

The following figure illustrates a basic Web interface session.

![Diagram of a basic Web interface session](image)

**Figure 1. A Basic Web Interface Session**

Following is a typical set of interactions among a user device, a NetScaler running the Web interface, and a server farm.

1. A user authenticates to the Web interface through a Web browser or by using the XenApp plug-in.
2. The Web interface reads the user's credentials and forwards the information to the Citrix XML Service running on servers in the server farm.
3. The Citrix XML Service on the designated server retrieves from the servers a list of resources that the user can access. These resources constitute the user's resource set and are retrieved from the Independent Management Architecture (IMA) system.
4. The Citrix XML Service then returns the user's resource set to the Web interface running on the NetScaler.
5. The user clicks an icon that represents a resource on the HTML page.
6. The Web interface queries the Citrix XML Service for the least busy server.
7. The Citrix XML Service returns the address of this server to the Web interface.
8. The Web interface sends the connection information to the Web browser.
9. The Web browser initiates a session with the server.
Prerequisites

The following prerequisites are required before you begin installing and configuring the Web interface.

- XenApp or XenDesktop farms are set up and running in your environment. For more information about XenApp, see the XenApp documentation at http://edocs.citrix.com/. For more information about XenDesktop, see the XenDesktop farms documentation at http://edocs.citrix.com/.

- Conceptual knowledge of the Web interface. For more information about Web interface running on a server, see the Web interface documentation at http://edocs.citrix.com/.
Installing the Web Interface

To install the Web interface, you need to install the following files:

- **Web interface tar file.** The setup file for installing the Web interface on the NetScaler appliance. This tar file also includes Apache Tomcat Web server version 6.0.35. The file name has the following format: nswi-<version number>.tgz (for example, nswi-1.5.tgz).

- **JRE tar file.** The JRE tarball. You can use the Diablo Latte JRE version 1.6.0-7 for 64-bit FreeBSD 6.x/amd64 platform available on FreeBSD Foundation Web site at http://www.freebsdfoundation.org/java/java16. Alternatively, you can use OpenJDK6 package for FreeBSD 6.x/amd64. You can download openjdk6-b17_2.tbz from https://citrix.sharefile.com/d/c85aeeffcc05643f8.

**Note:** On a high availability setup, when installing the web interface with tar files (web interface and JRE) that are already available on the appliance, ensure that the files are available in the same location on both the primary and secondary appliances; otherwise, the web interface will not be installed on the secondary appliance.

Copy the tar files to a local workstation or to the /var directory of the appliance.

These files install all the Web interface components and JRE on the hard drive and configure automatic startup of the Tomcat Web server with Web interface at appliance startup time. Both tar files are internally expanded in the /var/wi directory on the hard drive.

**Note:** After installing web interface on the appliance and before creating a web interface site, you must place the client plugin in the appliance by using the appropriate Upload Plugins utility provided on the web interface details pane.

To install the Web interface and JRE tar files by using the command line interface

At the command prompt, type:

```
install wi package -wi <URL> -jre <URL>
```

Examples

```
> install wi package -wi sftp://username:password@10.102.29.12/var/nswi-1.5.tgz -jre <url>
> install wi package -wi ftp://username:password@10.102.29.15/var/nswi-1.5.tgz -jre <url>
```
To install the Web interface and JRE tar files by using the configuration utility

In the navigation pane, click Web Interface, and select Install Web Interface, and then specify the install path for web interface tar file and JRE tar file.

Parameter Descriptions (of commands listed in the CLI procedure)

install wi package

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
Configuring the Web Interface

To configure the web interface, you create a web interface site and bind one or more XenApp or XenDesktop farms to it. You then configure the web interface to work behind an HTTP or an HTTPS virtual server or Access Gateway.

- **Using an HTTP or an HTTPS virtual server.** You create an HTTP or an HTTPS virtual server on the NetScaler appliance and bind the web interface service, running on port 8080 of the NetScaler appliance, to the virtual server. Clients on the LAN use the virtual server IP address to access the web interface. When using this access method, the URL format for the web interface site is as follows:

  `<HTTP or HTTPS>://<HTTP or HTTPS vserver IP address>:<vserver port number>/<web interface site path>`

  The following access methods are available for clients accessing the web interface site when it is configured using an HTTP or an HTTPS virtual server:

  - **Direct.** Actual address of a XenApp or XenDesktop server is sent to the clients.
  
  - **Alternate.** Alternate address of a XenApp or XenDesktop server is sent to the clients.
  
  - **Translated.** Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to the clients from a specified network. When you use this option, you have to define internal address to external address and port mappings.

- **Using Access Gateway.** You associate the web interface site with Access Gateway. You associate the web interface site with Access Gateway. Remote clients use the Access Gateway URL to access the web interface site. With this access method, the URL format for the web interface site is as follows:

  `HTTPS://<Access Gateway URL>/<web interface site path>`

  The following access methods are available for clients accessing the web interface site when it is configured using an Access Gateway:

  - **Gateway Direct.** Actual address of a XenApp or XenDesktop server is sent to Access Gateway.
  
  - **Gateway Alternate.** Alternate address of a XenApp server is sent to Access Gateway. You cannot use this mode to access XenDesktop servers.
  
  - **Gateway Translated.** Translated address, from the defined internal addresses to external addresses and ports mapping table, is sent to Access Gateway. When you use this option, you have to define internal address to external address and port mappings.
Configuring a Web Interface Site for LAN Users Using HTTP

In this scenario, user and the Web interface setup are on the same enterprise LAN. The enterprise has both a XenApp and a XenDesktop farm. Users access the Web interface by using an HTTP vserver. The Web interface exposes its own login page for authentication. The vserver IP address is used to access the Web interface.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTP vserver HTTP_WI is also created. Client C1 uses the IP address of the HTTP_WI vserver to access the WINS1 site.

Figure 1. A Web Interface Site Configured for LAN Users Using HTTP
To configure a Web interface site for LAN users using HTTP by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Path* (You cannot change the name of an existing Web interface site.)
   - Site Type
   - Published Resource Type
   - Kiosk Mode
   - Authentication Methods
   - Login Title
   - Web Session Timeout
   - Enable access through receiver client
   * A required parameter.
5. In Default Access Methods, select the Direct or Alternate or Translated option and configure the following parameters:
   - Virtual Server
   - Protocol (select HTTP)
   - IP Address
   - Port

Note:
When you create the HTTP vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTP virtual server.

For more information about services and virtual servers, see the "Traffic Management."

6. Click Next.

7. On the wizard’s Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.
To change the access method for a client IP address or network, select the association, and then click Open.

8. In the Configure Access Method dialog box, configure the following parameters:

   - Client IP Address* (You cannot change this parameter after setting it.)
   - Netmask (You cannot change this parameter after setting it.)
   - Access Method

   * A required parameter.

   **Note:** Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client’s IP address available with the web interface.

9. Click Next.

10. On the wizard’s Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

   **Note:** The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client’s IP address or network.

11. In the Configure Address Translations dialog box, configure the following parameters:

   - Internal IP Address
   - Internal Port
   - External IP Address
   - External Port
   - Access Type

   * A required parameter.

12. Click Next.

13. On the wizard’s Configure XenApp/XenDesktop Farm page, do one of the following:

   - To add a XenApp or XenDesktop farm, click Add.
   - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.

14. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:

   - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
   - XML Service Addresses*
   - XML Service Port
   - Transport
· Load Balance

* A required parameter.

15. Click Next, and then click Finish.

16. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.
To configure a Web interface site for LAN users using HTTP by using the command line interface

1. Add a Web interface site. Set Direct or Alternate or Translated for the defaultAccessMethod parameter. At the command prompt, type:

add wi site <sitePath> -siteType ( XenAppWeb | XenAppServices )
-publishedResourceType ( Online | Offline | DualMode ) -kioskMode ( ON | OFF )
-wiAuthenticationMethods ( Explicit | Anonymous ) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

Example

> add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccessMethod Direct

2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:

bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr>
-clientNetMask <netmask>

3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport ( HTTP | HTTPS ) -loadBalance ( ON | OFF )

Example

> bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
> bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF

5. Create a service that is a logical representation of the Web interface service running on the NetScaler appliance. At the command prompt, type:

add service <name> <IP address> <serviceType> <port>

Example

> add service WI_Loopback_Service 127.0.0.1 HTTP 8080

6. Add an HTTP vserver. At the command prompt, type:

add lb vserver <virtualServerName> <protocol> <IPAddress> <port>

Example
7. Bind the Web interface service to the HTTP vserver. At the command prompt, type:

   bind lb vserver <virtualServerName> <serviceName>

   Example

   > bind lb vserver HTTP_WI WI_Loopback_Service

Configuring a Web Interface Site for LAN Users Using HTTPS

In this scenario, user accounts and the Web interface setup are on the same enterprise LAN. Users access the Web interface by using an SSL-based (HTTPS) vserver. The Web interface exposes its own login page for authentication. SSL offloading is done by this vserver on the NetScaler. The vserver IP address is used to access the Web interface instead of the NetScaler IP address (NSIP).

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop farm XD1 are bound to it. An HTTPS vserver HTTPS_WI is also created. Client C1 uses the IP address of the HTTPS_WI vserver to access the WINS1 site.

Figure 1. A Web Interface Site Configured for LAN Users Using HTTPS
To configure a Web interface site for LAN users using HTTPS by using the configuration utility

1. In the navigation pane, click Web Interface.

2. In the details pane, click Web Interface Wizard.

3. On the wizard Introduction page, click Next.

4. On the wizard Configure Web Interface Site page, configure the following parameters:
   · Site Path* (You cannot change the name of an existing Web interface site.)
   · Site Type
   · Published Resource Type
   · Kiosk Mode
   · Authentication Methods
   · Login Title
   · Web Session Timeout
   · Enable access through receiver client
   * A required parameter.

5. In Default Access Methods, select the Direct or Alternate or Translated option and configure the following parameters:
   · Virtual Server
   · Protocol (select HTTPS)
   · IP Address
   · Port

   **Note:**

   When you create the HTTPS vserver by using the configuration utility, the configuration utility automatically creates a service, which logically represents the Web interface service running on the NetScaler appliance, and binds the service to the HTTPS virtual server.

   For more information about services and virtual servers, see the "Traffic Management."

6. Click Next.

7. On the wizard's Specify a server Certificate page, you create or specify an existing SSL certificate-key pair. The SSL certificate-key pair is automatically bound to the HTTPS vserver.
For more information, see "Binding an SSL Certificate Key Pair to the Virtual Server."

8. Click Next.

9. On the wizard’s Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.
   - To change the access method for a client IP address or network, select the association, and then click Open.

10. In the Configure Access Method dialog box, configure the following parameters:
    - Client IP Address* (You cannot change this parameter after setting it.)
    - Netmask (You cannot change this parameter after setting it.)
    - Access Method
    * A required parameter.

    **Note:** Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client’s IP address available with the web interface.

11. Click Next.

12. On the wizard’s Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

    **Note:** The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client’s IP address or network.

13. In the Configure Address Translations dialog box, configure the following parameters:
    - Internal IP Address
    - Internal Port
    - External IP Address
    - External Port
    - Access Type
    * A required parameter.

14. On the wizard’s Configure XenApp/XenDesktop Farm page, do one of the following:
    - To add a XenApp or XenDesktop farm, click Add.
    - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.

15. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:
    - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
    - XML Service Addresses*
Configuring a Web Interface Site for LAN Users Using HTTPS

- XML Service Port
- Transport
- Load Balance

* A required parameter.

16. Click Next, and then click Finish.

17. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.
To configure a Web interface site for LAN users using HTTPS by using the command line

1. Add a Web interface site. Set Direct or Alternate or Translated for the defaultAccessMethod parameter. At the command prompt, type:

   add wi site <sitePath> -siteType ( XenAppWeb | XenAppServices )
   -publishedResourceType ( Online | Offline | DualMode ) -kioskMode ( ON | OFF )
   -wiAuthenticationMethods ( Explicit | Anonymous ) -webSessionTimeout
   <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>

   Example

   > add wi site WINS1 -siteType XenAppWeb -publishedResourceType Online -kioskMode ON -defaultAccessMethod Direct

2. (Optional) Set an access method for a Client's IP address or network. At the command prompt, type:

   bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr>
   -clientNetMask <netmask>

3. If you have set the Translated access method for a Client's IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

   bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort
   <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

   bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport
   ( HTTP | HTTPS ) -loadBalance ( ON | OFF )

   Example

   > bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
   > bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF

5. Create a service that is a logical representation of the Web interface service running on
   the NetScaler appliance. At the command prompt, type:

   add service <name> <IPAddress> <serviceType> <port>

   Example

   > add service WI_Loopback_Service 127.0.0.1 HTTP 8080

6. Add an HTTPS vserver. At the command prompt, type:

   add lb vserver <name>@ <protocol> <IPAddress> <port>

   Example
Configuring a Web Interface Site for LAN Users Using HTTPS

7. Bind the Web interface service to the HTTPS vserver. At the command prompt, type:

```
bind lb vserver <name>@<serviceName>
```

**Example**

```
> bind lb vserver HTTPS_WI WI_Loopback_Service
```

8. Create an SSL certificate key pair. At the command prompt, type:

```
add ssl certkey <certificate-KeyPairName> -cert <certificateFileName> -key <privateKeyFileName>
```

**Example**

```
> add ssl certkey SSL-Certkey-1 -cert /nsconfig/ssl/test1.cer -key /nsconfig/ssl/test1
```

9. Bind the SSL certificate key pair to the HTTPS vserver. At the command prompt, type:

```
bind ssl vserver <vserverName> -certkeyName <certificate-KeyPairName>
```

**Example**

```
> bind ssl vserver HTTPS_WI -certkeyName SSL-Certkey-1
```

10. Add a rewrite action. At the command prompt, type:

```
add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-pattern <expression>]
```

**Example**

```
> add rewrite action Replace_HTTP_to_HTTPS INSERT_AFTER "HTTP.RES.HEADER("Location").Value(0).Prefix(4)" "s"
```

11. Create a rewrite policy and bind the rewrite action to it. At the command prompt, type:

```
add rewrite policy <name> <rule> <action>
```

**Example**

```
> add rewrite policy rewrite_location "HTTP.RES.STATUS == 302 && HTTP.RES.HEADER("Location").Value(0).startswith("http:" \")" Replace_HTTP_to_HTTPS
```

12. Bind the rewrite policy to the HTTPS vserver. At the command prompt, type:

```
bind lb vserver <VserverName> -policyname <rewritePolicyName> -priority <value> -type response
```

**Example**

```
> bind lb vserver HTTPS_WI -policyname rewrite_location -priority 10 -type response
```

Configuring a Web Interface Site for Remote Users Using Access Gateway

In this scenario, user accounts and the Web interface setup are on different networks. Users access a Web interface site by using the Access Gateway URL. SmartAccess is automatically enabled.

The following figure illustrates the Web interface running on the NetScaler appliance NS1. A Web interface site WINS1 is created and a XenApp farm XA1 and a XenDesktop XD1 are bound to it. An Access Gateway VPN vserver AGEE_WI is also configured. The client uses the Access Gateway URL of the AGEE_WI to access the WINS1 site.

Figure 1. A Web Interface Site Configured for Remote Users Using Access Gateway
To configure a Web interface site for remote users using Access Gateway by using the configuration utility

1. In the navigation pane, click Web Interface.
2. In the details pane, click Web Interface Wizard.
3. On the wizard Introduction page, click Next.
4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Path* (You cannot change the name of an existing Web interface site.)
   - Site Type
   - Published Resource Type
   - Kiosk Mode
   - Authentication Methods
   - Login Title
   - Web Session Timeout
   - Enable access through receiver client

   * A required parameter.
5. In Default Access Methods, select the Gateway Direct or Gateway Alternate or Gateway Translated option and configure the following parameters:
   - Authentication Point
   - Access Gateway URL
   - Add DNS Entry
   - Trust SSL Certificate
   - STA Server URL
   - STA Server URL (2)
   - Session Reliability
   - Use two STA Servers
6. Click Next.
7. On the wizard's Configure Access Methods page, do one of the following:
   - To set an access method for a client IP address or network, click Add.
To change the access method for a client IP address or network, select the association, and then click Open.

8. In the Configure Access Method dialog box, configure the following parameters:
   - Client IP Address* (You cannot change this parameter after setting it.)
   - Netmask (You cannot change this parameter after setting it.)
   - Access Method
     * A required parameter.

   **Note:** Before you configure access method based on the client IP address, you must enable USIP mode on the web interface service to make the client’s IP address available with the web interface.

9. Click Next.

10. On the wizard's Configure Address Translations page, click Add for adding a mapping between an Internal IP address and an external IP address.

    **Note:** The Configure Address Translations page appears on the wizard when you set the Translated access method for a Client’s IP address or network.

11. In the Configure Address Translations dialog box, configure the following parameters:
    - Internal IP Address
    - Internal Port
    - External IP Address
    - External Port
    - Access Type
      * A required parameter.

12. Click Next.

13. On the wizard's Configure XenApp/XenDesktop Farm page, do one of the following:
    - To add a XenApp or XenDesktop farm, click Add.
    - To modify an existing XenApp or XenDesktop farm, select the farm, and then click Open.

14. In the Create XenApp/XenDesktop Farm or Configure XenApp/XenDesktop Farm dialog box, configure the following parameters:
    - Name* (You cannot change the name of an existing XenApp or XenDesktop farm.)
    - XML Service Addresses*
    - XML Service Port
    - Transport
15. Click Next, and then click Finish.

16. Verify that the Web interface site you configured is correct by selecting the site and viewing the Details section at the bottom of the pane. To view the Web interface site, in the navigation pane, expand System, expand Web Interface, and then click Sites.

To configure a Web interface site for remote users using Access Gateway by using the command line interface

1. Add a Web interface site. Set GatewayDirect or GatewayAlternate or GatewayTranslated for the defaultAccessMethod parameter. At the command prompt, type:

```
add wi site <sitePath> <agURL> <staURL> -sessionReliability ( ON | OFF ) -useTwoTickets ( ON | OFF ) -secondSTAURL <string> -authenticationPoint (WebInterface | AccessGateway ) -siteType ( XenAppWeb | XenAppServices ) -publishedResourceType ( Online | Offline | DualMode ) -kioskMode ( ON | OFF ) -wiAuthenticationMethods ( Explicit | Anonymous ) -webSessionTimeout <positive_integer> -defaultAccessMethod <defaultAccessMethod> -loginTitle <string>
```

Example

```
```

2. (Optional) Set an access method for a Client’s IP address or network. At the command prompt, type:

```
bind wi site <sitePath> -accessMethod <accessMethod> -clientIpAddress <ip_addr> -clientNetMask <netmask>
```

3. If you have set the Translated access method for a Client’s IP address or network then provide Internal IP and external IP address mappings. At the command prompt, type:

```
bind wi site <sitePath> -translationInternalIp <ip_addr> -translationInternalPort <port|*> -translationExternalIp <ip_addr> -translationExternalPort <port|*> [-accessType <accessType>]
```

4. Bind XenApp or XenDesktop farms to the Web interface site. At the command prompt, type:

```
bind wi site <sitePath> <farmName> <xmlServerAddresses> -xmlPort <value> -transport ( HTTP | HTTPS ) -loadBalance ( ON | OFF )
```

Example

```
> bind wi site WINS1 XA1 10.102.46.6 -xmlPort 80 -transport HTTP -LoadBalance OFF
> bind wi site WINS1 XD1 10.102.46.50 -xmlPort 80 -transport HTTP -LoadBalance OFF
```

Using Smart Card Authentication for Web Interface through Access Gateway

The web interface on the NetScaler appliance supports single sign-on with a smart card through Access Gateway. You log on to Access Gateway by using a valid client certificate, either served from the local certificate store or from a smart card. After successful authentication, you are redirected to the web interface.

Requirements

- Make sure that you install the latest web interface tar file (nswi-1.5.tgz). This tar file provides support for smart card authentication.

- You must configure Delegation on the Active Directory. Follow the Active Directory Configuration section under Procedure, as described in the article at http://support.citrix.com/article/CTX124603.
To use smart card authentication for a web interface site through Access Gateway by using the configuration utility

1. In the navigation pane, click Web Interface.

2. In the details pane, click Web Interface Wizard.

3. On the wizard Introduction page, click Next.

4. On the wizard Configure Web Interface Site page, configure the following parameters:
   - Site Type
   - Site Path
   - Published Resource Type
   - Authentication Methods
   - Login Title
   - Language
   - Web Session Timeout
   - Kiosk Mode

5. Select GatewayDirect as the Default Access Method.

6. Select Access Gateway as the Authentication Point.

7. Select or create a Access Gateway Vserver. For more information, see “http://support.citrix.com/proddocs/topic/access-gateway-10/agee-config-settings-ag-wizard-tsk.html.”

8. Click Settings to set the ICA mode, SSO, and WIhome.

10. Click the SmartCard Settings link to configure certificate-based authentication on Access Gateway. You can skip these steps if certificate-based authentication is already configured on Access Gateway. In the Smart Card Settings wizard do the following:

   a. Specify the CA certificate. Install a CA certificate or use an already installed certificate for the Access Gateway virtual server to authenticate the client certificate.

   b. Configure authentication policies. Create a certificate-based authentication policy and bind it to Access Gateway vserver as follows:
      i. Click Insert Policy. In the Policy Name column, select New Policy.
      ii. In the Create Authentication Policy dialog box, specify a name for the policy, select Authentication Type as CERT, and click New.
iii. In the Create Authentication Server dialog box, specify the server Name and the User Name Field and click Create.

iv. Bind the policy to the Access Gateway Vserver with ns_true as expression and default priority.

c. Configure SSL-based client authentication with Client Certificate set as Optional.

d. Click Finish.

11. Continue with the wizard as described in "Configuring a Web Interface Site for Remote Users Using Access Gateway."

To use smart card authentication for a web interface site through Access Gateway by using the command line interface

At the command prompt, type:

```
add wi site <sitePath> <agURL> <staURL> -authenticationPoint AccessGateway -agAuthenticationMethod SmartCard -defaultAccessMethod GatewayDirect
```

Additionally, smart card support on web interface requires certificate-based authentication on the Access Gateway. Additionally, smart card support on web interface requires certificate-based authentication on the Access Gateway. If you do not have certificate-based authentication already configured on the Access Gateway vserver, do the following:

1. Configure an Access Gateway vserver and bind the server and CA certificate to it.

   ```
   add vpn vserver <vpnvserver_name> SSL <AccessGateway_VIP> <port>
   bind ssl vserver <vpnvserver_name> -certkeyName <Server_Cert_Key_Pair>
   bind ssl vserver <vpnvserver_name> -certkeyName <Root_Cert_as_CKP> -CA
   set ssl vserver <vpnvserver_name> -clientAuth ENABLED -clientCert Optional
   add dns nameserver <dns_server_ip>
   ```

2. Configure a certificate-based authentication policy and bind itcertAction_name to the Access Gateway vserver.

   ```
   add authentication certAction <certAction_name> -userNameField <string>
   add authentication certPolicy <certPolicy_name> <rule> <certAction_name>
   bind vpn vserver <vserver_name> -policy <certPolicy_name>
   ```

3. Configure the web interface site in ICA proxy mode through a session policy and then bind it to Access Gateway vserver.
Using Smart Card Authentication for Web Interface through Access Gateway

```
add vpn sessionAction <sessionAction_name> -defaultAuthorizationAction ALLOW -SSO ON -wihome "<WI_URL>" -wiPortalMode NORMAL -icaprox ON

add vpn sessionPolicy <sessionPolicy_name> <rule> <sessionAction_name>

bind vpn vserver <vpnvserver_name> -policyName <sessionPolicy_name>

bind vpn vserver <vpnvserver_name> -staServer "<sta_server_url>"
```

**Parameter Descriptions (of commands listed in the CLI procedure)**

**add wi site**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add vpn vserver**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**bind ssl vserver**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**set ssl vserver**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add dns nameserver**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add authentication certAction**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add authentication certPolicy**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
Using Smart Card Authentication for Web Interface through Access Gateway

**bind vpn vserver**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add vpn sessionAction**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top

**add vpn sessionPolicy**

No parameters provided in this topic or the command has no parameters. View description(s) in command reference Top
Using the WebInterface.conf Dialog Box

The WebInterface.conf dialog box in the configuration utility displays the content of the webinterface.conf file for a Web Interface site.

You can do the following from this dialog box:

- Edit the WebInterface.conf file and save the changes.
- Search the file’s content for instances of a text string.
- Easily save the WebInterface.conf file to your local computer.

To search a string in the webinterface.conf file by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select the web interface site, and click WebInterface.conf.

2. In the WebInterface.conf dialog box, use the following controls:

   - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
     - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
     - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
     - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
     - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the webinterface.conf to your local system by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, click WebInterface.conf and select Save output text to a file.
Using the config.xml Dialog Box

The Config.xml dialog box in the configuration utility displays the content of the config.xml file for a Web Interface site of site type XenApp/XenDesktop Services Site.

You can do the following from this dialog box:

- Edit the config.xml file and save the changes.
- Search the file’s content for instances of a text string.
- Easily save the config.xml file to your local computer.

To search a string in the config.xml file by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select XenApp/XenDesktop services site, and click Config.xml.

2. In the Config.xml dialog box, use the following controls:

   - Find. Displays the following search options that you can use to find one or more instances of a text string in a configuration:
     - Look for. Provides a space for you to type the text string that you want to locate in the configuration. As you type the text, the first instance is displayed. If the word you are looking for is not in the file, the Look for text box will change color.
     - Next. Finds and highlights the next occurrence of the text string you typed in Look for.
     - Previous. Finds and highlights the previous occurrence of the text string you typed in Look for.
     - Mark All. Highlights all instances of the text string at one time you typed in Look for. Scroll to review each highlighted instance.

To save the content of the config.xml to the local system by using the configuration utility

1. In the navigation pane, expand Web Interface, and then click Sites, select XenApp/XenDesktop Services Site.

2. Click Config.xml and select Save output text to a file.

## Traffic Management

The following topics cover configuration and installation information for NetScaler traffic management features.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache Redirection</td>
<td>Analyzes incoming requests and forwards the requests for already cached data to cache servers. Dynamic HTTP requests and non-cacheable requests are forwarded to the origin servers. Cache redirection is a policy-based feature.</td>
</tr>
<tr>
<td>Content Switching</td>
<td>Analyzes client requests and redirects the requests to specific servers on the basis of geographical area, authorization credentials, and device from which the request was initiated.</td>
</tr>
<tr>
<td>DataStream</td>
<td>Ensures optimal distribution of traffic from the application and web servers to the database servers. Enables you to segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.</td>
</tr>
<tr>
<td>Domain Name System</td>
<td>Provides authoritative domain name server (ADNS server) functionality for a domain. The NetScaler appliance functions as a DNS end resolver and forwarder, and also helps in name resolution when fully qualified domain names are not configured.</td>
</tr>
<tr>
<td>Firewall Load Balancing</td>
<td>Distributes the traffic across multiple firewalls, providing fault tolerance, increased throughput, and high availability.</td>
</tr>
<tr>
<td>Global Server Load Balancing</td>
<td>Enables disaster recovery and ensures continuous availability of applications by protecting against points of failure in a wide area network (WAN).</td>
</tr>
<tr>
<td>Link Load Balancing</td>
<td>Load balances outbound traffic across multiple Internet connections to transmit packets seamlessly over the best possible link.</td>
</tr>
<tr>
<td>Load Balancing</td>
<td>Distributes user requests for web pages and other protected applications across multiple servers to prevent server overloading and failure. Load balancing also provides fault tolerance.</td>
</tr>
<tr>
<td>SSL Offload and Acceleration</td>
<td>Offloads SSL processing from a server to the NetScaler appliance to accelerate SSL transactions.</td>
</tr>
<tr>
<td>Web 2.0 Push</td>
<td>Offloads connection management from Web 2.0 servers. Instead of having to maintain a long-lived connection to each client, a Web 2.0 server can maintain a single connection to the NetScaler appliance. The appliance relays the server's data to waiting clients over the connections that it maintains with them.</td>
</tr>
</tbody>
</table>
Cache Redirection

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.
Cache Redirection

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler® appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler resides directly in front of the clients. In a server-side deployment, the NetScaler is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.
Cache Redirection Policies

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The NetScaler provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

**Note:** Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.
Displaying the Built-in Cache Redirection Policies

You can display the available cache redirection policies by using the command line interface or the configuration utility.

To display the built-in cache redirection policies by using the command line interface

At the command prompt, type:

`show cr policy [<policyName>]`

Example

```
> show cr policy
1) Cache-By-Pass RULE: NS_NON_GET          Policy:bypass-non-get
2) Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE || NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA)    Policy:bypass-cache-control
3) Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE || NS_EXT_CFМ || NS_EXT_EX || NS_URL_PATH_CGIBIN || NS_URL_PATH_EXEC || NS_URL_PATH_BIN)         Policy:bypass-dynamic-url
4) Cache-By-Pass RULE: NS_URL_TOKENS       Policy:bypass-urltokens
5) Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF && NS_EXT_NOT_JPEG)     Policy:bypass-cookie
Done
>```

To display the built-in cache redirection policies by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies. The configured cache redirection policies appear in the details pane.

2. Select one of the configured policies to view details.
Configuring a Cache Redirection Policy

A cache redirection policy includes one or more expressions (also called rules). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the NetScaler considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection uses the classic policy format. Each policy has a name and includes an expression or a set of expressions that are combined by using logical operators.

To add a cache redirection policy by using the command line interface

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

- `add cr policy <policyName> -rule <expression>`
- `show cr policy [<policyName>]`

Examples

Policy with a simple expression:

```bash
> add cr policy Policy-CRD-1 -rule “REQ.HTTP.URL != ‘/*.jpeg’”
Done
> show cr policy Policy-CRD-1
  Cache-By-Pass RULE: REQ.HTTP.URL != ‘/*.jpeg’   Policy:Policy-CRD-1
Done
>
```

Policy with a compound expression:

```bash
> add cr policy Policy-CRD-2 -rule “REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == ‘/*.cgi’ || REQ.HTTP.URL != ‘/*.gif’)”
Done
> show cr policy Policy-CRD-2
  Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == ‘/*.cgi’ || REQ.HTTP.URL != ‘/*.gif’)   Policy:Policy-CRD-2
Done
>
```
Policy that evaluates a header:

> add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
Done
> show cr policy Policy-CRD-3
   Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS    Policy:Policy-CRD-3
Done
>

To modify or remove a cache redirection policy by using the command line interface

- To modify a cache redirection policy, use the set cr policy command, which is just like using the add cr policy command, except that you enter the name of an existing policy.

- To remove a policy, use the rm cr policy command, which accepts only the <name> argument. You can only remove a cache redirection policy that is not bound to a cache redirection virtual server. If the policy is bound to a virtual server, you must first unbind the policy, and then remove it from the NetScaler.

For details on unbinding a cache redirection policy, see "Unbinding a Policy from a Cache Redirection Virtual Server."

Parameters for creating a cache redirection policy

**policyName**

Name of the cache redirection policy. This is a mandatory parameter, and the value cannot be changed after the policy is created.

**rule**

An expression that the NetScaler evaluates to identify non-cacheable requests. Can consist of multiple expressions joined by AND and OR operators.
To configure a cache redirection policy with a simple expression by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies.

2. In the details pane, click Add.

3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.

4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:

   - Expression Type-General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -URL
   - Operator - !=
   - Value* - /*.jpeg

The simple expression in the following example checks for an If-Modified-Since header in a request:

   - Expression Type -General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -HEADER
   - Operator - EXISTS
   - Header Name - If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.
To configure a cache redirection policy with a compound expression by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Policies.

2. In the details pane, click Add.

3. In the Name text box, enter a name for the policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:

   - **Match Any Expression.** The policy matches the traffic if one or more individual expressions match the traffic.
   - **Match All Expressions.** The policy matches the traffic only if every individual expression matches the traffic.
   - **Tabular Expressions.** Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:

     - The AND [ & & ] operator, to require that, to match the policy, a request match both the current expression and the following expression.
     - The OR [ | | ] operator, to require that, to match the policy, a request match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.
     
     You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

     - The BEGIN SUBGROUP [+ ( ] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -( .)
     - The END SUBGROUP [+ ) ] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)
     
     - **Advanced Free-Form.** Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you type your compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler classic expressions language.

     For more information about creating classic expressions in the Advanced Free-Form text area, see “Configuring Classic Policies and Expressions”.

Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression
5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click Add to display the Add Expression dialog box.

You should leave the expression type set to General for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

- **REQ.** Configures the NetScaler appliance to examine incoming connections, or requests.
- **RES.** Configures the appliance to examine outgoing connections, or responses.

7. In the Protocol drop-down list, choose a protocol for your expression.

The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four of the following choices, or three of them, are available:

- **HTTP.** Configures the appliance to examine the HTTP header.
- **SSL.** Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
- **TCP.** Configures the appliance to examine the TCP header.
- **IP.** Configures the appliance to examine the source or destination IP.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Qualifier</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP</td>
<td>METHOD</td>
<td>The HTTP method used in the request.</td>
</tr>
<tr>
<td><strong>URL</strong></td>
<td>The contents of the URL header.</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td></td>
</tr>
<tr>
<td><strong>URLTOKENS</strong></td>
<td>The URL tokens in the HTTP header.</td>
<td></td>
</tr>
<tr>
<td><strong>VERSION</strong></td>
<td>The HTTP version of the connection.</td>
<td></td>
</tr>
<tr>
<td><strong>HEADER</strong></td>
<td>The header portion of the HTTP request.</td>
<td></td>
</tr>
<tr>
<td><strong>URLLEN</strong></td>
<td>The length of the contents of the URL header.</td>
<td></td>
</tr>
<tr>
<td><strong>URLQUERY</strong></td>
<td>The query portion of the contents of the URL header.</td>
<td></td>
</tr>
<tr>
<td><strong>URLQUERYLEN</strong></td>
<td>The length of the query portion of the URL header.</td>
<td></td>
</tr>
<tr>
<td><strong>SSL</strong></td>
<td>The SSL client certificate as a whole.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT</strong></td>
<td>The SSL client certificate as a whole.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.SUBJECT</strong></td>
<td>The contents of the client certificate subject field.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.ISSUER</strong></td>
<td>The client certificate issuer.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.SIGALGO</strong></td>
<td>The signature algorithm used in the client certificate.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.VERSION</strong></td>
<td>The client certificate version.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.VALIDFROM</strong></td>
<td>The date from which the client certificate is valid. (The start date.)</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.VALIDTO</strong></td>
<td>The date after which the client certificate is no longer valid. (The end date.)</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CERT.SERIALNUMBER</strong></td>
<td>The client certificate serial number.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CIPHER.TYPE</strong></td>
<td>The encryption method used in the client certificate.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.CIPHER.BITS</strong></td>
<td>The number of significant bits in the encryption key.</td>
<td></td>
</tr>
<tr>
<td><strong>CLIENT.SSL.VERSION</strong></td>
<td>The SSL version of the client certificate.</td>
<td></td>
</tr>
</tbody>
</table>
TCP  | SOURCEPORT | The source port of the TCP connection.
---|---|---
DESTPORT | The destination port of the TCP connection.
MSS | The maximum segment size (MSS) of the TCP connection.
IP  | SOURCEIP | The source IP of the connection.
DESTIP | The destination IP of the connection.

9. Choose the operator for your expression from the Operator drop-down list.

Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

- `==` . Matches the following text string exactly.
- `!=` . Does not match the following text string.
- `>` . Is greater than the following integer.
- `CONTAINS` . Contains the following text string.
- `CONTENTS` . The contents of the designated header, URL, or URL query.
- `EXISTS` . The specified header or query exists.
- `NOTCONTAINS` . Does not contain the following text string.
- `NOTEXISTS` . The specified header or query does not exist.

If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.

For example, if you want this policy to select requests sent to the host `shopping.example.com`, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.

12. Click OK to add your expression to the Expression list.

13. Repeat steps 4 through 11 to create additional expressions.

14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.
Built-in Cache Redirection Policies

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers in the request and their values.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use the simpler of two NetScaler expressions languages, called *classic expressions*. For a complete description of classic expressions and how to configure them, see [http://support.citrix.com/article/CTX132362](http://support.citrix.com/article/CTX132362).

The NetScaler provides the following built-in cache redirection policies:

<table>
<thead>
<tr>
<th>built in Policy Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bypass-non-get</td>
<td>Bypass the cache if the request uses an HTTP method other than GET.</td>
</tr>
<tr>
<td>bypass-cache-control</td>
<td>Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.</td>
</tr>
</tbody>
</table>
| bypass-dynamic-url   | Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions:  
  - cgi  
  - asp  
  - exe  
  - cfm  
  - ex  
  - shtml  
  - htx  
  Also bypass the cache if the URL starts with any of the following:  
    - /cgi-bin/  
    - /bin/  
    - /exec/ |
| bypass-urltokens     | Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =. |
### Built-in Cache Redirection Policies

<table>
<thead>
<tr>
<th><strong>bypass-cookie</strong></th>
<th>Bypass the cache for any URL that has a cookie header and an extension other than .gif or .jpg.</th>
</tr>
</thead>
</table>

Cache Redirection Configurations

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent.** A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.

- **Forward proxy.** A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.

- **Reverse proxy.** Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.
Configuring Transparent Redirection

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the response does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see "Directing Policy Hits to the Cache instead of the Origin."

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the NetScaler on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.
Enabling Cache Redirection and Load Balancing

The NetScaler cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

**To enable cache redirection and load balancing by using the command line interface**

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

- `enable ns feature cr lb`
- `show ns feature`

**Example**

```bash
> enable ns feature cr lb
Done
> show ns feature

<table>
<thead>
<tr>

```
Enabling Cache Redirection and Load Balancing

To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
   a. In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
   b. In Enable/Disable Feature(s)? dialog box, click Yes.

3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
   a. In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
   b. In Enable/Disable Feature(s)? dialog box, click Yes.
Configuring Edge Mode

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns off collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

To enable edge mode by using the command line interface

At the command prompt, type the following commands to enable edge mode and verify the setting:

- `enable ns mode Edge`
- `show ns mode`

Example

> enable ns mode edge
Done

> show ns mode

<table>

Parameters for enabling edge mode

Mode

The name of the mode to be enabled. This is a mandatory argument.

To enable edge mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Configure modes.

3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.

4. In Enable/Disable Feature(s)? dialog box, click Yes.
Configuring a Cache Redirection Virtual Server

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the NetScaler represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

To add a cache redirection virtual server in transparent mode by using the command line interface

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

- add cr vserver <name> <serviceType> [<IPAddress> <port>] [-cacheType <cacheType>] [-redirect <redirect>] [-cacheVserver <string>]
- show cr vserver [<name>]

Example

add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect POLICY -cacheVserver Vserver-LB-1
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: UP   ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default: Content Precedence: RULE     Cache: TRANSPARENT
  On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
  Redirect: POLICY     Reuse: ON     Via: ON ARP: OFF

Done
>
To modify or remove a cache redirection virtual server by using the command line interface

- To modify a virtual server, use the `set cr vserver` command, which is just like using the `add cr vserver` command, except that you enter the name of an existing virtual server.

- To remove a virtual server, use the `rm cr vserver` command, which accepts only the `<name>` argument.

Parameters for adding a cache redirection virtual server

**name**

Name of the cache redirection virtual server. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the cache redirection virtual server is created. You should choose a name that helps identify the type of service being added. Maximum length of the name can be 127 characters.

**serviceType**

The type of data that the virtual server will handle. For typical web traffic, the protocol is HTTP. Possible Values: HTTP, SSL.

**IPAddress**

The IP address of the virtual server that you are adding. For transparent cache redirection, assign an asterisk (*) as the IP address, so that the virtual server listens on all IP addresses configured on the NetScaler.

**port**

The port number on which the virtual server receives traffic.

**cacheType**

The type of cache redirection you are configuring. Possible values: TRANSPARENT, REVERSE, FORWARD.

**redirect**

The redirect method to be used. Possible values: CACHE, ORIGIN, POLICY.

For normal operation, specify POLICY based redirection and bind appropriate cache redirection policies to the virtual server.

**cacheVserver**

The name of a load balancing virtual server to which this redirection virtual server sends cache requests.
Configuring a Cache Redirection Virtual Server

To add a cache redirection virtual server in transparent mode by using the configuration utility

1. In the navigation pane, click Cache Redirection, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding a cache redirection virtual server” as shown:
   
   - Name*—name
   - Port*—port
   * A required parameter

4. In the Protocol drop-down list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.

5. Click the Advanced tab.

6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.

7. If you have already configured load balancing virtual servers for cache redirection, select a virtual server from the Cache Server drop-down list.

8. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.

9. Select the new cache redirection virtual server to display the details of its configuration.
Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

**To bind policies to a cache redirection virtual server by using the command line interface**

At the command prompt, type:

- `bind cr vserver <name> -policyName <string>`
- `show cr vserver [<?name>]

**Example**

```
> bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
Done
> bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
Done

> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: UP   ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default: Content Precedence: RULE     Cache: TRANSPARENT
  On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY     Reuse: ON     Via: ON ARP: OFF

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: bypass-dynamic-url
3) Cache bypass Policy: bypass-urltokens
4) Cache bypass Policy: bypass-cookie
Done
```

>
Parameters for binding policies to a cache redirection virtual server

name

The name of the cache redirection virtual server you are binding the policy to.

policyName

The name of the policy being bound to the cache redirection virtual server. The policy must already be created on the NetScaler appliance before it is bound.

To bind a user-defined policy to a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection and click Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.
Unbinding a Policy from a Cache Redirection Virtual Server

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

To unbind a policy from a cache redirection virtual server by using the command line interface

At the command prompt, type:

- `unbind cr vserver <name> -policyName <string>`
- `show cr vserver [<name>]`

Example

```
unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
> show cr vserver Vserver-CRD-1
    Vserver-CRD-1 (*:80) - HTTP   Type: CONTENT
    State: UP   ARP:DISABLED
    Client Idle Timeout: 180 sec
    Down state flush: ENABLED
    Disable Primary Vserver On Down : DISABLED
    Default:    Content Precedence: RULE    Cache: TRANSPARENT
    On Policy Match: ORIGIN L2Conn: OFF   OriginUSIP: OFF
    Redirect: POLICY    Reuse: ON   Via: ON ARP: OFF

1) Cache bypass  Policy: bypass-cache-control
Done
>
```
To unbind a user-defined policy from a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection and click Virtual Servers.

2. Click the virtual server that you want to configure, and then click Open.

3. On the Policies tab, under Policy Name, select the policy that you want to unbind.

4. Click Unbind Policy, and then click OK.
Creating a Load Balancing Virtual Server

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see "Load Balancing."

To create a load balancing virtual server by using the command line interface

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

- add lb vserver <name> <serviceType> [IPAddress] [port]
- show lb vserver [name]

Example

> add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
Done
> show lb vserver Vserver-LB-CR
  Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul 2 08:47:52 2010
  Time since last state change: 0 days, 00:00:08.470
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services : 0 (Total) 0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
  Push Multi Clients: NO
  Push Label Rule: none
Done
>
Parameters for creating a load balancing virtual server

name

The name of the virtual server being created.

serviceType

The type of traffic the virtual server will be receiving. For all web traffic, create virtual servers of type HTTP or, for secure Web traffic, HTTPS.

IPAddress

The IP address of the virtual server. This is the IP address that will receive incoming traffic.

port

The port number on which the incoming traffic will be received.

To create a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a load balancing virtual server" as shown:
   
   - Name*-name
   - IP Address*- IPAddress
   - Port*-port
   * A required parameter

4. In the Protocol* drop down list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.

5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.
Configuring an HTTP Service

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

To configure an HTTP service by using the command line interface

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

- add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
- show service [<name>]

Example

> add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
Done
> show service Service-HTTP-1
  Service-HTTP-1 (10.102.29.40:80) - HTTP
  State: DOWN
  Last state change was at Fri Jul 2 09:14:17 2010
  Time since last state change: 0 days, 00:00:13.820
  Server Name: 10.102.29.40
  Server ID: 0  Monitor Threshold: 0
  Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
  Use Source IP: NO
  Client Keepalive(CKA): NO
  Access Down Service: NO
  TCP Buffering(TCPB): NO
  HTTP Compression(CMP): YES
  Idle timeout: Client: 180 sec Server: 360 sec
  Client IP: DISABLED
  Cache Type: TRANSPARENT Redirect Mode:
  Cacheable: NO
  SC: OFF
  SP: ON
  Down state flush: ENABLED

  1) Monitor Name: tcp-default
     State: DOWN  Weight: 1
     Probes: 3  Failed [Total: 3 Current: 3]
     Last response: Failure - Time out during TCP connection establishment stage
To modify or remove a service by using the command line interface

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.

- To remove a service, use the rm service command, which accepts only the <name> argument.

Parameters for adding an HTTP service

name

The name of the service you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of service being added. (Cannot be changed after the service has been created.)

IP

The physical IP address of the server that the service you are configuring represents. Make sure that the server is reachable by the NetScaler.

port

The port number on which the service sends and receives data to and from the server.

serviceType

The type of data that will be transferred between the NetScaler and the server. Typically, for web server caches, the serviceType is HTTP.

cacheType

The type of cache redirection you are configuring.
To add an HTTP service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for adding an HTTP service" as shown:
   
   - Service Name*—name
   - Server*—IP
   - Port*—port
   * A required parameter

4. In the Protocol* drop-down list, select a supported protocol (for example, HTTP).

5. Click Create, and then click Close.
Binding/Unbinding a Service to/from a Load Balancing Virtual Server

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

- `bind lb vserver <name> <serviceName>`
- `show lb vserver [<name>]`

Example

```bash
> bind lb vserver vserver-LB-CR service-HTTP-1
Done
> show lb vserver Vserver-LB-CR
  Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul  2 08:47:52 2010
  Time since last state change: 0 days, 00:42:25.610
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services :  1 (Total)       0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer: None
  Push Multi Clients: NO
  Push Label Rule: none

  1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
     Done
> ```
To unbind a service from a load balancing virtual server by using the command line interface

To unbind a service, use the unbind lb vserver command instead of bind lb vserver.

Parameters for binding/unbinding a service to/from a load balancing virtual server

- **name**
  
  The virtual server name from which the service will be bound/unbound. This is a mandatory argument. Maximum Length: 127

- **serviceName**
  
  The service name (created with the addService command) that will be unbound. Maximum Length: 127

To bind/unbind a service from a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.

3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.

4. Click OK.
Disabling the Use the Proxy Port Setting for Transparent Caching

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client’s IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client’s source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see “Configuring the Source Port for Server-Side Connections.”
Assigning a Port Range to the NetScaler

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

To assign a source port range to a NetScaler appliance by using the command line interface

At the command prompt, type:

```
set ns param -crPortRange <startPortNumber-endPortNumber>
```

Parameters for assigning source port range

- **startPortNumber**
  
  Lower limit of the port range

- **endPortNumber**

  Upper limit of the port range

  The range should be from 1024 through 65535.

To assign a source port range to a NetScaler appliance by using the NetScaler configuration utility

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
4. Click OK.
Enabling Load Balancing Virtual Servers to Redirect Requests to Cache

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

To enable load balancing virtual servers to redirect requests to the cache by using the command line interface

At the command prompt, type:

- set lb vserver <name> [-cacheable (YES | NO)]
- show lb vserver [<name>]

Example

set lb vserver Vserver-LB-CR -cacheable YES
> show lb vserver vserver-LB-CR
  Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul  2 08:47:52 2010
  Time since last state change: 0 days, 01:05:51.510
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Port Rewrite : DISABLED
  No. of Bound Services :  1 (Total)       0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Cacheable: YES  PQ: OFF SC: OFF
  Vserver IP and Port insertion: OFF
For transparent cache redirection, the NetScaler intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

**To turn off caching for a load balancing virtual server by using the command line interface**

To turn off caching for a load balancing virtual, use the unset lb vserver command instead of set lb vserver. Specify a value of NO value for the `-cacheable` parameter.

**To enable or disable load balancing virtual servers to redirect requests to the cache by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.

3. On the Advanced tab, select/clear Cache Redirection check box.

4. Click OK.
Configuring Forward Proxy Redirection

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the NetScaler is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the NetScaler compares the request with a policy for caching. If the request is not cacheable, the NetScaler queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the NetScaler forwards the request to a load balancing virtual server for the cache.

The NetScaler relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the NetScaler. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a forward proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see "Configuring a Cache Redirection Policy."
Creating a DNS Service

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

To create a DNS service by using the command line interface

At the command line, type the following commands to create a DNS service and verify the configuration:

- add service <name> <IP> <serviceType> <port>
- show service [<name>]

Example

add service Service-DNS-1 10.102.29.41 DNS 53
show service Service-DNS-1
  Service-DNS-1 (10.102.29.41:53) - DNS
  State: DOWN
  Last state change was at Fri Jul  2 10:14:32 2010
  Time since last state change: 0 days, 00:00:13.550
  Server Name: 10.102.29.41
  Server ID : 0  Monitor Threshold : 0
  Max Conn: 0  Max Req: 0  Max Bandwidth: 0 kbits
  Use Source IP: NO
  Client Keepalive(CKA): NO
  Access Down Service: NO
  TCP Buffering(TCPB): NO
  HTTP Compression(CMP): NO
  Idle timeout: Client: 120 sec  Server: 120 sec
  Client IP: DISABLED
  Cacheable: NO
  SC: OFF
  SP: OFF
  Down state flush: ENABLED

1)  Monitor Name: ping-default
  State: DOWN  Weight: 1
  Probes: 3  Failed [Total: 3 Current: 3]
  Last response: Failure - Probe timed out.
  Response Time: 2000.0 millisec

Done
Parameters for creating a DNS service

name

The name of the service you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of service being added. (Cannot be changed after the service has been created.)

IP

The physical IP address of the server that the service you are configuring represents. Make sure that the server is reachable by the NetScaler.

port

The port number on which the service sends and receives data to and from the server.

serviceType

The type of data that will be transferred between the NetScaler and the server. Typically, for DNS service, the serviceType is DNS.

To add an DNS service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a DNS service" as shown:
   - Service Name*—name
   - Server*—IP
   - Port*—port
   * A required parameter

4. In the Protocol* drop down list, select a supported protocol (for example, DNS).

5. Click Create, and then click Close.
Creating a DNS Load Balancing Virtual Server

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

To create a DNS load balancing virtual server by using the command line interface

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

- `add lb vserver <name> <serviceType>`
- `show lb vserver [<name>]`

Example

```
> add lb vserver Vserver-DNS-1 DNS
Done
> show lb vserver Vserver-DNS-1
  Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul 2 10:32:28 2010
  Time since last state change: 0 days, 00:00:08.10
  Effective State: DOWN    ARP:DISABLED
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services : 0 (Total)     0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
Done
>```

Parameters for creating a DNS load balancing virtual server

- `name`
Creating a DNS Load Balancing Virtual Server

The name of the virtual server being created.

serviceType

The type of traffic the virtual server will be receiving.

**To create a DNS load balancing virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.

4. In the Protocol drop down list, select a supported protocol (for example, **DNS**).

5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.
Binding the DNS Service to the Virtual Server

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

To bind the DNS service to the load balancing virtual server:

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

- `bind lb vserver <name> <serviceName>`
- `show lb vserver <name>`

Example

```plaintext
> bind lb vserver Vserver-DNS-1 Service-DNS-1
Done
> show lb vserver Vserver-DNS-1
  Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul 2 10:32:28 2010
  Time since last state change: 0 days, 00:12:16.80
  Effective State: DOWN  ARP:DISABLED
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services :  1 (Total)       0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE

1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN   Weight: 1
Done
> ```
To unbind a DNS service from the load balancing virtual server:

Use the unbind lb vserver command instead of bind lb vserver.

Parameters for Binding/Unbinding a DNS service to/from a load balancing virtual server

name
The name of the virtual server to/from which the service will be bound/unbound. This is a mandatory argument. Maximum Length: 127

serviceName
The name of the service (created with the addService command) that will be bound or unbound. Maximum Length: 127

To Bind/Unbind a DNS service to/from a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.

3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.

4. Click OK.
Configuring a Client Web Browser to Use a Forward Proxy

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.
Configuring Reverse Proxy Redirection

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the NetScaler receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the backend server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Enabling Cache Redirection and Load Balancing."

For details on how to create a load balancing virtual server, see "Creating a Load Balancing Virtual Server."

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding Services to the Virtual Server."

For details on how to create a reverse proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type REVERSE.
Configuring Mapping Policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).

- Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).

- Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

To configure a mapping policy for reverse proxy mode by using the command line interface

At the command prompt, type the following command to add a policy map and verify the configuration:

- add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]
- show policy map [<mapPolicyName>]

Example
The following command maps a domain in a client request to a target domain:

```
> add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
Done
> show policy map myMappingPolicy
1)  Name: myMappingPolicy
    Source Domain: www.mycompany.com    Source Url:
    Target Domain: www.myrealcompany.com    Target Url:
Done
>
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
Done
> show policy map myOtherMappingPolicy
1)  Name: myOtherMappingPolicy
    Target Domain: www.myrealcompany.com    Target Url: /realnews.html
Done
>
```

### Parameters for creating a mapping policy

**mapPolicyName**

The name of the map policy you are creating.

**sd**

The publicly known source domain name. This is the domain name with which a client request arrives at a reverse proxy virtual server for cache redirection.

**su**

The source URL. Specify all or part of the source URL, in the following format: `/[[prefix] [\*]] [.suffix]`

**td**

The domain name sent to the server. The source domain name is replaced with this name.

**tu**

The target URL. Specify the target URL in the following format: `/[[prefix] [\*]] [.suffix]`
To configure a mapping policy for reverse proxy mode by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Map Policies.

2. In the details pane, click Add.

3. In the Create Map Policy dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for creating a mapping policy" as shown:

   - Name*- mapPolicyName
   - Source Domain*-sd
   - Target Domain*-td
   - Source URL-su
   - Target URL-tu
   * A required parameter

4. Click Create, and then click Close. The Map pane displays the new mapping policy.

To bind the mapping policy to the cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

   - bind cr vserver <name> -policyName <string> [targetVserver]
   - show cr vserver <name>

Example

> bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
Done
> show cr vserver Vserver-CRD-3
Vserver-CRD-3 (10.102.29.50:88) - HTTP Type: CONTENT
  State: UP
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default: Vserver-LB-CR Content Precedence: RULE Cache: REVERSE
  On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY Reuse: ON Via: ON ARP: OFF

1)      Policy:         Target: Vserver-LB-CR Priority: 0 Hits: 0
1)      Map: myMappingPolicy Target: Vserver-LB-CR
Done
To bind the mapping policy to the cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.

3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.

4. In the Policy Name column, select the policy from drop down list.

5. In the Target column, click the down arrow, and then select the vserver from drop down list.

6. Click OK.
Selective Cache Redirection

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The NetScaler first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the NetScaler evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the NetScaler sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the NetScaler, which is configured as a Layer 4 switch that receives traffic on port 80.

The NetScaler can direct requests for images (for example, .gif and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

**Note:** The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the NetScaler, see "Configuring Cache Redirection."
Enabling Content Switching

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the NetScaler, you must enable content switching.

To enable content switching by using the command line interface

At the command prompt, type:

- `enable ns feature cs`
- `show ns feature`

**Example**

```
> enable ns feature cs
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>ON</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>4) Content Switching</td>
<td>CS</td>
<td>ON</td>
</tr>
<tr>
<td>5) Cache Redirection</td>
<td>CR</td>
<td>ON</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>23) HTML Injection</td>
<td>HTMLInjection</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Done
```
To enable cache redirection and load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Configure basic features.

3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.

4. In Enable/Disable Feature(s)? dialog box, click Yes.
Configuring a Load Balancing Virtual Server for the Cache

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see "Creating a Virtual Server".

For details on how to configure services that represent the cache server, see "Configuring an HTTP Service."

For details on how to bind the service to a virtual server, see "Binding/Unbinding a Service to/from a Load Balancing Virtual Server."

For details on how to create a transparent proxy cache redirection server, see "Configuring a Cache Redirection Virtual Server", and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see "Binding Policies to the Cache Redirection Virtual Server."

Configuring a Cache Redirection Policy for a Specific Type of Content

To identify requests that contain a .gif or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

**Note:** If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do not have ".gif" or ".jpeg" extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in "Configuring a Cache Redirection Policy."
Configuring Policies for Content Switching

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .gif and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see “Content Switching.”

You must first create the content switching policy and then bind it to the cache redirection virtual server.

To create a content switching policy by using the command line interface

At the command line, type:

- add cs policy <policyName> [-url <string> | -rule <expression>]
- show cs policy [<policyName>]

Examples

> add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
Done
> show cs policy Policy-CS-JPEG
  Rule: REQ.HTTP.URL == '/*.jpeg'  Policy: Policy-CS-JPEG
  Hits: 0
Done
>
> add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/ *.gif'"
Done
> show cs policy Policy-CS-GIF
  Rule: REQ.HTTP.URL == '/ *.gif'  Policy: Policy-CS-GIF
  Hits: 0
Done
>
> add cs policy Policy-CS-JPEG-URL -url /*.jpg
Done
Parameters for creating a content switching policy

**policyName**

Name of the content switching policy. This is a mandatory parameter, and the value cannot be changed after the policy is created.

**url**

The URL, with wildcards. Specify the string value in this format: // [[prefix ] [^*]] [.suffix]

Maximum value: 208

**rule**

An expression that the NetScaler evaluates to identify non-cacheable requests. Can consist of multiple expressions joined by AND and OR operators.

To create a URL-based content switching policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, click Add.

3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.

4. Select the URL radio button.

5. In the Value text box, type the string value (for example, /sports).

6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.
To create a rule-based content switching policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, click Add.

3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.

4. Select the Expression radio button, and then click Configure.

5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.
   The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.

6. Enter your policy expressions.
   - If you are using classic syntax and need further instructions, see “Configuring Classic Policies and Expressions.”
   - If you are using the default syntax and need further instructions, see “Configuring Default Syntax Expressions: Getting Started.”

7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

To bind the content switching policy to a cache redirection virtual server by using the command line interface

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

- `bind cs vserver <name> <targetVserver> [-policyName <string>]`
- `show cs vserver [<name>]`

**Example**

```plaintext
> bind cs vserver Vserver-CR-1 lbcachepjpeg -policyName Policy-CS-JPEG
Done
> bind cs vserver Vserver-CR-1 lbcachegif -policyName Policy-CS-GIF
```
Parameters for binding a content switching policy to a cache redirection virtual server

**name**

The name of the cache redirection virtual server to which you are binding the content switching policy.

**targetVserver**

The name of the load balancing virtual server to which cacheable requests that match the content switching policy are sent.

**policyName**

The name of the content switching policy that decides the cache server to which cacheable content of a specific type is sent.

**Note:** You are binding the content switching policy to a cache redirection virtual server and not to a content switching virtual server, even though you are using the `bind cs vserver` command.
To bind the content switching policy to a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to bind the policy (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.

4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.

5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.

6. Click OK.
Configuring Precedence for Policy Evaluation

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

To configure precedence for policy evaluation by using the command line interface

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

- set cr vserver <name> [-precedence (RULE | URL)]
- show cr vserver <name>

Example

> set cr vserver Vserver-CRD-1 -precedence URL
Done
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
  State: UP ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down: DISABLED
  Default: Content Precedence: URL Cache: TRANSPARENT
  On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY Reuse: ON Via: ON ARP: OFF
To configure precedence for policy evaluation by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure precedence, (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.
Administering a Cache Redirection Virtual Server

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.
Viewing Cache Redirection Virtual Server Statistics

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual server, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

To view statistics for a cache redirection virtual server by using the command line interface

At the command prompt, type:

`stat cr vserver [<name>]`

Example

```
> stat cr vserver Vserver-CRD-1

Vserver Summary

<table>
<thead>
<tr>
<th>Vserver</th>
<th>IP</th>
<th>Port</th>
<th>Protocol</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vserver-CRD-1</td>
<td>0.0.0.0</td>
<td>80</td>
<td>HTTP</td>
<td>UP</td>
</tr>
</tbody>
</table>

VServer Stats:

</table>

Done
```

>
To view statistics for a cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to view statistics, (for example, Vserver-CRD-1), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server.

To view the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.

2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.

3. To view the statistics by using the dashboard utilities, click the Dashboard tab.

4. Click Applet Client or Web Start Client next to Statistical Utility.

6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.
Enabling or Disabling a Cache Redirection Virtual Server

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

To Enable or Disable a cache redirection virtual servers by using the command line interface

At the command line, type one of the following commands:

- `enable cr vserver <name>`
- `show cr vserver <name>`
- `disable cr vserver <name>`
- `show cr vserver <name>`

Examples

```
> enable cr vserver Vserver-CRD-1
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: UP      ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default:       Content Precedence: URL Cache: TRANSPARENT
                 On Policy Match: ORIGIN L2Conn: OFF     OriginUSIP: OFF
  Redirect: POLICY     Reuse: ON     Via: ON ARP: OFF
1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
Done
>
> disable cr vserver Vserver-CRD-1
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: OUT OF SERVICE   ARP:DISABLED
```
Enabling or Disabling a Cache Redirection Virtual Server

Client Idle Timeout: 180 sec
Down state flush: ENABLED
Disable Primary Vserver On Down: DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
Done

To Enable or Disable a cache redirection virtual servers by using the configuration utility

2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

3. In the details pane, select the virtual server that you want to enable or disable, (for example, Vserver-CRD-1), and then click Statistics.

4. In the Proceed dialog box, click Yes.
Directing Policy Hits to the Cache Instead of the Origin

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the onPolicyMatch parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. CACHE - Directs all matching requests to the cache.
2. ORIGIN - Directs all matching requests to the origin server.

Note: For this option to work, you must select the cacheredirection type as POLICY.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

To change the destination for a policy hit to the origin or the cache by using the command line interface

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

- set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]
- show cr vserver <name>

Example

> set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
Done
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
  State: UP ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
Directing Policy Hits to the Cache Instead of the Origin

Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
   Done

To change the destination for a policy hit to the origin or the cache by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.

4. Select CACHE or ORIGIN from the Redirect To drop-down list.

5. Click OK.
Backing Up a Cache Redirection Virtual Server

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the `backupVServer` parameter, which specifies Backup Virtual Server. Maximum Length: 127

**To specify a backup cache redirection virtual server by using the command line interface**

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

- `set cr vserver <name> [-backupVServer <string>]`
- `show cr vserver <name>`

**Example**

```plaintext
> set cr vserver Vserver-CRD-1 -backupVServer Vserver-CRD-2
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
  State: UP ARP:DISABLED
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default: Content Precedence: URL Cache: TRANSPARENT
  On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY Reuse: ON Via: ON ARP: OFF
  Backup: Vserver-CRD-2

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
Done
```
To specify a backup cache redirection virtual server by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.

4. In the Backup Virtual Server drop-down list, select the virtual server.

5. Click OK.
Managing Client Connections for a Virtual Server

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.
Configuring Client Timeout

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

To configure client timeout by using the command line interface

At the command prompt, type the following commands to configure client timeout and verify the configuration:

- `set cr vserver <name> [-cltTimeout <secs>]`
- `show cr vserver <name>`

Example

```
> set cr vserver Vserver-CRD-1 -cltTimeout 6000
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
State: UP  ARP:DISABLED
Client Idle Timeout: 6000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default:        Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE  L2Conn: OFF   OriginUSIP: OFF
Redirect: POLICY        Reuse: ON     Via: ON ARP: OFF
Backup: Vserver-CRD-2
1)      Cache bypass  Policy: bypass-cache-control
2)      Cache bypass  Policy: Policy-CRD
Done
```
To configure client timeout by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.

4. In the Client Time-out(secs) text box, enter the time-out value in seconds.

5. Click OK.
Inserting Via Headers in the Requests

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

To enable or disable Via-header insertion in client requests by using the command line interface

At the command prompt, type:

- set cr vserver <name> [-via (ON|OFF)]
- show cr vserver <name>

Example

> set cr vserver Vserver-CRD-1 -via ON
Done
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
  State: UP ARP:DISABLED
  Client Idle Timeout: 6000 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default: Content Precedence: URL Cache: TRANSPARENT
  On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY Reuse: ON Via: ON ARP: OFF
  Backup: Vserver-CRD-2

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
Done
>
To enable or disable Via-header insertion in client requests by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.

4. Select the Via check box.

5. Click OK.
Reusing TCP Connections

You can configure the NetScaler appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the NetScaler. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

To enable or disable the reuse of TCP connections by using the command line interface

At the command prompt, type:

- `set cr vserver <name> [-reuse (ON|OFF)]`
- `show cr vserver <name>`

Example

```
> set cr vserver Vserver-CRD-1 -reuse ON
Done
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: UP  ARP:DISABLED
  Client Idle Timeout: 6000 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default:        Content Precedence: URL Cache: TRANSPARENT
  On Policy Match: CACHE  L2Conn: OFF   OriginUSIP: OFF
  Redirect: POLICY        Reuse: ON     Via: ON ARP: OFF
  Backup: Vserver-CRD-2

  1) Cache bypass  Policy: bypass-cache-control
  2) Cache bypass  Policy: Policy-CRD

Done
```
To enable or disable the reuse of TCP connections by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.

4. Select the Reuse check box.

5. Click OK.
Configuring Delayed Connection Cleanup

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

To enable of disable the down state flush option by using the command line interface

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

- set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
- show cr vserver <name>

Example

> set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
  Done
> show cr vserver Vserver-CRD-1
  Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
  State: UP   ARP:DISABLED
  Client Idle Timeout: 6000 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  Default:     Content Precedence: URL Cache: TRANSPARENT
  On Policy Match: CACHE   L2Conn: OFF OriginUSIP: OFF
  Redirect: POLICY     Reuse: ON   Via: ON ARP: OFF
  Backup: Vserver-CRD-2

1)   Cache bypass Policy: bypass-cache-control
2)   Cache bypass Policy: Policy-CRD
    Done
To enable or disable the reuse of TCP connections by using the configuration utility

1. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.

3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.

4. Select the Down state flush check box.

5. Click OK.
N-Tier Cache Redirection

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the NetScaler appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the NetScaler appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called n-tier cache redirection.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a NetScaler appliance have to be fully transparent. However, if you configure transparent cache redirection, with the NetScaler appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

How N-tier Cache Redirection Is Implemented

To solve the problem, NetScaler n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier NetScaler appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier NetScaler appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the NetScaler from which it received the request and send the response to the same NetScaler.

The lower-tier NetScaler appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the NetScaler to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier NetScaler, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier NetScaler appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier NetScaler appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.
The upper-tier NetScaler appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination NetScaler from the source port range.

## Setup Necessary for Configuring N-Tier CRD

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier NetScaler appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination port.
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier NetScaler appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier NetScaler and bind all the services to the virtual server.

For each lower-tier NetScaler appliance:

- Configure the cache redirection port range on the NetScaler. Assign an exclusive range to each lower-tier NetScaler.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this NetScaler. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
  - Add a source IP expression to include the client IP in the header.
  - Enable the Use Port Range option.
How N-Tier Cache Redirection Works During a Cache Hit

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.
Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.

2. L1NS1 load balances the request to L2NS2.

3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.

4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.

5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the NetScaler in the upper tier.

6. The router forwards the response to Client A.

How N-Tier Cache Redirection Works During a Cache Bypass

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.
Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier NetScaler, L1NS2.
5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the NetScaler in the upper tier.
7. The router forwards the response to Client A.

How N-Tier Cache Redirection Works During a Cache Miss

The following figure shows how cache redirection works when a client request is not cached.
Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.
Traffic Flow

1. Client sends a request, and the router forwards it to L1NS1.

2. L1NS1 load balances the request to L2NS2.

3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.

4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the NetScaler in the lower tier. L2NS3 intercepts the traffic.

5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.

6. The origin server sends the response to an upper-tier NetScaler, L1NS2.

7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate NetScaler in the lower tier, L2NS3.

8. L2NS3 forwards the response to the router.

9. The router forwards the response to Client A.
Configuring the Upper-Tier NetScaler Appliances

Configure each of the upper-tier NetScaler appliances as follows.

**To configure an upper-tier appliance for n-tier cache redirection by using the command line interface**

At the command prompt, type the following commands:

- `add service <name>@ <serviceIP> <serviceType> <port>`
  
  Run this command for each service to be added.

- `add lb vserver <name>@ ANY * <port> -persistenceType <persistenceMethod> -lbMethod <lbMethod> -m MAC -sessionless ENABLED -cltTimeout <client_Timeout_Value>`

- `bind lb vserver <name>@ <serviceName>`
  
  Run this command for each service to be bound.

- `enable ns mode l3`

- `add ns pbr <name> <action> -srcPort <sourcePortNumber> -destPort <startPortNumber-endPortNumber> -nexthop <serviceIpAddress> -protocol TCP`

- `apply ns pbrs`

  Run this command after adding all the necessary PBRs.

**Parameters for configuring a service**

- **name**
  
  Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

- **serverName**

  Either the name of a previously created server object, or the IP address of the load-balanced server that hosts this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.
If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDPHTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP.

**port**

Port on which the service listens. The port number must be a positive number not greater than 65534.

### Parameters for creating a virtual server

**name**

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

**IPAddress**

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

**serviceType**

The type of services to which the virtual server distributes requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, and MSSQL. HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP

**port**

Port on which the virtual server listens for client connections. The port number must be between 0-65535.
To configure an upper-tier appliance for n-tier cache redirection by using the configuration utility

1. Enable L3 mode:
   a. In the navigation pane, click System, and then click Settings.
   b. In the Settings group, click the Configure modes link.
   c. Select the Layer 3 Mode (IP Forwarding) check box.
   d. Click OK.

2. Configure policy-based routing (PBR):
   a. In the navigation pane, click Network, and then click PBRs.
   b. In the Policy-Based Routing (PBRs) pane, click Add.
   c. Type a name for the PBR.
   d. Select the action as Allow.
   e. In the Next Hop box, type the IP address of the service, which represents a lower-tier NetScaler.
   f. Select TCP from the Protocol drop-down list.
   g. Type the source port and the range of the destination port corresponding to the lower-tier NetScaler being added.
   h. Click Create.
   i. In the details pane, select the PBR and click Apply.
   j. Repeat Step (i) to Step (vii) for each lower-tier NetScaler.

3. Create a service for each lower-tier NetScaler:
   a. In the navigation pane, expand Load Balancing, and then click Services.
   b. In the details pane, click Add.
   c. Specify the name, protocol, IP address, and port. The protocol should be ANY.
   d. Click Create.

4. Configure a load balancing virtual server:
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   b. In the details pane, click Add.
   c. Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be *.
d. In the Services tab, select the services that represent the lower-tier NetScaler appliances.

e. In the Advanced tab, select the Redirection Mode as MAC Based and select the Sessionless check box.

f. Click Create.
Configuring the Lower-Tier NetScaler Appliances

Configure each of the lower-tier NetScaler appliances as follows.

**To configure a lower-tier appliance for n-tier cache redirection by using the command line interface**

At the command prompt, type the following commands:

- `add service <name>@<cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP" -cachetype transparent`
  
  Repeat for each cache server.

- `add lb vserver <name>@<serviceType> -m MAC`
  
  `bind lb vserver <name>@<cacheServiceName>`
  
  Repeat for each cache server.

- `add cr vserver <name> <serviceType> * <port> -srclExpr "HTTP.REQ.HEADER("\"ClientIP\")" -originusip ON -cacheVserver <cachevServerName> -usePortRange ON`

- `set ns param-crPortRange <startPortNumber-endPortNumber>`

**Parameters for configuring a service**

**name**

Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**serverName**

Either the name of a previously created server object, or the IP address of the load-balanced server that hosts this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.

If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.
serviceType

The type of connections that the service will handle. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDPHTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP.

port

Port on which the service listens. The port number must be a positive number not greater than 65534.

Parameters for creating a virtual server

name

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

IPAddress

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

serviceType

The type of services to which the virtual server distributes requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, and MSSQLHTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP

port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.
To configure a lower-tier appliance for n-tier cache redirection by using the configuration utility

1. Create a service for each cache server. To create a service:
   a. In the navigation pane, expand Load Balancing, and then click Services.
   b. In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
   c. In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
   d. In the Cache Type box, select Transparent Cache.
   e. Click Create.

2. Configure a load balancing virtual server:
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   b. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
   c. In the Services tab, select the services that represent the cache servers.
   d. In the Advanced tab, for Redirection Mode, select MAC Based.
   e. Click Create.

3. Configure a cache redirection virtual server:
   a. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
   b. In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
   c. For Cache Type, select Transparent.
   d. On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type \texttt{HTTP.REQ.HEADER("ClientIP")}.
   e. Click Create.

4. Assign a source port range for the NetScaler:
   a. In the navigation pane, click System, and then click Settings.
   b. In the Settings group, click the Change global system settings link.
   c. In the Cache Redirection Port Range group, specify the port range for the NetScaler by typing a port number for Start Port and a port number for End Port.
   d. Click OK.
In today’s complex Web sites, you may want to present different content to different users. For example, you may want to allow users from the IP range of a customer or partner to have access to a special Web portal. You may want to present content relevant to a specific geographical area to users from that area. You may want to present content in different languages to the speakers of those languages. You may want to present content tailored to specific devices, such as smartphones, to those who use the devices. The Citrix NetScaler content switching feature enables the NetScaler appliance to distribute client requests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.
How Content Switching Works

Content Switching enables the NetScaler appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content on the basis of various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.

- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client’s browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.

- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.

- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture
A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a content group—a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using NetScaler classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the NetScaler appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see “Configuring Default Syntax Policies.”

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer, you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.
Configuring Basic Content Switching

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of web sites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

**Note:** After creating a content group, you can modify its content switching virtual server to customize the configuration. For information on modifying the configuration of an existing content switching virtual server, see "Customizing the Basic Content Switching Configuration." For information on disabling and re-enabling entities, unbinding policies, and removing entities, see "Managing a Content Switching Setup."
Enabling Content Switching

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

**To enable content switching by using the command line interface**

At the command prompt, type the following commands to enable content switching and verify the configuration:

- `enable ns feature CS`
- `show ns feature`

**Example**

```
> enable feature ContentSwitch
Done
> show feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>4) Content Switching</td>
<td>CS</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>22) Responder</td>
<td>RESPONDER</td>
<td>ON</td>
</tr>
<tr>
<td>23) HTML Injection</td>
<td>HTMLInjection</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Done
```
To enable content switching by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Content Switching check box, and then click OK.
4. In the Enable/Disable Features(?) dialog box, click Yes.
Creating Content Switching Virtual Servers

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

To create a virtual server by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <protocol> <IPAddress> <port>
```

Example

```
add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
```

Parameters for configuring content switching

vServerName

Name of the content switching virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and blank space.

IPAddress

IP address of the virtual server. This IP address (VIP) is usually a public IP address to which the clients send connection requests.

port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

protocol

Protocol of the requests processed by the content switching virtual server. Choose one of the following service types:

- **HTTP**. For HTTP services.
- **TCP**. For non-RFC implementation of HTTP services.
Creating Content Switching Virtual Servers

- **UDP.** For DNS, ICMP, and other UDP-based services.
- **FTP.** For FTP services. This setting ensures that the NetScaler appliance takes care of the specifics of the FTP protocol.
- **SSL.** For HTTPS services. Select this type to encrypt HTTP traffic between the NetScaler appliance and the server.
- **SSL_TCP.** For secure TCP services.
- **RTSP.** For Real-Time Streaming Protocol services.
- **DNS.** For domain name servers.
- **SIP-UDP.** For SIP servers.
- **ANY.** For services that accept all traffic of any protocol type.
- **RADIUS.** For RADIUS authentication services.
- **RDP.** For remote desktop services.
- **MYSQL.** For MySQL database servers.
- **MSSQL.** For Microsoft SQL Servers.

To add a content switching virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Content Switching) dialog box, in the Name, IP Address, and Port text boxes, type the name, IP address, and port of the virtual server, (for example, Vserver-CS-1, 10.102.29.161, and 80).

   **Note:** If you need to enter an IPv6 address, select the IPv6 check box before you enter the address.

4. In the Protocol list, select the type of the virtual server (for example, HTTP).

5. Click Create, and then click Close.
Configuring a Load Balancing Setup for Content Switching

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see "Load Balancing." For detailed instructions on setting up a basic load balancing configuration, see "Setting Up Basic Load Balancing."
Configuring a Content Switching Action

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Consequently, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

**Note:** You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server. For more information, see "Binding Policies to a Content Switching Virtual Server."
Configuring an Action that Specifies the Name of the Target Load Balancing Virtual Server

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface

At the command prompt, type:

- `add cs action <name> -targetLBVserver <string> [-comment <string>]`
- `show cs action <name>`

Example

```
> add cs action mycsaction -targetLBVserver mylbvserver -comment "Forwards requests to mylbvserver."
Done
> show cs action mycsaction
    Name: mycsaction
    Target LB Vserver: mylbvserver
    Hits: 0
    Undef Hits: 0
    Action Reference Count: 0
    Comment: "Forwards requests to mylbvserver."

Done
>
```
Parameters for creating a content switching action that specifies the name of the target load balancing virtual server

name (Name)

Name for the content switching action. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the content switching action is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my csaction” or ‘my csaction’).

targetLBVserver (Target LB Virtual Server)

Name of the load balancing virtual server to which to forward requests matching the rule in the content switching policy.

comment (Comment)

Any comments that you might want to associate with the content switching action.

To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Actions.

2. In the details pane, do one of the following:

   · To create a content switching action, click Add.

   · To modify a content switching action, select the content switching action, and then click Open.

3. In the Create Content Switching Action or Configure Content Switching Action dialog box, set the following parameters:

   · Name*

   · Target LB Virtual Server* (Under Target LB Virtual Server, click Name.)

   · Comment

* A required parameter

4. Click Create.
Configuring an Action that Specifies an Expression for Selecting the Target at Run Time

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple `TRUE` (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests on the basis of the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as `mylb_`. For example, load balancing virtual servers for HTML pages and PDF files could be named `mylb_html` and `mylb_pdf`, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is "mylb_"+HTTP.REQ.URL.SUFFIX. If the content switching virtual server receives a request for an HTML page, the expression returns `mylb_html`, and the request is switched to virtual server `mylb_html`.

**To create a content switching action that specifies an expression, by using the command line interface**

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

- `add cs action <name> -targetVserverExpr <expression> [-comment <string>]`
- `show cs action <name>`

**Example**

```
> add cs action mycsaction1 -targetVserverExpr "mylb_" + HTTP.REQ.URL.SUFFIX
Done
> show cs action mycsaction1
Name: mycsaction1
Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
Target LB Vserver: No_Target
```
Parameters for creating a content switching action that specifies an expression

name (Name)

Name for the content switching action. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the content switching action is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my csaction" or 'my csaction').

targetVserverExpr (Target LB Expression)

Expression in the default syntax, for computing the name of the load balancing virtual server at run time.

Comment (Comment)

Any comments that you might want to associate with the content switching action.

To configure a content switching action that specifies an expression by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Actions.

2. In the details pane, do one of the following:
   - To create a content switching action, click Add.
   - To modify a content switching action, select the content switching action, and then click Open.

3. In the Create Content Switching Action or Configure Content Switching Action dialog box, set the following parameters:
   - Name*
   - Target LB Expression* (Under Target LB Virtual Server, click Expression.)
   - Comment
   - * A required parameter

4. Click Create.
Configuring Content Switching Policies

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using NetScaler classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The NetScaler appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.

- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.

- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

  **Note:** A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about NetScaler classic policies and expressions, see "Configuring Classic Policies and Expressions." For information about Default Syntax policies, see "Configuring Default Syntax Expressions."

To create a content switching policy by using the command line interface

At the command prompt, type one of the following commands:

- `add cs policy <policyName> -domain <domain>`
- `add cs policy <policyName> -url <URLValue>`
- `add cs policy <policyName> -rule <RULEValue>`
- `add cs policy <policyName> -rule <RULEValue> -action <actionName>`
Configuring Content Switching Policies

Example

add cs policy Policy-CS-1 -url "/sports/*"
add cs policy Policy-CS-1 -domain "example.com"
add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ(10.217.84.0)"
add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009 Dec)"
add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1

Parameters for configuring content switching policies

policyName (Name)

Name for the content switching policy. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters. If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my policy” or ‘my policy’).

Cannot be changed after the policy is created.

domain (Domain)

The domain in the URL. The NetScaler appliance uses the domain to choose the correct content for each incoming request.

URLValue (URL)

An absolute or relative URL. The NetScaler appliance uses the URL to choose the correct content for each incoming request.

RULEValue (Expression)

A classic or default syntax policy expression that defines the appropriate content for each request.

action (Action)

Name of the content switching action to be used by the policy.
**To create a content switching policy by using the configuration utility**

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, click Add.

3. In the Create Content Switching Policy dialog box, in the Name text box, type the name of the policy (for example, Policy-CS-1).

4. Choose the type of policy that you want to create, and configure the policy.
   - To create a domain-based policy, in the Domain text box, type the domain (for example, example.com).
   - To create a URL-based policy, click URL, and in the Value text box, type an absolute or relative URL (for example, http://www.example.com/sports, or just /sports).
   - To create a rule-based policy, click Configure, and do the following:
     a. In the Create Expression dialog box, choose the expression syntax you want to use.
        - If you want to use default syntax, accept the default and proceed to the next step.
        - If you want to use classic syntax, click Switch to Classic Syntax.

        The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.
     b. Enter your policy expressions.
        - If you are using classic syntax and need further instructions, see **Configuring Classic Policies and Expressions**.
        - If you are using the default syntax and need further instructions, see **Configuring Default Syntax Expressions**.

5. Click Create, and then click Close. The policy you created appears in the Content Switching Policies pane.
Configuring Content Switching Policy Labels

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

For information about policy labels, see the "Creating Policy Labels."

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the NetScaler command line or the configuration utility to configure content switching policy labels. In the NetScaler command-line interface (CLI), you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the NetScaler configuration utility, you perform both tasks in a single dialog box.

To create a content switching policy label by using the command line interface

At the command prompt, type:

```bash
add cs policylabel <labelName> <cspolicylabelTypetype>
```

Example

```bash
add cs policylabel testpollab http
```
Parameters for creating content switching policy labels

name (Name)

Name for the policy label. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at sign (@), equal sign (=), and hyphen (-) characters. If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my label” or ‘my label’). The label name must be unique within the list of policy labels for content switching. Cannot be changed after the policy label is created.

type (Label type)

Protocol supported by the policy label. All policies bound to the policy label must either match the specified protocol or be a subtype of that protocol. Available settings function as follows:

- **HTTP**—Supports policies that process HTTP traffic. Used to access unencrypted Web sites.
- **SSL**—Supports policies that process HTTPS/SSL encrypted traffic. Used to access encrypted Web sites.
- **TCP**—Supports policies that process any type of TCP traffic, including HTTP.
- **SSL_TCP**—Supports policies that process SSL-encrypted TCP traffic, including SSL.
- **UDP**—Supports policies that process any type of UDP-based traffic, including DNS.
- **DNS**—Supports policies that process DNS traffic.
- **ANY**—Supports all types of policies except HTTP, SSL, and TCP.
- **SIP_UDP**—Supports policies that process UDP based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).
- **RTSP**—Supports policies that process Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data, such as audio, video, and other types of streamed media.
- **RADIUS**—Supports policies that process Remote Authentication Dial In User Service (RADIUS) traffic. RADIUS supports combined authentication, authorization, and auditing services for network management.
- **RDP**—Supports policies that process remote desktop traffic.
- **MYSQL**—Supports policies that process MYSQL traffic.
- **MSSQL**—Supports policies that process Microsoft SQL traffic.

All policies bound to the policy label must either match the designated protocol or be a subtype of the designated protocol.
To bind a policy to a content switching policy label by using the command line interface

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

- `bind cs policylabel <labelName> <policyName> <priority> [-targetVserver <string>] | [-gotoPriorityExpression <expression>] | [-invoke <labeltype> <labelName>]`

- `show cs policylabel <labelName>`

**Example**

```bash
bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
show cs policylabel testpollab
  Label Name: testpollab
  Label Type: HTTP
  Number of bound policies: 1
  Number of times invoked: 0
  1) Policy Name: test_Pol
     Priority: 100
     Target Virtual Server: LBVIP
```

**Note:** If a policy is configure with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configure with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

**Parameters for binding a policy to a content switching policy label**

- **labelName**
  
  Name of the policy label to which to bind a content switching policy.

- **policyName**
  
  Name of the content switching policy to bind to the content switching policy label.

- **priority**
  
  Unsigned integer that determines the priority of the policy relative to other policies in this policy label. Smaller the number, higher the priority.

- **targetVserver**
  
  Name of the virtual server to which to forward requests that match the policy.
gotoPriorityExpression

Expression or other value specifying the priority of the next policy to be evaluated if the current policy rule evaluates to TRUE. Alternatively, you can specify one of the following values:

- **NEXT.** Go to the policy with the next higher priority.
- **END.** End evaluation. (This is the default. Evaluation stops if the gotoPriorityExpression parameter is not set.)
- **USE_INVOCATION_RESULT.** Applicable if this entry invokes another policy label. If the final Goto in the invoked policy label has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy label performs a NEXT.

invoke

Invoke other policy labels. After evaluating the policies in the invoked policy label, the appliance continues to evaluate policies that are bound to the current policy label (the selected bind point).

labelType

Type of policy label to be invoked.

To unbind a policy from a policy label by using the command line interface

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

- `unbind cs policylabel <labelName> <policyName>`
- `show cs policylabel <labelName>`

**Example**

```bash
unbind cs policylabel testpollab test_Pol
show cs policylabel testpollab
  Label Name: testpollab
  Label Type: HTTP
  Number of bound policies: 0
  Number of times invoked: 0
```

Parameters for unbinding a policy from a content switching policy label

**labelName**
Name of the policy label from which to unbind a content switching policy.

**policyName**

Name of the content switching policy to unbind from the label.

To remove a policy label by using the command line interface

At the command prompt, type:

```
rm cs policylabel <labelName>
```

To manage a content switching policy label by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policy Labels.
2. In the details pane, do one of the following:
   - To create a new policy label, click Add.
   - To modify an existing policy label, select the policy label, and then click Open.
3. In the Create Content Switching Policy Label dialog box, set the following parameters:
   - Name*
   - Label Type*
   * A required parameter
4. To add a policy to a list, click Insert Policy, and then click one of the policies in the drop-down list. If you click New Policy, create a new policy as described in "Creating Content Switching Policies."
5. For the policy that you added to the list, set the following parameters:
   - Priority* (The default value is 100. To modify the value, double-click in the Priority column.)
   - Target
   - Goto Expression
   - Invoke
   * A required parameter
6. To automatically renumber the policies, click Regenerate Priorities.
7. Click Create or OK.
After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

**Note:** If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see Configuring a Content Switching Action.

### To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the command line interface

At the command prompt, type:

```bash
bind cs vserver <name> [-lbvserver <string> -targetLBVServer <string> -priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>)]
```

**Example**

```bash
bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT
bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression 'q.header("a").count' -flowtype REQUEST -invoke policylabel label1
bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -priority 20
```

**Note:** The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.
To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, double-click the virtual server for which you want to bind the policy (for example, Vserver-CS-1).

3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy. A list of existing policies appears in the Policy Name drop-down list. You can either select an existing policy or create a new policy:
   - Select an existing policy that you previously created to bind to the virtual server.
   - Select New Policy from the Policy Name drop-down list to create a new content switching policy. After you create a new policy, it is automatically bound to the virtual server.

4. Click OK.
Verifying the Configuration

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.
Viewing the Properties of Content Switching Virtual Servers

You can view the properties of content switching virtual servers that you have configured on the NetScaler. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

**Note:** If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

- `show cs vserver`
- `show cs vserver <name>`

**Example**

1. `show cs vserver Vserver-CS-1`

   Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
   State: UP
   Last state change was at Thu Jun 30 10:48:59 2011

To view the properties of content switching virtual servers by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, click a virtual server to display its configuration details at the bottom of the screen.

3. To display the names of the policies that are bound to the content switching virtual server, double-click the virtual server and then click the Policies tab.
Viewing Content Switching Policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

- show cs policy
- show cs policy <PolicyName>

**Example**

show cs policy

show cs policy Policy-CS-1

To view the properties of content switching policies by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, double-click a policy to view the details.

3. To view the policy labels and virtual servers that this policy is bound to, on the Content Switching Policies pane, click Show Bindings.
Viewing a Content Switching Virtual Server Configuration by Using the Visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

**Note:** The Visualizer requires a graphical interface, so it is available only through the configuration utility.
To view a content switching configuration by using the Visualizer in the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Content Switching Visualizer window, you can adjust the viewable area as follows:

   - Click the Zoom In and Zoom Out icons to increase or decrease the viewable area.
   - Click the Save Image icon to save the graph as an image file.
   - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.

4. To view configuration details for entities that are bound to this virtual server, you can do the following:

   - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
   - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   - To view the configuration details for a monitor, click the icon for the monitor, click the Related Tasks tab, and then click View Monitor.

5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click Statistics.

6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff.

7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.

8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.

   **Note:** This option is available only on NetScaler nCore builds.
9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.

10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see AppExpert.
Customizing the Basic Content Switching Configuration

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.
Configuring Case Sensitivity for Policy Evaluation

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the NetScaler appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

To configure case sensitivity by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -caseSensitive (ON|OFF)
```

Example

```
set cs vserver Vserver-CS-1 -caseSensitive ON
```

Parameters for configuring case sensitivity

**vServerName**

The name of the content switching virtual server that you are configuring. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

**caseSensitive**

The URL lookup case option on the content switching vserver. If case sensitivity of a content switching virtual server is set to 'ON', the URLs /a/1.html and /A/1.HTML are treated differently and may have different targets (set by content switching policies).

If case sensitivity is set to 'OFF', the URLs /a/1.html and /A/1.HTML are treated the same, and will be switched to the same target.

Possible values: ON, OFF

Default value: ON
To configure case sensitivity by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure case sensitivity (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select Case Sensitivity check box, and then click OK.
Setting the Precedence for Policy Evaluation

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You do not normally have to configure precedence: the default precedence works correctly in many cases. If you want to make sure that one policy or set of policies is applied first, however, and another policy or set of policies is applied only if the first set does not match a request, you can configure either URL-based precedence or rule-based precedence.

Precedence with URL-Based Policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an “HTTP 404 Not Found” error message is sent to the client.

Note: You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served
based on client attributes (such as Accept-Language), you must use rule-based precedence.

**Precedence with Rule-Based Policies**

If you configure precedence based on rules, which is the default setting, the request is tested on the basis of the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an “HTTP 404 Not Found” error message is sent to the client.

**To configure precedence by using the command line interface**

At the command prompt, type:

```
set cs vserver <name> -precedence ( RULE | URL )
```

**Example**

```
set cs vserver Vserver-CS-1 -precedence RULE
```

**Parameters for configuring precedence**

**vServerName**

The name of the content switching virtual server that you are configuring. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**precedence**

The type of precedence to use for both RULE-based and URL-based policies on the content switching virtual server. With the precedence set to RULE, incoming requests are evaluated against the rule-based content switching policies. If none of the rules match, the URL in the request is evaluated against the URL-based content switching policies. Possible values: RULE, URL. Default: RULE.
To configure precedence by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure precedence, (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, under Precedence, click Rule or URL, and then click OK.
Configuring per-VLAN Wildcarded Virtual Servers

If you want to configure content switching for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```
add cs vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
```

Example

```
add cs vserver Vserver-CS-vlan1 ANY * *
   -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
```

Parameters for configuring per-VLAN wildcarded virtual servers

**name**

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ \ . (period) : (colon) # and space ( ).

**IPAddress**

IP address of the virtual server. For wildcarded virtual servers bound to VLANs, this is always *.

**type**

Behavior of the service. Select one of the following service types: HTTP, SSL, TCP, FTP, RTSP, SSL_TCP, UDP, DNS, SIP_UDP, ANY, RADIUS, RDP, MYSQL, MSSQL.

**port**

Port on which the virtual server listens for client connections. The port number must be in the range 0-65535. For wildcarded virtual servers bound to VLANs, the setting is
normally *.

**listenpriority**

The priority assigned to the listen policy. This can be any positive integer. Priority is evaluated in reverse order; the lower the number, the higher the priority assigned to the listen policy.

**rule**

The policy rule to use to identify the VLAN that you want this virtual server to listen to. This rule is:

CLIENT.VLAN.ID.EQ(<integer>)

For <integer>, substitute the ID number assigned to the VLAN.
To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, do one of the following:

   - To create a new virtual server, click Add.
   - To modify an existing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Services tab, type or select values for the following parameters:

   - Name*—name
   - Protocol*—type
   - IP address*—IPAddress
   - Port—port
   * A required parameter

4. In the Advanced tab, expand Listen Policy, and then type or select values for the following parameters:

   - Listen Priority*—priority
   - Listen Policy Rule*—rule
   * A required parameter

5. Click Create or OK, depending on whether you are creating a new virtual server or modifying an existing virtual server.

6. Click Close. The virtual server that you created now appears in the Virtual Servers page.

7. To remove a virtual server, in the Virtual Servers pane select the virtual server, and then click Remove.

After you have created this virtual server, you bind it to one or more services as described in Binding Services to the Virtual Server.
Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -mssqlServerVersion <mssqlServerVersion>
- show cs vserver <name>

Example

> set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2
Done
> show cs vserver myMSSQLcsvip
  myMSSQLcsvip (192.0.2.13:1433) - MSSQL  Type: CONTENT
  State: UP
  . . .
  . . .
  MSSql Server Version: 2008R2
  . . .
  . . .
Done
>

Parameters for configuring the MS SQL Server version setting

name

The name of the virtual server for which you want to configure the MS SQL Server version setting.
mssqlServerVersion

The version of MS SQL Server that you are using. Following are the possible values:

- 70, for Microsoft SQL Server 7.0
- 2000, for Microsoft SQL Server 2000
- 2000SP1, for Microsoft SQL Server 2000 Service Pack 1 (SP1)
- 2005, for Microsoft SQL Server 2005
- 2008, for Microsoft SQL Server 2008
- 2008R2, for Microsoft SQL Server 2008 R2

To set the Microsoft SQL Server version parameter by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the setting, and then click Open.

3. In the Configure Virtual Server dialog box, do the following:
   a. In the advanced tab, click MsSql.
   b. In the Server Version list, select the version of your Microsoft SQL Server product.
   c. Click Create or OK, and then click Close.
Protecting the Content Switching Setup against Failure

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

- Configure a backup content switching virtual server.
- Configure spillover for preventing the overloading of the primary and diverting excess traffic to the backup virtual server.
- Specify a redirect URL, the URL to which the content is switched if both the primary and backup content switching virtual servers are DOWN.
- Enable the State Update option for marking a content switching virtual server as DOWN when the load balancing virtual server is DOWN.
- Flush the surge queues when the queues become too long.
Configuring a Redirection URL

You can configure a redirect URL to communicate the status of the NetScaler appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user’s browser.

To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -redirectURL <URLValue>
```

Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

Parameters for configuring a redirect URL

vServerName

The name of the content switching virtual server that you are configuring. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

URLValue

URL to which traffic is redirected if the content switching virtual server becomes unavailable. This value must not exceed 127 characters. The domain specified in the URL
must not match the domain specified in the domain name argument of a content switching policy. If the same domain is specified in both arguments, the request is redirected continuously to the same unavailable virtual server in the NetScaler, and the user cannot get the requested content.

To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure a redirect URL (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, in the Redirect URL text box, type the redirect URL (for example, http://www.newdomain.com/mysite/maintenance).

4. Click OK.
Configuring a Backup Virtual Server

If the primary content switching virtual server is marked DOWN or DISABLED, the NetScaler appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter Disable Primary When Down to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

Note: If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

To set up a backup content switching virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON|OFF)
```

Example

```
set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -disablePrimaryOnDown ON
```

Parameters for configuring a backup virtual server

**primaryVServer**

The name of the primary virtual server for which you are configuring a backup. This alphanumeric string is required and cannot be changed after the virtual server is
Configuring a Backup Virtual Server

created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

backupVServer

The name of the backup virtual server that you are configuring. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

You can create a virtual server and specify the name, IP address, port, and type as described in Creating Content Switching Virtual Servers. You can use the name of the content switching virtual server as a backup content switching virtual server.

disablePrimaryOnDown

Configures the appliance to leave the former primary virtual server as secondary until you manually set it to take over as the primary. Possible Values: ON, OFF. Default: OFF.

To set up a backup content switching virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to set up a backup content switching virtual server (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.

4. In the Backup Virtual Server list, select the backup virtual server (for example, Vserver-CS-2).

5. If you want to configure the backup server to remain as the primary server after the primary virtual server is brought back up, select the Disable Primary When Down check box.

6. Click OK.
Diverting Excess Traffic to a Backup Virtual Server

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -soMethod <methodType> -soThreshold <thresholdValue> -soPersistence <persistenceValue> -soPersistenceTimeout <timeoutValue>
```

**Example**

```
set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```

**Parameters for configuring spillover**

**vServerName**

The name of the content switching virtual server for which you are configuring spillover. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**soMethod**

Type of spillover used to divert traffic to the backup content switching virtual server when the virtual server reaches the spillover threshold. The valid options for this
parameter are: CONNECTION, BANDWIDTH, and NONE. For more information about how each of these methods work, see Load Balancing.

soThreshold

For the CONNECTION spillover type, the Threshold value is the maximum number of connections a virtual server can handle before spillover. For the BANDWIDTH spillover type, the Threshold value is the amount of incoming and outgoing traffic (in kilobits per second) that a virtual server can handle before spillover occurs. The minimum value is 1, and the maximum value is 4294967294.

soPersistence

The spillover persistence state. If you enable spillover persistence, the NetScaler maintains sourceIP-based persistence over primary virtual server and backup content switching virtual servers. The valid options for this parameter are: ENABLED and DISABLED. The default value is DISABLED.

soPersistenceTimeout

This value sets the timeout for spillover persistence. The default value is 2 minutes. The minimum value is 2 minutes, and the maximum value is 1440 minutes.

To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure spillover (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, under Spillover, in the Method list, select the type of spillover, and in Threshold text box, type the threshold value (for example, Connection and 1000).

4. Select the Persistence check box and, in Persistence Time-out (min) text box, type the timeout value (for example, 2).

5. Click OK.
Configuring the State Update Option

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

**When State Update is disabled:**

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

**When State Update is enabled:**

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

**To configure the state update option by using the command line interface**

At the command prompt, type:

```
add cs vserver <name> <protocol> <ipAddress> <port> -stateUpdate ENABLED
```

**Example**

```
add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED -cltTimeout 180
```
Parameters for configuring state update option

**vServerName**

Name of the content switching virtual server. This alphanumeric string is required and cannot be changed after the content switching virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and blank space.

**ipAddress**

IP address of the virtual server. This IP address (VIP) is usually a public IP address to which the clients send connection requests.

**port**

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

**protocol**

Protocol of the requests processed by the content switching virtual server. Possible values: HTTP, TCP, UDP, FTP, SSL, SSL_TCP, RTSP, DNS, SIP-UDP, ANY.

**stateUpdate**

Status of the content switching virtual server according to the status of the bound load balancing virtual server. Possible values: ENABLED, DISABLED. DEFAULT: DISABLED.
To configure the state update option by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, do one of the following:
   - To add a virtual server, click Add.
   - To modify a virtual server, select the server, and click Open.

3. In the Create Virtual Server (Content Switching) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring content switching” as shown:
   - Name-vServerName
   - IP Address-ipAddress
     - **Note**: If you need to enter an IPv6 address, select the IPv6 check box before you enter the address.
   - Port-port
   - Protocol-protocol

4. On the Advanced tab, select the State Update check box.

5. Click Create.

6. Select the new virtual server, click Open, and verify the settings.
Flushing the Surge Queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

**Note:** You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

**Note:** Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:
Flushing the Surge Queue

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.

- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.

- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.

- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.

- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.

- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
```

### Examples

1.

```
flush ns surgeQ -name SVC1ANZGB -serverName 10.10.10.1 80
```

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address 10.10.10.1 and port 80.

2.

```
flush ns surgeQ
```

The above command flushes all the surge queues on the appliance.

### Parameters for flushing a surge queue

- **name**
  
  Name of a virtual server, service or service group

- **serverName**
  
  Name of a service group member
To flush a surge queue by using the configuration utility

1. In the navigation pane, expand Load Balancing.

2. To select an entity, do one of the following:
   - To flush the surge queue of a virtual server, click Virtual Servers, and then select the virtual server.
   - To flush the surge queue of a service, click Services, and then select the service.
   - To flush the surge queue of all the members in a service group, click Service Groups, and then select the service group.
   - To flush the surge queue of a specific member in a service group, click Service Groups, and in the action pane, click Manage Members. In the Manage Members of a Service Group dialog box, select the service group member.

   **Note:** You can select multiple entities in any window.

   **Note:** To flush the surge queue of a content switching virtual server, in Steps 1 and 2, expand Content Switching, and then select a virtual server.

3. In the action pane, click Flush Surge Queue.

4. Click OK.

   **Note:** On the appliance, if there are other entities with the same name as you selected, you are alerted that the surge queues of those entities would also be flushed. Take an appropriate action.
Managing a Content Switching Setup

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.
Unbinding Policies from the Content Switching Virtual Server

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

To unbind a policy from a content switching virtual server by using the command line interface

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

Example

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

Parameters for unbinding content switching policies

**vServerName**

The name of the content switching virtual server from which you are unbinding the policy. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**policyName**

The name of the policy that you are unbinding.
To unbind a policy from a content switching virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server form which you want to unbind the policy (for example, Vserver-CS-1), and click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, in the Active column, clear the check box next to the policy that you want to unbind from the virtual server (for example, Policy-CS-1).

4. Click OK.
Removing Content Switching Virtual Servers

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the NetScaler appliance first unbinds all policies from the content switching virtual server, and then removes it.

To remove a content switching virtual server by using the command line interface

At the command prompt, type:

```
rm cs vserver <name>@
```

Example

```
rm cs vserver Vserver-CS-1
```

To remove a content switching virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.
2. In the details pane, select the virtual server that you want to remove (for example, Vserver-CS-1), and then click Remove.
3. In the Remove dialog box, click Yes.
Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `disable cs vserver <name>@`
- `enable cs vserver <name>@`

Example

`disable cs vserver Vserver-CS-1`
`enable cs vserver Vserver-CS-1`

To disable or re-enable a virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to disable (for example, Vserver-CS-1).

3. Disable or re-enable the virtual server by clicking Disable or Enable, and then clicking Yes to confirm your choice.
Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the NetScaler configuration.

To rename a virtual server by using the command line interface

At the command prompt, type:

rename cs vserver <name>@<newName>@

Example

rename cs vserver Vserver-CS-1 Vserver-CS-2

To rename a virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to rename (for example, Vserver-CS-1).

3. Click Rename.

4. In the Name text box, type a new name for the virtual server.

5. Click OK to save your changes.
Managing Content Switching Policies

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

Table 1. Examples of URL-Based Policies

<table>
<thead>
<tr>
<th>Type of URL-Based Policy</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain and Exact URL</td>
<td>Requests must match the configured domain name and configured URL (an exact prefix match if only the prefix is configured; or an exact match of the prefix and suffix if both the prefix and suffix are configured).</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td><code>add cs policy Policy-CS-1 -url /sports/tennis/index.html -domain &quot;www.domainxyz.com&quot;</code></td>
</tr>
<tr>
<td>Domain and Wild Card URL</td>
<td>Requests must match the exact domain name and a partial prefix of the configured URL.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td><code>add cs policy Policy-CS-1 -url /*.jsp -domain &quot;www.domainxyz.com&quot;</code></td>
</tr>
<tr>
<td>Domain Only</td>
<td>Requests need match only the configured domain name.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td><code>add cs policy Policy-CS-1 -domain &quot;www.domainxyz.com&quot;</code></td>
</tr>
</tbody>
</table>
The Exact URL  | The incoming URL must exactly match the URL specified by the policy. If only a URL prefix rule is configured, there must be an exact prefix match with the incoming URL. If a URL prefix and suffix-based rule is configured, there should be an exact match of the prefix and suffix with the incoming URL.

Example:
```
add cs policy Policy-CS-1 -url /sports/tennis/index.html
```

Prefix Only (Wild Card URL)  | All the incoming URLs must start with the configured prefix.

Example:
```
add cs policy Policy-CS-1 -url /sports*
```

Suffix Only (Wild Card URL)  | All incoming URLs must end with the configured URL suffix.

Example:
```
add cs policy Policy-CS-1 -url /*.jsp
```

Prefix and Suffix (Wild Card URL)  | All incoming URLs must start with the configured prefix and end with the configured suffix.

Example:
```
add cs policy Policy-CS-1 -url /sports/*.jsp
```

Note: You can configure rule-based content switching using classical policy expressions or advanced policy expressions. For more information about configuring policy expressions, see “Policy Configuration and Reference.”

To modify, remove, or rename a policy by using the command line interface

At the command prompt, type one of the following commands:
Managing Content Switching Policies

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`

- `rm cs policy <policyName>`

**Example**

```bash
set cs policy Policy-CS-1 -domain "www.domainxyz.com"
set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ(10.100.148.0)"
set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
set cs policy Policy-CS-1 -url /sports/*
```

```bash
rm cs policy Policy-CS-1
```

**Parameters for configuring content switching policies**

- **policyName**

- **newPolicyName**
  
  New name for the content switching policy.

- **domain**

  The domain name. The alphanumeric string can range from 3 to 63 characters, and can consist of any characters that are allowed in a domain name.

- **rule**

  A NetScaler advanced policy expression that defines which requests to forward to a particular content switching virtual server.

- **url**

  A URL or partial URL that enables the NetScaler appliance to choose requests to forward to a particular content switching server.
To modify, remove, or rename a policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, select the policy that you want to modify (for example, Policy-CS-1).

3. Modify, remove, or rename the policy.
   - To modify the policy, click Open and then make the changes that you want. For example, you can type a new domain name in the Domain text box. Then, click Yes to confirm your changes.
   - To remove the policy, click Remove, and then click Yes to confirm your choice.
   - To rename the policy, click Rename, and specify the new name in the Name text field in the Rename CSW Policy dialog box, and then click OK.

4. In the Configure Content Switching Policies dialog box, in the Domain text box, type the domain name (for example, www.domainxyz.com).

5. Click OK.
Modifying a Content Switching Configuration by Using the Visualizer

You can use the Visualizer to modify a load balancing virtual server to which the content switching virtual server is bound. You can also modify a service or group of similar services, or a monitor. For more information, see “The Load Balancing Visualizer.”
Managing Client Connections

To ensure efficient management of client connections, you can configure the content switching virtual servers on the NetScaler appliance to use the following features:

- Redirecting client requests to a cache
- Enabling delayed cleanup of virtual server connections
- Rewriting ports and protocols for redirection
- Inserting the IP address and port of a virtual server in the request header
- Setting a time-out value for idle client connections
- Configuring the ICMP Response. You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.
Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (source IP:source port:destination IP:destination port) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

- set cs vserver <name> -l2Conn (ON | OFF)
- show cs vserver <name>

Example

> set cs vserver mycsvserver -l2Conn ON
Done
> show cs vserver mycsvserver
mycsvserver (192.0.2.56:80) - HTTP Type: CONTENT
State: UP
... ...
L2Conn: ON Case Sensitivity: ON
... ...
Done
>

Parameters for identifying connections with the 4-tuple and layer 2 connection parameters

name (Name)

The name of the content switching virtual server.
Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

**L2Conn**

Identify connections to the virtual server with the 4-tuple and the Layer 2 connection parameters (MAC address, VLAN ID, and channel ID). Possible values: ON, OFF.

**To set the L2Conn option for a content switching virtual server by using the configuration utility**

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, click the content switching virtual server for which you want to set the L2Conn option, and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select L2 Connection.

4. Click OK.
Redirecting Client Requests to a Cache

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see "Cache Redirection."

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

`set cs vserver <name> -cacheable <Value>`

Example

`set cs vserver Vserver-CS-1 -cacheable yes`

Parameters for configuring cache redirection

vServerName

The name of the virtual server that you are configuring.

cacheable

Route virtual server requests to the cache redirection virtual server before sending them to the configured servers. Possible values: YES, NO. Default: NO.
To configure cache redirection on a virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure cache redirection (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, select the Cache Redirection check box.

4. Click OK.
Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -downStateFlush <Value>
```

Example

```
set cs vserver Vserver-CS-1 -downStateFlush enabled
```

Parameters for configuring down state flush

**vServerName**

The name of the virtual server that you are configuring.

**downStateFlush**

Perform delayed cleanup of connections on the virtual server. Possible values: ENABLED, DISABLED. Default: ENABLED.

To configure the down state flush setting on a virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure down state flush (for example, Vserver-CS-1), and click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.

4. Select the Down state flush check box, and then click OK.
Enabling Delayed Cleanup of Virtual Server Connections
Rewriting Ports and Protocols for Redirection

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the NetScaler appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

\[\text{set cs vserver <name> -redirectPortRewrite <Value>}\]

Example

\[\text{set cs vserver Vserver-CS-1 -redirectPortRewrite enabled}\]

Parameters for redirect port rewrite

\text{vServerName}

The name of the virtual server that you are configuring.

\text{redirectPortRewrite}

State of port rewrite while performing HTTP redirect. Possible values: ENABLED and DISABLED. Default: DISABLED.
To configure HTTP redirection on a virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure HTTP redirection (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.

4. Select the Redirect Port Rewrite check box, and then click OK.
Inserting the IP Address and Port of a Virtual Server in the Request Header

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

Note: This option is not supported for wildcarded virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -insertVserverIPPort <vServerIPPORT>
```

Example

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
```

Parameters for virtual server IP port insertion

**vServerName**

The name of the virtual server that you are configuring.

**insertVserverIPPort**

Virtual IP address and port header insertion option for the virtual server.

VIPADDR-Header contains the virtual server IP address and port number without any translation.
Inserting the IP Address and Port of a Virtual Server in the Request Header

If VIPADDR is not specified, the header is inserted with the name specified in the default header tag vip-header and the virtual server IP and port are inserted in the request with the default header tag vipHeader.

If VIPADDR is specified, the header is inserted with the user-specified name in vipHeader. The virtual server IP and port are inserted in the request with the user-specified header tag vipHeader.

OFF - The virtual IP and port header insertion option is disabled. The virtual server and port number are not inserted.

V6TOV4MAPPING - If the virtual server uses an IPv6 address and the server uses IPv4, this setting maps the virtual server address and port to the IPv4 address.

Possible values: OFF, VIPADDR, and V6TOV4MAPPING. Default: OFF.

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure virtual server port insertion (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.

4. In the Vserver IP Port Insertion list, select the VIPADDR or V6TOV4MAPPING, and then type the port header in a text box next to Vserver IP Port Insertion box.

5. Click OK.
Setting a Time-out Value for Idle Client Connections

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cltTimeout <Value>
```

Example

```
set cs vserver Vserver-CS-1 -cltTimeout 100
```

Parameters for setting the client time-out value

vServerName

The name of the virtual server that you are configuring.

cltTimeout

Idle time (in seconds) after which the client connection is terminated. The default values are:

- 180 seconds for HTTP/SSL-based services.
- 9000 seconds for other TCP-based services.
- 180 seconds for DNS-based services.
- 180 seconds for other UDP-based services.  

Maximum value: 31536000.
To set a time-out value for idle client connections by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to set a time-out value (for example, Vserver-CS-1), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, click the Advanced tab.

4. In the Client Time-out (secs) text box, type the time-out value (for example, 100).

5. Click OK.
DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, usernames, character sets, and packet size.

You can either configure load balancing to switch requests based on load balancing algorithms or elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameters. You can further configure monitors to track the state of database servers.

**Note:** NetScaler DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.
How NetScaler DataStream Works

In DataStream, the NetScaler is placed in-line between the application and/or Web servers and the database servers. On the NetScaler appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

![DataStream Entity Model](image)

Figure 1. *DataStream Entity Model*

As shown in this figure, a DataStream configuration can consist of an optional content switching virtual server (CS), a load balancing setup consisting of load balancing virtual servers (LB1 and LB2) and services (Svc1, Svc2, Svc3, and Svc4), and content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the NetScaler appliance. The NetScaler, then, authenticates the clients using the database user credentials configured on the NetScaler appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2), which, then, distributes the requests to the appropriate database servers (represented by services on the NetScaler) based on the load balancing algorithm. The NetScaler uses the same database user credentials to authenticate the connection with the...
database server.

If a content switching virtual server is not configured on the NetScaler, the clients (application or Web servers) send their requests to the IP address of a load balancing virtual server configured on the NetScaler appliance. The NetScaler authenticates the client by using the database user credentials configured on the NetScaler appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set
Configuring Database Users

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

**Note:** Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

**To add a database user by using the command line interface**

At the command prompt, type

```
add db user <username> - password <password>
```

**Example**

```
> add db user nsdbuser -password dd260427edf
```

**Parameters for creating a database user**

**username**

The database user name. This is a mandatory argument. The maximum length of the user name is 127 characters.

**password**

The password used to log on to the database. The maximum length of the password is 127 characters.
To add a database user by using the configuration utility

1. In the navigation pane, expand System, and then click Database Users.
2. In the details pane, click Add.
3. In the Create Database User dialog box, specify values for the following parameters.
   - User Name
   - Password
   - Confirm Password
4. Click Create, and then click Close. The user you created appears in the Database Users pane.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler.

To reset the password of a database user by using the command line interface

At the command prompt, type

```
set db user <username> -password <password>
```

Example

```
> set db user nsdbuser -password dd260538abs
```
To reset the password of database users by using the configuration utility

1. In the navigation pane, expand System, and then click Database Users.

2. In the details pane, select the database user for which you want to reset the password, and then click Open.

3. In the Configure Database User dialog box, modify the values for the following parameters.
   - Password
   - Confirm Password
4. Click OK.

If a database user no longer exists on the database server, you can remove the user from the NetScaler. However, if the user continues to exist on the database server and you remove the user from the NetScaler, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

```
rm db user <username>
```

Example

```
> rm db user nsdbuser
```

To remove a database user by using the configuration utility

1. In the navigation pane, expand System, and then click Database Users.

2. In the details pane, select the database user that you want to remove, and then click Open.

3. In the Proceed message box, click Yes.
Configuring a Database Profile

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

To create a database profile by using the command line interface

At the command line, type the following commands to create a database profile and verify the configuration:

- add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness (YES | NO )] [-kcdAccount <string>]
- show db dbProfile

Example

```
> add dbProfile myDBProfile -interpretQuery YES -stickiness YES -kcdAccount mykcdacct
Done
> show dbProfile myDBProfile
 Name: myDBProfile
 Interpret Query: YES
 Stickyness: YES
 KCD Account: mykcdacct
 Reference count: 0
 Done
>
```

Parameters for creating a database profile

**name (Name)**

Name for the database profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Can be changed after the database profile is created.

CLI Users: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my dbprofile" or 'my dbprofile').
Configuring a Database Profile

**interpretQuery (Interpret Query)**

Perform deep inspection of queries, and base load balancing decisions on the contents of queries.

**stickiness (Stickiness)**

Examine the query and determine whether it is associated with an earlier query. If it is, forward the query through the server connection that was used for the previous query.

**kcdAccount (KCD Account)**

Name of the Kerberos Constrained Delegation (KCD) account to use for authenticating users connecting to the virtual server.

To create a database profile by using the configuration utility

1. Navigate to System > Profiles.
2. In the details pane, on the Database Profiles tab, do one of the following:
   - To create a database profile, click Add.
   - To modify a database profile, click the profile, and then click Open.
3. In the Create Database Profile or Configure Database Profile dialog box, set the following parameters:
   - Name*
   - KCD Account
   - Interpret Query
   - Stickiness
   * Required parameter
4. Click Create or OK, and then click Close.

To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

```
set (lb | cs) vserver <name> -dbProfileName <string>
```
Parameters for binding a database profile to a load balancing or content switching virtual server

**name**

Name of the load balancing or content switching virtual server.

**dbProfileName**

Name of the database profile to bind to the virtual server.

To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing or Content Switching, depending on the type of virtual server to which you want to bind the database profile.

2. Click Virtual Servers.

3. In the details pane, select the virtual server, and then click Open.

4. In the Configure Virtual Server (Load Balancing) or Configure Virtual Server (Content Switching) dialog box, on the Profiles tab, in the Database Profile list, select the database profile.

5. Click OK.
Configuring Load Balancing for DataStream

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

For instructions about configuring load balancing, see Load Balancing.

Parameter values specific to DataStream

Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

MS SQL Server Version

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the Microsoft SQL Server Version Setting.
Configuring Content Switching for DataStream

You can segment traffic according to information in the SQL query, on the basis of database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties, such as user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MYSQL and MS SQL database servers. You can use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

Note: For information about default syntax expressions, see Default Syntax Expressions: DataStream.

Parameter values specific to DataStream

Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

MS SQL Server Version

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see Configuring the Microsoft SQL Server Version Setting.

For instructions about configuring content switching, see "Content Switching".
To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors, MYSQL-ECV and MSSQL-ECV. This monitor provides the ability to send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler. For information about configuring monitors, see Monitors.

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

Parameters specific to DataStream

type

Type of monitor. Use the MYSQL-ECV monitor type for MySQL databases and MSSQL-ECV monitor type for MS SQL databases.

sqlQuery

SQL query for the MYSQL-ECV and MSSQL-ECV monitors. After the connection to the database server is authenticated, you can run this query to the server.

evalRule

Rule evaluated to determine the state of the monitor. A rule consists of default syntax expressions.

database

Name of the database that needs to be probed. During authentication, this database name is used to connect to the database.

userName

User name to connect to the database. This is looked up in the database user list to extract the database.

Examples

In the following example, the value of the error message is evaluated to determine the state of the server.
add lb monitor lb_mon1 MYSQL_ECV -sqlQuery "select * from table2;" -evalrule "mysql.res.error.message.contains("Invalid User\")" -database "NS" -userName "user1"

In the following example, the number of rows in the response is evaluated to determine the state of the server.

add lb monitor lb_mon4 MYSQL_ECV -sqlQuery "select * from table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -userName "user2"

In the following example, the value of a particular column is evaluated to determine the state of the server.

add lb monitor lb_mon3 MYSQL_ECV -sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem(2) == 345.12" -database "NS" -userName "user3"
DataStream Use Cases

The following topics describe how you can configure DataStream for various scenarios.

- Configuring DataStream for a Master/Slave Database Architecture
- Configuring the Token Method of Load Balancing for DataStream
Configuring DataStream for a Master/Slave Database Architecture

A commonly used deployment scenario is the master/slave database architecture where the master database replicates all information to the slave databases.

For master/slave database architecture, you may want all WRITE requests to be sent to the master database and all READ requests to the slave databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

![DataStream Entity Model for Master/Slave Database Setup](image)

In this example scenario, a service (Svc_mysql_1) is created to represent the master database and is bound to a load balancing virtual server (Lb_vsr_mysql_master). Three more services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) are created to represent the three slave databases, and they are bound to another load balancing virtual server (Lb_vsr_mysql_slave).

A content switching virtual server (Cs_vsr_mysql_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server (Lb_vsr_mysql_master), and all READ requests to the load balancing virtual server (Lb_vsr_mysql_slave).
When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the NetScaler.

Table 1. Entity and Policy Names and Values

</tbody>
</table>

To configure DataStream for a master/slave database setup by using the command line interface

At the command prompt, type

- `add service Svc_mysql_1 10.102.29.5 mysql 3306`
- `add service Svc_mysql_2 10.102.29.6 mysql 3306`
- `add service Svc_mysql_3 10.102.29.7 mysql 3306`
- `add service Svc_mysql_4 10.102.29.8 mysql 3306`
- `add lb vserver Lb_vsr_mysql_master mysql 10.102.29.201 3306`
- `add lb vserver Lb_vsr_mysql_slave mysql 10.102.29.202 3306`
- `bind lb vserver Lb_vsr_mysql_master svc_mysql_1`
- `bind lb vserver Lb_vsr_mysql_slave svc_mysql_2`
To configure DataStream for a master/slave database setup by using the configuration utility

Add four services, one to represent the master database server and three to represent the slave database servers.

To add a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as listed in the table “Entity and Policy Names and Values”.
   - Service Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close. The service you created appears in the Services pane.

Add two load balancing virtual servers.
To create a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as listed in the table "Entity and Policy Names and Values".
   - Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close.

Bind the service Svc_mysql_1 to the load balancing virtual server Lb_vsr_mysql_master, and bind the three services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) to the load balancing virtual server Lb_vsr_mysql_slave.

To bind a service to a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server to which you want to bind the service (for example, Lb_vsr_mysql_master).

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Svc_mysql_1).

5. Click OK.

Create a content switching virtual server.
To add a content switching virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Content Switching) dialog box, specify values for the following parameters as listed in the table “Entity and Policy Names and Values.”
   - Name
   - IP Address
   - Protocol
   - Port
4. Click Create, and then click Close.

Create a content switching policy to evaluate all READ requests.

To create a content switching policy by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type the name of the policy (for example, Cs_select).
4. Choose the type of policy that you want to create, and configure the policy. To create a rule-based policy, click Configure, and do the following:
   - In the Create Expression dialog box, choose the expression syntax you want to use and enter your policy expressions as listed in the table “Entity and Policy Names and Values.”
5. Click Create, and then click Close.

Bind the content switching policy to the content switching virtual server. You should also select a load balancing virtual server as the target for the policy so that, after the content switching virtual server evaluates the policy, it routes requests that match the policy to the load balancing virtual server to forward them to the appropriate database server.
To bind the policy to the content switching virtual server and select a load balancing virtual server target by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, double-click the virtual server to which you want to bind the policy (for example, Cs_vsr_mysql_1).

3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy, and in the Policy Name column, select the policy that you want to bind to the virtual server (for example, Cs_select).

4. In the Target column next to the policy, select the load balancing virtual server that you want to assign as the target for the policy (for example, Lb_vsr_mysql_slave).

5. Click OK.

Set the load balancing virtual server, Lb_vsr_mysql_master, as the default virtual server for the content switching virtual server by binding the content switching virtual server to this load balancing virtual server. This ensures that the content switching virtual server routes requests that do not match the Cs_select policy to the load balancing virtual server to forward them to the appropriate database server.

To bind the content switching virtual server to a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Content Switching, and then click Policies.

2. In the details pane, double-click the virtual server to which you want to bind the policy (for example, Cs_vsr_mysql_1).

3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click Insert Policy, and in the Policy Name column, select (Default).

4. In the Target column next to the policy, select the load balancing virtual server that you want to assign as the target for the policy (for example, Lb_vsr_mysql_slave).

5. Click OK.
Configuring the Token Method of Load Balancing for DataStream

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the NetScaler sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

<table>
<thead>
<tr>
<th>MySQL</th>
<th>MS SQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL.REQ.QUERY.TEXT</td>
<td>MSSQL. REQ.QUERY.TEXT</td>
</tr>
<tr>
<td>MYSQL.REQ.QUERY.TEXT(n)</td>
<td>MSSQL. REQ.QUERY.TEXT(n)</td>
</tr>
<tr>
<td>MYSQL.REQ.QUERY.COMMAND</td>
<td>MSSQL. REQ.QUERY.COMMAND</td>
</tr>
<tr>
<td>MYSQL.CLIENT.USER</td>
<td>MSSQL.CLIENT.USER</td>
</tr>
<tr>
<td>MYSQL.CLIENT.DATABASE</td>
<td>MSSQL.CLIENT.DATABASE</td>
</tr>
<tr>
<td>MYSQL.CLIENT.CAPABILITIES</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how the NetScaler DataStream feature works when you configure the token method of load balancing.

![Diagram](image)

Figure 1. How DataStream Works with the Token Method of Load Balancing

In this example, the token is the name of the database. A request with token `books` is sent to Database Server1 and a request with token `music` is sent to Database Server2. All subsequent requests with token `books` are sent to Database Server1 and requests with token `music` are sent to Database Server2. This configuration provides pseudo
To configure this example by using the command line interface

At the command prompt, type:

- add service Service1 192.0.2.9 MYSQL 3306
- add service Service2 192.0.2.11 MYSQL 3306
- add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -rule MYSQL.CLIENT.DATABASE
- bind lb vserver token_lb_vserver Service1
- bind lb vserver token_lb_vserver Service2
To configure this example by using the configuration utility

1. Add two services to represent the two database servers.
   a. In the navigation pane, expand Load Balancing, and then click Services.
   b. In the details pane, click Add.
   c. In the Create Service dialog box, set the following parameters.
      · Service Name
      · IP Address
      · Protocol
      · Port
   d. Click Create, and then click Close.

2. Add one load balancing virtual server and set the token load balancing method.
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   b. In the details pane, click Add.
   c. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters.
      · Name
      · IP Address
      · Protocol
      · Port
   d. On the Method and Persistence tab, under LB Method, in the Method drop list, select Token.
   e. In the Rule box, type MYSQL.CLIENT.DATABASE.
   f. Click Create, and then click Close.
3. Bind the two services to the load balancing virtual server.
   
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   
   b. In the details pane, select the virtual server to which you want to bind the service (for example, token_lb_vserver).
   
   c. Click Open.
   
   d. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service1).
   
   e. Click OK.
Figure 3. Binding Services to a Virtual Server by Using the Configuration Utility
DataStream Reference

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how NetScaler handles transaction requests and special queries that modify the state of a connection.

You can also configure the NetScaler appliance to generate audit log messages for the DataStream feature.
# Supported Database Versions, Protocols, and Authentication Methods

<table>
<thead>
<tr>
<th></th>
<th>MySQL Database</th>
<th>MS SQL Database</th>

</thead>
<tbody>
<tr>
<td><strong>Protocols</strong></td>
<td>MySQL protocol version 10.</td>
<td>TDS protocol version 7.1 and higher.</td>
</tr>
<tr>
<td><strong>Authentication Methods</strong></td>
<td>MySQL native authentication is supported.</td>
<td>SQL server authentication is supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Currently Windows authentication is not supported.</td>
</tr>
</tbody>
</table>
Character Sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request may be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be multiplexed onto a connection with a different character set.

NetScaler parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

- SET NAMES <charset> COLLATION <collation>
- SET CHARACTER SET <charset>
In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

NetScaler explicitly parses each and every query to determine the beginning and end of a transaction.

In MySQL protocol, the response contains two flags to indicate whether the connection is a transaction, the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. NetScaler parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the NetScaler begins connection multiplexing.
Special Queries

There are special queries, such as SET and PREPARE, that modify the state of the connection and may break request switching, and therefore, these need to be handled differently.

On receiving a request with special queries, NetScaler sends an OK response to the client and additionally, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the NetScaler first, looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, NetScaler creates a new connection, and sends the stored query first, and then, sends the request with the non-special query.

In case of SET, USE db, and INIT_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which NetScaler has a modified behavior.

**SET query**

The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, NetScaler is unable to differentiate between local and global variables. For this query, the NetScaler uses the 'store and forward' mechanism described earlier.

**USE <db> query**

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

**INIT_DB command**

Using this query, the user can change the database associated with a connection. In this case, NetScaler parses the <init_db> value sent and modifies a field in the server side connection to reflect the new database to be used.

**COM_PREPARE**

NetScaler stops request switching on receiving this command.

**PREPARE query**

This query is used to create prepared statements that are associated with a connection. For this query, the NetScaler uses the 'store and forward' mechanism described earlier in this section.
Special Queries
Audit Log Message Support

You can now configure the NetScaler appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with "CS" and error messages for server-side connections begin with "SS." Additional information is provided where necessary. For example, log messages for closed connections (CS_CONN_CLOSED) include only the connection ID. However, log messages for established connections (CS_CONN_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.
You can configure the Citrix NetScaler appliance to function as an authoritative domain name server (ADNS server) for a domain. You can add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the NetScaler appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within your network or outside your network. You can configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the NetScaler appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the NetScaler as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the Transmission Control Protocol (TCP) for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).
How DNS Works on the NetScaler

You can configure the NetScaler appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the NetScaler, including service (SRV) records, IPv6 (AAAA) records, address (A) records, mail exchange (MX) records, canonical name (CNAME) records, pointer (PTR) records, start of authority (SOA) records, and text (TXT) records. Also, you can configure the NetScaler to load balance external DNS name servers.

The NetScaler can be configured as the authority for a domain. To do this, you add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the NetScaler as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a client sends a DNS request, the NetScaler appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the NetScaler Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the NetScaler authoritative for the subdomain, by adding a "glue record" for each of the subdomain name servers. If GSLB is configured, the NetScaler makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.
The NetScaler appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the NetScaler appliance. This enables the NetScaler to provide quick responses for repeated translations. You must also create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The NetScaler provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The NetScaler checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The NetScaler also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called _negative caching_. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- **NXDOMAIN error message** - If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler. The NetScaler caches the response locally, then returns the error message to the client.
How DNS Works on the NetScaler

- NODATA error message - The NetScaler sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The NetScaler supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the NetScaler queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the NetScaler as a DNS forwarder. A forwarder passes DNS requests to external name servers. The NetScaler allows you to add external name servers and provides name resolution for domains outside the network. The NetScaler also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).
Round Robin DNS

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when a large number of requests arrive.

When the NetScaler receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The NetScaler performs this function automatically. You do not have to configure this behavior.

**Functional Overview**

If the NetScaler is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. If the NetScaler is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The NetScaler then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, the third response contains the third record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

**Round Robin DNS Example**

As an example of round robin DNS, consider DNS records that have been added as follows:

```
add dns addRec ns1 1.1.1.1
add dns addRec ns1 1.1.1.2
add dns addRec ns1 1.1.1.3
add dns addRec ns1 1.1.1.4
```

The domain, abc.com is linked to an NS record as follows:

```
add dns nsrec abc.com. ns1
```

When the NetScaler receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```
ns1.  1H IN A  1.1.1.1
```
Round Robin DNS

ns1.  1H IN A  1.1.1.2
ns1.  1H IN A  1.1.1.3
ns1.  1H IN A  1.1.1.4

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

ns1.  1H IN A  1.1.1.2
ns1.  1H IN A  1.1.1.3
ns1.  1H IN A  1.1.1.4
ns1.  1H IN A  1.1.1.1

In the third DNS response, the third IP address, 1.1.1.2 is served as the first record:

ns1.  1H IN A  1.1.1.3
ns1.  1H IN A  1.1.1.4
ns1.  1H IN A  1.1.1.1
ns1.  1H IN A  1.1.1.2
Configuring DNS Resource Records

You configure resource records on the Citrix® NetScaler® appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types and the number of records (per record type) that you can configure for a domain on the NetScaler.

Table 1. Record Type and Number Configurable

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Number of Records</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address (A)</td>
<td>25</td>
</tr>
<tr>
<td>IPv6 (AAAA)</td>
<td>5</td>
</tr>
<tr>
<td>Mail exchange (MX)</td>
<td>12</td>
</tr>
<tr>
<td>Name server (NS)</td>
<td>16</td>
</tr>
<tr>
<td>Service (SRV)</td>
<td>8</td>
</tr>
<tr>

</table>
Creating SRV Records for a Service

The SRV record provides information about the services available on the NetScaler appliance. An SRV record contains the following information: name of the service and the protocol, domain name, TTL, DNS class, priority of the target, weight of records with the same priority, port of the service, and host name of the service. The NetScaler chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

To add an SRV record by using the command line interface

At the command prompt, type the following commands to add an SRV record and verify the configuration:

- `add dns srvRec <domain> <target> -priority <positive_integer> -weight <positive_integer> -port <positive_integer> [-TTL <secs>]`
- `sh dns srvRec <domain>`

Example

```
> add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -weight 1 -port 80
Done
> show dns srvRec _http._tcp.example.com
1)   Domain Name : _http._tcp.example.com
    Target Host : nameserver1.com
    Priority : 1  Weight : 1
    Port : 80    TTL : 3600 secs
Done
> 
```

To modify or remove an SRV record by using the command line interface

- To modify an SRV record, type the `set dns srvRec` command, the name of the domain for which the SRV record is configured, the name of the target host that hosts the associated service, and the parameters to be changed, with their new values.

- To remove an SRV record, type the `rm dns srvRec` command, the name of the domain for which the SRV record is configured, and the name of the target host that hosts the associated service.
Parameters for configuring an SRV record

**domain**

The domain name that is offering the services. The domain name includes the service offered and the transport layer protocol (for example, _ftp._tcp.abc.com). This is a mandatory argument. Maximum length: 255.

**target**

The host for the specified service. This is a mandatory argument. Maximum length: 255.

**priority**

The priority that is assigned to the target host. The lower the priority value, the higher the priority. Clients always attempt to use the SRV record that has the lowest priority value. This is a mandatory argument. Minimum value: 0. Maximum value: 65535.

**weight**

Weight for the target host. If two records have the same priority, the NetScaler selects the server based on the value of this parameter. This is a mandatory argument. Minimum value: 0. Maximum value: 65535.

**port**

The port name on which the target host is listening for client requests. This is a mandatory argument. Minimum value: 0. Maximum value: 65535.

**TTL**

To configure an SRV record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click SRV Records.

2. In the details pane, do one of the following:
   - To create a new SRV record, click Add.
   - To modify an existing SRV record, select the SRV record, and then click Open.

3. In the Create SRV Record or Configure SRV Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an SRV record” as shown:
   - Domain Name*—domain (cannot be changed for an existing SRV record)
   - Target*—target (cannot be changed for an existing SRV record)
   - Priority*—priority
   - Weight*—weight
   - Port*—port
   - TTL—TTL
   * A required parameter

4. Click Create or OK.
Creating AAAA Records for a Domain Name

An AAAA resource record stores a single IPv6 address.

To add an AAAA record by using the command line interface

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

- add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
- show dns aaaaRec <hostName>

Example

> add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57ab
Done
> show dns aaaaRec www.example.com
1) Host Name : www.example.com
   Record Type : ADNS      TTL : 5 secs
   IPV6 Address : 2001:db8::1428:57ab
Done
>

To remove an AAAA record and all of the IPv6 addresses associated with the domain name, type the rm dns aaaaRec command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the rm dns aaaaRec command, the domain name for which the AAAA record is configured, and the IPv6 addresses that you want to remove.

Parameters for configuring an AAAA record

**hostName**

The domain name for which the Address record is added. This is a mandatory argument.

*Maximum length: 255.*

**IPv6Address**

The IPv6 address of the domain name.
Creating AAAA Records for a Domain Name

**TTL**

To add an AAAA record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click AAAA Records.

2. In the details pane, click Add.

3. In the Create AAAA Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an AAAA record” as shown:
   - Host Name*—hostName
   - IPv6 Address*—IPv6Address
   - TTL-TTL
   * A required parameter

4. Click Add. The IPv6 address appears in the IP box.

5. Click Create, and then click Close.
Creating Address Records for a Domain Name

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the NetScaler deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

To add an Address record by using the command line interface

At the command prompt, type the following commands to add an Address record and verify the configuration:

- add dns addRec <hostName> <IP Address> [-TTL <secs>]
- show dns addRec <hostName>

Example

```
> add dns addRec ns.example.com 192.0.2.0
Done
> show dns addRec ns.example.com
1)  Host Name : ns.example.com
    Record Type : ADNS                      TTL : 5 secs
    IP Address : 192.0.2.0
Done
```

To remove an Address record and all of the IP addresses associated with the domain name, type the rm dns addRec command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the rm dns addRec command, the domain name for which the Address record is configured, and the IP addresses that you want to remove.

Parameters for configuring an Address record

hostName
Creating Address Records for a Domain Name

The domain name for which the Address record is being added. This is a mandatory argument. Maximum length: 255.

**IPAddress**

The IP address of the domain name.

**TTL**

**To add an Address record by using the configuration utility**

1. In the navigation pane, expand DNS, expand Records, and then click Address Records.

2. In the details pane, click Add.

3. In the Create Address Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring Address records” as shown:

   - Host Name*—hostName
   - IP Address*—IPAddress
   - TTL—TTL

   * A required parameter

4. Click Add. The IP address appears in the IP Address box.

5. Click Create, and then click Close.
Creating MX Records for a Mail Exchange Server

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

To add an MX record by using the command line interface

At the command prompt, type the following commands to add an MX record and verify the configuration:

```
add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]
show dns mxRec <domain>
```

Example

```
> add dns mxRec example.com -mx mail.example.com -pref 1
Done
> show dns mxRec example.com
1) Domain : example.com  MX Name : mail.example.com
   Preference : 1    TTL : 5 secs
Done
>
```
To modify or remove an MX record by using the command line interface

- To modify an MX record, type the set dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.

- To set the TTL parameter to its default value, type the unset dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and `-TTL` without any TTL value. You can use the unset dns mxRec command to unset only the TTL parameter.

- To remove an MX record, type the rm dns mxRec command, the name of the domain for which the MX record is configured, and the name of the MX record.

Parameters for configuring an MX record

**domain**

The domain for which the MX record is added. This is a mandatory argument. Maximum length: 255.

**mx**

The MX record name. This is a mandatory argument. Maximum length: 255.

**pref**

The route priority number. This is a mandatory argument. Minimum value: 0. Maximum value: 65535.

**Note:** A domain name can have multiple mail routes, with a priority number assigned to each. The mail route with the lowest number identifies the server responsible for the domain. Other listed mail servers are used as backups.

**TTL**

To add an MX record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click Mail Exchange Records.

2. In the details pane, do one of the following:
   - To create a new MX record, click Add.
   - To modify an existing MX record, select the MX record, and then click Open.

3. In the Create Mail Exchange Record or Configure Mail Exchange Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an MX record” as shown:
   - Domain Name*—domain (cannot be changed for an existing MX record)
   - Mail Exchange*—mx (cannot be changed for an existing MX record)
   - Preference No.*—pref
   - TTL—TTL
   * A required parameter

4. Click Create or OK.
Creating NS Records for an Authoritative Server

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

To create an NS record by using the command line interface

At the command prompt, type the following commands to create an NS record and verify the configuration:

- add dns nsRec <domain> <nameServer> [-TTL <secs>]
- show dns nsRec <domain>

Example

> add dns nsRec example.com nameserver1.example.com
Done
> show dns nsRec example.com
1) Domain : example.com NameServer : nameserver1.example.com
   TTL : 5 sec
Done
>

To remove an NS record, type the rm dns nsRec command, the name of the domain to which the NS record belongs, and the name of the name server.

Parameters for configuring an NS record

domain

The domain name for which the name server record is being added.

nameServer

The name server for the domain.

TTL

To create an NS record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click Name Server Records.

2. In the details pane, click Add.

3. In the Create Name Server Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an NS record” as shown:
   - Domain Name*: domain
   - Name Server*: nameServer
   - TTL*: TTL
   * A required parameter

4. Click Create, and then click Close.
Creating CNAME Records for a Subdomain

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

To add a CNAME record by using the command line interface

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

- `add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]`
- `show dns cnameRec <aliasName>`

Example

```
> add dns cnameRec www.example.com www.example.com
Done
> show dns cnameRec www.example.com
     Alias Name      Canonical Name  TTL
       1)      www.example.com        www.example.com       5 secs
Done
>
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

Parameters for configuring a CNAME record

- `aliasName`
  
  Domain name for the defined alias. Maximum length: 256.

- `canonicalName`
  
  Alias name for the specified domain. Maximum length: 256.

- `TTL`
Creating CNAME Records for a Subdomain

To add a CNAME record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click Canonical Records.

2. In the details pane, click Add.

3. In the Create Canonical Name Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a CNAME record” as shown:
   - Alias Name*—aliasName
   - Canonical Name*—canonicalName
   - TTL—TTL
     * A required parameter

4. Click Create, and then click Close.
NetScaler ADC when deployed in a proxy mode does not always send the query for an address record to the back-end server. This happens when for a answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- NetScaler should be deployed in a proxy mode
- The response from the back-end server should have a CNAME chain, for which the record type of last entry in the answer section must be a CNAME and the question type not a CNAME
- The response from the back-end server cannot be a No-data or NX-Domain
- The response from the back-end server has to be a authoritative response
Creating NAPTR Records for Telecommunications Domain

NAPTR (Naming Address Pointer) is one of the most commonly used DNS record in telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

NetScaler ADCs support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in NetScaler. NetScaler caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record is served from the cache.

To create a NAPTR record by using command line interface

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference> [flags<string>] [services<string>] [regexp<expressions> | -replacement<string>] [-TTL<secs>]
```

To remove a NAPTR record by using command line interface

```
rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-services <string>] [-regexp <expression> | -replacement <string>] ) | -recordId <positive_integer> @
```
Creating NAPTR Records for Telecommunications Domain

To configure a NAPTR record using configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click NAPTR Records.

2. In the Create NAPTR Record dialog box, set the following parameters:
   - Domain—Name of the domain for the NAPTR record. Maximum length: 255 characters.
   - Order—Integer specifying the order in which the NAPTR records must be processed in order to accurately represent the ordered list of rules. The ordering is from lowest to highest. Maximum value: 65535.
   - Preference— Integer specifying the preference of this NAPTR among NAPTR records. Maximum value: 65535.
   - Flags— Flags for this NAPTR record. Maximum length: 255 characters.
   - Regular Expression—Regular expression that specifies the substitution expression for this NAPTR. Maximum length: 255 characters.
   - Replacement—The replacement domain name for this NAPTR record. Maximum length: 255 characters.
   - TTL— Time to Live (TTL), in seconds, for the record.

3. Click Create, and then click Close.
Creating PTR Records for IPv4 and IPv6 Address

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string "in-addr.arpa." appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix ".IP6.ARPA" as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.1.2.3.4.IP6.ARPA.

To add a PTR record by using the command line interface

At the command prompt, type the following commands to add a PTR record and verify the configuration:

- add dns ptrRec <reverseDomain> <domain> [-TTL <secs>]
- show dns ptrRec <reverseDomain>

Example

> add dns ptrRec 0.2.0.192.in-addr.arpa example.com
Done
> show dns ptrRec 0.2.0.192.in-addr.arpa
1) Reverse Domain Name : 0.2.0.192.in-addr.arpa
   Domain Name : example.com TTL : 3600 secs
Done
>

To remove a PTR record, type the rm dns ptrRec command and the reverse domain name associated with the PTR record

Parameters for configuring a PTR record

reverseDomain

Reversed representation of the domain name that the PTR record must point to. Possible suffix values are in-addr.arpa. for IPv4 addresses and ip6.arpa. for IPv6 addresses. This is
Creating PTR Records for IPv4 and IPv6 Address

- domain
  The domain name for which reverse mapping is being done. This is a mandatory argument. Maximum length: 255.

- TTL

To add a PTR record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click PTR Records.

2. In the details pane, click Add.

3. In the Create PTR Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a PTR record” as shown:
   - Choose suffix*—(Select .in-addr.arpa. to specify a PTR record for an IPv4 address or .ip6.arpa. to specify a PTR record for an IPv6 address. The string that you select is appended to the reversed IP address to form the reverse domain name.)
   - IP Address*—(The IP address of the domain name. The Reverse Domain Name box displays the reverse domain name that is generated when you are entering the IP address. After you enter the IP address, verify that the reverse domain name is correct.)
   - Domain*—domain
   - TTL—TTL
     * A required parameter

4. Click Add.

The domain name appears in the Domain list. Add as many domain names as you want to the Domain list.

5. Click Create, and then click Close.
Creating SOA Records for Authoritative Information

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (e-mail), and default (minimum) time-to-live (TTL) values for records.

To create an SOA record by using the command line interface

At the command prompt, type the following commands to add an SOA record and verify the configuration:

- add dns soaRec <domain> -originServer <originServerName> -contact <contactName>
- sh dns soaRec <domain>

Example

> add dns soaRec example.com -originServer nameserver1.example.com -contact admin.example.com
  Done
> show dns soaRec example.com
  1)  Domain Name : example.com
      Origin Server : nameserver1.example.com
      Contact : admin.example.com
      Serial No. : 100    Refresh : 3600 secs   Retry : 3 secs
      Expire : 3600 secs   Minimum : 5 secs   TTL : 3600 secs
  Done
>

To modify or remove an SOA record by using the command line interface

- To modify an SOA record, type the set dns soaRec command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the rm dns soaRec command and the name of the domain for which the record is configured.
Parameters for configuring an SOA record

- **domain**
  
  Domain name for which the SOA record is added.

- **originServer**
  
  Name of the origin server for the given domain.

- **contact**
  
  Contact person for this ADNS server. This is typically an e-mail address in which the at sign (@) is replaced by a period (.).

To configure an SOA record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click SOA Records.

2. In the details pane, do one of the following:
   
   - To create an SOA record, click Add.
   
   - To configure an existing SOA record, select the SOA record, and then click Open.

3. In the Create SOA Record or Configure SOA Record dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an SOA record” as shown:
   
   - Domain Name*—domain
   
   - Origin Server*—originServer
   
   - Contact*—contact
   
   * A required parameter

4. Click Create, and then click Close.
Creating TXT Records for Holding Descriptive Text

Domain hosts store TXT records for informative purposes. A TXT record’s RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain, including information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the NetScaler appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.

To create a TXT resource record by using the command line interface

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

```
add dns txtRec <domain> <string> ... [-TTL <secs>]
show dns txtRec [<domain> | -type <type>]
```

Example

```
> add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.com" -TTL 36000
Done
> show dns txtRec www.example.com
1) Domain : www.example.com   Record id: 13783   TTL : 36000 secs Record Type : ADNS
   "Contact: Mark"
   "Email: mark@example.com"
Done
```

To remove a TXT resource record by using the command line interface

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:
Creating TXT Records for Holding Descriptive Text

- \texttt{rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)}
- \texttt{show dns txtRec [<domain> | -type <type>]} 

Example

You can use the \texttt{show dns txtRec} command first to view the record ID of the TXT resource record that you want to remove, as shown:

\begin{verbatim}
> show dns txtRec www.example.com
1) Domain : www.example.com Record id: 36865 TTL : 36000 secs Record Type : ADNS
   "Contact: Evan"
   "Email: evan@example.com"
2) Domain : www.example.com Record id: 14373 TTL : 36000 secs Record Type : ADNS
   "Contact: Mark"
   "Email: mark1@example.com"
Done
\end{verbatim}

The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

\begin{verbatim}
> rm dns txtRec www.example.com -recordID 36865
Done
> show dns txtRec www.example.com
1) Domain : www.example.com Record id: 14373 TTL : 36000 secs Record Type : ADNS
   "Contact: Mark"
   "Email: mark1@example.com"
Done
\end{verbatim}

Parameters for configuring a TXT resource record

\textbf{domain (Domain)}

The name of the domain for which you want to create a TXT resource record. Maximum length: 255 characters.

\textbf{string (Text)}

The information that you want stored in the TXT resource record. Enclose the string in single or double quotation marks. You can add up to six strings in each TXT resource record. Each string can contain a maximum of 255 characters. If the string that you want to add contains more than 255 characters, evaluate whether breaking down the string into two or more smaller strings, subject to the limit of six strings per resource record, works for you.

\textbf{TTL}

To configure a TXT record by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click TXT Records.

2. In the Create TXT Record dialog box, set the following parameters:
   · Domain
   · Text
     (Enter the string in Text, and then click Add. Repeat until you have added the strings you want. If you want to remove a string that you have added, click the cross next to the string.)
   · TTL (seconds)

3. Click Create.

4. In the details pane, verify that the details displayed for the TXT record are correct.
Viewing DNS Statistics

You can view the DNS statistics generated by the Citrix® NetScaler® appliance. The DNS statistics include runtime, configuration, and error statistics.

To view DNS records statistics by using the command line interface

At the command prompt, type:

```
stat dns
```

Example

```
> stat dns
DNS Statistics

Runtime Statistics
Dns queries 21
NS queries 8
SOA queries 18
.
.
.
Configuration Statistics
AAAA records 17
A records 36
MX records 9
.
.
.
Error Statistics
Nonexistent domain 17
No AAAA records 0
No A records 13
.
.
.
Done
>
```
To view DNS records statistics by using the configuration utility

1. Navigate to Traffic Management > DNS.

2. In the navigation pane, click DNS.

3. In the details pane, click Statistics.
Configuring a DNS Zone

A DNS zone entity on the Citrix® NetScaler® appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the NetScaler appliance.

You must create a DNS zone on the appliance in the following scenarios:

- The NetScaler appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.

- The NetScaler appliance owns only a subset of the records in a zone, and all the other resource records in the zone are hosted on a set of back-end name servers for which the appliance is configured as a DNS proxy server. A typical configuration where the NetScaler appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. Only the GSLB domain names are owned by the NetScaler appliance, while all the other records are owned by the back-end name servers. The zone must be created with the proxyMode parameter set to YES.

If the NetScaler appliance does not host any of the resource records in a zone, you need not create a zone on the appliance.

Note: If the NetScaler is operating as the authoritative DNS server for a zone, you must create Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the NetScaler is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the NetScaler appliance. For more information about creating SOA and NS records, see Configuring DNS Resource Records.

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Additionally, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

To create a DNS zone on the NetScaler appliance by using the command line interface

At the command prompt, type the following command to add a DNS zone to the NetScaler appliance and verify the configuration:

- add dns zone <zoneName> -proxyMode ( YES | NO )

- show dns zone [<zoneName> | -type <type>]

Example
To modify or remove a DNS zone by using the command line interface

- To modify a DNS zone, type the set dns zone command, the name of the DNS zone, and the parameters to be changed, with their new values.
- To remove a DNS zone, type the rm dns zone command and the name of the dns zone.

Parameters for configuring a DNS zone

zoneName

The name of the zone being added. This is a mandatory argument. Maximum length: 255

proxyMode

Specifies whether the zone is deployed in proxy mode. This is a mandatory argument. Possible values: YES, NO. Default value: ENABLED
To configure a DNS zone by using the configuration utility

1. In the navigation pane, expand DNS, and then click Zones.

2. In the details pane, do one of the following:
   - To create a DNS zone, click Add.
   - To modify an existing DNS zone, select the zone, and then click Open.

3. In the Create DNS Zone or Configure DNS Zone dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a DNS zone,” as shown:
   - DNS Zone*—zoneName (cannot be changed for an existing DNS zone)
   - Proxy Mode—proxyMode
     * A required parameter

4. Click Create or OK.

5. In the details pane, click the name of the zone you just configured and verify that the settings displayed at the bottom of the screen are correct.
You can configure the Citrix® NetScaler® appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the NetScaler resolves DNS requests for all types of DNS records that belong to the domain. To configure the NetScaler to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the NetScaler. Normally, the ADNS service uses the Mapped IP address (MIP). However, you can configure the ADNS service with any NetScaler-owned IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. NetScaler as an ADNS

The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

Table 1. Example of ADNS Service Configuration

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Type</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADNS Service</td>
<td>Service-ADNS-1</td>
<td>10.102.29.51</td>
<td>ADNS</td>
<td>53</td>
</tr>
</tbody>
</table>
To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see "Load Balancing".

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the NetScaler for the IP address of the domain. Because the NetScaler is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model

**Note:** In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the NetScaler: ANY query (for more information about the ANY query, see DNS ANY Query), and negative responses, such as NODATA and NXDOMAIN.
Creating an ADNS Service

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see "Global Server Load Balancing". You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see Configuring Services.

**Note:** You can configure the ADNS service to use MIP, SNIP, or any new IP address.

When you create an ADNS service, the NetScaler responds to DNS queries on the configured ADNS service IP and port.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.
Configuring the ADNS Setup to Use TCP

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the client must use the Transmission Control Protocol (TCP). To enable DNS communications over TCP, you must configure the NetScaler appliance to use the TCP protocol for DNS. The NetScaler then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the NetScaler. The NetScaler listens on port 53 with the IP address of the ADNS service to accept the new TCP connections from the client.

To configure the NetScaler to use the TCP protocol, you must configure an ADNS_TCP service. For instructions on creating an ADNS_TCP service, see “Load Balancing”.

**Important:** To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS_TCP services. The IP address of the ADNS_TCP service must be same as the IP address of the ADNS service.
Adding DNS Resource Records

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see Configuring DNS Resource Records.
Removing ADNS Services

For instructions on removing services, see Load Balancing.
Configuring Domain Delegation

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

Creating an SOA Record

For instructions on configuring SOA records, see Creating SOA Records for Authoritative Information.

Creating an NS Record for a Name Server

For instructions on configuring an NS record, see Creating NS Records for an Authoritative Server. In the Name Server drop-down list, select the primary authoritative name server, for example, ns1.abc.com.

Creating an Address Record

For instructions on configuring Address records, see Creating Address Records for a Domain Name. In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.
Creating an NS Record for Domain Delegation

For instructions on configuring NS records, see Creating NS Records for an Authoritative Server. In the Name Server drop-down list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

Creating a Glue Record

NS records are usually defined immediately after the SOA record (but this is not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, Configuring DNS Resource Records.

For instructions on configuring Address records, see Creating Address Records for a Domain Name. In Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.
Configuring the NetScaler as a DNS Proxy Server

As a DNS proxy server, the Citrix® NetScaler® appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. NetScaler as DNS proxy

By default, the NetScaler appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the NetScaler returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the NetScaler. The NetScaler then returns the address to the client.

For requests for a domain that has been cached earlier, the NetScaler serves the Address record of the domain from the cache without querying the configured DNS server.

The NetScaler discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the NetScaler retrieves the record from the server and updates its cache. To avoid this delay, the NetScaler proactively updates the cache by retrieving the record from the server.
before the record expires.

The following table lists sample names and the values of the entities that need to be configured on the NetScaler.

Table 1. Example of DNS Proxy Entity Configuration

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Type</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>LB virtual server</td>
<td>Vserver-DNS-1</td>
<td>10.102.29.40</td>
<td>DNS</td>
<td>53</td>
</tr>
<tr>
<td>Services</td>
<td>Service-DNS-1</td>
<td>10.102.29.50</td>
<td>DNS</td>
<td>53</td>
</tr>
<tr>
<td></td>
<td>Service-DNS-2</td>
<td>10.102.29.51</td>
<td>DNS</td>
<td>53</td>
</tr>
</tbody>
</table>

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the NetScaler.

![Figure 2. DNS Proxy Entity Model](image)

**Note:** To configure DNS proxy, you need to know how to configure load balancing services and virtual servers. For information about configuring load balancing services and virtual servers, see “Load Balancing”, and then configure DNS proxy setup.
Creating a Load Balancing Virtual Server

To configure a DNS Proxy on the NetScaler ADC, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see “Load Balancing”.
Creating DNS Services

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see "Load Balancing".
To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see Load Balancing™.
Configuring the DNS Proxy Setup to Use TCP

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use the Transmission Control Protocol (TCP). When a client sends the Citrix® NetScaler® appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the NetScaler. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The NetScaler relays the response to the client with the truncation bit intact and waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The NetScaler appliance then forwards the request to the name server and relays the response to the client.

To configure the NetScaler to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type DNS_TCP. You can configure monitors of type DNS_TCP to check the state of the services. For instructions on creating DNS_TCP virtual servers, services, and monitors, see “Load Balancing.”

For updating the records proactively, the NetScaler uses a TCP connection to the server to retrieve the records.

**Important:** To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure DNS and DNS_TCP services. The IP address of the DNS_TCP service must be same as that of the DNS service.
Enabling Caching of DNS Records

To complete the process of configuring a DNS proxy on the NetScaler, you must enable caching of DNS records. You must also specify minimum and maximum time-to-live (TTL) values for the records that are cached. The TTL values are measured in seconds.

To enable caching of DNS records by using the command line interface

At the command prompt, type the following commands to enable caching of DNS records and verify the configuration:

- set dns parameter -cacheRecords Yes
- show dns parameter

Example

> set dns parameter -cacheRecords YES
Done
> show dns parameter

. . .
Cache Records : YES
. . .
Done
>

To enable caching of DNS records by using the configuration utility

1. In the navigation pane, click DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable records caching check box, and then click OK.
Configuring Time-to-Live Values for DNS Entries

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 2147483647. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.

To specify the minimum and/or maximum TTL by using the command line interface

At the NetScaler command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

- set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
- show dns parameter

Example

> set dns parameter -minTTL 1200 -maxTTL 1800
Done
> show dns parameter
DNS parameters:
  DNS retries: 5
  Minimum TTL: 1200               Maximum TTL: 1800
  
Done
>

To specify the minimum and/or maximum TTL by using the configuration utility

1. In the navigation pane, click DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

Note: When the TTL expires, the record is deleted from the cache. The NetScaler proactively contacts the servers and obtains the DNS record just before the DNS record expires.
Flushing DNS Records

You can delete all DNS records present in the cache. For example, you might want to flush
DNS records when a server is restarted after modifications are made.

To delete all proxy records by using the command line
interface

At the NetScaler command prompt, type:

    flush dns proxyRecords

To delete all proxy records by using the configuration utility

1. In the navigation pane, expand DNS, expand Records, and then click Address Records.

2. In the details pane, click Flush Proxy Records.
Adding DNS Resource Records

You can add DNS records to a domain for which the Citrix® NetScaler® appliance is configured as a DNS proxy server. For information about adding DNS records, see Configuring DNS Resource Records.
Removing a Load Balancing DNS Virtual Server

For information about removing a load balancing virtual server, see Load Balancing.
Limiting the Number of Concurrent DNS Requests on a Client Connection

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the `<clientip:port>:-<vserver ip:port>` tuple. Concurrent DNS requests are those requests that the NetScaler appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped till the outstanding request count goes below the limit. This limit does not apply to the requests that the NetScaler appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve a large number of concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

To specify the maximum number of concurrent DNS requests allowed on a single client connection by using the command line interface

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

- `set dns parameter -maxPipeline <positive_integer>`
- `show dns parameter`

Example

```
> set dns parameter -maxPipeline 1000
Done
> show dns parameter
   DNS parameters:
   DNS retries: 5
   Max DNS Pipeline Requests: 1000
Done
> 
```
Parameters for specifying the maximum number of concurrent DNS requests on a single client connection

maxPipeline

Specifies the maximum number of concurrent DNS requests that are allowed on a single client connection. A value of 0 (zero) implies that there is no limit to the number of concurrent DNS requests that are allowed on a single client connection. Default value: 255

To specify the maximum number of concurrent DNS requests allowed on a single client connection by using the configuration utility

1. In the navigation pane, click DNS.

2. In the details pane, click Change DNS settings.

3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests, which corresponds to the parameter described in “Parameters for specifying the maximum number of concurrent DNS requests on a single client connection.”

4. Click OK.
Configuring the NetScaler as an End Resolver

A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name to obtain its IP address. The NetScaler can provide end-to-end resolution for DNS queries.

In recursive resolution, the NetScaler appliance queries different name servers recursively to access the IP address of a domain. When the NetScaler receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the NetScaler appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the NetScaler does not allow you to delete all 13 records; at least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.
In the process shown in the diagram, when the name server receives a query for the address of s1.s2.s3.com, it first checks the root name servers for s1.s2.s3.com. A root name server reports back with the address of the .com name server. If the address of s1.s2.s3.com is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for s3.com, then for s2.s3.com to retrieve the address of s1.s2.s3.com. In this way, resolution always starts from root name servers and ends with the domain’s authoritative name server.

**Note:** For recursive resolution functionality, caching should be enabled.
Enabling Recursive Resolution

To configure the NetScaler appliance to function as an end resolver, you must enable recursive resolution on the appliance.

To enable recursive resolution by using the command line interface

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

- `set dns parameter -recursion ENABLED`
- `show dns parameter`

Example

```
> set dns parameter -recursion ENABLED
Done
> show dns parameter
  DNS parameters:
    
    Recursive Resolution : ENABLED
    
    Done
```

To enable recursive resolution by using the configuration utility

1. In the navigation pane, click DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.
Setting the Number of Retries

The NetScaler appliance can be configured to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

To set the number of DNS retries by using the command line interface

At the command prompt, type the following commands to set the number of retries and verify the configuration:

- set dns parameter -retries <positive_integer>
- show dns parameter

Example

> set DNS parameter -retries 3
Done
> show dns parameter
  DNS parameters:
  DNS retries: 3
  .
  .
  .
Done
>

To set the number of retries by using the configuration utility

1. In the navigation pane, click DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.
Configuring the NetScaler as a Forwarder

A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server’s network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder accumulates external DNS information in its cache as it resolves DNS queries. To configure the NetScaler as a forwarder, you must add an external name server (a name server other than the Citrix NetScaler appliance).

The NetScaler appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the NetScaler appliance as a forwarder, you must add the name servers to which it should forward name resolution queries. You can specify the lookup priority to specify the name service that the NetScaler appliance must use for name resolution.
Adding a Name Server

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

While adding name servers, you can provide an IP address or a virtual IP address (VIP). If you add an IP address, the NetScaler load balances requests to the configured name servers in round robin method. If you add a VIP, you can configure any load balancing method.

Example 1, which follows the command synopsis below, adds a local name server. Example 2 specifies the name of a load balancing virtual server of service type DNS.

**Note:** To verify the configuration, you can also use the `sh dns <recordtype> <domain>` command. If the queried records are not present in the cache, the resource records are fetched from the configured external name servers.

### To add a name server by using the command line interface

At the command prompt, type the following commands to add a name server and verify the configuration:

- `add dns nameServer ((<IP> [-local]) | <dnsVserverName>)`
- `show dns nameServer [<IP> | <dnsVserverName>]`

**Example 1**

```bash
> add dns nameServer 10.102.9.20 -local
Done
> show dns nameServer 10.102.9.20
1) 10.102.9.20: LOCAL - State: UP
Done
>
```

**Example 2**

```bash
> add dns nameServer dnsVirtualNS
Done
> show dns nameServer dnsVirtualNS
1) dnsVirtualNS - State: DOWN
Done
>
```
To remove a name server by using the NetScaler command line, at the NetScaler command prompt, type the `rm dns nameServer` command followed by the IP address of the name server.

**Parameters for adding a name server**

**IP**

The IP address of the name server.

**local**

Specifies that the IP address belongs to a local recursive name server.

**dnsVserverName**

The name of a DNS virtual server. Maximum length: 127.

**To add a name server by using the configuration utility**

1. In the navigation pane, expand DNS, and then click Name Servers.

2. In the details pane, click Add.

3. In the Create Name Server dialog box, do one of the following:

   - To add an IP address, click IP Address, and in the IP Address text box, type the IP address of the name server, for example, **10.102.29.10**. If you are adding an external name server, clear the Local check box.
   
   - To add a DNS virtual server, click DNS Virtual Server, and select a DNS virtual server. Click New if you want to create a new load balancing virtual server. The Create Virtual Server (Load Balancing) dialog box appears.

4. Click Create, and then click Close.

**Note:** When name servers are added in the Forwarder mode, the Local option must be cleared. When name servers are added in the End Resolver mode, the Local option must be selected.
Setting DNS Lookup Priority

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

To set the lookup priority to DNS by using the command line interface

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

- set dns parameter -nameLookupPriority (DNS | WINS)
- show dns parameter

Example

```
> set dns parameter -nameLookupPriority DNS
Done
> show dns parameter
  
  Name lookup priority : DNS
  
  Done
```

To set lookup priority to DNS by using the configuration utility

1. In the navigation pane, click DNS.

2. In the details pane, under Settings, click Change DNS settings.

3. In the Configure DNS Parameters dialog box, under Name Lookup Priority, select DNS or WINS, and then click OK.

Note: If the DNS virtual server that you have configured is DOWN and if you set the -nameLookupPriority to DNS, the NetScaler does not attempt WINS lookup. Therefore, if a
Setting DNS Lookup Priority

DNS virtual server is not configured or is disabled, set the -nameLookupPriority to WINS.
Disabling and Enabling Name Servers

The following procedure describes the steps to enable or disable an existing name server.

To enable or disable a name server by using the command line interface

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

- (enable | disable) dns nameServer <IPAddress>
- show dns nameServer <IPAddress>

Example

> disable dns nameServer 10.102.9.19
   Done
> show dns nameServer 10.102.9.19
   1) 10.102.9.19: LOCAL  -  State: OUT OF SERVICE
      Done
> 

To enable or disable a name server by using the configuration utility

1. In the navigation pane, expand DNS, and then click Name Servers.
2. In the details pane, select the name server that you want to enable or disable.
3. Click Enable or Disable. If a name server is enabled, the Disable option is available. If a name server is disabled, the Enable option is available.
Configuring DNS Suffixes

You can configure DNS suffixes that enable the NetScaler appliance to complete non-fully qualified domain names (non-FQDNs) during name resolution. For example, during the process of resolving the domain name abc (which is not fully qualified), if a DNS suffix example.com is configured, the appliance appends the suffix to the domain name (abc.example.com) and resolves it. If DNS suffixes are not configured, the appliance appends a period to the non-FQDNs and resolves the domain name.

Creating DNS Suffixes

DNS suffixes have significance and are valid only when the NetScaler is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.

To create DNS suffixes by using the command line interface

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

- add dns suffix <dnsSuffix>
- show dns suffix <dnsSuffix>

Example

> add dns suffix example.com
Done
> show dns suffix example.com
1)      Suffix: example.com
Done
>

To remove a DNS suffix by using the NetScaler command line, at the NetScaler command prompt, type the rm dns suffix command and the name of the DNS suffix.

To create DNS suffixes by using the configuration utility

1. In the navigation pane, expand DNS, and then click DNS Suffix.
2. In the details pane, click Add.
3. In the Create DNS Suffix dialog box, type the suffix (for example, example.com).
4. Click Create, and then click Close.
DNS ANY Query

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.
Behavior in ADNS Mode

In the ADNS mode, the NetScaler appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the NetScaler can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.
Behavior in DNS Proxy Mode

In proxy mode, the NetScaler appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.
Behavior for GSLB Domains

If a GSLB domain is configured on the NetScaler appliance and an ANY query is sent for the GSLB domain (or GSLB site domain), the appliance returns the IP address of the GSLB service that it selects through the Load Balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the NetScaler to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the NetScaler.

**Note:** If records for a domain are distributed between the NetScaler and a server, only records configured on the NetScaler are returned.

The NetScaler provides the option to configure DNS views and DNS policies. These are used for performing global server load balancing. For more information, see [Global Server Load Balancing](#).
DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard that aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting User Datagram Protocol (UDP) responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

You can configure DNSSEC on the Citrix® NetScaler® ADC. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the NetScaler ADC is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of backend name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.
Configuring DNSSEC

Configuring DNSSEC involves enabling DNSSEC on the Citrix® NetScaler® appliance, creating a Zone Signing Key and a Key Signing Key for the zone, adding the two keys to the zone, and then signing the zone with the keys.

The NetScaler ADC does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—NetScaler is the ADNS and generates the signatures itself.

2. Proxy—NetScaler acts as a DNSSEC proxy. It is assumed that the NetScaler is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.
Enabling and Disabling DNSSEC

You must enable DNSSEC on the NetScaler ADC for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the NetScaler ADC to respond to clients with DNSSEC-specific information.

To enable or disable DNSSEC by using the command line interface

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

- set dns parameter -dnssec ( ENABLED | DISABLED )
- show dns parameter

Example

> set dns parameter -dnssec ENABLED
Done
> show dns parameter
   DNS parameters:
   DNS retries: 5
   .
   .
   .
   DNSEC Extension: ENABLED
   Max DNS Pipeline Requests: 255
Done
>

Parameters for enabling and disabling DNSSEC

dnssec

Enable or disable DNSSEC on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default value: ENABLED
To enable or disable DNSSEC by using the configuration utility

1. In the navigation pane, click DNS.

2. In the details pane, click Change DNS settings.

3. In the Configure DNS Parameters dialog box, select or clear the Enable DNSSEC Extension check box.
Creating DNS Keys for a Zone

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the Zone Signing Key, is used to sign all the resource record sets in the zone. The second pair is called the Key Signing Key and is used to sign only the DNSKEY resource records in the zone.

When the Zone Signing Key and Key Signing Key are created, the suffix .key is automatically appended to the names of the public components of the keys and the suffix .private is automatically appended to the names of their private components.

Additionally, the NetScaler ADC also creates a Delegation Signer (DS) record and appends the suffix .ds to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the /nsconfig/dns/ directory, but it is not automatically published in the zone. After you create a key by using the create dns key command, you must explicitly publish the key in the zone by using the add dns key command. The process of generating a key has been separated from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as bind-keygen) by using Secure File Transfer Protocol (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see Publishing a DNS Key in a Zone.

Perform the steps described in this topic to create a Zone Signing Key and then repeat the steps to create a Key Signing Key. The example that follows the command syntax first creates a Zone Signing Key pair for the zone example.com. The example then uses the command to create a Key Signing Key pair for the zone.

To create a DNS key by using the command line interface

At the NetScaler command prompt, type the following command to create a DNS key:

```
create dns key -zoneName <string> -keyType <keyType> -algorithm RSASHA1 -keySize <positive_integer> -fileNamePrefix <string>
```

**Example**

```
> create dns key -zoneName example.com -keyType zsk -algorithm RSASHA1 -keySize 1024 -fileNamePrefix example.com
File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
This operation may take some time, Please wait...
Done
> create dns key -zoneName example.com -keyType ksk -algorithm RSASHA1 -keySize 4096 -fileNamePrefix example.com
File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
This operation may take some time, Please wait...
```
Parameters for creating a DNS Key

zoneName

The name of the zone for which the key is being added. This is a mandatory argument.

keyType

The type of key. This is a mandatory argument. Possible values: KSK, KeySigningKey, ZSK, ZoneSigningKey.

Default value: ZSK

algorithm

The algorithm that must be used to generate the keys. This is a mandatory argument. Possible values: RSASHA1. Default value: RSASHA1.

keySize

The key strength. This is a mandatory argument. Default value: 512

fileNamePrefix

A common prefix for the public and private components of the key pair. During key generation, the .key and .private suffixes are appended automatically to the file name prefix.
To create a DNS key by using the configuration utility

1. In the navigation pane, click DNS.

2. In the details area, click Create DNS Key.

3. In the Create DNS Key dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a DNS Key,” as shown:

   - Zone Name*—zoneName
   - Type*—keyType
   - Algorithm*—algorithm
   - Size*—keySize
   - File Name Prefix*—fileNamePrefix

* A required parameter

**Note:** For File Name Prefix, if you want to modify the file name prefix of an existing key, click the arrow next to the Browse button, click either Local or Appliance (depending on whether the existing key is stored on your local computer or in the /nsconfig/dns/ directory on the appliance), browse to the location of the key, and then double-click the key. The File Name Prefix box is populated with only the prefix of the existing key. Modify the prefix accordingly.

4. Click Create, and then click Close.
Publishing a DNS Key in a Zone

A key (Zone Signing Key or Key Signing Key) is published in a zone by adding the key to the NetScaler ADC. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the /nsconfig/dns/ directory. Therefore, if you used other means to generate the key—means other than the create dns key command on the NetScaler ADC (for example, by using the bind-keygen program on another computer)—make sure that the key is added to the /nsconfig/dns/ directory before you publish the key in the zone.

If the key has been generated by another program, you can import the key to your local computer and use the NetScaler configuration utility to add the key to the /nsconfig/dns/ directory. Or, you can use other means to import the key to the directory, such as the Secure File Transfer Protocol (SFTP).

You must use the add dns key command for each public-private key pair that you want to publish in a given zone. If you created a Zone Signing Key pair and a Key Signing Key pair for a zone, use the add dns key command to first publish one of the key pairs in the zone and then repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the Zone Signing Key pair (that was created for the example.com zone) in the zone. The example then uses the command to publish the Key Signing Key pair in the zone.

To publish a key in a zone by using the command line interface

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

```
add dns key <keyName> <publickey> <privatekey> [-expires <positive_integer> [-units>] [-notificationPeriod <positive_integer> [-units>]] [-TTL <secs>]
```

```
add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.com.zsk.rsasha1.1024.private
Done
```

```
add dns key example.com.ksk example.com.ksk.rsasha1.4096.key example.com.ksk.rsasha1.4096.private
Done
```

```
show dns zone example.com
  Zone Name : example.com
  Proxy Mode : NO
  Domain Name : example.com
```
Parameters for publishing a key in a zone

**KeyName**

The name given to a public-private key pair. This is a mandatory argument. Maximum length: 31.

**publickey**

File name of the public key that is used for signing the zone. This is a mandatory argument. Maximum length: 63

**privatekey**

File name of the private key that is used for signing the zone. This is a mandatory argument. Maximum length: 63

**expires**

Time for which the key is valid. Default value: 120 days. Minimum value: 1. Maximum value: 32767.

**units**

Units for the expiry time. Possible values: MINUTES, HOURS, DAYS. Default value: DAYS.

**notificationPeriod**

Number of days, hours, or minutes prior to expiry of a key when a notification should be generated. Default value: 7 days. Minimum value: 1. Maximum value: 32767.

**units**

Units for the notification period. Possible values: MINUTES, HOURS, DAYS. Default value: DAYS.

**TTL**

To publish a key in a DNS zone by using the NetScaler configuration utility

1. In the navigation pane, expand DNS, and then click Keys.

2. In the details pane, click Add.

3. In the Add DNS Key dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding a key to the NetScaler ADC,” as shown:
   - DNS Key Name*—keyName
   - Public Key*—publickey
   - Private Key*—privatekey
   - Expires—expires
   - Notification Period—notificationPeriod
   - TTL—TTL
   * A required parameter

   **Note:** For Public Key and Private Key, to add a key that is stored on your local computer, click the arrow next to the Browse button, click Local, browse to the location of the key, and then double-click the key.

4. Click Create, and then click Close.
Configuring a DNS Key

You can configure the parameters of a key that has been published in a zone. You can modify the key’s expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the NetScaler ADC automatically re-signs all the resource records in the zone with the key, provided that the zone is currently signed with the particular key.

To configure a key by using the command line interface

At the command prompt, type the following command to configure a key and verify the configuration:

- set dns key <keyName> [-expires <positive_integer> [units]] [-notificationPeriod <positive_integer> [units]] [-TTL <secs>]
- show dns key [<keyName>]

Example

> set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3 DAYS -TTL 3600
Done
> show dns key example.com.ksk
1)    Key Name: example.com.ksk
      Expires: 30 DAYS   Notification: 3 DAYS   TTL: 3600
      Public Key File: example.com.ksk.rsasha1.4096.key
      Private Key File: example.com.ksk.rsasha1.4096.private
Done
>

Parameters for configuring a key

keyName

The name given to a public/private key pair. This is a mandatory argument. Maximum length: 31.

expires

Time for which the key is valid. Default value: 120 days. Minimum value: 1. Maximum value: 32767.
Configuring a DNS Key

units

Units for the expiry time. Possible values: MINUTES, HOURS, DAYS. Default value: DAYS.

notificationPeriod

Number of days, hours, or minutes prior to expiry of a key when a notification should be generated. Default value: 7 days. Minimum value: 1. Maximum value: 32767.

units

Units for the notification period. Possible values: MINUTES, HOURS, DAYS. Default value: DAYS.

TTL

To configure a key by using the configuration utility

1. In the navigation pane, expand DNS, and then click Keys.

2. In the details pane, click the key that you want to configure, and then click Open.

3. In the Configure DNS Key dialog box, modify the values of the following parameters, which correspond to parameters described in “Parameters for configuring a key,” as shown:
   · Expires—expires
   · Notification Period—notificationPeriod
   · TTL—TTL

4. Click OK.
Signing and Unsigning a DNS Zone

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the NetScaler ADC creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the Key Signing Key to sign the DNSKEY resource record set. Finally, it uses the Zone Signing Key to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, you must save the configuration.

To sign a zone by using the command line interface

At the command prompt, type the following command to sign a zone and verify the configuration:

- `sign dns zone <zoneName> [-keyName <string> ...]`
- `show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]`
- `save config`

Example

```bash
> sign dns zone example.com -keyName example.com.zsk example.com.ksk
Done
> show dns zone example.com
Zone Name : example.com
Proxy Mode : NO
Domain Name : example.com
  Record Types : NS SOA DNSKEY RRSIG NSEC
Domain Name : ns1.example.com
  Record Types : A RRSIG NSEC
Domain Name : ns2.example.com
  Record Types : A RRSIG
Domain Name : ns2.example.com
  Record Types : RRSIG NSEC
Done
> save config
Done
> save config
```
To unsign a zone by using the command line interface

At the command prompt, type the following command to unsign a zone and verify the configuration:

- `unsign dns zone <zoneName> [-keyName <string> ...]`
- `show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]`

**Example**

```plaintext
> unsign dns zone example.com -keyName example.com.zsk example.com.ksk
Done
> show dns zone example.com
    Zone Name : example.com
    Proxy Mode : NO
    Domain Name : example.com
        Record Types : NS SOA DNSKEY
    Domain Name : ns1.example.com
        Record Types : A
    Domain Name : ns2.example.com
        Record Types : A
```

**Parameters for signing and unsigning a DNS zone**

- **zoneName**
  
  The name of the zone being signed. This is a mandatory argument. Maximum length: 255.

- **keyName**
  
  The name given to a public/private key pair. Maximum length: 127
To sign or unsign a zone by using the configuration utility

1. In the navigation pane, expand DNS, and then click Zones.

2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.

3. In the Sign/Unsign DNS Zone dialog box, do one of the following:

   · To sign the zone, select the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to sign the zone.

   You can sign the zone with more than one Zone Signing Key or Key Signing Key pair.

   · To unsign the zone, clear the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to unsign the zone.

   You can unsign the zone with more than one Zone Signing Key or Key Signing Key pair.

4. Click OK.
Viewing the NSEC Records for a Given Record in a Zone

You can view the NSEC records that the NetScaler ADC automatically creates for each owner name in the zone.

To view the NSEC record for a given record in a zone by using the command line interface

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

`show dns nsecRec `<hostName>` | -type (ADNS | PROXY | ALL)`

Example

```
> show dns nsecRec example.com
1) Domain Name : example.com
   Next Nsec Name: ns1.example.com
   Record Types : NS SOA DNSKEY RRSIG NSEC
Done
>
```

Parameters for viewing the NSEC record for a given record in a zone

**hostName**

The domain name whose information is to be displayed.

Maximum length: 255

**type**

The NSEC record type. The type can take 3 values:

ADNS - If this is specified, all of the authoritative NSEC records will be displayed.

PROXY - If this is specified, all of the proxy NSEC records will be displayed.

ALL - If this is specified, all of the NSEC records will be displayed.
Possible values: ALL, ADNS, PROXY

**To view the NSEC record for given record in a zone by using the configuration utility**

1. In the navigation pane, expand DNS, expand Records, and then click Next Secure Records.

2. In the details pane, click the name of the record for which you want to view the NSEC record. The NSEC record for the record you select is displayed in the Details area.
Removing a DNS Key

You remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the /nsconfig/dns/ directory. If the key files are no longer needed, they have to be explicitly removed from the directory.

To remove a key from the NetScaler ADC by using the command line interface

At the command prompt, type the following command to remove a key and verify the configuration:

- `rm dns key <keyName>`
- `show dns key <keyName>`

**Example**

```bash
> rm dns key example.com.zsk
Done
> show dns key example.com.zsk
ERROR: No such resource [keyName, example.com.zsk]
> 
```

Parameters for removing a key from the NetScaler ADC

- **keyName**
  
The name given to a public/private key pair. This is a mandatory argument. Maximum length: 31
To remove a key from the NetScaler ADC by using the configuration utility

1. Navigate to Traffic Management > DNS > Keys.

2. In the navigation pane, expand DNS, and then click Keys.

3. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.
Configuring DNSSEC When the NetScaler ADC is Authoritative for a Zone

When the Citrix® NetScaler® ADC is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create keys (the Zone Signing Key and the Key Signing Key) for the zone, add the keys to the ADC, and then sign the zone, as described in Creating DNS Keys for a Zone, Publishing a DNS Key in a Zone, and Signing and Unsigning a DNS Zone, respectively.

If any global server load balancing (GSLB) domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see Enabling and Disabling DNSSEC.

Finally, after you configure DNSSEC for the authoritative zone, you must save the NetScaler configuration.
Configuring DNSSEC for a Zone for Which the NetScaler ADC Is a DNS Proxy Server

The procedure for signing a zone for which the Citrix® NetScaler® ADC is configured as a DNS proxy server depends on whether or not the ADC owns a subset of the zone information owned by the backend name servers. If it does, the configuration is considered a partial zone ownership configuration. If the ADC does not own a subset of the zone information, the NetScaler configuration for managing the backend servers is considered a zone-less DNS proxy server configuration. The basic DNSSEC configuration tasks for both NetScaler configurations are the same. However, signing the partial zone on the NetScaler ADC requires some additional configuration steps.

**Note:** The terms zone-less proxy server configuration and partial zone are used only in the context of the NetScaler appliance.

**Important:** When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained, and the response from the server is not cached. In releases prior to 10.5.e build xx.x, the ADC unset the CD bit before passing it to the server and also cached the server response.
Configuring DNSSEC for a Zone-Less DNS Proxy Server Configuration

For a zone-less DNS proxy server configuration, zone signing must be performed on the backend name servers. On the NetScaler ADC, you configure the ADC as a DNS proxy server for the zone. You create a load balancing virtual server of protocol type DNS, configure services on the ADC to represent the name servers, and then bind the services to the load balancing virtual server. For more information about these configuration tasks, see Configuring the NetScaler as a DNS Proxy Server.

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers, and then relays the response from the name server to the client. Additionally, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records, and does not include the RRSIG resource records that are specific to DNSSEC.
Configuring DNSSEC for a Partial Zone Ownership Configuration

In some NetScaler configurations, even though the authority for a zone lies with the backend name servers, a subset of the resource records that belong to the zone might be configured on the NetScaler ADC. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a partial zone on the ADC. The ADC owns the partial zone. All other records are owned by the backend name servers.

A typical partial zone configuration on the NetScaler ADC is seen when global server load balancing (GSLB) domains are configured on the ADC, and the GSLB domains are a part of a zone for which the backend name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves including the partial zone information in the backend name server zone files, signing the zone on the backend name servers, and then signing the partial zone on the ADC. The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

To sign the zone on the backend name servers

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.

2. Create keys and use the keys to sign the zone on the backend name servers.
To sign the partial zone on the NetScaler ADC

1. Create a zone with the name of the zone that is owned by the backend name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

   For example, if the name of the zone that is configured on the backend name servers is example.com, you must create a zone named example.com on the ADC, with the proxyMode parameter set to YES. For more information about adding a zone, see Configuring a DNS Zone.

   **Note:** Do not add SOA and NS records for the zone. These records should not exist on the ADC for a zone for which the ADC is not authoritative.

2. Import the keys (from one of the backend name servers) to the ADC and then add them to the /nsconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see Publishing a DNS Key in a Zone.

3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource records in the partial zone, respectively. For more information about signing a zone, see Signing and Unsigning a DNS Zone.
Configuring DNSSEC for GSLB Domain Names

If global server load balancing (GSLB) is configured on the Citrix® NetScaler® ADC and the ADC is authoritative for the zone to which the GSLB domain names belong, all GSLB domain names are signed when the zone is signed. For more information about signing a zone for which the ADC is authoritative, see Configuring DNSSEC When the NetScaler Appliance Is Authoritative for a Zone.

If the GSLB domains belong to a zone for which the backend name servers are authoritative, you must first sign the zone on the name servers, and then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone. For more information, see Configuring DNSSEC for a Partial Zone Ownership Configuration.
From a DNSSEC perspective, zone maintenance involves rolling over Zone Signing Keys and Key Signing Keys when key expiry is imminent. These zone maintenance tasks have to be performed manually. The process of re-signing a zone is performed automatically and does not require manual intervention.
Re-Signing an Updated Zone

When a zone is updated, that is, when new records are added to the zone or existing records are changed, the process of re-signing the new (or modified) record is performed automatically by the Citrix® NetScaler® ADC. If a zone contains multiple Zone Signing Keys, the ADC re-signs the new (or modified) record with the key with which the zone is signed at the point in time when the re-signing is to be performed.
Rolling Over DNSSEC Keys

On the NetScaler ADC, you can use the pre-publish and double signature methods to perform a rollover of the Zone Signing Key and Key Signing Key. More information about these two rollover methods is available in RFC 4641, “DNSSEC Operational Practices.”

The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called dnskeyExpiry. Three MIB variables, dnskeyName, dnskeyTimeToExpire, and dnskeyUnitsOfExpiry are sent along with the dnskeyExpiry SNMP trap. For more information, see Citrix NetScaler SNMP OID Reference at http://support.citrix.com/article/CTX132381.

Pre-Publish Key Rollover

RFC 4641, “DNSSEC Operational Practices” defines four stages for the pre-publish key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

  **Example**

  Consider the key, example.com.zsk1, with which the zone example.com is currently signed. The zone contains only those RRSIGs that were generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone (that is, the key is added to the ADC), but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record (that corresponds to the new key) enough time to propagate to the secondary name servers.

  **Example**

  A new key example.com.zsk2 is added to the example.com zone. The zone is not signed with example.com.zsk2 until the pre-roll phase is complete. The example.com zone contains DNSKEY resource records for both example.com.zsk1 and example.com.zsk2.

**NetScaler commands**

Perform the following tasks on the ADC:
Double Signature Key Rollover

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.
Example

Consider the key, example.com.zsk1, with which the zone example.com is currently signed. The zone contains only those RRSIGs that were generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

Stage 2: New DNSKEY. The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

Example

A new key example.com.zsk2 is added to the example.com zone. The zone is signed with example.com.zsk2. The example.com zone now contains the RRSIGs generated from both keys.

NetScaler commands

Perform the following tasks on the ADC:

- Create a new DNS key by using the create dns key command.
  
  For more information about creating a DNS key, including an example, see Creating DNS Keys for a Zone.

- Publish the new key in the zone by using the add dns key command.
  
  For more information about publishing the key in the zone, including an example, see Publishing a DNS Key in a Zone.

- Sign the zone with the new key by using the sign dns zone command.
  
  For more information about signing a zone, including examples, see Signing and Unsigning a DNS Zone.

Stage 3: DNSKEY Removal. When the RRSIGs that were generated by the old DNS key expire, the old DNS key is removed from the zone.

Example

The old DNS key example.com.zsk1 is removed from the example.com zone.

NetScaler commands

On the ADC, you remove the old DNS key by using the rm dns key command.

For more information about removing a key from a zone, including an example, see Removing a DNS Key.
Offloading DNSSEC Operations to the NetScaler ADC

For DNS zones for which your DNS servers are authoritative, you can offload DNSSEC operations to the NetScaler ADC. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response on the fly before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see Configuring a DNS Zone.

You must create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see Domain Name System Security Extensions.

After you configure DNS offloading, you must flush the DNS cache on the ADC. Flushing the DNS cache ensures that any unsigned records in the cache are removed and subsequently replaced by signed records. For information about flushing the DNS cache, see Enabling Caching of DNS Records.

**Note:** DNSSEC offloading is supported on all NetScaler MPX platforms, except the NetScaler MPX 9700/10500/12500/15500 FIPS platform. The feature is also supported on NetScaler virtual appliances hosted on NetScaler SDX platforms.

**To enable DNSSEC offloading for a zone by using the command line interface**

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

- add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec ( ENABLED | DISABLED )]
Offloading DNSSEC Operations to the NetScaler ADC

- show dns zone

Example

```plaintext
> add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec ENABLED
Done
> show dns zone example.com
  Zone Name : example.com
  Proxy Mode : YES
  DNSSEC Offload: ENABLED    NSEC: ENABLED
Done
> 
```

Parameters for enabling DNSSEC offloading for a zone

- **dnssecOffload**
  
  Offload DNSSEC operations for the DNS zone to the NetScaler appliance.

- **nsec**
  
  Generate NSEC records for the zone. The NetScaler appliance typically includes NSEC records in its response to the client when a DNS server sends an NXDOMAIN or NODATA response. When disabled, the NetScaler appliance does not include NSEC records in its response.

To enable DNSSEC offloading for a zone by using the configuration utility

1. In the navigation pane, expand DNS, and then click Zones.

2. In the details pane, do one of the following:
   - To create a zone on the ADC, click Add.
   - To configure DNSSEC offloading for an existing zone, click the zone, and then click Open.

3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.

4. Optionally, if you want the ADC to generate NSEC records for the zone, select the NSEC check box.

5. Click OK.
Firewall Load Balancing

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a NetScaler appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two NetScaler appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single NetScaler appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The multiple-firewall environment involves configuring a NetScaler appliance sandwiched between two firewalls.

**Important:** If you configure static routes on the NetScaler for the destination IP address and enable L3 mode, the NetScaler uses its routing table to route the traffic instead of sending the traffic to the load balancing vserver.

**Note:** For FTP to work, an additional virtual server or service should be configured on the NetScaler with IP address and port as * and 21 respectively, and the service type specified as FTP. In this case, the NetScaler manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the NetScaler. Also, you can configure only a few types of persistence and monitors.

**Firewall Load Balancing Methods**

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
Firewall Load Balancing

- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

Firewall Persistence

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

Firewall Server Monitoring

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.
Sandwich Environment

A NetScaler deployment in a sandwich mode is capable of load balancing network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a NetScaler is located on each side of a set of firewalls. The NetScaler placed between the firewalls and the Internet, called the external NetScaler that handles ingress traffic selects the best firewall, based on the configured method. The NetScaler between the firewalls and the private network, called the internal NetScaler tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal NetScaler can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.
Figure 1. Firewall Load Balancing (Sandwich)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.
Configuring the External NetScaler in a Sandwich Environment

Perform the following tasks to configure the external NetScaler in a sandwich environment:

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature LB`
- `show ns feature`

Example

```
> enable ns feature LoadBalancing
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
</tbody>
</table>
```

332
Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

Parameters for configuring a wildcard service for each firewall

**name**

Name of the service. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**serverName**

Either the name of a previously created server object, or the IP address of the load-balanced server, that is associated with this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.

If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP. For a wildcard service, specify a service type of ANY.

**port**
Port on which the service listens. The port number must be a positive number not greater than 65535. For a wildcard service, specify an asterisk (*) as the port number.

**Note:** For more information about the SSL and SSL_TCP service types, see SSL Offload and Acceleration.

To configure a wildcard service for each firewall by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a wildcard service for each firewall” as shown:
   - Service Name
   - Server

4. In Protocol, select ANY, and in Port, select *.

5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
bind lb monitor <monitorName> <serviceName>

Example

add monitor monitor-HTTP-1 HTTP -dest 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
To bind a PING monitor, type the following command:
bind monitor PING fw-svc1

Parameters for configuring a monitor

monitorName (Name)

The name of the monitor. This is a mandatory argument. Maximum Length: 31.

type (Type)

The type of monitor. This is a mandatory argument. Default: PING.

destIP (Destination IP)

The IP address to which the probe is sent. If the destination IP address is set to 0, the
destination IP address is that of the server to which the monitor is bound. Default value: 0

transparent (Transparent)

The state of the monitor for transparent devices, such as firewalls, based on the
responsiveness of the services behind them. If the monitoring of transparent devices is
enabled, the destination IP address should be specified. The probe is sent to the
specified destination IP address using the MAC address of the transparent device.
Possible values: YES, NO. Default value: NO
To create and bind a transparent monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor” as shown:

   - Name*
   - Type*
   - Destination IP
   - Transparent
   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server for traffic coming from the Internet

To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

Example

```
add lb vserver Vserver-LB-1 ANY * *
```

Parameters for configuring a wildcard virtual server for traffic coming from the Internet

- **name**

  Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )
IP Address

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

Service Type

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

Port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a wildcard virtual server for traffic coming from the Internet” as shown:

   - Name—name

4. In Protocol, select ANY, and in IP Address and Port, select *.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

Example

```
set lb vserver Vserver-LB-1 -m MAC
```
Parameter for configuring the virtual server in MAC rewrite mode

The load balancing redirection mode. Possible Values: IP, MAC. Default: IP.

If set to IP, the destination IP address of the request is changed to the IP address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server.

If set to MAC, the destination MAC address is changed to the MAC address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server. With this setting, the destination IP address of the traffic is not changed.

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind services to the wildcard virtual server

To bind a service to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind a service to the wildcard virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

**Note:** You can bind a service to multiple virtual servers.

---

**Save and Verify the Configuration**

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

**To save and verify the configuration by using the command line interface**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

**Example**

```
save config
sh lb vserver FWLBVIP1
FWLBVIP1 (*:*.*) - ANY    Type: ADDRESS
  State: UP
  Last state change was at Mon Jun 14 06:40:14 2010

2) Monitor Name: ping
   State: UP    Weight: 1
   Probes: 3    Failed [Total: 0 Current: 0]
   Last response: Success - ICMP echo reply received.
   Response Time: 1.415 millisecond

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.

2. In the Save Config dialog box, click Yes.

3. In the navigation pane, click Load Balancing, and then click Virtual Servers.

4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.

5. In the navigation pane, click Load Balancing, and then click Services.

6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.
Configuring the Internal NetScaler ADC in a Sandwich Environment

Perform the following tasks to configure the internal NetScaler in a sandwich environment:

For traffic from the server (egress):
- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers:
- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature LB`
- `show ns feature`
Example

> enable ns feature LoadBalancing
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Change basic features.

3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.

4. In the Enable/Disable Feature(s)? message box, click Yes.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

Example

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

Parameters for configuring a wildcard service for each firewall

name
Name of the service. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ · (period) : (colon) # and space ( ).

**servername**

Either the name of a previously created server object, or the IP address of the load-balanced server, that is associated with this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.

If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP. For a wildcardservice, specify a service type of ANY.

**port**

Port on which the service listens. The port number must be a positive number not greater than 65535. For a wildcard service, specify an asterisk (*) as the port number.

*Note:* For more information about the SSL and SSL_TCP service types, see [SSL Offload and Acceleration](#).

**To configure a wildcard service for each firewall by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a wildcard service for each firewall” as shown:

   - Service Name—name
   - Server—servername

4. In Protocol, select ANY, and in Port, select *.

5. Click Create, and then click Close. The service you created appears in the Services pane.
Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
```

```
bind lb monitor <monitorName> <serviceName>
```

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

Parameters for configuring a monitor

**monitorName (Name)**

The name of the monitor. This is a mandatory argument. Maximum Length: 31.

**type (Type)**

The type of monitor. This is a mandatory argument. Default: PING.

**destIP (Destination IP)**

The IP address to which the probe is sent. If the destination IP address is set to 0, the destination IP address is that of the server to which the monitor is bound. Default value: 0
transparent (Transparent)

The state of the monitor for transparent devices, such as firewalls, based on the responsiveness of the services behind them. If the monitoring of transparent devices is enabled, the destination IP address should be specified. The probe is sent to the specified destination IP address using the MAC address of the transparent device. Possible values: YES, NO. Default value: NO

To create and bind a transparent monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor”, as shown:
   - Name*
   - Type*
   - Destination IP
   - Transparent
   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

add lb vserver <name> ANY **

Example

add lb vserver Vserver-LB-1 ANY **
Parameters for creating a virtual server

name

Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

IPAddress

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

serviceType

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS_TCP, and RTSP. Default: HTTP.

port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server” as shown:

   - Name—name

4. In Protocol, select ANY, and in IP Address and Port, select *.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

set lb vserver <name>@ -m <RedirectionMode>
Parameter for configuring the virtual server in MAC rewrite mode

m

The load balancing redirection mode. Possible Values: IP, MAC. Default: IP.

If set to IP, the destination IP address of the request is changed to the IP address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server.

If set to MAC, the destination MAC address is changed to the MAC address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server. With this setting, the destination IP address of the traffic is not changed.

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.

3. On the Advanced tab, under Redirection Mode, click MAC-Based.

4. Click OK.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

bind lb vserver <name> <serviceName>

Example

bind lb vserver Vserver-LB-1 Service-HTTP-1
To bind firewall services to the wildcard virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

add service <name> <serverName> HTTP <port>

Example

add service Service-HTTP-1 10.102.29.5 HTTP 80

Parameters for configuring a service

name

Name of the service. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

serverName

Either the name of a previously-created server object, or the IP address of the load-balanced server, that is associated with this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.
If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

**port**

Port on which the service listens. The port number must be a positive number not greater than 65535.

Note: For more information about the SSL and SSL_TCP service types, see SSL Offload and Acceleration.

**To configure a service for each virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a service” as shown:

   - Service Name—name
   - Server—serverName
   - Port—port

4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.

5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configure a monitor for each service**

**To bind a monitor to a service by using the command line interface**

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

Example

```
bind mon monitor-HTTP-1 Service-HTTP-1
```
To bind a monitor to a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.

3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.

4. In the Configured box, click OK.

Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

`add lb vserver <name> HTTP <ip> <port>`

Example

`add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80`

Parameters for creating a virtual server

**name**

Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

**IPAddress**

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

**serviceType**

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

**port**
Port on which the virtual server listens for client connections. The port number must be between 0-65535.

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server” as shown:
   - Name—name
   - IP Address—IPAddress

   **Note:** If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0000:0005:0600:700a:888b).

   - Port—port

4. Under Protocol, select HTTP.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Bind HTTP services to the HTTP virtual server

To bind HTTP services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

**Example**

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind HTTP services to the wildcard virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you’ve finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

```
save config
show lb vserver FWLBVIP2
FWLBVIP2 (::*): ANY Type: ADDRESS
State: UP
Last state change was at Mon Jun 14 07:22:54 2010
Time since last state change: 0 days, 00:00:32.760
Effective State: UP
Client Idle Timeout: 120 sec
Down state flush: ENABLED
Disable Primary Vserver On Down: DISABLED
No. of Bound Services: 2 (Total) 2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: MAC
Persistence: NONE
Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
Done
show service fw-int-svc1
fw-int-svc1 (10.102.29.5: *) - ANY
State: DOWN
```
Last state change was at Thu Jul 8 14:44:51 2010
Time since last state change: 0 days, 00:01:50.240
Server Name: 10.102.29.5
Server ID: 0 Monitor Threshold: 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive (CKA): NO
Access Down Service: NO
TCP Buffering (TCPB): NO
HTTP Compression (CMP): NO
Idle timeout: Client: 120 sec Server: 120 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1
   State: DOWN Weight: 1
   Probes: 9 Failed [Total: 9 Current: 9]
   Last response: Failure - Time out during TCP connection establishment stage
   Response Time: 2000.0 millisec

2) Monitor Name: ping
   State: UP Weight: 1
   Probes: 3 Failed [Total: 0 Current: 0]
   Last response: Success - ICMP echo reply received.
   Response Time: 1.275 millisec

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.

2. In the Save Config dialog box, click Yes.

3. In the navigation pane, click Load Balancing, and then click Virtual Servers.

4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.

5. In the navigation pane, click Load Balancing, and then click Services.

6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.
After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

**Example**

```
>stat lb vserver -detail
Virtual Server(s) Summary
<table>
<thead>
<tr>
<th>vsvrIP</th>
<th>port</th>
<th>Protocol</th>
<th>State</th>
<th>Req/s</th>
<th>Hits/s</th>

<td>0/s</td>
</tr>
</tbody>
</table>
```
Parameters for displaying statistics

detail

Include the statistics for hits per second and the total number of hits.

name

Name of the virtual server whose statistics are displayed.

To display virtual server statistics by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click Statistics.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

stat service <name>

Example

stat service Service-HTTP-1
To view the statistics of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

In the enterprise setup, the NetScaler is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The NetScaler selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.
Configuring the NetScaler in an Enterprise Environment

Perform the following tasks to configure a NetScaler in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature LB`
- `show ns feature`
Example

> enable ns feature LoadBalancing
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Change basic features.

3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.

4. In the Enable/Disable Feature(s)? message box, click Yes.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

add service <name> <serverName> ANY *

Example

add service Service-HTTP-1 10.102.29.5 ANY *

Parameters for configuring wildcard service for each firewall

name
Name of the service. This alphanumeric string is required and cannot be changed after
the service is created. The name must not exceed 127 characters, and the leading
caracter must be a number or letter. The following characters are also allowed: @ _ · (period) : (colon) # and space ( ).

serverName

Either the name of a previously created server object, or the IP address of the
load-balanced server, that is associated with this service, in either IPv4 or IPv6 format.
When you provide the IP address of the service, a server object is created with this IP
address as its name. You can also create a server object manually, and then select the
server name instead of an IP address from the drop-down menu that is associated with
this field.

If the server is not reachable from the NetScaler or is not active, the service is
designated as DOWN.

serviceType

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP,
TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default:
HTTP. For a wildcardservice, specify a service type of ANY.

port

Port on which the service listens. The port number must be a positive number not
greater than 65535. For a wildcardservice, specify an asterisk (*) as the port number.

Note: For more information about the SSL and SSL_TCP service types, see SSL Offload and
Acceleration.

To configure a wildcard service for each firewall by using the
configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which
   correspond to parameters described in “Parameters for configuring a wildcard service
   for each firewall” as shown:

   · Service Name—name
   · Server—serverName

4. In Protocol, select ANY, and in Port, select *.

5. Click Create, and then click Close. The service you created appears in the Services
   pane.
Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]`
- `bind lb monitor <monitorName> <serviceName>`

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

Parameters for configuring a monitor

monitorName (Name)

The name of the monitor. This is a mandatory argument. Maximum Length: 31.

type (Type)

The type of monitor. This is a mandatory argument. Default: PING.

destIP (Destination IP)

The IP address to which the probe is sent. If the destination IP address is set to 0, the destination IP address is that of the server to which the monitor is bound. Default value: 0
transparent (Transparent)

The state of the monitor for transparent devices, such as firewalls, based on the responsiveness of the services behind them. If the monitoring of transparent devices is enabled, the destination IP address should be specified. The probe is sent to the specified destination IP address using the MAC address of the transparent device. Possible values: YES, NO. Default value: NO

To create and bind a transparent monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor, as shown:

   - Name*
   - Type*—type
   - Destination IP
   - Transparent
   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

Example

```
add lb vserver Vserver-LB-1 ANY * *
```
Parameters for creating a virtual server

name

Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ · (period) : (colon) # and space ( )

IPAddress

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

serviceType

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server” as shown:

   - Name—name

4. In Protocol, select ANY, and in IP Address and Port, select *.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```
Parameter for configuring the virtual server in MAC rewrite mode

m

The load balancing redirection mode. Possible Values: IP, MAC. Default: IP.

If set to IP, the destination IP address of the request is changed to the IP address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server.

If set to MAC, the destination MAC address is changed to the MAC address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server. With this setting, the destination IP address of the traffic is not changed.

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.

3. On the Advanced tab, under Redirection Mode, click MAC-Based.

4. Click OK.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

`bind lb vserver <name> <serviceName>`

Example

`bind lb vserver Vserver-LB-1 Service-HTTP-1`
To bind firewall services to the wildcard virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <servername> HTTP <port>
```

Example

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

Parameters for configuring a service

name

Name of the service. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

servername

Either the name of a previously-created server object, or the IP address of the load-balanced server, that is associated with this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.
If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

**port**

Port on which the service listens. The port number must be a positive number not greater than 65535.

**Note:** For more information about the SSL and SSL_TCP service types, see [SSL Offload and Acceleration](#).

---

**To configure a service for each virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a service” as shown:
   
   - Service Name—name
   - Server—serverName
   - Port—port

4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.

5. Click Create, and then click Close. The service you created appears in the Services pane.

---

**Configure a monitor for each service**

**To bind a monitor to a service by using the command line interface**

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

**Example**

```
bind mon monitor-HTTP-1 Service-HTTP-1
```
To bind a monitor to a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.
3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.
4. In the Configured box, click OK.

Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
```

Example

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

Parameters for creating a virtual server

**name**

Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ -. (period) : (colon) # and space ( )

**IPAddress**

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

**serviceType**

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP

**port**
Port on which the virtual server listens for client connections. The port number must be between 0-65535.

**To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server” as shown:

   - Name—name
   - IP Address—IPAddress

   *Note:* If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, `1000:0000:0000:0000:0005:0600:700a:888b`).

   - Port—port

4. Under Protocol, select HTTP.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Bind HTTP services to the HTTP virtual server**

**To bind HTTP services to the wildcard virtual server by using the command line interface**

At the command prompt, type:

```plaintext
bind lb vserver <name> <serviceName>
```

**Example**

```plaintext
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

**To bind HTTP services to the wildcard virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

**Note:** You can bind a service to multiple virtual servers.

**Save and Verify the Configuration**

When you’ve finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

**To save and verify the configuration by using the command line interface**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `save ns config`
- `show vserver`

**Example**

```
save config
show lb vserver FWLBVIP2
   FWLBVIP2 (::*:*) - ANY Type: ADDRESS
   State: UP
   Last state change was at Mon Jun 14 07:22:54 2010
   Time since last state change: 0 days, 00:00:32.760
   Effective State: UP
   Client Idle Timeout: 120 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down: DISABLED
   No. of Bound Services: 2 (Total) 2 (Active)
   Configured Method: LEASTCONNECTION
   Current Method: Round Robin, Reason: A new service is bound
   Mode: MAC
   Persistence: NONE
   Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5:*): ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9:*): ANY State: UP Weight: 1
Done
show service fw-int-svc1
   fw-int-svc1 (10.102.29.5:*): ANY
   State: DOWN
```
To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.

2. In the Save Config dialog box, click Yes.

3. In the navigation pane, click Load Balancing, and then click Virtual Servers.

4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.

5. In the navigation pane, click Load Balancing, and then click Services.

6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.
Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the command line interface**

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

**Example**

```
>stat lb vserver -detail
Virtual Server(s) Summary
     vsrIP  port Protocol State  Req/s  Hits/s
  One   *    80 HTTP UP     5/s     0/s
  Two   *     0  TCP DOWN  0/s     0/s
 Three  *   2598 TCP DOWN  0/s     0/s
dnsVirtualNS 10.102.29.90  53 DNS DOWN  0/s     0/s
```
Parameters for displaying statistics

- **detail**
  Include the statistics for hits per second and the total number of hits.

- **name**
  Name of the virtual server whose statistics are displayed.

To display virtual server statistics by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click Statistics.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```plaintext
stat service <name>
```

Example

```plaintext
stat service Service-HTTP-1
```
To view the statistics of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

Multiple-Firewall Environment

**Note:** This feature is available in NetScaler release 9.3.e and 10.

In a multiple-firewall environment, the NetScaler appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a NetScaler. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

Figure 1 shows a multiple-firewall load balancing environment.
With a configuration like the one shown in Figure 1, you can configure the NetScaler to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example, with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.
The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.
Configuring the NetScaler in a Multiple-Firewall Environment

To configure a NetScaler appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the NetScaler. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the NetScaler device.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature <featureName>`
- `show ns feature`

Example

```
enable ns feature LoadBalancing
Done
show ns feature
Feature Acronym Status
******** ********
1) Web Logging WL OFF
2) Surge Protection SP ON
3) Load Balancing LB ON
```
Parameters for enabling load balancing

featureName (Name)

The name of the feature you want to enable. This is a mandatory argument.

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the Settings pane, under Modes and Features, click Change basic features.

3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

Configuring a wildcard service for each firewall

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type the following command to configure support for all the protocols and ports:

```
add service <name>@<serverName> <serviceType> <port_number>
```

Example

```
add service fw-svc1 10.102.29.5 ANY *
```

Parameters for configuring a wildcard service for each firewall

service_name
Name of the service. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

**serverName**

Either the name of a previously created server object, or the IP address of the load-balanced server, that is associated with this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field. If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP. For a wildcardservice, specify the service type as ANY.

**port**

Port on which the service listens. The port number must be a positive number not greater than 65535. For a wildcard service, specify an asterisk (*) as the port number.

**Note:** For more information about the SSL and SSL_TCP service types, see SSL Offload and Acceleration.

**To configure a wildcard service for each firewall by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Services dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a wildcard service for each firewall”, as shown:
   - Service Name—name
   - Server—servername
     * A required parameter

4. In Protocol, select Any and in Port, select *.

5. Click Create, and then click Close. The service you created appears in the Services pane.
Configuring a monitor for each service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*> [-transparent (YES | NO )]]`
- `bind lb monitor <monitorName> <serviceName>`

Example

```
add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
bind monitor monitor-HTTP-1 fw-svc1
```

Parameters for configuring a monitor

**monitorName (Name)**

The name of the monitor. This is a mandatory argument. Maximum Length: 31.

**type (Type)**

The type of monitor. This is a mandatory argument. Default: PING.

**destIP (Destination IP)**

The IP address to which the probe is sent. If the destination IP address is set to 0, the destination IP address is that of the server to which the monitor is bound. Default value: 0
transparent (Transparent)

The state of the monitor for transparent devices, such as firewalls, based on the responsiveness of the services behind them. If the monitoring of transparent devices is enabled, the destination IP address should be specified. The probe is sent to the specified destination IP address using the MAC address of the transparent device. Possible values: YES, NO. Default value: NO

To create and bind a transparent monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor, as shown:
   - Name*
   - Type*—type
   - Destination IP
   - Transparent
   * A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

Configuring a virtual server to load balance the traffic sent to the firewalls

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

To configure a virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type the following command:

add lb vserver <name>@ <serviceType> <IPAddress> <port_number>

Example

add lb vserver Vserver-LB-1 ANY * *
Parameters for creating a virtual server

name

Name of the virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ · . (period) : (colon) # and space ( ).

serviceType

The type of services to which the virtual server distributes requests. Possible values: HTTP, SSL, FTP, TCP, SSL_TCP, UDP, SSL_BRIDGE, NNTP, DNS, ANY, SIP-UDP, DNS-TCP, and RTSP. Default: HTTP.

IPAddress

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

port

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

To configure a virtual server to load balance the traffic sent to the firewalls by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server”, as shown:

   - Name—name

4. In Protocol, select Any, and in IP Address and Port, select *.

5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.
To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type the following command:

```
set lb vserver <name>@ -m <RedirectionMode>
```

Example

```
set lb vserver Vserver-LB-1 -m MAC
```

Parameters for creating a virtual server

- **m**

  The load balancing redirection mode. Possible values are IP, IPTUNNEL, TOS, MAC. Default: IP.

  If set to IP, the destination IP address of the request is changed to the IP address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server.

  If set to MAC, the destination MAC address is changed to the MAC address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server. With this setting, the destination IP address of the traffic is not changed.

  If set to IPTUNNEL, NetScaler uses an IP tunnel to communicate to the server.

  If set to TOS, NetScaler uses the TOS id to communicate to the server.

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.

3. On the Advanced tab, under the Redirection Mode mode, click Open.

4. Click Ok.

Binding firewall services to the virtual server

To access a service on NetScaler, you need to bind it to a wildcard virtual server.
To bind firewall services to the virtual server by using the command line interface

At the command prompt, type the following command:

bind lb vserver <name>@ <serviceName>

Example

bind lb vserver Vserver-LB-1 Service-HTTP-1

To bind firewall services to the virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service-HTTP-1).

4. Click Ok.

Configuring the multiple-firewall load balancing on the NetScaler Appliance

To load balance traffic on both the sides of a NetScaler using firewall load balancing, you need to enable multiple-firewall load balancing by using the vServerSpecificMac parameter.

To configure multiple-firewall load balancing by using the command line interface

At the command prompt, type the following command:

set lb parameter -vServerSpecificMac <status>

Example

set lb parameter -vServerSpecificMac ENABLED
Parameters for configuring multiple-firewall load balancing

vServerSpecificMac

Specifies the two-fold firewall load balancing mode. If set to ENABLED, the traffic from a set of firewalls is load balanced by another set of firewalls on the other side of NetScaler. If set to DISABLED, NetScaler adopts the default behavior and the traffic that is already load balanced is not re-load balanced.

To configure multiple-firewall load balancing by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then in the Load Balancing pane click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.

Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example

save config
show lb vserver FWLBVIP2
    FWLBVIP2 (*:*): ANY    Type: ADDRESS
    State: UP
    Last state change was at Mon Jun 14 07:22:54 2010
    Time since last state change: 0 days, 00:00:32.760
    Effective State: UP
    Client Idle Timeout: 120 sec
    Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
No. of Bound Services : 2 (Total)       2 (Active)
Configured Method: LEASTCONNECTION
Current Method: Round Robin, Reason: A new service is bound
Mode: MAC
Persistence: NONE
Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
Done

show service fw-int-svc1
fw-int-svc1 (10.102.29.5:* - ANY
State: DOWN
Last state change was at Thu Jul  8 14:44:51 2010
Time since last state change: 0 days, 00:01:50.240
Server Name: 10.102.29.5
Server ID : 0 Server ID : 0
Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): NO
Idle timeout: Client: 120 sec Server: 120 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1
   State: DOWN Weight: 1
   Probes: 9 Failed [Total: 9 Current: 9]
   Last response: Failure - Time out during TCP connection establishment stage
   Response Time: 2000.0 millisec
2) Monitor Name: ping
   State: UP Weight: 1
   Probes: 3 Failed [Total: 0 Current: 0]
   Last response: Success - ICMP echo reply received.
   Response Time: 1.275 millisec

Done
To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.

2. In the Save Config dialog box, click Yes.

3. In the navigation pane, click Load Balancing, and then click Virtual Servers.

4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.

5. In the navigation pane, click Load Balancing, and then click Services.

6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.
Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the command line interface**

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

**Example**

```
>stat lb vserver -detail
Virtual Server(s) Summary
  vsvrIP  port Protocol State  Req/s  Hits/s
One      * 80 HTTP    UP     5/s    0/s
Two      *  0 TCP     DOWN  0/s    0/s
Three    * 2598 TCP    DOWN  0/s    0/s
```
### Parameters for displaying statistics

**detail**

Include the statistics for hits per second and the total number of hits.

**name**

Name of the virtual server whose statistics are displayed.

### To display virtual server statistics by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click Statistics.

### Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

**Example**

```
stat service Service-HTTP-1
```
To view the statistics of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

Global Server Load Balancing

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in case of an outage.

Following are some typical GSLB configurations:

- **Active-active data center setup.** Consists of multiple active data centers. Client requests are load balanced across active data centers.

- **Active-standby data center setup.** Consists of an active and a standby data center. When a failover occurs as a result of a disaster event, the standby data center becomes operational.

- **Proximity setup.** Directs client requests to the data center that is closest in geographical distance or network distance.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server’s IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

**Note:** To take full advantage of the NetScaler GSLB features, you should use NetScaler appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary Metric Exchange Protocol (MEP) to exchange site metrics.
How GSLB Works

With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list, sending the first IP address to the end of the list and promoting the others after it responds to each DNS request. This technique ensures equal distribution of the load, but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistence.

When you configure GSLB on NetScaler appliances and enable Metric Exchange Protocol (MEP), the appliances use the DNS infrastructure to connect the client to the data center that best meets the criteria that you set. The criteria can designate the least loaded data center, the closest data center, the data center that responds most quickly to requests from the client’s location, a combination of those metrics, and SNMP metrics. An appliance keeps track of the location, performance, load, and availability of each data center and uses these factors to select the data center to which to send a client request.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB virtual servers, load balancing and/or content switching servers, and ADNS services.
GSLB Sites

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be NetScaler appliances. The data centers are called GSLB sites. Each GSLB site is managed by a NetScaler appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only NetScaler appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.
GSLB Services

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the NetScaler appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in a different data center is remote from that GSLB virtual server.
A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a NetScaler appliance, a GSLB virtual server does not have its own virtual IP address (VIP).
Load Balancing or Content Switching Virtual Servers

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server’s virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server’s VIP address.

For more information about load balancing or content switching virtual servers and services, see Load Balancing, or Content Switching.
ADNS Services

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the NetScaler appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.
DNS VIPs

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the NetScaler appliance. DNS requests for domains for which the NetScaler appliance is authoritative can be sent to a DNS VIP.
Configuring Global Server Load Balancing (GSLB)

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, www.mycompany.com, which is hosted on two geographically separated server farms or data centers. Both server farms use NetScaler appliances. The NetScaler appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the www.mycompany.com domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology

To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both NetScaler appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a NetScaler cluster setup, see Setting Up GSLB in a Cluster.
Configuring a Standard Load Balancing Setup

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the NetScaler appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see Load Balancing.
Configuring an Authoritative DNS Service

When you configure the NetScaler appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

**Note:** For the NetScaler to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see "Domain Name System".

### To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

- `add service <name> <IP>@ ADNS <port>`
- `show service <name>`

**Example**

```
add service Service-ADNS-1 10.14.39.21 ADNS 53
show service Service-ADNS-1
```

### To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

`set service <name> <IPAddress> ADNS <port>`

**Example**

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
```

### To remove an ADNS service by using the command line interface

At the command prompt, type the following command:
Parameters for configuring an ADNS service

name

The name of the ADNS service you are creating. This alphanumeric string is required and cannot be changed after the service is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

IP Address

The IP address of the server that the ADNS service represents. You can configure the ADNS service to use a mapped IP address (MIP), subnet IP address (SNIP), or any new NetScaler-owned IP address.

port

The port on which the service communicates with the application on the server. This number must correspond to the protocol that the application supports. The port number must always be a positive number not exceeding 65535.

To configure an ADNS service by using the configuration utility

1. In the navigation pane, expand Load Balancing and click Services.

2. In the details pane, do one of the following:
   
   · To create a new service, click Add.
   
   · To modify an existing service, select the service, and then click Open.

3. In the Create Service or Configure Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring an ADNS service” as shown:

   · Service Name*—name
   
   · Service Name*—name
   
   · Protocol*—(Select ADNS as the protocol.)
   
   · Port*—port

4. Click Create or OK, and then click Close. The server that you created appears in the GSLB Services pane.
Configuring a Basic GSLB Site

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB setup, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every NetScaler appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

To create a GSLB site by using the command line interface

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

- add gslb site <siteName> <siteIPAddress>
- show gslb site <siteName>

Example

add gslb site Site-GSLB-East-Coast 10.14.39.21
show gslb site Site-GSLB-East-Coast

To modify or remove a GSLB Site by using the command line interface

- To modify a GSLB site, use the set gslb site command, which is just like using the add gslb site command, except that you enter the name of an existing GSLB Site.

- To unset a site parameter, use the unset gslb site command, followed by the siteName value and the name of the parameter to be reset to its default value.

- To remove a GSLB site, use the rm gslb site command, which accepts only the <name> argument.
Parameters for configuring a GSLB site

**siteName**

A name for the data center you are adding as a GSLB site. This alphanumeric string is
required and cannot be changed after the site is created. The name must not exceed 127
characters, and the leading character must be a number or letter. The following
characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**siteIPAddress**

The IP address of the GSLB site. This IP address is a system-owned IP address. You can
use any IP address configured as a SNIP, MIP, or GSLB site IP address. This is a mandatory
parameter.

**Note:** To avoid a site going down during an HA failover event in a GSLB setup with an
independent network configuration high availability deployment, the GSLB site IP address
must be on the same subnet as the virtual IP (VIP) address of the load balancing or
content switching virtual server that is bound to the service(s) provided by that GSLB
site. In an independent network configuration high availability deployment, two nodes do
not share the same subnet IPs (SNIPs) or mapped IPs (MIPs), but they have common VIPs.

To configure a basic GSLB site by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Sites.

2. In the details pane, do one of the following:

   · To create a new site, click Add.

   · To modify an existing site, select the site, and then click Open.

3. In the Create GSLB Site or Configure GSLB Site dialog box, specify values for the
   following parameters, which correspond to parameters described in “Parameters for
   configuring a GSLB site” as shown:

   · Name*—siteName

   · Site IP Address*—siteIPAddress

   * A required parameter

4. Click Create or OK, and then click Close. The GSLB site you created appears in the GSLB
   Sites pane.

To view the statistics of a GSLB site by using the command line interface

At the command prompt, type:

```
stat gslb site <siteName>
```
Example

stat gslb site Site-GSLB-East-Coast

To view the statistics of a GSLB site by using the configuration utility

1. In the navigation pane, expand GSLB and click Sites.
2. In the GSLB Sites pane, select the GSLB site whose statistics you want to view.
3. Click Statistics.
Configuring a GSLB Service

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

Creating GSLB Services

To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

- add gslb service <serviceName> <serverName | IP> <serviceType> <port>-siteName <string>
- show gslb service <serviceName>

Example

add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 -siteName Site-GSLB-East-Coast
show gslb service Service-GSLB-1
To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the `set gslb service <serviceName>` command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the `add gslb service` command for details about the parameters. Example

  ```
  > set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -maxClient 8
  Done
  > sh gslb service SKP_GSLB_NOTCNAME_SVC2
  SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
  ...
  Max Conn: 8  Max Bandwidth: 25 kbits
  ```

- To reset a parameter to its default value, you can use the `unset gslb service <serviceName>` command and the parameters to be unset. Example

  ```
  > unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandWidth
  Done
  > sh gslb service SKP_GSLB_NOTCNAME_SVC2
  SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
  ...
  Max Conn: 8  Max Bandwidth: 0 kbits
  ```

- To remove a GSLB service, use the `rm gslb service <serviceName>` command.

Parameters for configuring a GSLB service

**serviceName (Service Name)**

The name of the service being configured. This alphanumeric string is required. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**siteName (Site Name)**

The name of the GSLB site that this service represents.

**serviceType (Service Type)**

The type of service or protocol used in client requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, ANY, MSSQL, MYSQL, RADIUS, RDP, SIP_UDP, RTSP.

**port (Port)**

Port number on which the service runs.

**serverName or ipAddress (Server IP)**
To create a GSLB service by using the configuration utility

1. In the navigation pane, expand GSLB and click Services.

2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.

3. In the Create GSLB Service or Configure GSLB Service dialog box, set the following parameters:
   - Service Name*
   - Site Name*
   - Server Name - The servers added to the NetScaler configuration are displayed in a dropdown list. If you want to add a new server, click New..., and then in the Create Server dialog box, type the necessary details. For more information about creating servers, see “Adding a Server.”
   - Service Type
   - Port

   **Note:** In the Site Name and Server Name lists, the most recently used value is displayed as selected. Make sure that you select the site and server you want to specify.

4. Click Create, and then click Close. The GSLB service you created appears in the GSLB Services pane.

To view the statistics of a GSLB service by using the command line interface

At the command prompt, type:

stat gslb service <serviceName>

**Example**

stat gslb service Service-GSLB-1
To view the statistics of a GSLB service by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. In the GSLB Services pane, select the GSLB Service whose statistics you want to view.
3. Click Statistics.

Enabling and Disabling GSLB Services

Before you use a GSLB service for load balancing, it must be enabled. If the service is disabled, it is not included in load balancing even though it exists on the NetScaler appliance.

To enable or disable a GSLB service by using the command line interface

At the command prompt, type one of the following commands:

- `enable service <name>`
- `disable service <name>`

Example

```
> enable service Service-GSLB-1
Done
> disable service Service-GSLB-1
Done
```

To enable or disable a GSLB service by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Services.
2. In the GSLB Services pane, select the GSLB service which you want to enable or disable.
3. Click enable or disable.
Configuring a GSLB Virtual Server

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

Creating GSLB Virtual Servers

To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

- add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
- show gslb vserver <name>

Example

add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
show gslb vserver Vserver-GSLB-1
show gslb vserver Vserver-GSLB-2

To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the set gslb vserver command, which is just like using the add gslb vserver command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the unset gslb vserver command followed by the vservenName value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the rm gslb vserver command, which accepts only the <name> argument.

Parameters for configuring a GSLB server

- name
Configuring a GSLB Virtual Server

The name of the GSLB virtual server. This alphanumeric string is required and cannot be changed after the virtual server is created. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**serviceType**

The service type of the virtual server, that is, the type of content in the processed requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RDP, ANY.

**ipType**

Specifies whether this virtual server supports services that use the IPv4 or IPv6 protocol for IP addresses. Possible values: IPv4, IPv6. Default: IPv4.

To create a GSLB virtual server by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the details pane, do one of the following:
   
   - To create a new GSLB virtual server, click Add.
   
   - To modify an existing GSLB virtual server, select the service, and then click Open.

3. In the Create GSLB Virtual Server or Configure GSLB Virtual Server dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a GSLB virtual server” as shown:
   
   - Name*—name
   
   - Service Type*—serviceType
   
   - IPv6—ipType (To specify IPv6, select the check box. For IPv4, clear the check box.) * A required parameter

4. Click Create or OK, and then click Close. The GSLB virtual server that you created appears in the GSLB Virtual Servers pane.

To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name>
```

**Example**

```
stat gslb vserver Vserver-GSLB-1
```
To view the statistics of a GSLB virtual server by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. In the details pane, select the GSLB virtual server whose statistics you want to view.
3. Click Statistics.

Statistics of a GSLB service

When you run the stat gslb service command from the command line or click on the Statistics link from the configuration utility, the following details of the service will be displayed:

- Request bytes. Total number of request bytes received on this service or virtual server.
- Response bytes. Number of response bytes received by this service or virtual server.
- Current client established connections. Number of client connections in ESTABLISHED state.
- Current load on the service. Load on the service (Calculated from the load monitor bound to the service).

The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

Enabling and Disabling GSLB Virtual Servers

When you create a GSLB virtual server, it is enabled by default. If you disable it, it cannot process traffic. A disabled GSLB virtual server is not included in GSLB configuration but is not removed from the NetScaler appliance.

To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

- enable gslb vserver <name>@
- disable gslb vserver <name>@

Example

```
enable gslb vserver Vserver-GSLB-1
disable gslb vserver Vserver-GSLB-1
```
To enable or disable a GSLB virtual server by using the configuration utility

1. Select a virtual server and, from the Action list, select enable or disable.
Binding GSLB Services to a GSLB Virtual Server

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

- `bind gslb vserver <name> -serviceName <string>`
- `show gslb vserver <name>`

Example

```
bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
show gslb vserver Vserver-GSLB-1
```

To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
unbind gslb vserver <name> -serviceName <string>
```
To bind GSLB services by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the details pane, select the GSLB Virtual Server to which you want to bind the services (for example, Vserver-GSLB-1).

3. Click Open.

4. On the Services tab, in the Active column, select the check boxes next to the GSLB services that you want to bind to the GSLB virtual server.

5. Click OK.
Binding a Domain to a GSLB Virtual Server

To make a NetScaler appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the NetScaler adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see "Domain Name System".

To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

- `bind gslb vserver <name> -domainName <string>`
- `show gslb vserver <name>`

**Example**

bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
show gslb vserver Vserver-GSLB-1

To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

`unbind gslb vserver <name> -domainName <string>`
To bind a domain to a GSLB virtual server by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.

3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
   - To create a new Domain, click Add.
   - To modify an existing Domain, select the domain, and then click Open.

4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for Binding or Unbinding a Domain to a GSLB Virtual Server” as shown:
   - Domain Name*—domainName (for example, www.mycompany.com)
   * A required parameter

5. Click Create.

6. Click OK.

To view the statistics of a domain by using the command line interface

At the command prompt, type:

stat gslb domain <name>

Example

stat gslb domain www.mycompany.com

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the NetScaler appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.
To view the statistics of a domain by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.

3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click Statistics.
Synchronizing a Configuration in a GSLB Setup

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each NetScaler, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point of time, ensure that all the GSLB sites have the same configuration. To have the same configuration on all the GSLB sites, you can use the NetScaler appliance's GSLB configuration synchronization option.

The NetScaler appliance from which you use the synchronization option is referred to as the 'master node' and the GSLB sites on which the configuration is copied as 'slave nodes'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the master node.

Synchronization (may also be referred to as 'auto sync') is carried out in the following manner:

- The master node finds the differences between the configuration of the master node and slave node, and changes the configuration of the slave node to make it similar to the master node.

  If you force a synchronization (use the 'force sync' option), the NetScaler deletes the GSLB configuration from the slave node and then configures the slave to make it similar to the master node.

- During synchronization, if a command fails, synchronization is not aborted.

- Synchronization is done only on the parent sites. If a GSLB site is configured as a child site, its configuration is not affected by synchronization.

**Note:** On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). The source IP address that will be used for auto-sync is the NSIP of the master node (NSIP of the configuration coordinator in a cluster setup).

If you use the `saveconfig` option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The master node saves its configuration immediately before it initiates the process of synchronization.

2. After the process of synchronization is complete, the slave nodes save their configuration. A slave node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave node, you must manually investigate the cause of the failure and take corrective action.

Limitations of synchronization:
On the master node, the names of the remote GSLB sites must be identical to the names of sites configured on the NetScaler appliances hosting those sites.

During the synchronization, traffic disruptions may occur.

NetScaler can synchronize only up to 80000 lines of the configuration.

Synchronization may fail:

- If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
- If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the master node and then try to synchronize.
- If the RPC node passwords are different for NetScaler IP address (NSIP) and GSLB Site IP address.
- If the RPC node passwords are different for NetScaler IP address (NSIP) and loopback IP address.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes should be same.
- If you rename any GSLB entity that are part of your GSLB configuration (use “show gslb runningConfig” command to display the GSLB configuration). You need to use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and re-added to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the master node, management access should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the NetScaler.

For more information about adding the GSLB site IP addresses and enabling Management Access, see "Configuring a Basic GSLB Site" and "Configuring NetScaler-Owned IP Addresses".

- The GSLB configuration on the NetScaler appliance that is considered as the master node is complete and appropriate to be copied on all the sites.

- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB need to have the GSLB site entity of their respective local sites.

- You are not synchronizing sites that, by design, do not have the same configuration.

Important: After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Run the `sync gslb config` command only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.
To synchronize a GSLB configuration by using the command line interface

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

- `sync gslb config [-preview | -forceSync <string> | -nowarn | -saveconfig] [-debug]`
- `show gslb syncStatus`

**Example**

```
> sync gslb config
[WARNING]: Syncing config may cause configuration loss on other site.
Please confirm whether you want to sync-config (Y/N)? [N]:y
Sync Time: Dec 9 2011 10:56:9
Retrieving local site info: ok
Retrieving all participating gslb sites info: ok
Gslb_site1[Master]:
    Getting Config: ok
Gslb_site2[Slave]:
    Getting Config: ok
    Comparing config: ok
    Applying changes: ok
Done
```

**Parameters for synchronizing a GSLB configuration**

<no option>

If no option is passed to this command, synchronization happens on all the GSLB sites in the auto sync method.

preview (Preview)

Do not synchronize the GSLB sites, but only display the commands that would be applied on the slave node upon synchronization. Mutually exclusive with the saveConfig option.

forceSync <string> (Force Sync)

Forcibly synchronize the specified site even if a dependent configuration on the remote site is preventing synchronization or if one or more GSLB entities on the remote site have the same name but are of a different type. Possible values:

- The name of the remote site that you want to synchronize with the local site.
- The string `all-sites`.

If you specify `all-sites`, all the sites in the GSLB setup are synchronized with the site on the master node.
Note: If you select the force sync option, the synchronization starts without displaying the commands that are going to be executed.

nowarn

Suppress the warning and the confirmation prompt that are displayed before site synchronization begins. This option can be used in automation scripts that must not be interrupted by a prompt. Appears only if you use the forceSync and debug options.

saveconfig

Save the configuration on all the nodes participating in the synchronization process, automatically. The master saves its configuration immediately before synchronization begins. Slave nodes save their configuration after the process of synchronization is complete. A slave node saves its configuration only if the configuration difference was applied successfully on it. Mutually exclusive with the preview option.

debug (Debug)

Generate verbose output when synchronizing the GSLB sites. The debug option generates more verbose output than a sync gslb config command in which the option is not used, and is useful when you want to analyze synchronization issues.

To synchronize a GSLB configuration by using the configuration utility

1. In the navigation pane, click GSLB.

2. In the GSLB pane, under GSLB Configuration, click Synchronize configuration on remote sites.

3. In the Synchronize GSLB Configuration dialog box, select one of the following settings from the Synchronization Option list:
   - Preview
   - Force Sync
   - Debug

4. If you select Force Sync as the synchronization option, in the GSLB Site Name text box, type the name of the remote site that you want to synchronize with the local site, or type all-sites.

5. If you want the participating sites to save their configuration automatically, select Save Configuration.

6. Click Run.

7. If you want to save the output of the Run command to your local system, click Save output text to a file.

8. Click Close.
Viewing and Configuring a GSLB Setup by Using the GSLB Visualizer

The configuration utility includes a GSLB Visualizer tool, which provides an alternative way to view and configure entities in a GSLB configuration. The visualizer displays all configured GSLB domains, GSLB services, GSLB sites, ADNS services, and any monitors that are bound to the services. It also displays all the load balancing, content switching, cache redirection, and Access Gateway virtual servers that the GSLB services represent.

If you want to view the configurations of remote GSLB sites, you must configure the sites with public IP addresses and enable management access for each of them.

You can use the GSLB Visualizer to perform the following GSLB configuration tasks:

- Add, view, and configure GSLB domains and GSLB services.
- View and configure GSLB sites and ADNS services for each site.
- View and configure any monitors that are bound to the services.
- View and configure the content switching, load balancing, cache redirection, or Access Gateway virtual server that each GSLB service represents.
- View statistics for GSLB domains, sites, ADNS services, and virtual servers.
- View configuration details of any displayed entity.
- View load balancing and content switching virtual servers.
- View bindings for GSLB services, ADNS services, monitors, and virtual servers.
- Enable and disable GSLB services, ADNS services, monitors, and virtual servers.
- Copy the properties of any displayed entity to a document or spreadsheet.
- Remove a domain from the GSLB setup.
- Save the visual representation of the GSLB setup as an image.
To open the Visualizer and locate an entity

1. In the navigation pane, click GSLB.
2. In the details pane, under Getting Started, click GSLB Visualizer, and then do the following.
   - To pan the view of the displayed image, click as blank area of the image, hold down the mouse button, and drag the image.
   - To adjust the viewable area click Zoom In to increase or Zoom Out to decrease the size of the objects. You can readjust the viewable area by clicking Best Fit.
   - To locate a specific item, begin typing the item's name in the Search field. Entities whose names match the typed characters are highlighted. Continue typing until the item is uniquely identified. To clear the Search field, click the x adjacent to the field.

To add a GSLB domain and/or configure GSLB services and sites for the domain

1. Open the GSLB Visualizer and click Domain. Alternatively, if domains already exist in the GSLB setup, click the name of an existing domain.
2. Under Related Tasks, click Add.
3. Follow the instructions in the GSLB Wizard to add a GSLB domain and configure GSLB services and sites for the domain.

To view the configuration details of an entity

Open the GSLB Visualizer and do one of the following:

- To view a brief summary of an entity, place the pointer on the entity. A brief summary of the entity appears at the bottom of the viewable area.
- To view the detailed configuration information of the entity, click the entity. The configuration details for that entity appear in the Details area.

To modify a GSLB domain, site, service, monitor, or ADNS service

Open the GSLB Visualizer and do one of the following:

- Click the entity that you want to modify. Then, under Related Tasks, click Open.
- Double-click the entity that you want to modify.
Right-click the entity that you want to modify, and then click Open. (This option is not available for GSLB sites.)

**To view the entities to which a GSLB service, ADNS service, monitor, or virtual server is bound**

Open the GSLB Visualizer and do one of the following:

- Click the entity whose binding information you want to view, and then, under Related Tasks, click Show Bindings.
- Right-click the entity, and then click Show Bindings.

**To view the Visualizer for load balancing and content switching virtual servers from the GSLB Visualizer**

Open the GSLB Visualizer and do one of the following:

- Click the load balancing or content switching virtual server whose Visualizer you want to view, and then, under Related Tasks, click Visualizer.
- Right-click the virtual server, and then click Visualizer.

**To view statistics for a GSLB service, site, ADNS service, or virtual server**

Open the GSLB Visualizer and do one of the following:

- Click the entity whose statistics you want to view, and then, under Related Tasks, click Statistics.
- Right-click the entity whose statistics you want to view, and then click Statistics. (This option is not available for GSLB sites.)

**To enable or disable a GSLB service, ADNS service, monitor, or virtual server**

Open the GSLB Visualizer and do one of the following to enable or disable the entity:

- To enable the entity, click the entity and, under Related Tasks, click Enable. Alternatively, right-click the entity that you want to enable, and then click Enable.
- To disable the entity, click the entity and, under Related Tasks, click Disable. Alternatively, right-click the entity that you want to disable, and then click Disable.
To copy the properties of an entity to a document or spreadsheet

Open the GSLB Visualizer and do one of the following:

- Click the entity whose properties you want to copy, and then, under Related Tasks, click Copy Properties.

- Right-click the entity, and then click Copy. (This option is not available for GSLB sites.)

To save the visual representation of the GSLB setup as an image

1. Open the GSLB Visualizer.

2. If necessary, adjust the viewable area by using the Best Fit, Zoom In, and Zoom Out buttons.

3. Click Save Image.

4. In the Save Graph Image dialog box, browse to the folder in which you want to save the image.

5. In File Name text box, type the name, and then click Save.

To remove a domain from the GSLB setup

1. Open the GSLB Visualizer and do one of the following:

   - Click the domain that you want to remove, and then, under Related Tasks, click Remove.

   - Right-click the domain, and then click Remove.

2. Under Remove?, click Yes.
Configuring the Metrics Exchange Protocol (MEP)

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for the Citrix NetScaler. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metrics can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) or a mapped IP address (MIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, MIP, the NetScaler IP address (NSIP), or a virtual IP address (VIP) as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the NetScaler appliances.

**Note:** You cannot configure a GSLB site IP address as the source IP address for site metrics exchange.

If the source and target sites for a MEP connection (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services. When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metrics exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service allows the NetScaler to interact with a non-NetScaler load balancing device. The NetScaler can monitor non-NetScaler devices but cannot perform load balancing on them. The NetScaler can monitor non-NetScaler devices, and can perform load balancing on them if monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.
Configuring Site Metric Exchange

Site metrics exchanged between the GSLB sites include the status of each load balancing and content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The NetScaler appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

To enable or disable site metric exchange by using the command line interface

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

- `set gslb site <siteName> -metricExchange(ENABLED|DISABLED)`
- `show gslb site <siteName>`

Example

```
set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable or disable site metric exchange by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Metric Exchange and click OK.
To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

- `set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)`
- `show gslb site <<siteName>`

Example

```bash
set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable or disable network metric information exchange by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Network Metric Exchange and click OK.
You can enable or disable the exchange of persistence information at each site. This information is exchanged every 5 seconds between NetScaler appliances participating in GSLB.

For details about configuring persistence, see "Configuring Persistent Connections".

To enable/disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence information exchange and verify the configuration:

- `set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)`
- `show gslb site <siteName>`

Example

```bash
set gslb site Site-GSLB-East-Coast -sessionExchange ENABLED
set gslb site Site-GSLB-East-Coast -sessionExchange DISABLED
show gslb site Site-GSLB-East-Coast
```

To enable/disable persistence information exchange by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Sites.
2. In the details pane, select the site, and then click Open.
3. In the Configure GSLB Site dialog box, select or clear the check box next to the Persistence Session Entry Exchange and click OK.
Configuring Site-to-Site Communication

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The NetScaler appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a NetScaler-owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address or a mapped IP (MIP) address, but you might want to specify an IP address of your choice.
Changing the Password of an RPC Node

You can secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the `show rpcNode` command to compare the encrypted form of the password before and after the change.

To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

- set ns rpcNode <IPAddress> {-password}
- show ns rpcNode

Example

> set rpcNode 192.0.2.4 -password mypassword
Done
> show rpcNode
.
.
.
2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e
   SrcIP: *                Secure: OFF
Done
>

To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the password parameter, without a value.
Parameters for changing the password of an RPC node

**IPAddress**

The IP address of the GSLB site to which the RPC node belongs. This is the value of the IPAddress field in the output of the show rpcNode CLI command.

**password**

The password that the RPC node must use to authenticate itself to other nodes in the GSLB configuration. By default, a password is configured for all RPC nodes. If you change the password for an RPC node, make sure you propagate that change to the RPC node at each of the other sites. Maximum length: 31 characters.

To change the password of an RPC node by using the configuration utility

1. In the navigation pane, expand Network, and then click RPC.

2. In the details pane, click the RPC node for which you want to change the password, and then click Open.

3. In the Configure RPC Node dialog box, in Password and Confirm Password, specify the password that you want the RPC node to use.
Encrypting the Exchange of Site Metrics

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the NetScaler appliance encrypts all communication sent from the node to other RPC nodes.

To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

- set ns rpcNode <IPAddress> [-secure ( YES | NO )]
- show rpcNode

Example

> set rpcNode 192.0.2.4 -secure YES
Done
> show rpcNode
.
.
.
3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: ON Done
>

To unset the secure parameter by using the command line interface

To unset the secure parameter by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the secure parameter, without a value.

Parameters for encrypting the exchange of site metrics

IPAddress
Encrypting the Exchange of Site Metrics

The IP address of the GSLB site to which the RPC node belongs. This is the value of the IPAddress field in the output of the show rpcNode CLI command.

secure (Secure)

Encrypt all communication sent from the RPC node. Possible values: YES, NO. Default: NO.

To encrypt the exchange of site metrics by using the NetScaler configuration utility

1. In the navigation pane, expand Network, and then click RPC.

2. In the details pane, click the RPC node whose communication you want to encrypt, and then click Open.

3. In the Configure RPC Node dialog box, click Secure.

4. Click OK.
Configuring the Source IP Address for an RPC Node

By default, the NetScaler appliance uses a NetScaler-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address or MIP address. If neither a SNIP address nor a MIP address is available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NetScaler IP (NSIP) address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address or a MIP address.

To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

- set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*>]
- show ns rpcNode

Example

> set rpcNode 192.0.2.4 -srcIP 192.0.2.3
Done
> show rpcNode
.
.
.
2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: OFF
Done
>

To unset the source IP address parameter by using the command line interface

To unset the source IP address parameter by using the NetScaler command line, type the unset rpcNode command, the IP address of the RPC node, and the srcIP parameter, without a value.
Parameters for specifying a source IP address of an RPC node

**IPAddress**

The IP address of the GSLB site to which the RPC node belongs. This is the value of the IPAddress field in the output of the `show rpcNode` CLI command.

**srcIP**

The subnet IP (SNIP) address, mapped IP (MIP) address, NetScaler IP (NSIP) address, or virtual IP (VIP) address that you want the appliance to use as the source IP address for exchanging site metrics. By default, the appliance uses a SNIP address or a MIP address, but you can configure the node to use a SNIP address or MIP address of your choice, or the NSIP address. For a remote node, you also have the option of configuring a VIP address as the source IP address. If neither a SNIP address nor a MIP address is available, and you have not configured a source IP address, a GSLB site cannot exchange site metrics with other sites. The default setting is an asterisk (*), which indicates that the default setting (SNIP address or MIP address) is being used.

To specify a source IP address for an RPC node by using the NetScaler configuration utility

1. In the navigation pane, expand Network, and then click RPC.

2. In the details pane, click the RPC node for which you want to assign a specific source IP address for site metrics exchange, and then click Open.

3. In the Configure RPC Node dialog box, in Source IP Address, enter the IP address that you want the RPC node to use as the source IP address.
Customizing Your GSLB Configuration

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.
Modifying Maximum Connections or Maximum Bandwidth for a GSLB Service

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

- set gslb service <serviceName> [-maxClients <positive_integer>] [-maxBandwidth <positive_integer>]
- show gslb service <serviceName>

Example

set gslb service Service-GSLB-1 -maxBandwidth 100 -maxClients 100
show gslb service Service-GSLB-1

Parameters for modifying the maximum clients or bandwidth of a GSLB service

maxClients

The maximum number of simultaneous client connections that the GSLB service can handle.

maxBandwidth

The maximum bandwidth, in kbps, that a GSLB service can handle.
To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. In the navigation pane, expand GSLB and click Services.

2. In the details pane, select the service to be modified and click Open.

3. In the Configure GSLB Service dialog box specify values for one or both of the following parameters, which correspond to parameters described in “Parameters for modifying the maximum clients or bandwidth for a service” as shown:
   - Max Clients—maxClients
   - Max Bandwidth—maxBandwidth

4. Click OK.

5. Verify that the Details area displays the values that you entered.
Creating CNAME-Based GSLB Services

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMEs) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the NetScaler appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the NetScaler provides the CNAME with the corresponding A record (IP address). The NetScaler appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different NetScaler appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a NetScaler appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.
Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

```
add gslb service <serviceName> -cnameEntry <string> -siteName <string>
```

Example

```
add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -siteName Site-GSLB-East-Coast
add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -siteName Site-GSLB-West-Coast
```

Parameters for creating a CNAME based GSLB service

**serviceName (Service Name)**

The name of the CNAME-based GSLB service being configured.

**cnameEntry (DNS Canonical Name)**

The canonical name of the GSLB domain that the GSLB service will handle.

**siteName (Site Name)**

The name of the GSLB site that the GSLB service represents.
To create a CNAME-based GSLB service by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Services.

2. In the details pane, click Add.

3. In the Create GSLB Service dialog box, set the following parameters:
   - Service Name*
   - Site Name*
   - Type should be Canonical name based.
   - DNS Canonical name*
     * A required parameter

4. Click Create, and then click Close.
Changing the GSLB Method

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a NetScaler appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the NetScaler responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The NetScaler appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.
Specifying a GSLB Method Other than Static Proximity or Dynamic (RTT)

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see "Load Balancing."

To change the GSLB method by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -lbMethod GSLBMeth
```

Example

```
set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
```

To change the GSLB method by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. In the details pane, select a GSLB virtual server and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click OK, and verify that the method you selected appears under Details at the bottom of the screen.
Configuring Static Proximity

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client’s local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.
A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a NetScaler appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the NetScaler appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as www.maxmind.com and www.ip2location.com).

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the NetScaler appliance. Specifying an incorrect value for the format option can corrupt the internal data.

**Note:** The default location of the database file is /var/netscaler/locdb, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both NetScaler appliances.

The following abbreviations are used in this section:

- **CSHN.** Short name of a country based on the country code standard of ISO-3166.
- **LCN.** Long name of the country.
- **RC.** Region code based on ISO-3166-2 (for US and Canada). The region code “FIPS-10-4” is used for the other regions.

**Note:** Some databases provide short country names according to ISO-3166 and long country names as well. The NetScaler uses short names when storing and matching qualifiers.

To create a static proximity database, log on to the UNIX shell of the NetScaler appliance and use an editor to create a file with the location details in one of the NetScaler-supported formats.

**To add a static location file by using the command line interface**

At the command prompt, type:

```
add locationFile <locationFile> [-format <format>]
```
Adding a Location File to Create a Static Proximity Database

- show locationFile

Example

> add locationFile /var/nsmap/locdb/nsgeo1.0 -format netscaler
  Done
> show locationFile
  Location File: /var/nsmap/locdb/nsgeo1.0
  Format: netscaler
  Done

Parameters for adding a static location file

locationFile

The name of the location file. Must include the absolute path to the file. If the full path is not given, the default path /var/netscaler/locdb is assumed. In a high availability setup, the static database must be stored in the same location on both systems.

format

To add a static location file by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Location.

2. In the details pane, click the Static Database tab, and then click Add.

3. In the Create Location File dialog box, in the Location Filename text box, type the name of the location file, or click Browse to select the location file (for example, type or select /var/nsmap/locdb/nsgeo1.0).

   Note: The location file must be existing on the NetScaler appliance.

4. In the Location Format box, select the format of the location (for example, netscaler).

5. Click Create and click Close.

You can view an imported location file database by using the View Database dialog box in the configuration utility. There is no NetScaler command line equivalent.
To view a static location file by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Location.
2. On the Static Database tab, select the location file, and then click View Database.
3. In the View Database dialog box, and click Find to use the following controls to filter and sort the database information.
   a. **Search In**. Choose the field to search from the drop-down list.
   b. **Criterion**. Choose the search criterion from the drop-down list. The list contains a standard set of search criteria. “Contains” is the default choice.
   c. **Look For**. Type the text or number to search for.
   d. **Find Now**. Click this button to perform the search.
   e. **Clear**. Click this button to reset the search controls to their initial state.
4. Click Close to close the View Database dialog box and return to the Static Database tab.

To convert a location file into the netscaler format

By default, when you add a location file, it is saved in the netscaler format. You can convert a location file of other formats into the netscaler format. See the list of supported formats in the table, Parameters for adding a static location file.

**Note:** The nsmap option can be accessed only from the command line interface. The conversion is possible only into the netscaler format.

To convert the static database format, at the NetScaler command prompt, type the following command:

```
nsmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
```

**Example**

```
normap -f ip-country-region-city -o nsfile.ns ip-country-region-city.cvs
```
Adding Custom Entries to a Static Proximity Database

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 50 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

- add location <IPfrom> <IPto> <preferredLocation> [-longitude <integer>[-[latitude <integer>]]]
- show location

Example

>add location 192.168.100.1 192.168.100.100 *.us.ca.mycity

>show location

Parameters for adding custom entries

**IPfrom**

First IP address in the range, in dotted decimal notation. This is a mandatory argument.

**IPto**

Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

**preferredLocation**

String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example,"NA.US.CA.San Jose.ATT.citrix".
Adding Custom Entries to a Static Proximity Database

**Note:** A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.

This is a mandatory argument. Maximum Length: 197

**longitude**

Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range.

**Note:** Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

**latitude**

Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range.

**Note:** Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

Maximum value: 180

To add custom entries by using the configuration utility

1. Navigate to GSLB > Location.

2. On the Custom Entries tab, click Add.

3. Specify values for the following parameters, which correspond to parameters described in “Parameters for adding custom entries” as shown:

   - From IP Address*—IPfrom
   - To IP Address*—IPto
   - Location Name*—preferredLocation

   * A required parameter

4. Click Create, and then click Close. The custom entry that you have created appears on the Custom Entries tab.
Setting the Location Qualifiers

The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. The NetScaler has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 - “Continent”
- Qualifier 2 - “Country”
- Qualifier 3 - “State”
- Qualifier 4 - “City”
- Qualifier 5 - “ISP”
- Qualifier 6 - “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 - “Qualifier 1”
- Qualifier 2 - “Qualifier 2”
- Qualifier 3 - “Qualifier 3”
- Qualifier 4 - “Qualifier 4”
- Qualifier 5 - “Qualifier 5”
- Qualifier 6 - “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the NetScaler appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.
To set the location qualifiers by using the command line interface

At the command prompt, type:

```
set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
```

Example

```
set locationparameter -context custom -q1label asia
```

Parameters for setting the location qualifiers

- **context**
  The context in which a static proximity decision is made. Possible Values: geographic, custom.

- **q1label**
  The label for the 1st qualifier.

- **q2label**
  The label for the 2nd qualifier.

- **q3label**
  The label for the 3rd qualifier.

- **q4label**
  The label for the 4th qualifier.

- **q5label**
  The label for the 5th qualifier.

- **q6label**
  The label for the 6th qualifier.
To set the location qualifiers by using the configuration utility

1. In the navigation pane, expand GSLB and click Location.
2. Click Location Parameters.
3. In the Context drop-down list, select the appropriate context (for example, Custom).
4. In the Qualifier Label -1 text box, type the qualifier (for example, Asia).
5. Click OK.
Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

- `set gslb vserver <name> -lbMethod STATICPROXIMITY`
- `show gslb vserver <name>`

Example

```bash
set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
show gslb vserver
```

To specify static proximity by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB Virtual Server that you want to set to static proximity (for example, vserver-GSLB-1).

3. Click Open.

4. On the Method and Persistence tab, under Method, select Static Proximity from the Choose Method list.

5. Click OK.

6. Verify that the Details pane shows static proximity as the GLSB method.
Synchronizing GSLB Static Proximity Database

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the /var/netscaler/locdb directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the rsync program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the rsync program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the `sync gslb config` command on Site1:

```
sync gslb config -nowarn
Sync Time: Feb 24 2014 14:56:16
Retrieving local site info: ok
Retrieving all participating gslb sites info: ok
0 bytes in 0 blocks
ok
site1[Master]:
   Getting Config: ok
site2[Slave]:
   Syncing gslb static proximity database: ok
   Getting Config: ok
   Comparing config: ok
   Applying changes: ok
Done
```
Configuring the Dynamic Method (RTT)

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client’s local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client’s DNS request for a domain comes to the NetScaler appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the Netscaler appliance as Load Balancing Monitors and are easily identified due to their use of the “ldns” prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp

These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```bash
set gslb parameter -ldnsprobeOrder DNS PING TCP
```

Unless they have been customized, the NetScaler appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the Netscaler uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric.

If RTT information is not available (for example, when a client’s local DNS server accesses the site for the first time), the NetScaler appliance selects a site by using the round robin
method and directs the client to the site.

To configure the dynamic method, you configure the site's GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.
To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The NetScaler appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all NetScaler appliances deployed in the GSLB domain.

**To configure a GSLB virtual server for dynamic RTT by using the command line interface**

At the command prompt, type:

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
```

**Example**

```
set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
```

**Parameters for configuring the dynamic RTT load balancing method**

- **name**
  
  The name of the GSLB virtual server for which you are configuring the load balancing method.

- **lbMethod**
  
  The load balancing method being configured for the GSLB virtual server. For the dynamic method, specify RTT.

- **tolerance**
  
  The RTT tolerance factor used for load balancing. It must be the same throughout the GSLB domain.
The minimum number of milliseconds by which the RTT metric must change to trigger an update of this metric in the database.

**To configure a GSLB virtual server for dynamic RTT by using the configuration utility**

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB Virtual server that you want to set to dynamic RTT (for example, vserver-GSLB-1).

3. Click Open.

4. On the Method and Persistence tab, under Method, select Dynamic Method (RTT) from the Choose Method list.

5. To change the tolerance factor, type the new value in the Tolerance (ms) text box. (For a description of the tolerance factor, see “Parameters for configuring the dynamic RTT load balancing method.”)

6. Click OK.
Setting the Probing Interval of Local DNS Servers

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

To modify the probing interval by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <integer> <units> -resptimeout <integer> <units>
```

Example

```
set lb monitor monitor-HTTP-1 HTTP -interval 10 sec -resptimeout 5 sec
```

Parameters for modifying the probing interval

- **interval**
  - Interval at which probes should be sent.

- **units**
  - monitor-interval/resptimeout units. Possible values are SEC, MSEC, and MIN. Default value is NSTMUNT_SEC.

- **type**
  - The type of monitor being configured. The following are valid monitor types:
    - **TCP** - The NetScaler appliance establishes a TCP connection with the monitor destination and then closes the connection. If the NetScaler observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is
disabled. By default, LRTM is disabled on this monitor. This is done only for UDP, and the service goes down immediately.

- **TCP-ECV** - The NetScaler appliance establishes a TCP connection with the monitor destination. When the connection is established, the appliance sends specific data to the service by using the `-send` parameter, and the appliance and expects a specific response through the receive parameter.

- **HTTP** - the NetScaler establishes a TCP connection with the monitor destination. After the connection is established, the NetScaler sends HTTP requests and compares the response code, in the response from the service, with the configured set of response codes.

- **HTTP-ECV** - the NetScaler establishes a TCP connection with the monitor destination. When the connection is established, the NetScaler sends the HTTP data specified by the `-send` parameter to the service and expects the HTTP response that the `-receive` parameter specifies. (HTTP body part, not including HTTP headers.) Empty response data matches any response. Expected data may be anywhere in the first 24K bytes of the HTTP body of the response.

- **PING** - the NetScaler sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

**Note:** The NetScaler also supports FTP, UDP, DNS, UDP-ECV, TCPS, HTTPS, TCPS-ECV, HTTPS-ECV, LDNS-PING, LDNS-TCP, and LDNS-DNS monitors.

For more information about monitors, see [Load Balancing](#).

**resptimeout**

Interval after which probe should be marked as FAILED.

---

**To modify the probing interval by using the configuration utility**

- In the navigation pane, expand Load Balancing and click Monitors.

- Select the monitor that you want to modify (for example, ping).

- Click Open.

- In the Configure Monitor dialog box, on the Standard Parameters tab, specify values for the following parameters, which correspond to parameters described in “Parameters for modifying the probing interval” as shown:
  - **Interval**—interval
  - **Response Time-out**—resptimeout (type the interval after which the probe should be marked as FAILED. Specify whether the value represents minutes, milliseconds, or seconds by selecting a value from the adjacent list)

- Click OK.
Overriding Static Proximity Behavior by Configuring Preferred Locations

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a preferred location for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see Configuring a DNS Action.

2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.

3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see Adding Custom Entries to a Static Proximity Database. When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to TRUE, the NetScaler appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of *.UK.*.* or Europe.UK.*.* is a perfect match for the preferred location *.UK.*.*.

- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

   If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.
2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```bash
> add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "Europe.UK"
Done
> add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION(".*.ZMB.*.*")" prefLoc11
Done
```

When the appliance receives a request from the location *.*.ZMB.*.*, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.

3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.

4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.

5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.
Configuring Persistent Connections

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. Persistence is useful for deployments that deal with e-commerce, such as shopping card usage, where the server needs to maintain the state of the connection to track the transaction. To maintain the state of connection, you must configure persistence on a virtual server. With persistence configured, NetScaler selects a data center to process a client request and forwards the IP address of the selected data center for all subsequent DNS requests. If the configured persistence applies to a site that is down, the NetScaler appliance uses a GSLB method to select a new site, and the new site becomes persistent for subsequent requests from the client.

The GSLB virtual server is responsible for DNS-based site persistence, and it controls the site persistence for a remote GSLB service. The NetScaler appliance supports persistence based on the source IP address or on HTTP cookies.

When you bring a physical service DOWN with a delay time, the physical service goes into the transition out of service (TROFS) state. Site persistence is supported as long as the service is in the TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

**Note:** If connection proxy is specified as the site persistence method and if you also want to configure persistence of the physical servers, do not configure SOURCEIP persistence. When the connection is proxied, an IP address owned by the NetScaler is used, and not the actual IP address of the client. Configure methods such as cookie persistence or rule-based persistence on the load balancing virtual server.
Configuring Persistence Based on Source IP Address

With source-IP persistence, when a DNS request is received at a data center, the NetScaler appliance first looks for an entry in the persistence table and, if an entry for the local DNS server exists and the server mentioned in the entry is configured, the IP address of that server is sent as the DNS response.

For the first request from a particular client, the NetScaler appliance selects the best GSLB site for the request and sends its IP address to the client. Since persistence is configured for the source IP address of the client, all subsequent requests by that client or another local DNS server in the same IP subnet are sent the IP address of the GSLB site that was selected for the first request.

For source-IP address based persistence, the same set of persistence identifiers must be configured on the GSLB virtual servers in all data centers. A persistence identifier is a number used by the data centers to identify a particular GSLB virtual server. A cookie transmits the persistence identifier, enabling the NetScaler appliance to identify the domain so that it can forward all appropriate requests to the same domain. When persistence is enabled, the persistence information is also exchanged as part of metrics exchange.

For the NetScaler appliance to support persistence across sites, persistence must be enabled on the GSLB virtual servers of all participating sites. When you use source IP address persistence on the network identifier, you must configure a subnet mask. For any domain, persistence takes precedence over any other configured GSLB method.

To configure persistence based on source IP address by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId <positive_integer> [-persistMask <netmask>] -[timeout <mins>]
```

Example

```
set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -persistenceId 23 -persistMask 255.255.255.255 -timeout 2
```
Parameters for configuring persistence based on source IP address

name

The name of the GSLB virtual server for which you are configuring source IP address based persistence.

PersistenceType

The type of persistence being configured for the GSLB virtual server. Possible Values: SOURCEIP, None.

PersistenceId

A positive integer used to identify the GSLB virtual server on all sites. Minimum value: 1. Maximum value: 65535.

PersistMask

The subnet mask used when SOURCEIP based persistence is enabled. Minimum Value: 128.0.0.0. Default: 0xFFFFFFFF.

timeout

The time, in minutes, for which persistence should be in effect for the GSLB virtual server. Minimum value: 2. Maximum value: 1440. Default: 2.

To configure persistence based on source IP address by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).

3. Click Open.

4. On the Method and Persistence tab, under Persistence, select SOURCEIP from the Persistence list and specify values for the following parameters, which correspond to parameters described in “Parameters for configuring persistence based on source IP address” as shown:
   - Time-out—timeout
   - Persistence Id—persistenceId
   - IPv4 Netmask or IPv6 Mask length—PersistMask

5. Click OK.
Configuring Persistence Based on HTTP Cookies

The NetScaler appliance provides persistence at the HTTP-request level by using connection proxy and HTTP redirect. With these persistence methods, the appliance uses an HTTP cookie (known as a “site cookie”) to reconnect the client to the same server. The NetScaler inserts the site cookie in the first HTTP response.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. The cookie expiration is based on the cookie timeout configured on the NetScaler appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

When the NetScaler appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. The physical server in that GSLB site adds a site cookie to the HTTP header, and connection persistence is in effect.

If the DNS entry in the client cache expires, and then the client sends another DNS query and is directed to a different GSLB site, the new GSLB site uses the site cookie present in the client request header to implement persistence. If the GSLB configuration at the new site uses connection-proxy persistence, the new site creates a connection to the GSLB site that inserted the site cookie, proxies the client request to the original site, receives a response from the original GSLB site, relays that response back to the client, and closes the connection. If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie.

**Note:** Connection proxy persistence can be configured only for local services. However, connection proxy persistence must be enabled on both local and remote GSLB services that are configured for the GSLB virtual server.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent from a domain participating in GSLB. The domain is obtained from the URL/Host header.
- Requests are sent from a local GSLB service whose public IP address matches the public IP address of an active service bound to the GSLB virtual server.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

If one of the conditions is not met, connection proxy does not occur, but a site cookie is added if the local GSLB service has connection proxy enabled AND:

- No site cookie is supplied; OR,
The site cookie refers to an IP address that is not an active GSLB remote service; OR,

- The cookie refers to the IP address of the virtual server on which the request is received.

The following are the limitations of using connection proxy site cookies:

- Site cookies do not work for non-HTTP(S) protocols.
- If an HTTP request is sent to a back-up virtual server, the virtual server does not add a cookie.
- Site cookies do not work if SSL client authentication is required.
- At the local site, the statistics for a GSLB service on a remote site are not the same as the statistics recorded for that service at the remote site. At the local site, the statistics for a remote GSLB service are slightly higher than the statistics that the remote site records for that same service.

Redirect persistence can be used only:

- For HTTP or HTTPS protocols.
- If the domain name is present in the request (either in the URL or in the HOST header), and the domain is a GSLB domain.
- When the request is received on a backup VIP or a GSLB local service that is in the down state.

To set persistence based on HTTP cookies by using the command line interface

At the command prompt, type:

```
set gslb service <serviceName> -sitePersiste ConnectionProxy [-sitePrefix <prefix>] HTTPRedi HTTTredirect -sitePrefix <prefix>)
```

**Example**

```
set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
set gslb service service-GSLB-1 -sitePersiste HTTPRedirect -sitePrefix vserver-GSLB-1
```

**Parameters for setting persistence based on HTTP cookies**

- **serviceName**
The name of the GSLB service for which connection proxy based cookie persistence is being configured.

**sitePersistence**

The type of persistence. Possible Values: connectionProxy, HTTPredirect, None.

**sitePrefix**

This is a mandatory parameter when you configure HTTP redirect based persistence on a GSLB service. When the service is bound to a GSLB virtual server, for each bound service-domain pair, a GSLB site domain is generated internally by concatenating the service's siteprefix and the domain's name. If a special string "NONE" is specified, the siteprefix string is not set.

**To set persistence based on cookies by using the configuration utility**

1. In the navigation pane, expand GSLB and click Services.

2. In the GSLB Services pane, select the service that you want to configure for site persistence (for example, service-GSLB-1).

3. Click Open.

4. On the Advanced tab, under Site Persistence type, specify values for the following parameters, which correspond to parameters described in “Parameters for setting persistence based on HTTP cookies” as shown:

   - Site Persistence type—sitePersistence

   - Site Prefix—sitePrefix

5. Click OK.
Configuring Transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.
Configuring Dynamic Weights for Services

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

**Note:** For details on assigning weights to load balancing services, see "Assigning Weights to Services".

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled:** The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.

SERVICECOUNT: The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.

SERVICEWEIGHT: The dynamic weight is the sum of the number of services bound to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT

Example

set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT

To set GSLB virtual server to use dynamic weights by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to set dynamic weights (for example, vserver-GSLB-1).
3. Click Open.
4. On the Method and Persistence tab, under Method, select SERVICECOUNT or SERVICEWEIGHT from the Dynamic Weight list.
5. Click OK.
Monitoring GSLB Services

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The NetScaler appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the NetScaler appliance uses the state of the service reported by the monitor. However, you can configure the NetScaler appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the NetScaler to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.
Adding or Removing Monitors

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

- `add lb monitor <monitorName>` -type `<monitorType>` -destPort `<portNumber>`
- `show lb monitor <monitorName>`

Example

add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
show lb monitor monitor-HTTP-1

To remove a monitor by using the command line interface

At the command prompt, type:

`rm lb monitor <monitorName>`

Parameters for adding a monitor

name

The name of the monitor being created. This alphanumeric string is required and cannot be changed after the monitor is created. The name must not exceed 31 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

type

The type of monitor being configured. The following are valid monitor types:

- **TCP** - The NetScaler appliance establishes a TCP connection with the monitor destination and then closes the connection. If the NetScaler observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor. This is done only for UDP, and the service goes down immediately.
**TCP-ECV** - The NetScaler appliance establishes a TCP connection with the monitor destination. When the connection is established, the appliance sends specific data to the service by using the -send parameter, and the appliance expects a specific response through the -receive parameter.

**HTTP** - the NetScaler establishes a TCP connection with the monitor destination. After the connection is established, the NetScaler sends HTTP requests and compares the response code, in the response from the service, with the configured set of response codes.

**HTTP-ECV** - the NetScaler establishes a TCP connection with the monitor destination. When the connection is established, the NetScaler sends the HTTP data specified by the -send parameter to the service and expects the HTTP response that the -receive parameter specifies. (HTTP body part, not including HTTP headers.) Empty response data matches any response. Expected data may be anywhere in the first 24K bytes of the HTTP body of the response.

**PING** - the NetScaler sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

*Note:* The NetScaler also supports FTP, UDP, DNS, UDP-ECV, TCPS, HTTPS, TCPS-ECV, HTTPS-ECV, LDNS-PING, LDNS-TCP, and LDNS-DNS monitors.

For more information about monitors, see [Load Balancing](#).

**destPort**

Destination TCP/UDP port of the probe (the port of the dispatcher to which the probe is sent). The port can be different from the server port to which the monitor is bound. The value 0 (zero) directs the probes to the bound server’s port. This parameter has no effect on PING type monitors.

---

**To add a monitor by using the configuration utility**

1. In the navigation pane, expand Load Balancing and click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding a monitor” as shown:

   - **Name**—name
   - **Type**—type
   - * A required parameter

4. On the Standard Parameters tab, in the Destination Port text box, type the destination port number (see “destPort” in the above parameter list).

5. Click Create, and then click Close.
Binding Monitors to a GSLB Service

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

**Note:** In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service’s monitoring threshold.

To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
bind monitor <name> <serviceName> [-state (Enabled | Disabled)] -weight <positiveInteger>
```

**Example**

```
bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
```

To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

```
set gslb service <ServiceName> -monThreshold <PositiveInteger>
```

**Example**

```
set gslb service service-GSLB-1 -monThreshold 9
```

Parameters for binding a monitor to a GSLB service

- **name**
  
  The name of the monitor to be bound to the service.

- **serviceName**
The name of the service to which to bind the monitor.

**weight**

**monThreshold**

The monitoring threshold for the service. Minimum value: 0. Maximum value: 65535.

---

**To bind the monitor to the GSLB service by using the configuration utility**

1. In the navigation pane, expand GSLB and click Services.

2. The details pane, select the service to which you want to bind the monitor (for example, select service-GSLB-1).

3. Click Open.

4. In the Configure GSLB Service dialog box, on the Monitors tab, select the monitor that you want to bind to the service (for example, monitor-HTTP-1).

5. Click Add.

6. In the Configured table, you can select the newly assigned monitor and enter a new weight value.

7. To enable the monitor, make sure the State check box is selected.

8. Repeat the preceding steps to add additional monitors.

9. In the Monitor Threshold text box, you can enter a threshold value.

10. Click OK.
Monitoring GSLB Sites

The NetScaler appliance uses MEP or monitors to determine the state of the GSLB sites. You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the NetScaler appliance stops monitoring when MEP returns to the UP state.

To configure monitor triggering by using the command line interface

At the command prompt, type:

```
set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN | MEPDOWN_SVCDOWN)
```

Example

```
> set gslb site Site-GSLB-North-America -triggerMonitor Always
    Done
```

To configure monitor triggering by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Sites.

2. In the details pane, select the site, and then click Open.

3. In the Configure GSLB Site dialog box, in the Trigger Monitors drop-down list, select an option for when to trigger monitoring.

4. Click OK.
Protecting the GSLB Setup Against Failure

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the NetScaler appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.
Configuring a Backup GSLB Virtual Server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the disablePrimaryOnDown option), or you can configure a timeout period after which the primary takes over.

If you configure both the timeout and the disablePrimaryOnDown option for the backup entity, the backup session time-out takes precedence over the disablePrimaryOnDown setting.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

- set gslb vserver <name> -backupVServer <name> [-backupSessionTimeout <timeoutValue>] [-disablePrimaryOnDown (ENABLED | DISABLED)]
- show gslb vserver <name>

Example

set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -backupSessionTimeout 3 -disablePrimaryOnDown ENABLED
show gslb vserver vserver-GSLB-1

Parameters for configuring a backup GSLB virtual server

name

The name of the GSLB virtual server for which you are configuring a backup.

backupVServer
The name of the GSLB virtual server being configured as a backup.

**backupSessionTimeout**

The time, in minutes, after which the former primary GSLB virtual becomes primary again after returning to the UP state.

**disablePrimaryOnDown**

Require manual intervention to return the former primary GSLB virtual server to primary status.

**To set GSLB virtual server as a backup virtual server by using the configuration utility**

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).

3. Click Open.

4. On the Advanced tab, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a backup GSLB virtual server” as shown:

   - Backup VServer—backupVServer
   - Backup Session Time-out (mins)—backupSessionTimeout
   - Disable Primary When Down—disablePrimaryOnDown

5. Click OK.
Configuring a GSLB Setup to Respond with Multiple IP Addresses

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the NetScaler appliance sends the best GSLB service as the first record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the NetScaler appliance sends the best service as the only record in the response.

To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

- `set gslb vserver <name> -MIR (ENABLED | DISABLED)`
- `show gslb vserver <name>`

Example

```
set gslb vserver vserver-GSLB-1 -MIR ENABLED
show gslb vserver vserverName
```

To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).

3. Click Open.

4. On the Advanced tab, under When this VServer is “UP,” select the Send all “active” service IP in response (MIR) check box.

5. Click OK.
A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

**Note:** You must configure this setting for each virtual server to which you want it to apply.

**To configure a GSLB virtual server for empty down responses by using the command line interface**

At the command prompt, type:

```bash
set gslb vserver\<name\> -EDR (ENABLED | DISABLED)
```

**Example**

```bash
> set gslb vserver\-GSLB\-1 -EDR ENABLED
Done
```
To set a GSLB virtual server for empty down responses by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).

3. Click Open.

4. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.

5. Click OK.
Configuring a Backup IP Address for a GSLB Domain

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site’s IP address.

**Note:** When a backup IP address is sent, persistence is not honored.

**To set a backup IP address for a domain by using the command line interface**

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

- `set gslb vserver <name> -domainName <string> -backupIP <IPAddress>`
- `show gslb vserver <name>`

**Example**

```plaintext
set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP 10.102.29.66
show gslb vserver vserver-GSLB-1
```

**Parameters for configuring a backup IP address for a domain**

- **vserverName**
  
  The name of the GSLB virtual server to which the domain you are configuring a backup IP address for is bound.

- **domainName**
  
  The name of the domain for which a backup IP address is being configured.

- **backupIP**
To set a backup IP address for a domain by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. In the GSLB Virtual Servers pane, select the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).

3. Click Open.

4. On the Domains tab, select a domain and click Open.

5. In the Configure GSLB Domain dialog box, in the Backup IP text box, type the IP address of the backup domain.

6. Click OK.
Diverting Excess Traffic to a Backup Virtual Server

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured either by the number of connections or by the bandwidth.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.

- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.

If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.

If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:

- set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -soPersistence (ENABLED | DISABLED) -soPersistenceTimeout <timeout>
- show gslb vserver <name>

Example

set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000 -soPersistence ENABLED -soPersistenceTimeout 2
show gslb vserver Vserver-GSLB-1

Parameters for configuring a backup GSLB virtual server

**name**

The name of the GSLB virtual server for which a backup virtual server is being configured.

**soMethod**

The type of spillover used to divert traffic to the backup GSLB virtual server when the primary virtual server reaches the threshold. Possible values:

- **CONNECTION.** Spillover based on number of connections exceeding the threshold.
- **DYNAMICCONNECTION.** Spillover based on the combined number of connections exceeding the threshold.
- **BANDWIDTH.** Spillover based on combined incoming and outgoing bandwidth.
- **HEALTH.** Spillover occurs if bound and active services and service groups fall below a threshold relative to all bound elements.
- **NONE.**
soThreshold

The threshold value that decides when traffic must spill over to the backup virtual server. The following threshold values are supported:

- For the CONNECTION (or) DYNAMICCONNECTION spillover type, the threshold value is the maximum number of connections that the sites under the primary GSLB virtual server will handle before spillover occurs.

- For the BANDWIDTH spillover type, the threshold value is the amount of incoming and outgoing traffic (in kilobits per second) that the GSLB virtual server will handle before spillover occurs. Minimum value: 1. Maximum value: 4,294,967,294.

- For HEALTH, the threshold value is a positive integer from 1 through 99. This integer represents a percentage of the sum of the binding weights of all of the enabled, bound, and active GSLB services and service groups relative to the sum of the binding weights of all enabled and bound services and service groups (active and inactive).

soPersistence

The configured spillover persistence state. If you enable spillover persistence, the NetScaler appliance maintains source-IP based persistence over the primary virtual server and backup virtual servers. Possible values: ENABLED, DISABLED. Default: DISABLED.

soPersistenceTimeout

backupVServer

The name of the GSLB virtual server being configured as a backup.

backupSessionTimeout

The time, in minutes, after which the former primary GSLB virtual becomes primary again after returning to the UP state.
To configure a backup GSLB virtual server by using the configuration utility

1. In the navigation pane, expand GSLB, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to configure as a backup (for example, Vserver-LB-1), and then click Open.

3. On the Advanced tab, under Spillover, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a backup GSLB virtual server” as shown:
   - Method— soMethod
   - Threshold— soThreshold
   - Persistence Time-out (min) — soPersistenceTimeout

4. Select the Persistence check box.

5. Click OK.
Managing Client Connections

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.
Enabling Delayed Cleanup of Virtual Server Connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the NetScaler appliance performs a delayed cleanup of connections to a GSLB service that is down.

**To enable delayed cleanup of virtual server connections by using the command line interface**

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

- `set gslb service <name> -downStateFlush (ENABLED | DISABLED)`
- `show gslb service <name>`

**Example**

```
> set gslb service Service-GSLB-1 -downStateFlush ENABLED
Done
> show gslb service Service-GSLB-1
Done
```

**Parameters for delayed connection cleanup**

- **name**
  
  The name of the GSLB service for which delayed connection cleanup is being configured.

- **downStateFlush**
  
  Enables or disables delayed cleanup of connections to the GSLB service. Possible Values: ENABLED or DISABLED.
To enable delayed cleanup of virtual server connections by using the configuration utility

1. In the navigation pane, expand GSLB and click Services.

2. In the GSLB Services pane, select the service (for example, service-GSLB-1), and then click Open.

3. On the Advanced tab, select the Down state flush check box.

4. Click OK.
Managing Local DNS Traffic by Using DNS Policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the NetScaler appliance.
DNS Expressions

The NetScaler appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called rules) are combined to create DNS policies that are then bound globally on the NetScaler appliance.

Following is the list of predefined DNS qualifiers available on the NetScaler appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS_AREC
- CLIENT.UDP.DNS.IS_AAAAREC
- CLIENT.UDP.DNS.IS_SRVREC
- CLIENT.UDP.DNS.IS_MXREC
- CLIENT.UDP.DNS.IS_SOAREC
- CLIENT.UDP.DNS.IS_PTRREC
- CLIENT.UDP.DNS.IS_CNAME
- CLIENT.UDP.DNS.IS_NSREC
- CLIENT.UDP.DNS.IS_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")
To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.

2. In the Qualifier box, select a qualifier (for example, LOCATION).

3. In the Operator box, select an operator (for example, ==).

4. In the Value box, type a value (for example, Asia, Japan....).

5. Click OK. Click Create and click Close. The rule is created.

6. Click OK.
Configuring DNS Actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.

- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see Overriding Static Proximity Behavior by Configuring Preferred Locations.

- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).

- Forward a request to the name server without performing a lookup in the appliance’s DNS cache.

- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, dns_default_act_Drop. If you want to bypass the DNS cache, use the built-in action, dns_default_act_Cachebypass. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

- add dns action <actionName> <actionType> (-IPAddress <ip_addr | ipv6_addr> ... | -viewName <string> | -preferredLocList <string> ...) [-TTL <secs>]

- show dns action [<actionName>]

Examples

Example 1: Configuring DNS Response Rewrite. The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

> add dns action dns_act_response_rewrite Rewrite_Response -IPAddress 192.0.2.20 192.0.2.56 198.51.100.10 Done
> show dns action dns_act_response_rewrite
1) ActionName: dns_act_response_rewrite ActionType: Rewrite_Response TTL: 3600 IPAddress: 192.0.2.20 192.0.2.56 198.51.100.10
Done

Example 2: Configuring a DNS-View Based Response. The following DNS action sends the client an IP address for which you have configured a DNS view:

> add dns action send_ip_from_view_internal_ip ViewName -viewName view_internal_ip
Done
> show dns action send_ip_from_view_internal_ip
1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName ViewName: view_internal_ip
Done

Example 3: Configuring a Response Based on a Preferred Location List. The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

> add dns action send_preferred_location GslbPrefLoc -preferredLocList NA.tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
Done
> show dns action send_preferred_location
1) ActionName: send_preferred_location ActionType: GslbPrefLoc PreferredLocList: "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3.*.*.*"
Done

Parameters for configuring a DNS action

**actionName (Action Name)**

The name of the DNS action. Maximum length: 127 characters. Must begin with a letter, a number, or the underscore character (_). Additional characters allowed, after the first character, are the number sign (#), period (.), space ( ), colon ( : ), at sign (@), equal sign (=) and hyphen (-). If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "dns action 1" or 'dns action 1').

**actionType (Type)**

The type of DNS action that you want to configure. Possible values: viewName, GslbPrefLoc, Rewrite_Response.

Use the viewName option if you want to specify the name of a DNS view. When you specify a DNS view, the appliance sends clients the IP address for which the view was created. The viewName option must be followed by the viewName parameter.

Use the GslbPrefLoc option if you want to specify a list of preferred locations for requests that match the DNS policy. The GslbPrefLoc option must be followed by the preferredLocList parameter.

Use the Rewrite_Response option if you want to specify a list of IP addresses with which you want to rewrite DNS responses. The Rewrite_Response option must be followed by
the IPAddress parameter.

**IPAddress (IP Address)**

The list of IP addresses for the `Rewrite_Response` action type. The list can contain up to 25 IPv4 addresses and up to 5 IPv6 addresses. Use spaces as separators between the address entries. If invalid or duplicate IP addresses are included in the list, the `add dns` action command succeeds, but the invalid/duplicate IP addresses are not included in the IP address list.

**TTL**

The time to live, in seconds, for the address records. Minimum value: 0. Maximum value: 2147483647. Default: 3600.

**viewName (View Name)**

The name of the view that is associated with the IP address that you want to send the client.

**preferredLocList (Preferred Location)**

The list of preferred locations to choose from when a DNS policy rule evaluates to `TRUE`. When a policy matches, the preferred location list is given priority over the static proximity database. Locations must be provided in the descending order of priority. If the policy evaluates to `TRUE`, the NetScaler appliance uses an algorithm to select one or more GSLB services that correspond to the preferred locations. If only one service is found and the service is up, the appliance returns the IP address of the service to the client in the DNS response. If multiple GSLB services are found, the appliance load balances the services that are up. The appliance implements site affinity by directing all subsequent requests from the same source location to the selected preferred location.

You can add up to a maximum of 8 preferred locations. Maximum length: 1583.
To configure a DNS action by using the NetScaler configuration utility

1. In the navigation pane, expand DNS, and then click Actions.

2. In the details pane, do one of the following:
   
   · To create a DNS action, click Add.
   
   · To modify a DNS action, select the DNS action that you want to modify, and then click Open.

3. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
   
   · Action Name (cannot be changed for an existing DNS action)
   
   · Type (cannot be changed for an existing DNS action)

   To set the Type parameter, do one of the following:

   · To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.

   · To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.

   · To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.

   · TTL (applicable only to the Rewrite Response action type)
Configuring DNS Policies

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks ('') as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.

- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.

- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the NetScaler appliance.

- A maximum of 64 policies are supported.

- DNS policies are global to the NetScaler and cannot be applied to a specific virtual server or domain.

- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
Configuring DNS Policies

- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see “Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol” in “Policy Configuration and Reference”.

To add a DNS policy by using the command line interface

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

- add dns policy <name> <rule> <actionName>
- show dns policy <name>

Example

> add dns policy policy-GSLB-1 `CLIENT.UDP.DNS.DOMAIN.EQ("domainname")` my_dns_action
Done
> show dns policy policy-GSLB-1
  Name: policy-GSLB-1
  Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
  Action Name: my_dns_action
  Hits: 0
  Undef Hits: 0
Done
To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```
rm dns policy <name>
```

Parameters for configuring a DNS policy

- **name**
  
  The name of the DNS policy being created.

- **rule**
  
  Expression to be used by the dns policy.

- **actionName (Action)**
  
  The name of the DNS action that you want to trigger if the policy evaluates to TRUE. The following built-in DNS actions are available, along with any custom actions that you have created:

  - **dns_default_act_Drop**. Drops the DNS request.
  
  - **dns_default_act_Cachebypass**. Bypasses the DNS cache and forwards the request to the name server.
To configure a DNS policy by using the NetScaler configuration utility

1. In the navigation pane, expand DNS, and then click Policies.

2. In the details pane, do one of the following:
   - To create a DNS policy, click Add.
   - To modify a DNS policy, select the DNS policy, and then click OK.

3. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
   - Policy Name (cannot be changed for an existing policy)
   - Action
   - Expression

   To specify an expression, do the following:
   a. Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
   b. In the second list, select the expression element that you want, and then enter a period.
   c. After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.

4. Click Create or OK, and then click Close.
Binding DNS Policies

DNS policies are bound globally on the NetScaler appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

**Note:** Even though the bind dns global command accepts `REQ_OVERRIDE` and `RES_OVERRIDE` as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the `REQ_DEFAULT` and `RES_DEFAULT` bind points.

To bind a DNS policy globally by using the command line interface

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

- `bind dns global <policyName> <priority> [-gotoPriorityExpression <string>] [-type <type>]`
- `show dns global -type <type>`

**Example**

```
> bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
Done
> show dns global -type REQ_DEFAULT
1) Policy Name: policy-GSLB-1
   Priority: 10
   GotoPriorityExpression: END

Done
```
To bind a DNS policy globally by using the configuration utility

1. In the navigation pane, expand DNS and click Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

```
show dns global
```

To view the global bindings of a DNS policy by using the configuration utility

1. In the navigation pane, expand DNS and click Policies.
2. In the details pane, click Global Bindings. The global bindings of all DNS policies appear in this dialog box.
Adding DNS Views

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company’s domain and have the server hosted in your company’s network, clients querying for the domain from within your company’s internal network can be provided with the server’s internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain’s public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see Configuring DNS Policies and Binding DNS Policies.

To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

- add dns view <viewName>
- show dns view <viewName>

Example

add dns view PrivateSubnet
show dns view PrivateSubnet

To remove a DNS view by using the command line interface

At the command prompt, type:

rm dns view <viewName>
To add a DNS view by using the configuration utility

1. In the navigation pane, expand DNS and click Views.

2. In the details pane, click Add.

3. In the Create DNS view dialog box, in the Name text box, enter the name of the DNS view.

4. Click Create, and then click Close. The DNS view that you created appears in the Views pane.

For details on how to create a DNS policy, see Configuring DNS Policies and for details on how to bind DNS policies globally, see Binding DNS Policies.
Configuring GSLB for Commonly Used Deployment Scenarios

GSLB is commonly used in the following deployment scenarios:

- GSLB for disaster recovery
- GSLB based on proximity
- GSLB based on scalability
- GSLB based on the number of Access Gateway users
- GSLB for XenDesktop
Configuring GSLB for Disaster Recovery

Disaster recovery capability is critical, because downtime is costly. A NetScaler appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.
Configuring GSLB for Disaster Recovery in an Active-Standby Data Center Setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to the active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
set gslb vserver <name> -backupVserver <string>
```

Example
To configure the standby site by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.

2. Select the GSLB virtual server for the primary site and click Open.

3. In the Configure GSLB Virtual Server dialog box, on the Advanced tab, in the Backup VServer drop-down list box, select a backup virtual server.

4. Click OK.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the ‘disable primary on down’ option.
Configuring for Disaster Recovery in an Active-Active Data Center Setup

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create GSLB a virtual server and GSLB services and bind the services to the virtual servers. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).
Configuring for Disaster Recovery with Weighted Round Robin

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the NetScaler appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual servers. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

- `add lb vserver <name>@ -weight <WeightValue> <ServiceName>`
- `set lb vserver <name>@ -weight <WeightValue> <ServiceName>`

Example
To set dynamic weight by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -dynamicWeight DynamicWeightType
```

Example

```
set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
```

To add weights to the GSLB services by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -serviceName GSLBServiceName -weight WeightValue
```

Example

```
set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
```

Parameters for configuring a backup GSLB virtual server

**lbVserverName**

The name of the load balancing virtual server whose services you are configuring weights for.

**serviceName**

The name of the service whose weights you are configuring.

**weight**

The weight associated with the service. Minimum Value: 1, Maximum Value: 100.
dynamicWeight

Configures the GSLB virtual server to use either the service count or the cumulative service weights as its dynamic weight. Possible Values: SERVICECOUNT, SERVICEWEIGHT, DISABLED Default Value: DISABLED.

To configure a virtual server to assign weights to services by using the configuration utility

1. In the navigation pane, expand Load Balancing and click Virtual Servers.
2. Select the virtual server (for example, Vserver-LB-1) and click Open.
3. On the Services tab, in the Weights spin box, type or select the weight of a service (for example, 4) next to Service-HTTP-1).
4. Click OK.

To add weights to the GSLB services by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. Select the virtual server (for example vserver-GSLB-1) and click Open.
3. On the Services tab, in the Weight spin box, type or select the weight of a service (for example, next to service-GSLB-1, type 1).
4. Click OK.

To set dynamic weight by using the configuration utility

1. In the navigation pane, expand GSLB and click Virtual Servers.
2. Select the virtual server (for example vserver-GSLB-1) and click Open.
3. On the Method and Persistence tab, under Method, in Dynamic Weight drop-down list, select SERVICEWEIGHT.
4. Click OK.
Configuring for Disaster Recovery with Data Center Persistence

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB setup and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the NetScaler appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

- set gslb service <serviceName> -sitePersistence <sitePersistence> -sitePrefix <string>
- show gslb service <serviceName>

Example

set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
show gslb service Service-GSLB-1
Parameters for configuring HTTP redirect

**serviceName**

The name of the GSLB service for which you are configuring site persistence.

**sitePersistence**

The type of site persistence being configured. Possible Values: ConnectionProxy, HTTPRedirect, None.

**sitePrefix**

When a service is bound to a GSLB virtual server, for each bound service-domain pair, a GSLB site domain is generated internally by concatenating the service’s siteprefix and the domain name. If a special string, "NONE," is specified, the siteprefix string is not set.

To configure HTTP redirect by using the configuration utility

1. In the navigation pane, expand GSLB and click Services.
2. Select the GSLB service to be configured and click Open.
3. On the Advanced tab, under Site Persistence options, select the HTTPRedirect option.
4. In the Site Prefix text box, enter the site prefix (for example, vserver-GSLB-1).
5. Click OK.
Configuring GSLB for Proximity

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

**Configuring Dynamic Method (RTT)**

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client’s local DNS server and gathers RTT metric information. The NetScaler then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see Configuring Dynamic RTT.

**Configuring Static Proximity**

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client’s local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.
To configure GSLB for proximity with static proximity, you must first configure the basic GSLB setup and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see Configuring Static Proximity.

## Configuring Static Proximity and Dynamic RTT

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring Global Server Load Balancing (GSLB).

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see Configuring Static Proximity and for details on how to configure dynamic RTT, see Configuring Dynamic RTT.
Configuring Parent-Child Topology

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

There are three fundamental entities that must be configured for GSLB:

- **Site**: A GSLB site represents a NetScaler or a high availability (HA) pair of NetScaler appliances that maintain GSLB state information and provide information about how the NetScaler nodes should communicate. A site can also represent a data center.

- **GSLB virtual server**: A GSLB virtual server represents a group of resources to which users can be directed, and the logic used to select one resource verses another.

- **GSLB service**: A GSLB service represents a target resource and is bound to a GSLB virtual server. The target resource might be a load balancing virtual server on a NetScaler, or it could represent a third party server.

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

**Relationships among GSLB Sites**

The concept of sites is central to NetScaler GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be:

1. To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.

2. To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites. Parent-child relationships can be used to build a two-level hierarchical GSLB design with the following characteristics:

- At the top level are parent sites that have peer relationships with other parents.

- Each parent can have multiple children, but each child can have only one parent.

- Each parent site exchanges health information with its children and with other parent sites.

- A child communicates only with its parent.
Note: In a parent-child relationship for GSLB, only the parent site does the GSLB resolution. The child sites act as normal load balancing sites.

Limitations of GSLB Parent-Child site configuration:

- You can configure 32 Parent sites and 1024 Child sites for each Parent site.
- On the Child site, by default, the nwmetricExchange and sessionExchange options are disabled.
- Round Trip Time (RTT) GSLB method is not recommended for GSLB Parent-Child site configuration.
- ADNS service or DNS load balancing virtual servers should be configured only in the Parent site.

Setting Up a Parent-Child Configuration for Global Server Load Balancing

If you have a firewall configured at a GSLB site, make sure that port 3011 is open. Follow the procedures at the following location to create services and virtual servers:

Configuring Global Server Load Balancing (GSLB) Figure 1. GSLB Parent-Child Topology

In the above figure:

- GSLB_Site11 and GSLB_Site12 are parent sites in a peer relationship.
- site11_lb1 and site11_lb2 are the child sites of GSLB_Site11, while site12_lb1 and site12_lb2 are the child sites of GSLB_Site12.

The configuration of each parent site includes the information about all the child sites associated with it, but the configuration of each child site pertains only to that child and its parent. A child site is not aware about any other parent site or other child sites in the configuration. For example, in the above figure, the configuration of child site site11_lb1 would include only information about its parent site, GSLB_Site11.

Note: GSLB auto sync syncs only the GSLB configuration across the parent sites. It does not sync any configuration to the child sites.
To set up a parent-child configuration for GSLB by using the NetScaler command line

1. On each parent site, enter the following command: add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr|ipv6_addr|*>] [-parentSite<string>] For example: # add gslb site gslb_site11 1.1.1.1 -publicIP 1.1.1.1

# add gslb site site11_lb1 1.1.1.1 -publicIP 1.1.1.1 -parentSite gslb_site11

# add gslb site site11_lb2 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11

# add gslb site site11_lb2 1.1.1.3 -publicIP 1.1.1.3 -parentSite gslb_site11

# add gslb site gslb_site12 3.3.3.1 -publicIP 3.3.3.1

# add gslb site site12_lb1 3.3.3.2 -publicIP 3.3.3.2 -parentSite gslb_site12

# add gslb site site12_lb2 3.3.3.3 -publicIP 3.3.3.3 -parentSite gslb_site12

The above command makes the parent site aware of its child sites as well as of the other parent site in the configuration.

2. On each child site, enter the following command: add gslb site<siteName><siteIPAddress> [-publicIP<ip_addr|ipv6_addr|*>] [-parentSite<string>] For example: # add gslb site site11_lb1 1.1.1.1 -publicIP 1.1.1.1

# add gslb site site11_lb1 1.1.1.2 -publicIP 1.1.1.2 -parentSite gslb_site11

The above command creates the child site and adds the parent-site information to child site’s configuration.

Network metrics, such as RTT and persistence session information, are synced only across the parent sites. Therefore, parameters like nwMetric and sessionExchange are disabled by default on all the child sites.

To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

Note: If you want to use different private and public IP address for GSLB services, add the corresponding GSLB-service related configuration to the child site in a separate procedure, not as part of the GSLB site configuration.
Link Load Balancing

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the Citrix® NetScaler® appliance to monitor and control traffic so that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the NetScaler and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. Configuring a basic setup involves configuring services, virtual servers, monitors, routes, an LLB method, and, optionally, configuring persistence. Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.
Configuring a Basic LLB Setup

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.
Configuring Services

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in "Creating and Binding a Transparent Monitor."

To create a service by using the command line interface

At the command prompt, type:

- `add service <name> <IP> <serviceType> <port>`
- `show service <name>`

Example

```
add service ISP1R_svc_any 10.10.10.254 any *
show service ISP1R_svc_any
   ISP1R_svc_any (10.10.10.254:*) - ANY
   State: DOWN
   Last state change was at Tue Aug 31 04:31:13 2010
   Time since last state change: 2 days, 05:34:18.600
   Server Name: 10.10.10.254
   Server ID : 0   Monitor Threshold : 0
   Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
   Use Source IP: NO
   Client Keepalive(CKA): NO
   Access Down Service: NO
   TCP Buffering(TCPB): YES
   HTTP Compression(CMP): NO
   Idle timeout: Client: 120 sec   Server: 120 sec
   Client IP: DISABLED
   Cacheable: NO
   SC: OFF
   SP: OFF
   Down state flush: ENABLED

1)   Monitor Name: ping
    State: UP    Weight: 1
    Probes: 244705  Failed [Total: 0 Current: 0]
    Last response: Success - ICMP echo reply received.
    Response Time: 1.322 millisec

Done
```
Parameters for creating a service

name

The name of the service. Maximum length: 127

IP

The IP address of the physical router for which a service will be added.

serviceType

The type of connections that the service will handle. Specify a service type of ANY.

port

Port on which the service listens. Specify an asterisk (*) as the port number.

To create services by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a service, as shown:

   · Service Name*—name
   · Server—IP
   · Protocol*—serviceType (Select ANY from the drop-down list.)
   · Port*—port
     * A required parameter

4. Click Create.

5. Repeat Steps 2-4 to create another service.

6. Click Close.

7. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Configuring an LLB Virtual Server and Binding a Service

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see "Configuring the LLB Method and Persistence."

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```
add lb vserver Router1-vip any
bind lb vserver Router-vip ISP1R_svc_any
sh lb vserver router-vip
  Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
  State: DOWN
  Last state change was at Thu Sep  2 10:51:32 2010
  Time since last state change: 0 days, 17:51:46.770
  Effective State: DOWN
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services : 1 (Total) 0 (Active)
  Configured Method: ROUNDROBIN
  Mode: IP
  Persistence: NONE
  Connection Failover: DISABLED

1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN  Weight: 1
Done
```
Parameters for creating an LLB virtual server

name

The name of the load balancing virtual server being added. Maximum length: 127

serviceType

The service type. Possible value: ANY.

Parameters for binding the service

name

The virtual server name to which the service is bound. Maximum length: 127

serviceName

The name of the service that is bound. Maximum Length: 127

To create a link load balancing virtual server and bind a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, click Add.

3. In the Create Virtual Servers (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating an LLB virtual server, as shown:

   - Name*—name
   - Protocol*—serviceType (Select ANY.)
     * A required parameter

   Note: Make sure Directly Addressable is unchecked.

4. Under the Services tab, in the Active column, select the check box for the service that you want to bind to the virtual server.

5. Click Create, and then click Close.

6. In the Load Balancing Virtual Servers tab, select the virtual server that you just created, and verify that the settings displayed in the Details pane are correct.
Configuring the LLB Method and Persistence

By default, the NetScaler appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

- set lb vserver <name> -lbMethod <lbMethod> -persistenceType <persistenceType>
- show lb vserver <name>

Example

```
set lb vserver router-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP
```

```
show lb vserver Router-vip
    Router-vip (0.0.0.0:0) - ANY    Type: ADDRESS
    State: DOWN
    Last state change was at Fri Sep  3 04:46:48 2010
    Time since last state change: 0 days, 00:52:21.200
    Effective State: DOWN
    Client Idle Timeout: 120 sec
    Down state flush: ENABLED
    Disable Primary Vserver On Down : DISABLED
    No. of Bound Services :  0 (Total)       0 (Active)
    Configured Method: ROUNDROBIN
    Mode: IP
    Persistence: SOURCEIP
    Persistence Mask: 255.255.255.255       Persistence v6MaskLength: 128   Persistence Timeout: 2 min
    Connection Failover: DISABLED
```

Parameters for configuring the LLB method and persistence

name
Configuring the LLB Method and Persistence

The name of the load balancing virtual server. Maximum Length: 127

**lbMethod**

The load balancing method. Possible values:

- **ROUNDROBIN**: Rotates the outgoing packets among the available links. This method distributes packets equally among the links, even if they operate at different speeds. Therefore, it can result in retransmissions or out-of-order packets.

- **DESTINATIONHASH**: Uses the hashed value of the destination IP address to select a link. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same link.

- **LEASTBANDWIDTH**: Selects the link that is currently serving the least amount of traffic, measured in megabits per second (Mbps).

- **LEASTPACKETS**: Selects the link that has received the fewest packets in the last 14 seconds.

**persistenceType**

Persistence type for the virtual server. Possible values:

- **SOURCEIP**: Persistence based on the source IP address of inbound packets. After the load balancing method selects a link for transmission of the first packet, the NetScaler directs all subsequent packets sent from the same source IP address to the same link.

- **DESTIP**: Persistence based on the destination IP address of outbound packets. After the load balancing method selects a link for transmission of the first packet, the NetScaler directs all subsequent packets for the same destination IP address to the same link.

- **SRCIPDESTIP**: Persistence based on the source IP address of inbound packets and destination IP address of outbound packets. After the load balancing method selects a link for transmission of the first packet, the NetScaler directs all subsequent requests from the same source IP address and to the same destination IP address to the same link.
To configure the link load balancing method and/or persistence by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the Load Balancing method and/or persistence settings, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, specify values for some or all of the following parameters, which correspond to parameters described in “Parameters for configuring the LLB method and persistence” as shown:

   - Method—lbMethod
   - Persistence—persistenceType

4. Click OK.

5. In the Load Balancing Virtual Servers pane, select the virtual server that you just configured and verify that the settings displayed in the Details pane are correct.
Configuring an LLB Route

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

- add lb route <network> <netmask> <gatewayName>
- show lb route [<network> <netmask>]

Example

add lb route 0.0.0.0 0.0.0.0 Router-vip
show lb route 0.0.0.0 0.0.0.0

<table>
<thead>
<tr>
<th>Network</th>
<th>Netmask</th>
<th>Gateway/VIP</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>1)</td>
<td>0.0.0.0</td>
<td>Router-vip</td>
<td>UP</td>
</tr>
</tbody>
</table>

To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

- add lb route6 <network> <gatewayName>
- show lb route6

Example

add lb route6 ::/0 llb6_vs
show lb route6

<table>
<thead>
<tr>
<th>Network</th>
<th>VIP</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>1)</td>
<td>llb6_vs</td>
<td>UP</td>
</tr>
</tbody>
</table>
Example

**Parameters for configuring the LLB route**

**network (Network)**

The IPv4 or IPv6 address of the network to which the route belongs.

**netmask (Netmask)**

The mask specifying the subnet to which the route belongs. This is required for IPv4 routes.

**gatewayName (Gateway Name)**

The name of the virtual server. Maximum Length: 127

**To configure an LLB route by using the configuration utility**

1. In the navigation pane, expand Network, and then click Routes.

2. In the details pane, select one of the following:
   
   - Click LLB to configure an IPv4 route.
   - Click LLBV6 to configure an IPv4 route.

3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
   
   - Network*
   - Netmask*—Required for IPv4 routes.
   - Gateway Name*—gatewayName
   * A required parameter

4. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.
Configuring an LLB Route

Figure 1. Basic LLB Setup

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.
Creating and Binding a Transparent Monitor

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

To create a transparent monitor by using the command line interface

At the command prompt, type:

- add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent YES
- show lb monitor [<monitorName>]

Example

add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
> show lb monitor monitor-1
1) Name.........: monitor-1  Type.......: PING  State.....: ENABLED
   Standard parameters:
   Interval.........:      5 sec  Retries...........:          3
   Response timeout.:     2 sec  Down time........:      30 sec
   Reverse.........:     NO  Transparent.......:        YES
   Secure..........:     NO  LRTM..............: ENABLED
   Action..........:  Not applicable  Deviation.........:      0 sec
   Destination IP...: 10.10.10.11
   Destination port.:  Bound service
   Iptunnel.........:     NO
   TOS..............:     NO  TOS ID..........:         0
   SNMP Alert Retries:     0  Success Retries..:      1
   Failure Retries..:     0
Parameters for creating a transparent monitor

monitorName (Name)

The name of the monitor. Maximum Length: 31 characters.

type (Type)

The type of monitor.

destIP (Destination IP)

The IP address to which the probe is sent. If the destination IP address is set to 0, the destination IP address is that of the server to which the monitor is bound. Default value: 0.

transparent (Transparent)

The state of the monitor for transparent devices, such as firewalls, based on the responsiveness of the services behind them. If the monitoring of transparent devices is enabled, the destination IP address should be specified. The probe is sent to the specified destination IP address by using the MAC address of the transparent device. Possible values: YES, NO. Default value: NO.

To create a transparent monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the Monitors pane, click Add.

3. In the Create Monitor dialog box, set the following parameters:

   - Name*
   - Type*
   - Destination IP
   - Transparent
     * A required parameter

4. Click Create, and then click Close.

5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.
To bind a monitor to a service by using the command line interface

At the command prompt, type:

- `bind lb monitor <monitorName> <serviceName>`
- `show service <name>`

Example

```
bind lb monitor monitor-HTTP-1 isp1R_svc_any
Done
> show service isp1R_svc_any
    ISP1R_svc_any (10.10.10.254:*) - ANY
    State: UP
    Last state change was at Thu Sep 2 10:51:07 2010
    Time since last state change: 0 days, 18:41:55.130
    Server Name: 10.10.10.254
    Server ID: 0    Monitor Threshold: 0
    Max Conn: 0     Max Req: 0     Max Bandwidth: 0 kbits
    Use Source IP: NO
    Client Keepalive(CKA): NO
    Access Down Service: NO
    TCP Buffering(TCPB): YES
    HTTP Compression(CMP): NO
    Idle timeout: Client: 120 sec  Server: 120 sec
    Client IP: DISABLED
    Cacheable: NO
    SC: OFF
    SP: OFF
    Down state flush: ENABLED

1)  Monitor Name: monitor-HTTP-1
    State: UP  Weight: 1
    Probes: 1256  Failed [Total: 0 Current: 0]
    Last response: Success - ICMP echo reply received.
    Response Time: 1.322 millisec

Done
```

Parameters for binding a monitor

**monitorName**

The name of the monitor to be bound. Maximum Length: 31 characters.

**serviceName**
The name of the service or a service group to which the monitor is to be bound. Maximum Length: 127 characters.

To bind a monitor to a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select a service to which you want to bind a monitor, and then click Open.

3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.

4. Click OK.

5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.
Configuring RNAT with LLB

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. This ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in "Configuring a Basic LLB Setup", and then configure RNAT. You must then enable use subnet IP (USNIP) mode.

To configure RNAT by using the command line interface

At the command prompt, type:

- set rnat <network> <netmask>
- show rnat

Example

```
set rnat 10.102.29.0 255.255.255.0
> show rnat
  1) Network: 10.102.29.0  Netmask: 255.255.255.0
     NatIP: *
```

Parameters for configuring RNAT

**network**

The network or subnet from which the traffic is flowing.

**netmask**

The subnet mask for the network.
To configure RNAT by using the configuration utility

1. In the navigation pane, expand Network, and then click Routes.

2. In the details pane, on the RNAT tab, click Configure RNAT.

3. In the Configure RNAT dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring RNAT” as shown:
   
   - Network*—network
   - Netmask*—netmask
   * A required parameter

4. Click Create, and then click Close. The RNAT route that you just created appears in the on the RNAT tab in the Routes pane.

To enable Use Subnet IP mode by using the command line interface

At the command prompt, type:

- enable ns mode USNIP
- show ns mode

Example

```
enable ns mode USNIP
> show ns mode

<table>
<thead>
<tr>
<th>Mode</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fast Ramp</td>
<td>FR</td>
<td>ON</td>
</tr>
<tr>
<td>....</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use Subnet IP</td>
<td>USNIP</td>
<td>ON</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

To enable Use Subnet IP mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In details pane, under Modes and Features, click Configure modes.

3. In the Configure Modes dialog box, select Use Subnet IP, and then click OK.

4. In the Enable/Disable Mode(s) message box, click Yes.
Configuring RNAT with LLB
Configuring a Backup Route

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the NetScaler appliance automatically uses it when the primary route fails. First create a primary virtual server as described in "Configuring an LLB Virtual Server and Binding a Service." To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup_Router-vip** is the secondary virtual server designated as the backup virtual server.

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.
To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -backupVserver <string>
```

Example

```
set lb vserver Router-vip -backupVServer Backup_Router-vip
> show lb vserver Router-vip
    Router-vip (0.0.0.0:0) - ANY   Type: ADDRESS
    State: UP
    Last state change was at Fri Sep 3 04:46:48 2010
    Time since last state change: 0 days, 03:09:45.600
    Effective State: UP
    Client Idle Timeout: 120 sec
    Down state flush: ENABLED
    Disable Primary Vserver On Down : DISABLED
    No. of Bound Services : 1 (Total) 1 (Active)
```
Configured Method: ROUNDROBIN
Mode: IP
Persistence: DESTIP Persistence Mask: 255.255.255.255 Persistence v6MaskLength: 128 Persistence Timeout: 2 min
Backup: Router2-vip
Connection Failover: DISABLED
Done

Parameters for setting up the secondary virtual server as the backup virtual server

ame

The name of the load balancing virtual server for which you are configuring a backup. Maximum Length: 127 characters.

backupVServer

The name of the backup virtual server. Maximum Length: 127 characters.

To set the secondary virtual server as the backup virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the secondary virtual server for which you want to configure the backup virtual server, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. In the Backup Virtual Server drop-down list, select the secondary backup virtual server, and then click OK.
Resilient LLB Deployment Scenario

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways Router1-vip and Router2-vip, respectively. Router1-vip is configured as a backup to Router2-vip and vice versa. All traffic with the destination IP specified as 30.30.30.30 is sent through Router1-vip and traffic with the destination IP specified as 30.30.31.31 is sent through Router2-vip.

![Figure 1. Resilient LLB Deployment Setup](image)

**Note:** If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

However, if any one of the gateways (Router1-vip or Router2-vip) is DOWN, traffic is routed through the backup router. In the following diagram, Router1-vip for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.
Figure 2. Resilient LLB Deployment Scenario

Note: If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.
Monitoring an LLB Setup

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
  vsvrIP   port  Protocol  State  Req/s  Hits/s
  One      *   80  HTTP    UP     5/s    0/s
  Two      *    0  TCP     DOWN   0/s    0/s
  Three    * 2598  TCP     DOWN   0/s    0/s
dnsVirtualNS  10.102.29.90  53  DNS     DOWN   0/s    0/s
  BRVSERV   10.10.1.1  80  HTTP    DOWN   0/s    0/s
  LBVIP     10.102.29.66  80  HTTP    UP     0/s    0/s
Done
```
Parameters for displaying statistics

detail

Include the statistics for hits per second and the total number of hits.

name

Name of the virtual server whose statistics are displayed.

To display virtual server statistics by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click Statistics.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

stat service <name>

Example

stat service Service-HTTP-1
To view the statistics of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

Load Balancing

The load balancing feature distributes user requests for web pages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance; when one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to:

- Distribute all requests for a specific protected website, application, or resource between two or more identically-configured servers.

- Use any of several different algorithms to determine which server should receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the NetScaler appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.
How Load Balancing Works

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the NetScaler appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. In some cases, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see Global HTTP Ports.
Load Balancing Basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

The load balancing virtual server can use any of a number of algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the NetScaler appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical NetScaler load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the local area network (LAN) or wide area network (WAN), the VIP is usually a private (ICANN non-routable) IP address.
Load Balancing Basics

- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.

- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the server.

- **Monitor.** An entity on the NetScaler appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The NetScaler appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:

- Configuring Load Balancing in Direct Server Return Mode
- Configuring LINUX Servers in DSR Mode
- Configuring DSR Mode When Using TOS
- Configuring Load Balancing in DSR Mode by Using IP Over IP
- Configuring Load Balancing in One-arm Mode
- Configuring Load Balancing in the Inline Mode
- Load Balancing of Intrusion Detection System Servers
- Load Balancing RDP services
Understanding the Topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the NetScaler appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The NetScaler appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Mandatory Parameters and Sample Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>IP Address</td>
</tr>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
</tr>
<tr>
<td>Services</td>
<td>Service-HTTP-1</td>
</tr>
<tr>
<td></td>
<td>Service-HTTP-2</td>
</tr>
<tr>
<td>Monitors</td>
<td>Default</td>
</tr>
</tbody>
</table>
The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 2. Load Balancing Entity Model
Use of Wildcards Instead of IP Addresses and Ports

In some cases you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases may require using a wildcard:

- If the NetScaler appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single NetScaler appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the NetScaler appliance determines the actual IP address or port and creates new records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each should be used.

<table>
<thead>
<tr>
<th>IP</th>
<th>Port</th>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
</table>
| *  | *    | TCP      | A general wildcard virtual server that accepts traffic sent to any IP address and port on the NetScaler appliance. When using a wildcarded virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.
| IP Address | * | TCP, UDP, and ANY | A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It will not dynamically learn them.

**Note:** You do not configure services or virtual servers for a global HTTP port. In this case, you configure a specific port as a global HTTP port (for example, `set ns param -httpPort 80`). The appliance then accepts all traffic that matches the port number, and processes it as HTTP traffic. The appliance dynamically learns and creates services for this traffic. |
**Use of Wildcards Instead of IP Addresses and Ports**

<table>
<thead>
<tr>
<th>*</th>
<th>port</th>
<th>SSL, SSL_TCP</th>
</tr>
</thead>
<tbody>
<tr>
<td>A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it should use. If <code>-cleartext</code> is not specified, the NetScaler appliance uses end-to-end SSL.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>*</th>
<th>port</th>
<th>Not applicable</th>
</tr>
</thead>
<tbody>
<tr>
<td>All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers; the NetScaler appliance learns them dynamically.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** If you have configured your NetScaler appliance as a transparent pass through that makes use of global (wildcard) ports, you may want to turn on Edge mode. For more information, see "Configuring Edge Mode."

The NetScaler appliance attempts to locate virtual servers and services by first attempting an exact match. If none is found, it continues to search for a match based on wildcards, in the following order:

1. Specific IP address and specific port number
2. Specific IP address and a * (wildcard) port
3. * (wildcard) IP address and a specific port
4. * (wildcard) IP address and a * (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server on the basis of the protocol used in the request, in the following order:
Use of Wildcards Instead of IP Addresses and Ports

1. HTTP
2. TCP
3. ANY
Configuring Global HTTP Ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the `set ns param` command. After configuring this port, the NetScaler appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single `set ns param` command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the `show ns param` command to view the ports that are currently configured.

**To configure a global HTTP port by using the command line interface**

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

- `set ns param -httpPort <port>`
- `show ns param`

**Example 1: Configuring a port as a global HTTP port**

In this example, port 80 is configured as a global HTTP port.

```
> set ns param -httpPort 80
Done
> show ns param
```

**Example 2: Adding ports when one or more global HTTP ports are already configured**

In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.
Parameters for configuring a global HTTP port

httpPort

The HTTP ports on the web server. This setting allows the system to perform connection off-load for any client request that has a destination port matching one of the configured ports. Minimum value: 1.
To configure a global HTTP port by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Settings, click Change HTTP parameters.

3. In the Configure HTTP Parameters dialog box, in the HTTP Port area, do the following:
   - To add a port, enter the port number, and then click Add.
   - To remove a port that has already been configured, click the port number, and then click Remove.

4. Click OK.
Setting Up Basic Load Balancing

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.
Enabling Load Balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature LB`
- `show ns feature`

Example

```
> enable ns feature LoadBalancing
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Done
```

To enable load balancing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message box, click Yes.
Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server’s name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.
Adding a Server

If you add a server to the list of servers before creating a service to represent that server, you can assign a name to the server. You can then specify the server's name instead of its IP address when you create a service. If you create a service from the configuration utility, you can select the server from the drop-down list. When adding the server to the list, you might want to assign it a name that helps identify the kind of services that you will create with it. You can also specify its state and add a comment.

When adding a server, you must identify it by specifying its IP address or domain name. If you specify the domain name, you can later change the IP address of the physical server without having to modify the server's entry in the list of servers on the appliance. The domain name is resolved to an IP address that is specified in an address record on the DNS.

During hardware maintenance or software upgrades, you may have to make the server DOWN. If the server is domain based, to override the IP address resolved by the DNS, you can configure an IP address mask and a translation IP address on the NetScaler appliance. For more information, see "Translating the IP Address of a Domain Based Server."

You can add a range of servers from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix or prefix. For example, server1, server2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address. For more information, see "Creating a Range of Virtual Servers."

To add a server by using the command line interface

At the command prompt, type:

```
add server <name> (<ipAddress> | (<domain> [-ipv6Address ( YES | NO )]) [-state ( ENABLED | DISABLED )] [-comment <string>]
```

**Examples**

```
add server myserver www.example.net -state DISABLED -comment "Web server for example.net"
Done
> show server myserver
  Name:    myserver   State:DISABLED
  Domain: www.example.net   Resolve Retry: 0 Secs
  Translation IP:         0.0.0.0  Translation Mask:         0.0.0.0
  Comment: "Web server for example.net"
Done
>
```
Parameters for configuring a server

name

The name assigned to the server. This alphanumeric string is required. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

ipAddress

IP address of the server, in either IPv4 or IPv6 format.

If the server is not reachable from the appliance or is not active, the service is marked as DOWN.

domain

Domain name that resolves to the IP address that represents the server.

ipv6Address

Resolve the domain name to an IPv6 address. Possible values: YES, NO. Default: NO.

state

The initial state of the server. Possible values: ENABLED, DISABLED. Default: ENABLED.

comment

A comment to help identify the server. Maximum length: 255 characters. To include spaces in a comment that you type on the command line, enclose the entire comment inside quotation marks. The quotation marks become part of the comment. They are not required if you use the configuration utility.
To add a server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Servers.

2. In the details pane, click Add.

3. In the Create Server dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a server” as shown above:
   - Server Name—name
   - IP Address—ipAddress (Select IP Address and type the address. Before typing an IPv6 address, select the IPv6 check box.)
   - Domain Name—domain (For a domain-name based server, select Domain Name and type the name of the server’s domain.)
   - Enable after Creating—state
   - Comment—comment

4. If you specify the domain name of the server and you want the domain name to be resolved to an IPv6 address, select the IPv6 Domain check box.

5. Click Create, and then click Close. The server you named appears in the Servers pane.
Creating a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the NetScaler appliance.

**HTTP**

Used for load-balanced servers that accept HTTP traffic, such as standard web sites and web applications. The HTTP service type enables the NetScaler appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the NetScaler appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 support described earlier.

**SSL**

Used for servers that accept HTTPS traffic, such as ecommerce web sites and shopping cart applications. The SSL service type enables the NetScaler appliance to encrypt and decrypt SSL traffic (perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL_BRIDGE, SSL_TCP, or TCP service types. If you do so, however, the NetScaler performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 support described above.

**FTP**

Used for servers that accept FTP traffic. The FTP service type enables the NetScaler appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service types for FTP servers.

**TCP**

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

**SSL_TCP**

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the NetScaler appliance performs both the Layer 4 load balancing and SSL offloading.
Creating a Service

**UDP**

Used for servers that accept UDP traffic. You can also use the ANY service type.

**SSL_BRIDGE**

Used for servers that accept SSL traffic when you do not want the NetScaler appliance to perform SSL offloading. Alternatively, you can use the SSL_TCP service type.

**NNTP**

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

**DNS**

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the NetScaler appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

**ANY**

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

**SIP-UDP**

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

**DNS-TCP**

Used for servers that accept DNS traffic, where the NetScaler appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the NetScaler appliance validates the packet format of each DNS request and response and can cache DNS responses, just as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

**RTSP**

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.
You can also use the TCP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NATting.

**DHCPRA**

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

**DIAMETER**

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

**SSL_DIAMETER**

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the NetScaler appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated as ENABLED. Thereafter, the NetScaler appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

**Note:** You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the configuration utility, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in case of an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

**To create a service by using the command line interface**

At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

**Example**

```
add service Service-HTTP-1 192.0.2.5 HTTP 80
```

**Parameters for configuring a service**

**name**

Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).
serverName

Either the name of a previously created server object, or the IP address of the load-balanced server that hosts this service, in either IPv4 or IPv6 format. When you provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.

If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

serviceType

The type of connections that the service will handle. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDPHTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP.

port

Port on which the service listens. The port number must be a positive number not greater than 65534.

**Note:** For more information about the SSL and SSL_TCP service types, see SSL Offload and Acceleration.

---

### To create a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a service” as shown:

   - Service Name—name
   - Server—servername
   - Protocol—serviceType
   - Port—port

4. Click Create, and then click Close. The service you created appears in the Services pane.
Troubleshooting

When binding a service group to a load balancing virtual server, the appliance displays the following error message:

Operation not permitted error

Are there any recommended settings that can resolve this issue?

Resolution: When creating a service, you must enable the Health Monitoring option. To resolve this issue, edit the service and select the Health Monitoring option.
Creating a Virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced Web sites, applications, or servers. Once load balancing is configured, users connect to the load-balanced Web site, application, or server through the virtual server’s IP address or FQDN.

**Note:** The virtual server is designated as DOWN until you bind the services that you created to it, and until the NetScaler appliance connects to those services and verifies that they are operational. Only then is the virtual server designated as UP.

**To create a virtual server by using the command line interface**

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port>
```

**Example**

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

**Parameters for creating a virtual server**

**name**

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

**IPAddress**

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

**serviceType**

The type of services to which the virtual server distributes requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, and MSSQLHTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP

**port**
Port on which the virtual server listens for client connections. The port number must be between 0-65535.

**To create a virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a virtual server” as shown:
   - Name—name
   - IP Address—IPAddress
     
     **Note:** If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0000:0005:0600:700a:888b).
   - Protocol—serviceType
   - Port—port
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.
After you have created services and a virtual server, you must bind the services to the virtual server. In most cases, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

<table>
<thead>
<tr>
<th>Virtual Server Type</th>
<th>Service Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP</td>
<td>SSL</td>
<td>You would normally bind an SSL service to an HTTP virtual server to do encryption.</td>
</tr>
<tr>
<td>SSL</td>
<td>HTTP</td>
<td>You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.</td>
</tr>
<tr>
<td>SSL_TCP</td>
<td>TCP</td>
<td>You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).</td>
</tr>
</tbody>
</table>

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserv <name> <serviceName>
```

Example

```
bind lb vserv Vserver-LB-1 Service-HTTP-1
```

To bind a service to a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the service.

3. Click Open.

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server.

5. Click OK.

**Note:** You can bind a service to multiple virtual servers.
Verifying the Configuration

After finishing your basic configuration, you should view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the configuration is up and running, you should view the statistics for each service and load balancing virtual server to check for possible problems.
Viewing the Properties of a Server Object

You can view properties such as the name, state, and IP address of any server object in your NetScaler appliance configuration.

**To view the properties of server objects by using the command line interface**

At the command prompt, type:

```
show server <serverName>
```

**Example**

```
show server server-1
```

**To view the properties of server objects by using the configuration utility**

In the navigation pane, expand Load Balancing, and then click Servers. The parameter values of the available servers appear in the details pane.
Viewing the Properties of a Virtual Server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

To view the properties of a load balancing virtual server by using the command line interface

At the command prompt, type:

```
show lb vserver <name>
```

Example

```
show lb vserver Vserver-LB-1
```

To view the properties of a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.

3. To view cache redirection and content switching virtual servers that are bound to this virtual server, click Show CS/CR Bindings.
Viewing the Properties of a Service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

To view the properties of services by using the command line interface

At the command prompt, type:

```
show service <name>
```

Example

```
show service Service-HTTP-1
```

To view the properties of services by using the configuration utility

In the navigation pane, expand Load Balancing, and then click Services. The details of the available services appear on the Services pane.
Viewing the Bindings of a Service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

To view the bindings of a service by using the command line

At the command prompt, type:

`show service bindings <name>`

Example

`show service bindings Service-HTTP-1`

To view the bindings of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service whose binding information you want to view.
3. Click Show Bindings. The bindings of the service you selected appear in the Binding details for Service: ServiceName dialog box.
Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

`stat lb vserver [-detail] [<name>]`

Example

```
>stat lb vserver -detail
Virtual Server(s) Summary
  vsrIP    port  Protocol  State  Req/s  Hits/s
One        * 80    HTTP     UP     5/s     0/s
Two        *  0    TCP      DOWN   0/s     0/s
Three      * 2598  TCP      DOWN   0/s     0/s
dnsVirtualNS 10.102.29.90    53    DNS     DOWN   0/s     0/s
BRVSERV    10.10.1.1    80    HTTP     DOWN   0/s     0/s
LBVIP      10.102.29.66    80    HTTP     UP      0/s     0/s
Done
```
Parameters for displaying statistics

detail

Include the statistics for hits per second and the total number of hits.

name

Name of the virtual server whose statistics are displayed.

To display virtual server statistics by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.

3. In the details pane, click Statistics.
Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

Example

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).

Customizing a Load Balancing Configuration

After you configure a basic load balancing setup, you can make a number of modifications to it so that it distributes load exactly as you need. The load balancing feature is complex. You can modify the basic elements by changing the load balancing algorithm, configuring load balancing groups and using them to create your load balancing configuration, configuring persistent client-server connections, configuring the redirection mode, and assigning different weights to different services that have different capacities.

The default load balancing algorithm on the NetScaler appliance is the least connection method, which configures the appliance to send each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers, causing the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can assign weights to different services, specifying what percentage of incoming load should be directed to each service, so that you can include servers with different capacities in the same load balancing setup without overloading the lower-capacity servers or allowing the higher-capacity servers to sit idle.
Load Balancing Algorithms

The load balancing algorithm defines the criteria that the NetScaler appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the NetScaler appliance supports, with a brief description of how each operates.

<table>
<thead>
<tr>
<th>Name</th>
<th>Server Selection Based On</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEASTCONNECTION</td>
<td>Which service currently has the fewest client connections. This is the default load balancing algorithm.</td>
</tr>
<tr>
<td>ROUNDROBIN</td>
<td>Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list.</td>
</tr>
<tr>
<td>LEASTRESPONSETIME</td>
<td>Which load balanced server currently has the quickest response time.</td>
</tr>
<tr>
<td>URLHASH</td>
<td>A hash of the destination URL.</td>
</tr>
<tr>
<td>DOMAINHASH</td>
<td>A hash of the destination domain.</td>
</tr>
<tr>
<td>DESTINATIONIPHASH</td>
<td>A hash of the destination IP address.</td>
</tr>
<tr>
<td>SOURCEIPHASH</td>
<td>A hash of the source IP address.</td>
</tr>
<tr>
<td>SRCIPDESTIPHASH</td>
<td>A hash of the source and destination IP addresses.</td>
</tr>
<tr>
<td>CALLIDHASH</td>
<td>A hash of the call ID in the SIP header.</td>
</tr>
<tr>
<td>SRCIPSRCPORTHASH</td>
<td>A hash of the client's IP address and port.</td>
</tr>
<tr>
<td>LEASTBANDWIDTH</td>
<td>Which service currently has the fewest bandwidth constraints.</td>
</tr>
<tr>
<td>LEASTPACKETS</td>
<td>Which service currently is receiving the fewest packets.</td>
</tr>
<tr>
<td>CUSTOMLOAD</td>
<td>Data from a load monitor.</td>
</tr>
<tr>
<td>TOKEN</td>
<td>The configured token.</td>
</tr>
<tr>
<td>LRTM</td>
<td>Fewest active connections and the lowest average response time.</td>
</tr>
</tbody>
</table>

Depending on the protocol of the service that it is load balancing, the NetScaler appliance sets up each connection between client and server to last for a different time interval. This
is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

<table>
<thead>
<tr>
<th>Granularity</th>
<th>Types of Load Balanced Service</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-based</td>
<td>HTTP or HTTPS</td>
<td>A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.</td>
</tr>
<tr>
<td>Connection-based</td>
<td>TCP and TCP-based protocols other than HTTP</td>
<td>A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.</td>
</tr>
<tr>
<td>Time-based</td>
<td>UDP and other IP protocols</td>
<td>A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period of time. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.</td>
</tr>
</tbody>
</table>

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as startup round robin, helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the NetScaler switches to the specified load balancing method depending on the request rate.

- If the Startup RR Factor is any number other than zero, NetScaler uses the round robin method for the specified number of requests before switching to the specified load balancing method.

- By default, the Startup RR Factor is set to zero.

**Note:** You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the NetScaler appliance.

To set the startup round-robin factor by using the command line interface
At the command prompt, type:

```
set lb parameter -startupRRFactor <positive_integer>
```

Example

```
set lb parameter -startupRRFactor 25000
```

**Parameter for setting the startup round-robin factor**

**startupRRFactor**

The number of requests for which the virtual server is to apply the round robin load balancing method (slow start mode) before switching to the load balancing method configured on the virtual server. Minimum value: 0, Maximum value: 4294967295. Default: 0.

**To set the startup round-robin factor by using the configuration utility**

1. In the navigation pane, click Load Balancing.

2. Under Settings, click Configure Load Balancing Parameters.

3. In the Configure Load Balancing Parameters dialog box, for Startup RR Factor type a value.

4. Click OK.
The Least Connection Method

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL_TCP services, the NetScaler appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.

- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server’s connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP packet in a session arrives, the NetScaler appliance creates a session between the source IP address and port and the destination IP address and port.

For Real-Time Streaming Protocol (RTSP) connections, the NetScaler appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the NetScaler appliance forwards incoming requests when using the least connection method.
Figure 1. Mechanism of the Least Connections Load Balancing Method

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  **Note:** The service with no active transaction is selected first.

- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.

- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of active transactions, the virtual server uses the round robin method to choose between them.

- Service-HTTP-3 receives the fifth request.

- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. At that time, the NetScaler appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

  **Note:** If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described above.
The Least Connection Method

<table>
<thead>
<tr>
<th>Incoming Connection</th>
<th>Service Selected</th>
<th>Current Number of Active Connections</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The NetScaler appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

\[ Nw = (\text{Number of active transactions}) \times (10000 / \text{weight}) \]

The following example shows how the NetScaler appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.
  
  **Note**: If services are not handling any active transactions, the NetScaler appliance uses the round robin method regardless of the weights assigned to each of the services.

- Service-HTTP-3 receives the second, third, fourth, fifth, sixth, and seventh requests because the service has lowest Nw value.
The Least Connection Method

- Service-HTTP-1 receives the eighth request. Because Service-HTTP-1 and Service-HTTP-3 now have same Nw value, the NetScaler performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the ninth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described above.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw (Number of active transactions) * (10000 / weight) value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>Nw = 2500</td>
<td></td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3</td>
<td>Nw = 5000</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3</td>
<td>Nw = 7500</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3</td>
<td>Nw = 10000</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3</td>
<td>Nw = 12500</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-3</td>
<td>Nw = 15000</td>
<td></td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-1</td>
<td>Nw = 20000</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same Nw values</td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-3</td>
<td>Nw = 17500</td>
<td></td>
</tr>
</tbody>
</table>

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the NetScaler appliance uses the least connection method when weights are assigned to the services.
The Least Connection Method

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

To configure the least connection method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Round Robin Method

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the NetScaler appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works

If you assign a different weight to each service, the NetScaler appliance performs weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
The Round Robin Method

- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

**Note:** You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

![Diagram of the Round Robin Load Balancing Method with Weighted Services](image)

**Figure 2.** How the Round Robin Load Balancing Method Works with Weighted Services

To configure the round robin method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Least Response Time Method

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the NetScaler appliance uses the least response time method to forward the connections.

![Diagram showing load balancing method](image)

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:
Service-HTTP-3 receives the first request, because the service is not handling any active transactions.

Service-HTTP-3 also receives the second and third requests, because the result is lowest of the three services.

Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the NetScaler appliance chooses between them by applying the Round Robin method.

Service-HTTP-3 receives the fifth request.

Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.

Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the NetScaler switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described above.

<table>

<td>N = 9</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 8)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The virtual server selects a service by using the value (Nw) in the following expression:
\[ Nw = (N) \times \left(\frac{10000}{\text{weight}}\right) \]

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The NetScaler appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

  If services are not handling any active transactions, the NetScaler selects them regardless of the weights assigned to them.

- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.

- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.

- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.

- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

The following table explains how connections are distributed in the three-service load balancing setup described above.

<table>

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw values of other services (Service-HTTP-2 and Service-HTTP-3) are equal to 105000.

The following diagram illustrates how the NetScaler appliance uses the least response time method when weights are assigned.

![Diagram showing the least response time load balancing method](image)

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

To configure the least response time method, see Configuring a Load Balancing Method that Does Not Include a Policy.

When a load balancing virtual server is configured to use the least response time method with monitors, it uses the existing monitoring infrastructure to select the service with the smallest number of active transactions and the fastest average response time. Before you use the least response time method with monitoring, you must bind application-specific monitors to each service and enable least response time method mode on these monitors. The NetScaler appliance then makes load balancing decisions based on the response times it calculates from monitoring probes. For more information about configuring monitors, see...
Configuring Monitors in a Load Balancing Setup.

You can use the least response time method with monitors to select non-HTTP and non-HTTPS services. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for various monitors.

<table>
<thead>
<tr>
<th>Monitor</th>
<th>Response Time Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PING</td>
<td>Time difference between the ICMP ECHO request and the ICMP ECHO response.</td>
</tr>
<tr>

<tr>
<td>HTTPS-ECV (monitors HTTPS requests)</td>
<td>Time difference is same as for the HTTP-ECV monitor</td>
</tr>
<tr>
<td>USER</td>
<td>Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.</td>
</tr>
</tbody>
</table>
The following example shows how the NetScaler appliance selects a service for load balancing by using the least response time method with monitors. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the NetScaler appliance follows when it forwards requests.

Figure 3. How the Least Response Time Load Balancing Method Works When Using Monitors

The virtual server selects a service by using the value (N) in the following expression:

\[ N = \text{Number of active transactions} \times \text{Response time that is determined by the monitor} \]

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the NetScaler appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.

Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the NetScaler appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value (Number of Active Transactions)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>N = 2</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td></td>
<td>(N = 0)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3</td>
<td>N = 4</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 2)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3</td>
<td>N = 6</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 4)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3</td>
<td>N = 8</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 6)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-2</td>
<td>N = 8</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td></td>
<td>(N = 7)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-3</td>
<td>N = 10</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 8)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-2</td>
<td>N = 9</td>
<td>Service-HTTP-2 has the lowest N value.</td>
</tr>
<tr>
<td></td>
<td>(N = 8)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1</td>
<td>N = 10</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(N = 9)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when the N value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 15.

The NetScaler appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The NetScaler appliance selects the service by using the value (Nw) in the following expression:

\[ Nw = (N) \times \left( \frac{10000}{weight} \right) \]
As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the seventh and the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the NetScaler appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>Nw = 5000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3</td>
<td>Nw = 10000</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3</td>
<td>Nw = 20000</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3</td>
<td>Nw = 25000</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-2</td>
<td>Nw = 26666.67</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-3</td>
<td>Nw = 30000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-2</td>
<td>Nw = 26666.67</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>
Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of the other services (Service-HTTP-2 and Service-HTTP-3) is equal to 75000.

The following diagram illustrates how the virtual server uses the least response time method when weights are assigned.

Figure 4. How the Least Response Time Load Balancing Method with Monitors Works When Weights Are Assigned

To configure the least response time method using monitors, see Configuring a Load Balancing Method that Does Not Include a Policy.
About Hashing Methods

Load balancing methods based on hashes of certain connection information or header information constitute the majority of the NetScaler appliance’s load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used Web sites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The NetScaler provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method
- Source IP Destination IP hash method
- Source IP Source Port hash method
- Call ID hash method
- Token method

These hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup. Most of them calculate two hash values:

- A hash of the service’s IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The NetScaler appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with highest hash value. As the appliance computes a hash value for each request and selects the service that will process the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.
Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the NetScaler appliance calculates the hash value for the last log
of the number of services. The NetScaler then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

**Note:** If the NetScaler appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. You should adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.
The URL Hash Method

When you configure the NetScaler appliance to use the URL hash method for load balancing the services, for selecting a service, the NetScaler generates a hash value of the HTTP URL present in the incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The NetScaler caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the NetScaler cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, NetScaler uses a specific algorithm and considers a part of the URL. By default, the NetScaler considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 to 4096 bytes. Generally, if long URLs are used where only a small number of characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. NetScaler selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the NetScaler selects Service-HTTP-2.

The following diagram illustrates this process.
The URL Hash Method

Figure 1. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, NetScaler sends requests with hash value U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see Configuring a Load Balancing Method that Does Not Include a Policy. Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.
The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the NetScaler gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the NetScaler appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the NetScaler appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Destination IP Hash Method

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the Destination IP Hash method.

To configure the destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Source IP Hash Method

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Source IP Destination IP Hash Method

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric; the hash-value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Source IP Source Port Hash Method

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see Connection Failover.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP source port hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure the call ID hash method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Least Bandwidth Method

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

![Diagram](image)

**Figure 1. How the Least Bandwidth Load Balancing Method Works**

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.

Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have the same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>

</tbody>
</table>

**Note:** If you enable the RTSP NAT option on the virtual server, the NetScaler appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about RTSP NAT option, see Managing RTSP Connections.

The NetScaler appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value \( Nw \) in the following expression:

\[
Nw = (N) \times \left(\frac{10000}{\text{weight}}\right)
\]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The
NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.

- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.

- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.

- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>Nw = 5000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>

<td>Service-HTTP-3</td>
<td>Nw = 17500</td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-2</td>
<td>Nw = 20000</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.
The Least Bandwidth Method

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

To configure the least bandwidth method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Least Packets Method

A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in last 14 seconds.
- Service-HTTP-2 has handled five packets in last 14 seconds.
- Service-HTTP-3 has handled two packets in last 14 seconds.

The following diagram illustrates how the NetScaler appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

The NetScaler appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second
request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.

- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current N Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>N = 3</td>
<td>Service-HTTP-3 has the lowest N value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1</td>
<td>N = 4</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3</td>
<td>N = 4</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1</td>
<td>N = 5</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3</td>
<td>N = 5</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1</td>
<td>N = 6</td>
<td>Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-2</td>
<td>N = 6</td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-3</td>
<td>N = 6</td>
<td></td>
</tr>
</tbody>
</table>

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about RTSP NAT option, see Managing RTSP Connections.

The NetScaler appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

\[ Nw = (N) \times \frac{10000}{weight} \]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:
The Least Packets Method

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.

- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.

- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.

- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

<table>
<thead>
<tr>
<th>Request Received</th>
<th>Service Selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-3</td>
<td>Nw = 5000</td>
<td>Service-HTTP-3 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-3</td>
<td>Nw = 7500</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-3</td>
<td>Nw = 10000</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-3</td>
<td>Nw = 12500</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-3</td>
<td>Nw = 15000</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1</td>
<td>Nw = 20000</td>
<td>Service-HTTP-1 and Service-HTTP-3 have the same Nw value.</td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-3</td>
<td>Nw = 17500</td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-2</td>
<td>Nw = 20000</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.
Figure 2. How the Least Packets Method Works When Weights Are Assigned

To configure the least packets method, see Configuring a Load Balancing Method that Does Not Include a Policy.
The Custom Load Method

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all of the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see Understanding Load Monitors. The following diagram illustrates how a load monitor operates.

![Diagram of how load monitors operate](image)

Figure 1. How Load Monitors Operate

The load monitor uses Simple Network Management Protocol (SNMP) probes to calculate load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics, described below, to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the NetScaler.
- Threshold value set for each metric.
The Custom Load Method

- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 megabytes (MB) of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. The three services respond to the request. The NetScaler appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how \( N \) is calculated.

<table>
<thead>
<tr>
<th>Request received</th>
<th>Service selected</th>
<th>Current N Value (Number of Active Transactions)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>

<tr>
<td></td>
<td>( (N = 70) )</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1</td>
<td>( N = 90 )</td>
<td>Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same ( N ) values.</td>
</tr>
<tr>
<td></td>
<td>( (N = 80) )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value \( Nw \) in the following expression:

\[
Nw = (N) \times \left(\frac{10000}{weight}\right)
\]

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest \( Nw \) value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest \( Nw \) value.
Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated.

<table>
<thead>
<tr>
<th>Request received</th>
<th>Service selected</th>
<th>Current Nw Value (Number of Active Transactions) * (10000 / Weight)</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-1</td>
<td>Service-HTTP-1</td>
<td>Nw = 75000</td>
<td>Service-HTTP-1 has the lowest Nw value.</td>
</tr>
<tr>
<td>Request-2</td>
<td>Service-HTTP-1</td>
<td>Nw = 100000</td>
<td></td>
</tr>
<tr>
<td>Request-3</td>
<td>Service-HTTP-1</td>
<td>Nw = 125000</td>
<td></td>
</tr>
<tr>
<td>Request-4</td>
<td>Service-HTTP-1</td>
<td>Nw = 150000</td>
<td></td>
</tr>
<tr>
<td>Request-5</td>
<td>Service-HTTP-1</td>
<td>Nw = 175000</td>
<td></td>
</tr>
<tr>
<td>Request-6</td>
<td>Service-HTTP-1</td>
<td>Nw = 200000</td>
<td></td>
</tr>
<tr>
<td>Request-7</td>
<td>Service-HTTP-1</td>
<td>Nw = 225000</td>
<td></td>
</tr>
<tr>
<td>Request-8</td>
<td>Service-HTTP-1</td>
<td>Nw = 250000</td>
<td></td>
</tr>
<tr>
<td>Request-9</td>
<td>Service-HTTP-2</td>
<td>Nw = 266666.67</td>
<td>Service-HTTP-2 has the lowest Nw value.</td>
</tr>
</tbody>
</table>

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the NetScaler appliance uses the custom load method when weights are assigned.
Figure 3. How the Custom Load Method Works When Weights Are Assigned

To configure the custom load method, see Configuring a Load Balancing Method that Does Not Include a Policy.
Configuring the Token Method

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

This method is content aware; it operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see Policy Configuration and Reference.

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the NetScaler searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the NetScaler appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.
To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

- `set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length> -dataoffset <offset>`
- `show lb vserver <name>`

Example

```bash
set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -dataoffset 25
show lb vserver LB-VServer-1
```

Parameters for Configuring the Token Load Balancing Method

- name
Configuring the Token Method

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

rule

A string. The string can be an existing rule name, or it can be an inline expression with a maximum of 256 characters.

datalength

Length of the token in bytes. This parameter is applicable to HTTP virtual servers and TCP virtual servers configured for Token load balancing. Valid values: 0-100. Default: No default.

dataoffset

Offset of the data to be taken as a token. This parameter is applicable to TCP virtual servers configured for Token load balancing. The token must be within the first 24 KB of the client TCP data. Valid values: 0-25400. Default: No default

To configure the Token load balancing method by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure a rule, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab and under LB Method, select Token.

4. Click Configure next to the Rule text box.

5. In the Create Expression dialog box, select Classic Syntax or Advanced Syntax.

6. Under Expression, click Add.

7. In the Add Expression dialog box, enter an expression. For more information about expressions, see Policy Configuration and Reference. For example, if you are configuring a classic expression, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA.

8. Click OK, and then click Close.

9. In the Create Expression dialog box, click Create. The expression you created appears in the Rule text box.

10. Click OK.
Configuring a Load Balancing Method That Does Not Include a Policy

After you select a load balancing algorithm for your load balancing setup, you must configure the NetScaler appliance to use that algorithm. You can configure it by using the NetScaler command line or by using the configuration utility.

**Note:**

The token method is policy based and requires more configuration than is described here. To configure the token method, see Configuring the Token Method.

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see The Destination IP Hash Method, The Source IP Hash Method, The Source IP Destination IP Hash Method, and The Source IP Source Port Hash Method.

**To set the load balancing method by using the command line interface**

At the command prompt, type:

```
set lb vserver <name> -lbMethod <method>
```

**Example**

```
set lb vserver Vserver-LB-1 -lbMethod LeastConnection
```

**Parameters for specifying a load balancing method**

- **name**
  
  Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

- **lbMethod**
  
  Load balancing method used by the virtual server. Possible values: ROUNDROBIN, LEASTCONNECTION, LEASTRESPONSETIME, URLHASH, DOMAINHASH, DESTINATIONIPHASH, SOURCEIPHASH, SRCIDESTIPHASH, LEASTBANDWIDTH, LEASTPACKETS, TOKEN, SRCIPSRCPORPTION, LRTM, CALLIDHASH, CUSTOMLOAD. Default: LEASTCONNECTION.
To set the load balancing method by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure an LB method, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab.

4. From the drop-down menu under LB Method, select a method, (for example, Least Response Time).

5. Click OK.
Persistence and Persistent Connections

Unless you configure persistence, a load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections. Different transmissions from the same client might be directed to different servers even though all of the transmissions are part of the same session. You must configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what the implications of each type is. You then need to configure the NetScaler appliance to provide persistent connections for those Web sites and Web applications that require them.

You can also configure backup persistence, which takes effect in the event that the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see Configuring RADIUS Load Balancing with Persistence.
About Persistence

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, Web-based email, or other network application. The persistence session remains in effect for a period of time, which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the NetScaler appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and be used as the basis for persistence.

The following table summarizes the persistence types available on the NetScaler appliance.

<table>
<thead>
<tr>
<th>Persistence Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source IP</td>
<td>SOURCEIP. Connections from the same client IP address are parts of the same persistence session.</td>
</tr>
<tr>
<td>HTTP Cookie</td>
<td>COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.</td>
</tr>
<tr>
<td>SSL Session ID</td>
<td>SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.</td>
</tr>
<tr>
<td>URL Passive</td>
<td>URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>Custom Server ID</td>
<td>CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.</td>
</tr>
<tr>
<td>Destination IP</td>

</tbody>
</table>

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your NetScaler appliance. The following table shows which types of persistence fall into each category.

#### Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Persistence Based on Source IP Address

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

**Caution:** In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single Web site or application are routed through the single gateway to the NetScaler appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session should be created. This issue is called the “Mega Proxy problem.” You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see Configuring Persistence Types That Do Not Require a Rule.

**Note:** If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the NetScaler appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.
Persistence Based on HTTP Cookies

When HTTP cookie persistence is configured, the NetScaler appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the NetScaler appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any NetScaler resources and therefore can accommodate an unlimited number of persistent clients.

Note: If the client’s Web browser is configured to refuse cookies, HTTP cookie-based persistence will not work. It might be advisable to configure a cookie check on the Web site, and warn clients that do not appear to be storing cookies properly that they will need to enable cookies for the Web site if they want to use it.

The format of the cookie that the NetScaler appliance inserts is:

NSC_XXXX=<ServiceIP >>ServicePort>

where:

- NSC_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period of time, the NetScaler appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

Note: If you set the time-out value to 0, the NetScaler appliance does not specify an expiration time, but sets a session cookie that is not saved when the client’s browser is shut down.

By default, the NetScaler appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the “Max-Age” attribute of the HTTP cookie. In this case, the client’s browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see Configuring Persistence Types That Do Not Require a Rule.
In the HTTP cookie, the appliance by default sets the httponly flag to indicate that the cookie is nonscriptable and should not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the httponly flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the httponly flag in the persistence cookie.

To change the httponly flag setting by using the command line interface

At the command prompt, type:

```bash
set lb parameter -httpOnlyCookieFlag (ENABLED|DISABLED)
```

Example

```bash
> set lb parameter -httpOnlyCookieFlag disabled
Done
> show lb parameter
Global LB parameters:
    Persistence Cookie HttpOnly Flag: DISABLED
    Use port for hash LB: YES
Done
```

Parameter for customizing the httponly flag

`httpOnlyCookieFlag`

Flag the persistence cookie as nonscriptable so that it is not revealed to the client application. Possible values: ENABLED, DISABLED. Default: ENABLED.
To change the `httponly` flag setting by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. In the Settings group, click Configure Load Balancing Parameters.

3. To not set the `httponly` flag in the persistence cookie, clear the Persistence Cookie `HTTPOnly` Flag check box.

4. Click OK.

5. Open the Configure Load Balancing Parameters dialog box and verify the setting you just configured.
Persistence Based on SSL Session IDs

When SSL Session ID persistence is configured, the NetScaler appliance uses the SSL Session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

**Note:**

There are two issues that users should consider before choosing this type of persistence. First, the NetScaler appliance does not encrypt or decrypt data when it forwards requests to services in an SSL bridge configuration, because it must maintain the data structures to keep track of the sessions. This type of persistence therefore consumes resources on the NetScaler appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support a very large number of concurrent persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server should renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client’s next request is received. This may result in the client’s activity on the Web site being interrupted and the client being required to reauthenticate or restart the session. It may also result in large numbers abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see Configuring Persistence Types That Do Not Require a Rule.
Persistence Based on Diameter AVP Number

You can use persistence based on the AVP number of a Diameter message to create persistent Diameter sessions. When the NetScaler appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

**Note:** If the AVP number is not defined in Diameter base-protocol RFC 3588, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

**To configure Diameter-based persistence on a virtual server by using the command line interface**

At the command prompt, type the following command:

```
set lb vserver <name> -PersistenceType <type-> persistAVPno <positive_integer>
```

**Example**

```
set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
```
Custom Server ID Persistence

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The NetScaler appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider should make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the NetScaler appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

**Note:** The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

**Example**

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
set service Service-1 10.102.29.5 -serverID 2345-photo-56789
set service Service-1 10.102.29.6 -serverID 2345-drawing-abb123
```

On virtual server Web11, enable Custom Server ID persistence.

**Example**

```
set lb vserver Web11 -persistenceType customserverID
bind lb vserver Web11 Service-[1-2]
```

Create the following expression so that all URL queries containing the string "sid=" are examined.

```
HTTP.REQ.URL.AFTER_STR("sid=")
```
When a client sends a request with the following URL to the IP address of Web11, the NetScaler directs the request to Service-2 and honors persistence.

Example

http://www.example.com/index.asp?&sid=2345-drawing-abb123

For more information about default-syntax policy expressions, see the Policy Configuration and Reference.

Parameters for configuring custom server ID persistence

ServiceName

The name of the service that you are configuring.

vServerName

The name of the virtual server

persistenceType

Method of persistence. Select CUSTOMSERVERID.

rule

Rule to examine the URL for server ID.
To configure custom server ID persistence by using the configuration utility

1. Assign a server ID to each of the services for which you want to configure custom server ID persistence.
   a. In the navigation pane, expand Load Balancing, and then click Services.
   b. In the details pane, select the service for which you want to specify a server ID, and then click Open.
   c. In the Configure Service dialog box, click the Advanced tab.
   d. Scroll down, and under Others, in the Server ID box, type an ID for the server.
   e. Click OK.

2. Configure custom server ID persistence on the virtual server to which the services are bound.
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   b. In the details pane, select the virtual server for which you want to specify persistence, and then click Open.
   c. On the Method and Persistence tab, in the Persistence group, select CUSTOMSERVERID.
   d. In the Rule box, type an expression, or click Configure, and use the options available in the Create Expression dialog box, to create the expression.
   e. Click OK.
Persistence Based on Destination IP Addresses

With destination IP address-based persistence, when the NetScaler appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see Link Load Balancing.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on the destination IP address, see Configuring Persistence Types That Do Not Require a Rule.
Persistence Based on Source and Destination IP Addresses

With source and destination IP address-based persistence, when the NetScaler appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Subsequently, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in Persistence Based on Source IP Address.

To configure persistence based on both source and destination IP addresses, see Configuring Persistence Types That Do Not Require a Rule.
Persistence Based on SIP Call ID

With SIP Call ID persistence, the NetScaler appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

To configure persistence based on SIP Call ID, see Configuring Persistence Types That Do Not Require a Rule.
Persistence Based on RTSP Session IDs

With RTSP Session ID persistence, when the NetScaler appliance receives a request from a new client, it creates a new persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see Monitoring SIP Services.

**Note:** RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that may issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see Configuring Persistence Types That Do Not Require a Rule.

**Important:** If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

### Parameter to Set When Configuring Services

**session**

Map the RTSP session ID by appending the IP address and port of the server to the session ID, guaranteeing that all session IDs are unique within the load balancing setup.

**Note:** When Session ID Mapping is enabled, the NetScaler appliance rejects any packet that does not contain a mapped ID. Possible values: ON and OFF. Default: OFF.

**Note:** If a client sends multiple SETUP requests on a single TCP connection, the NetScaler appliance sends those SETUP requests to the same service, because it makes a load balancing decision for every TCP connection. When this occurs, the appliance does not forward the SETUP requests to different servers based on the RTSP session ID.
Configuring URL Passive Persistence

With URL Passive persistence, when the NetScaler appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see Policy Configuration and Reference.

The following expression configures the appliance to examine requests for URL queries that contain the string "urlp=", extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

HTTP.REQ.URL.AFTER_STR("urlp=")

If URL passive persistence is enabled and the above expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

http://www.example.com/index.asp?urlp=0A661D0A0050

The persistence time-out value does not affect this persistence type; persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any NetScaler resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule. You set the persistence type to URLPASSIVE. You then perform the procedures provided below.

To configure URL passive persistence by using the command line interface

At the command prompt, type:

set lb vserver <vservername> [-rule <expression>]

Example

set lb vserver LB-VServer-1 -rule HTTP.REQ.URL.AFTER_STR("urlp=")
Parameters for Rule-Based Persistence

rule

Value used to set the URLPASSIVE persistence type. The value can be an existing rule name, or it can be a classic or advanced expression. The default value is none. The maximum length is 14999.

The rule evaluates either requests that are directed to the load balanced servers or responses from the servers.

To configure URL passive persistence by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in Persistence, select URLPASSIVE.

3. Click the Configure button next to the Rule field.

4. In the dialog box that appears, create the rule that you want to use. For more information about creating rules, see Policy Configuration and Reference.

5. Click OK.
Configuring Persistence Based on User-Defined Rules

When rule based persistence is configured, the NetScaler appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Subsequently, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL_TCP.

Rule based persistence requires a classic or default syntax expression. You can use a classic expression to evaluate request headers, or you can use a default syntax expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you could use a classic expression to configure persistence based on the contents of the HTTP Host header. You could also use a default syntax expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and default syntax expressions, see Policy Configuration and Reference.

The expressions that you can configure depends on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

**Note:** For a use case that involves configuring rule based persistence on the basis of Financial Information eXchange (‘FIX’) Protocol data transmitted over TCP, see Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream.

Rule based persistence can be used for maintaining persistence with entities such as Branch Repeater appliances, Branch Repeater plug-ins, cache servers, and application servers.

**Note:** On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in Configuring Persistence Types That Do Not Require a Rule, and set the persistence type to RULE. You then perform the procedures provided below. You can configure rule based persistence by using the configuration utility or the NetScaler command line.

### To configure persistence based on user-defined rules by using the command line interface

At the command prompt, type:

```plaintext
set lb vserver <vserverName> [-rule <expression>][-resRule <expression>]
```

---

660
Example

set lb vserver vsvr_name -rule http.req.header("cookie").value(0).typecast_nvlist_t(\'=\',\';\').value("server")

set lb vserver vsvr_name -resrule http.res.header("set-cookie").value(0).typecast_nvlist_t(\'=\',\';\').value("server")

Parameters for Rule-Based Persistence

**rule**

Value used to set the RULE persistence type. The value can be an existing rule name, or it can be a classic or default syntax expression. You can specify this parameter for services of type . You can specify an expression that evaluates requests from clients.

Maximum length: 1499 characters. Default: NONE.

**resRule**

Value used to set the RULE persistence type. The response rule evaluates responses from the load balanced servers. You can configure this parameter for services of type . The expression must be a default syntax expression that evaluates responses from the load balanced servers.

Maximum length: 1499 characters. Default: NONE.

To configure persistence based on user-defined rules by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click **Add**.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, choose the type of rule you want to configure.

   · If you want to base the rule on the request, click the Configure button next to the Rule field.

   · If you want to base the rule on the response, click the Configure button next to the Response Rule field.

4. In the dialog box that appears, select Switch to Classic Syntax or Switch to Advanced Syntax.

5. Select or create the rule that you want to use. Some examples of rules that you might find useful are provided below. For more information, see Policy Configuration and Reference.

6. Click OK.

**Example: Classic Expression for a Request Payload**
The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

http header User-Agent contains MyBrowser

**Example: Default syntax Expression for a Request Header**

The following default syntax expression does exactly the same thing as the previous classic expression.

HTTP.REQ.HEADER("User-Agent").CONTAINS ("MyBrowser")

**Example: Default syntax Expression for a Response Cookie**

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T(‘;’).VALUE("server")
Configuring Persistence Types That Do Not Require a Rule

To configure persistence, you must first set up a load balancing virtual server, as described in Setting Up Basic Load Balancing. You then configure persistence on the virtual server.

To configure persistence on a virtual server by using the command line interface

At the command prompt, type the following commands to configure persistence and verify the configuration:

- `set lb vserver <name> -PersistenceType <type> [-timeout <integer>]`
- `show lb vserver`

Example

```
set lb vserver Vserver-LB-1 -persistenceType SOURCEIP
show lb vserver
```

Note: For IP-based persistence, you can also set the persistMask parameter.

Parameters for configuring persistence

PersistenceType

Persistence type supported on the virtual server. Valid Values: SOURCEIP, COOKIEINSERT, SSLSESSION, RULE, URLPASSIVE, CUSTOMSERVERID, DESTIP, SRCIPDESTIP, CALLID, RTSPID, and NONE. Default: NONE.

PersistMask

Defines which IP range is used to determine whether a connection is part of an existing persistence session or not. This parameter is used only if the persistence type is IP-based. The default value, 255.255.255.255, specifies that only connections from the same IP are part of an existing session. Valid values include the full range of available subnet masks.

Note: Setting this parameter to 0 has the same effect as setting it to 255.255.255.255.

Timeout
The period, in minutes, for which a persistence session remains in effect. Maximum value: 1440 minutes. Default: 2 minutes.

**To configure persistence on a virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure persistence, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select the persistence type you want to use (for example, SOURCEIP).

4. In the Time-out and Netmask text boxes type the time-out and subnet mask values (for example, 2 and 255.255.255.255).

5. Click OK.
Configuring Backup Persistence

The NetScaler appliance uses backup persistence to choose a new type of persistence when the primary persistence type fails. For example, if the primary persistence type is set to Cookie Insert, and backup persistence is set to Source IP, the NetScaler appliance uses Source IP-based persistence when the cookie is missing from the HTTP header or when the client browser does not support cookies.

You can set a time-out value for backup persistence only when the primary persistence type is HTTP Cookie-based or RTSP session ID-based persistence, and the backup persistence type is Source IP-based.

To set backup persistence for a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -persistenceType <PersistenceType> -persistenceBackup <BackupPersistenceType>
```

Example

```
set lb vserver Vserver-LB-1 -persistenceType CookieInsert -persistenceBackup SourceIP
```

Parameter for configuring backup persistence

```
persistenceBackup
```

Backup persistence type for the group. Possible values: SOURCEIP, NONE. Default: NONE.
To set backup persistence for a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure backup persistence (for example, Vserver-LB-1), and then click Open.

3. The Configure Virtual Server (Load Balancing) dialog box, click the Method and Persistence tab.

4. In the Persistence list, select the persistence type you want (for example, COOKIEINSERT).

5. In the Time-out text box, type the time-out value you want (for example, 20).

6. In the Backup Persistence list, select the backup persistence type that you want to configure (for example, SOURCEIP).

7. In the Backup Time-out and Netmask text boxes, type the backup time-out value and netmask (for example, 20 and 255.255.255.255).

8. Click OK.
Configuring Persistence Groups

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see Persistence Based on HTTP Cookies.

To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
bind lb group <vServerGroupName> <vServerName> -persistenceType <PersistenceType>
```

Example

```
bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType CookieInsert
```

Parameters for configuring virtual server persistency groups

name

Name of the persistence group. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )
Configuring Persistence Groups

`persistenceType`

Persistence type for the group. Possible values: SOURCEIP, COOKIEINSERT, NONE.

**Note:** If you specify NONE, the persistence configured for each of the individual virtual servers is applied, and the persistence group does not function.

`persistMask`

Netmask specified when the persistency type is SOURCEIP.

`timeout`

Time period for which the persistence is in effect for a specific client. The value ranges from 2 through 1440 minutes. The default value is 2 minutes. The maximum value is 1440 minutes (1 day).

---

**To create a virtual server persistency group by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Persistency Groups.
2. On the Persistency Groups pane, click Add.
3. In the Create Persistency Group dialog box, in the Group Name text box type a name for the group (for example, Vserver-Group-1).
4. In the Persistence list, select a persistence type (for example, SOURCEIP).
5. In the Persistence Mask and Time-out text boxes, type the persistence mask and timeout values (for example, 255.255.255.255 and 2).
6. Under Virtual Server List, in the Available Virtual Server list box, select the virtual server that you want to bind to the group (for example, Vserver-LB-1), and then click Add.
7. Click Create, and then click Close. The virtual server group you created appears in the Persistency Groups pane.

You can also change the backup persistence type, backup persistence time-out, and cookie domain value on an existing persistency group.

---

**To modify a virtual server group by using the command line interface**

At the command prompt, type:

```
set lb group <vServerGroupName> -PersistenceBackup <BackupPersistenceType>
-persistMask <SubnetMaskAddress>
```

**Example**
set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask 255.255.255.255

Parameters for modifying virtual server persistency groups

PersistenceBackup

Backup persistence type for the group. The valid options for this parameter are: SOURCEIP and NONE

backupPersistenceTimeout

Maximum time, in minutes, for which the backup persistence is in effect for a specific client. Maximum value: 1440. Default: 2.

cookieDomain

Domain attribute of the HTTP cookie.

To modify a virtual server group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Persistency Groups.

2. In the Persistency Groups pane, select the virtual server group that you want to modify (for example, Vserver-Group-1), and click Open.

3. The Configure Virtual Server Group dialog box appears.

4. In the Backup Persistence list, select the type of backup persistence (for example, SOURCEIP).

5. In the Persistence Mask text box, type the subnet mask (for example, 255.255.255.255).

6. Click OK.
Configuring RADIUS Load Balancing with Persistence

Today’s complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users may connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the NetScaler appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in AAA Application Traffic. You must also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.
Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new NetScaler appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a NetScaler appliance with a previous configuration on it, and you are not certain that the feature you will use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see Enabling Load Balancing.
- For instructions on enabling the content switching feature, see Enabling Content Switching.
Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service will handle authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).

- **RADIUS accounting virtual server.** This virtual server and its associated service will handle accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user’s activities on your protected application or VPN.

*Important:* You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

### To configure a load balancing virtual server by using the command line interface

At the command prompt type the following commands to create a new load balancing virtual server and verify the configuration:

- `add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
- `show lb vserver <name>

To configure an existing load balancing virtual server, replace the above `add lb virtual server` command with the `set lb vserver` command, which takes the same arguments.

### To configure a content switching virtual server by using the command line interface

At the command prompt type the following commands to create a new content switching virtual server and verify the configuration:

- `add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule <rule>
- `show cs vserver <name>

To configure an existing content switching virtual server, replace the above `add cs vserver` command with the `set cs vserver` command, which takes the same arguments.

**Example**
add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813
    -lbmethod TOKEN -rule CLIENT.UDP.RADIUS.USERNAME

Parameters for configuring virtual servers

name

A name for your new virtual server, or the name of the existing virtual server you want
to modify. The name can begin with a letter, number, or the underscore symbol, and can
consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#),
space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

protocol

RADIUS

IPAddress

The IP address assigned to your virtual server. This is normally an Internet-routable IP.

Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in
IPv6 format. (For example, 1000:0000:0000:0000:0005:0600:700a:888b.)

port

The port on which your virtual server listens for connections.

lbmethod

TOKEN

rule

Which policy rule to use as the basis for persistence. The two supported rules are:

- CLIENT.UDP.RADIUS.USERNAME. Use the client login name.

- CLIENT.UDP.RADIUS.ATTR_TYPE(INT). Use the specified RADIUS attribute type. For
  INT, substitute the integer assigned to that attribute type as specified in RFC4014.
To configure a load balancing or content switching virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing or Content Switching, and then click Virtual Servers.

   **Note:** Except for the GUI location where you create or configure the virtual server, the process is the same.

2. In the details pane, do one of the following:

   - To create a new virtual server, click Add.
   - To modify an existing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server (Load balancing) or Configure Virtual Server (Content Switching) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring virtual servers" as shown:

   - Name*—name
   - Protocol*—protocol
   - IP address*—IPAddress
   - Port*—port

   * A required parameter

4. In the Method and Persistence tab, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring virtual servers" as shown:

   - Method*—method
   - Rule*—rule

   * A required parameter

5. Click Close. The virtual server that you created now appears in the Virtual Servers pane.
Configuring Services

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created. For instructions, see Configuring Services. You should set the service parameters as described in “Parameters for configuring services.”

**Note:** Once configured, these services are in the DISABLED state until the NetScaler appliance can connect to your RADIUS server’s authentication and accounting IPs and monitor their status.

**Parameters for configuring services**

**name**

A name for your new service, or the name of the existing service you want to modify. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

**IPAddress**

The IP address used to connect to the RADIUS server for authentication or accounting, as appropriate, in either IPv4 or IPv6 format. When you provide the IP address of the service, the NetScaler appliance automatically creates a server object with this IP address as its name.

**serviceType**

The service type, always RADIUS when configuring RADIUS load balancing with persistence.

**port**

The port on which your service listens for connections.
After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see Binding Services to the Virtual Server.
Configuring a Persistency Group for Radius

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. For instructions, see Configuring Persistence Groups. You should set the parameters as described in “Parameters for configuring RADIUS load balancing persistency groups.”

Parameters for configuring RADIUS load balancing persistency groups

name

The name of the load balancing persistency group that you are setting or binding. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

vservername

The name of the load balancing virtual server that you are binding to the load balancing persistency group. The name can have the same length and characteristics as the name described above.

newname

The new name of the load balancing persistency group that you are renaming. The name can have the same length and characteristics as the name described above.

rule

Which policy rule to use as the basis for persistence. The two supported rules are:

- CLIENT.UDP.RADIUS.USERNAME. Use the client login name.
- CLIENT.UDP.RADIUS.ATTR_TYPE(INT). Use the specified RADIUS attribute type. For INT, substitute the integer assigned to that attribute type as specified in RFC4014

Your RADIUS load balancing configuration is now complete.
Viewing Persistence Sessions

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

**Note:** A NetScaler nCore appliance uses multiple CPU cores for packet handling. Every session on the appliance is owned by a CPU core. If the appliance receives a request for which a session does not already exist, a session is created, and one of the cores is designated as the owner of that session. Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current. However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session. Consequently, in the output of successively executed `show lb persistentSessions` commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session continues to be active.

**To view a persistence session by using the command line interface**

At the command prompt, to view all persistence sessions type:

```
show lb persistentSessions [ <vServer> ]
```

**Example**

```
show lb persistentSessions myVserver
```

**Parameters for viewing a persistence session**

- **vServer**

  Name of the virtual server on which the persistence sessions are running.

**To view persistence sessions by using the configuration utility**

1. In the navigation pane, click Load Balancing.
2. In the details pane, under Monitor Sessions, click Virtual Server persistence sessions.
Clearing Persistence Sessions

You might need to clear persistence sessions from the NetScaler if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

**Note:** The functionality for clearing a particular session that is associated with a given virtual server is available only on NetScaler 10.e.

**To clear a persistence session by using the command line interface**

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```plaintext
- clear lb persistentSessions [<vServer> [-persistenceParam <string>]]
- show persistentSessions <vServer>
```

**Examples**

Example 1 clears all persistence sessions for load balancing virtual server lbvip1. Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

**Example**

```plaintext
> clear persistentSessions lbvip1
Done
> show persistentSessions
Done
>
```

**Example 2**

```plaintext
> show persistentSessions lbvip1
Type | SRC-IP   ... | PERSISTENCE-PARAMETER
---- | ---------- |---------------------
RULE | 0.0.0.0   ... | xls
RULE | 0.0.0.0   ... | txt
RULE | 0.0.0.0   ... | html
Done
> clear persistentSessions lbvip1 -persistenceParam xls
Done
```
Parameters for clearing persistence sessions

vServer (Virtual Server)

The name of the load balancing virtual server whose persistence sessions are to be flushed. If not specified, all persistence sessions will be flushed. Maximum Length: 127.

persistenceParam (Persistence Parameter)

The persistence parameter whose sessions you want to flush. Maximum Length: 127.

To clear persistence sessions by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. In the details pane, under Monitor Sessions, click Clear persistence sessions.

3. In the Clear Persistence Sessions dialog box, do one of the following:
   
   · If you want to clear all sessions for all virtual servers on the appliance, in Virtual Server, select All Virtual Servers.

   · If you want to clear all sessions for a given virtual server, in Virtual Server, select the virtual server.

   · If you want to clear a particular session, in Virtual Server, select the virtual server, and then, in Persistence Parameter, select the persistence parameter whose session you want to clear.

4. Click OK.
Overriding Persistence Settings for Overloaded Services

Note: This feature is available only on NetScaler 10.e.

When a service is loaded or is otherwise unavailable, service to clients is degraded. To work around this situation, you might have to configure the NetScaler appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the skippersistency parameter. With the parameter set, when the virtual server receives new connections for an overloaded service, the virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests. Persistence sessions associated with other services are not affected. The functionality is available for only virtual servers whose type is \texttt{ANY} or \texttt{UDP}.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see Understanding Load Monitors.

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- \textbf{Send each request to one of the other services}. The virtual server takes a load balancing decision and sends each request to one of the other services on the basis of the configured load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

  Both wildcard and IP address-based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- \textbf{Bypass the virtual server-service configuration}. The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server on the basis of the destination IP address in the request.

  Only wildcard virtual servers of type \texttt{ANY} and \texttt{UDP} support the bypass option. Wildcard virtual servers have a \texttt{*::*} IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the NetScaler appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. If you configure the virtual server to bypass the virtual server-service configuration for overloaded services, if a Branch Repeater appliance or firewall gets overloaded, the virtual server bridges requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.
To override persistence settings for overloaded services by using the command line interface

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

- set lb vserver <name> -skippersistency <skippersistency>
- show lb vserver <name>

Example

> set lb vserver mylbvserver -skippersistency ReLb
Done
> show lb vserver mylbvserver
  mylbvserver (*:*) - ANY Type: ADDRESS
  ... ...
  Skip Persistency: ReLb
  ... ...
Done
>

Parameters for overriding persistence for overloaded services

name

The name of the load balancing virtual server.

skippersistency

Disregard the persistence settings that are configured for the virtual server when the virtual server receives new connections for a service that is overloaded or unavailable. Possible values: Bypass, ReLb, None. Default value: None.

If you set the parameter to ReLb, the virtual server sends requests to other services on the basis of the configured load balancing method until the overloaded service returns to a state at which it can accept requests. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances. If all the services are overloaded, requests are dropped until a service becomes available.

If you set the parameter to Bypass, the virtual server bypasses the virtual server-service configuration and bridges the requests through to the servers.
To override persistence settings for overloaded services by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click the virtual server that you want to override persistence settings when services are overloaded, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Skip Persistency list, select the option that you want.

4. Click OK.
Troubleshooting

The statistics from the NetScaler VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?

**Cause:** The NetScaler appliance has the system limit of 250,000 persistence session for a core.

**Resolution:** To resolve this issue, you can perform any of the following tasks:

- Reduce the time out value for persistence
- Increase the number of cores for the appliance

After configuring Cookie Insert persistence on the NetScaler appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?

**Cause:** By default, the time-out value for Cookie Insert persistence is 120 seconds.

**Resolution:** When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

After configuring an HTTP virtual server on the NetScaler appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?

**Resolution:** Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

After configuring Cookie Insert persistence on the NetScaler appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.

**Cause:** Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and NetScaler appliance are in different time zones, the cookie is not valid. For example, when a client in EST time zone sends a cookie at 11:00 AM EST to a NetScaler appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

**Resolution:** Set the time-out value for Cookie Insert persistence to 0.

A NetScaler appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made
from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?

**Cause:** The NetScaler appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

**Resolution:** To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

The NetScaler appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the “State Error” error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.

**Cause:** Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

**Resolution:** Citrix recommends that you specify the Cookie Insert persistence method on the NetScaler appliance when load balancing Web Interface servers.
Configuring Diameter Load Balancing

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a NetScaler deployment:

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices situated at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The NetScaler appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.

- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 3588 bis. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The NetScaler uses message based load balancing.

**Example**

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.
How Diameter Load Balancing Works

A Diameter client opens a connection to the NetScaler appliance and sends a Diameter capability exchange (CER) message. Diameter messages are composed of command codes and each command has a set of Attribute-Value Pairs (AVPs), such as Origin-Host and Host-IP-Address.

The NetScaler selects a Diameter server, opens a connection to the server, and forwards the CER message to the server. The server reads the client identity and determines that it is directly connected to the client.

The Diameter server prepares the Diameter handshake reply and sends it to the NetScaler appliance. The appliance modifies the handshake and inserts its own identity. At this point, the Diameter client determines that it is directly connected to the NetScaler (the agent).

Note: Until the Diameter handshake is complete, all Diameter request messages from the client are queued on the selected server. The packets are forwarded to the server when the handshake is complete.

Load Balancing Diameter Traffic

When a client sends a request to the NetScaler appliance, the appliance parses the request and contextually load balances it to a Diameter server on the basis of a persist AVP. The NetScaler has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the NetScaler maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.

- NetScaler adds a route entry by putting its identity, because the client sees the NetScaler as a relay agent.

Note: If a Diameter message spans more than one packet, the NetScaler accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the NetScaler splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

Disconnecting a Session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the NetScaler receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the
NetScaler ignores them. The client sends a FIN, which the NetScaler broadcasts to all servers.

- When the NetScaler receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the NetScaler replies with FIN/ACK and removes connections from the reuse pool.

- If the NetScaler receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.

- If the NetScaler receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.
Configuring Load Balancing for Diameter Traffic

To configure the NetScaler appliance to load balance Diameter traffic, you must first set the Diameter parameters on the appliance, then add the Diameter monitor, add the Diameter services, bind the services to the monitor, add the Diameter load balancing virtual server, and bind the services to the virtual server.
To configure load balancing for Diameter traffic by using the command line interface

1. Configure the Diameter parameters.

   set ns diameter -identity <string> -realm <string> -serverClosePropagation <YES|NO>

   Example

   set ns diameter -identity mydomain.org -realm org -serverClosePropagation YES

2. Add a Diameter monitor.

   add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm <string>

   Example

   add lb monitor diameter_mon DIAMETER -originHost mydomain.org -originRealm org

3. Create the Diameter services.

   add service <name>@<IP>@DIAMETER <port>

   Example

   add service diameter_svc0 10.102.82.86 DIAMETER 3868
   add service diameter_svc1 10.102.82.87 DIAMETER 3868
   add service diameter_svc2 10.102.82.88 DIAMETER 3868
   add service diameter_svc3 10.102.82.89 DIAMETER 3868

4. Bind the Diameter services to the Diameter monitor.

   bind service <name>@monitorName <monitorName>

   Example

   bind service diameter_svc0 -monitorName diameter_mon
   bind service diameter_svc1 -monitorName diameter_mon
   bind service diameter_svc2 -monitorName diameter_mon
   bind service diameter_svc3 -monitorName diameter_mon

5. Add a Diameter load balancing virtual server with Diameter persistence.

   add lb vserver <name>@DIAMETER <IPAddress> <port> -persistenceType DIAMETER
   -persistAVPno <positive_integer>

   Example

   add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -persistenceType DIAMETER -persistAVPno 263

6. Bind the Diameter services to the Diameter load balancing virtual server.

   bind lb vserver <name>@<serviceName>
Example

bind lb vserver diameter_vs diameter_svc0
bind lb vserver diameter_vs diameter_svc1
bind lb vserver diameter_vs diameter_svc2
bind lb vserver diameter_vs diameter_svc3

7. Save the configuration.

    save ns config

Note: You can also configure load balancing of Diameter traffic over SSL by using the SSL_DIAMETER service type.
To configure load balancing for Diameter traffic by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, click Change Diameter Parameters.

3. In the Configure Diameter Parameters dialog box, specify values for the following parameters.
   - Host Identity
   - Realm
   - Server Close Propagation
4. Click OK to configure the Diameter parameters.

5. In the navigation pane, expand Load Balancing, and then click Monitors.

6. In the details pane, click Add.

7. In the Create Monitor dialog box, create a monitor with Type as Diameter.

8. On the Special Parameters tab, enter values for Origin Host and Origin Realm.

9. In the navigation pane, expand Load Balancing, and then click Services.

10. In the details pane, click Add.

11. In the Create Service dialog box, create a service with Protocol as Diameter and bind the created Diameter monitor to this service.

12. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

13. In the details pane, click Add.

14. In the Create Virtual Server (Load Balancing) dialog box, create a load balancing virtual server with Protocol as DIAMETER and bind the created Diameter services to this virtual server.

15. On the Method and Persistence tab, select the Persistence as DIAMETER and specify a AVP Number.
Customizing the Hash Algorithm for Persistence across Virtual Servers

The NetScaler appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the NetScaler command line to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

To change the use-port-number global setting by using the command line interface

At the command prompt, type:

```
set lb parameter -usePortForHashLb (YES | NO)
```

Example

```
> set lb parameter -usePortForHashLb NO
Done
> show lb parameter
Global LB parameters:
```
To change the use-port-number global setting by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. In the Settings group, click Configure Load Balancing Parameters.

3. To not use the port number to generate the hash value, clear the Use Port for Hash Based LB Methods check box.

4. Click OK.

5. Open the Configure Load Balancing Parameters dialog box and verify the setting you just configured.

To create a new service and specify a hash identifier for a service by using the command line interface

At the command prompt, type the following commands to set the hash ID and verify the setting:

```
add service < name > (< ip > |< serverName >) < serviceType > < port > -hashId < positive_integer >
```

```
show service <name>
```

Example

```
> add service flbkng 10.101.10.1 http 80 -hashId 12345
Done
>show service flbkng
flbkng (10.101.10.1:80) - HTTP
State: DOWN
Last state change was at Thu Nov 4 10:14:52 2010
Time since last state change: 0 days, 00:00:15.990
Server Name: 10.101.10.1
Server ID: 0   Monitor Threshold : 0

Down state flush: ENABLED
Hash Id: 12345

1)   Monitor Name: tcp-default
    State: DOWN   Weight: 1
```
To specify a hash identifier for an existing service by using the command line interface

Type the set service command, the name of the service, and \texttt{-hashID} followed by the ID value.

To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

\texttt{bind servicegroup <serviceGroupName> <memberName> <port> -hashId <positive_integer>}

\texttt{show servicegroup <serviceGroupName>}

Example

\texttt{bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222}

\texttt{>show servicegroup SRV}

\texttt{SRV - HTTP}

\texttt{State: ENABLED  Monitor Threshold : 0}

\texttt{...}

\texttt{1) 1.1.1.1:80 State: DOWN  Server Name: 1.1.1.1  Server ID: 123  Weight: 1}

\texttt{Hash Id: 32211}

\texttt{Monitor Name: tcp-default  State: DOWN}

\texttt{...}

\texttt{2) 2.2.2.2:80 State: DOWN  Server Name: 2.2.2.2  Server ID: 123  Weight: 1}

\texttt{Hash Id: 12345}

\texttt{Monitor Name: tcp-default  State: DOWN}

\texttt{...}

Done
Parameters for configuring a service

name

Name of the service. This alphanumeric string is required. The name must not exceed 127 characters, and the leading character must be a number or a letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

ip

IP address of the server that is associated with the service, in either IPv4 or IPv6 format.

servername

Name of the server that is associated with the service. The name must not exceed 127 characters, and the leading character must be a number or a letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

serviceType

Protocol supported by the service. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RDP, RADIUS.

port

The port number used for the service.

hashId

The hash identifier for the service. Must be unique for each service. Minimum value: 1, Maximum value: 4294967295.
To specify a hash identifier for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and click Services.

2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service and then click Open.

3. In the Create Service or Configure Service dialog box, specify values for the following parameters, which correspond to the parameters described in "Parameters for adding a service," as shown:
   - ServiceName*: name
   - Server*: ip or serverName
   - Protocol*: serviceType
   - Port*: port

4. Click the Advanced tab and then scroll down in the dialog box.

5. In the Hash ID box, type a unique hash ID value.

6. Click Create.

7. Open the service and verify the settings you just configured.

To specify a hash identifier for an already configured service group member by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. Select a service group, and then click Open.

3. On the Members tab, under Configured Members, in the row of the member for which you want to specify a hash ID value, double-click the space in the Hash ID column.

4. Type a unique hash ID value.

5. Click OK.

6. Open the service group and verify the hash IDs of the service group members you just configured.
Configuring the Redirection Mode

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The NetScaler appliance supports the following redirection modes:

- IP-Based forwarding (the default)
- MAC-Based forwarding

You can configure MAC-Based forwarding on networks that use direct server return (DSR) topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding, see Networking.

To configure the redirection mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

Example

```
set lb vserver Vserver-LB-1 -m MAC
```

Parameter for configuring the redirection mode

m

The load balancing redirection mode. Possible Values: IP, MAC. Default: IP.

If set to IP, the destination IP address of the request is changed to the IP address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server.

If set to MAC, the destination MAC address is changed to the MAC address of the server to which you are redirecting traffic, and the traffic is then forwarded to that server. With this setting, the destination IP address of the traffic is not changed.
To configure the redirection mode by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the redirection mode, and then click Open.

3. On the Advanced tab, under Redirection Mode, click either IP-Based or MAC-Based.

4. Click OK.
Configuring per-VLAN Wildcarded Virtual Servers

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
show vserver
```

Example

```
add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
show vserver Vserver-LB-vlan1
```

Parameters for configuring per-VLAN wildcarded virtual servers

- **name**
  
  Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

- **IPAddress**
  
  IP address of the virtual server. For wildcarded virtual servers bound to VLANs, this is always *

- **serviceType**
  
  Behavior of the service. Select one of the following service types: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDP.
port

Port on which the virtual server listens for client connections. The port number must be in the range 0-65535. For wildcarded virtual servers bound to VLANS, the setting is normally *.

listenpolicy

Use this parameter to specify the listen policy for LB Vserver. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1500 characters.

listenpriority

The priority assigned to the listen policy. This can be any positive integer. Priority is evaluated in reverse order; the lower the number, the higher the priority assigned to the listen policy.

rule

The policy rule to use to identify the VLAN that you want this virtual server to listen to. This rule is:

- CLIENT.VLAN.ID.EQ(<integer>)
- For <integer>, substitute the ID number assigned to the VLAN.
To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, do one of the following:
   
   - To create a new virtual server, click Add.
   
   - To modify an existing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Services tab, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring per-VLAN wildcarded virtual servers” as shown:
   
   - Name*—name
   - Protocol*—serviceType
   - IP address*—IPAddress
   - Port—port
   
   *A required parameter

4. In the Advanced tab, expand Listen Policy, and then specify values for the following parameters, which correspond to parameters described in “Parameters for configuring per-VLAN wildcarded virtual servers” as shown:
   
   - Listen Priority*—listenpriority
   - Listen Policy Rule*—rule
   
   *A required parameter

5. Click Create or OK, depending on whether you are creating a new virtual server or modifying an existing virtual server.

6. Click Close. The virtual server that you created now appears in the Virtual Servers page.

7. To remove a virtual server, in the Virtual Servers pane select the virtual server, and then click Remove.

After you have created this virtual server, you bind it to one or more services as described in Setting Up Basic Load Balancing.
Assigning Weights to Services

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the NetScaler appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

**Note:** If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

<table>
<thead>
<tr>
<th>Load Balancing Methods</th>
<th>Service Selection with Weights</th>
</tr>
</thead>
<tbody>
<tr>
<td>Round Robin</td>
<td>The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see The Round Robin Method.</td>
</tr>
<tr>
<td>Least Connection</td>
<td>The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see The Least Connection Method.</td>
</tr>
<tr>
<td>Least Response Time and Least Response Time Method using Monitors</td>
<td>The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see The Least Response Time Method.</td>
</tr>
<tr>
<td>Least Bandwidth</td>
<td>The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see The Least Bandwidth Method.</td>
</tr>
<tr>
<td>Least Packets</td>
<td>The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see The Least Packets Method.</td>
</tr>
<tr>
<td>Custom Load</td>
<td>The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see The Custom Load Method.</td>
</tr>
</tbody>
</table>
Assigning Weights to Services

| Hashing methods and Token method | Weighting is not supported by these load balancing methods. |

**To configure a virtual server to assign weights to services by using the command line interface**

At the command prompt, type:

```
set lb vserver <name> @ -weight <Value> <ServiceName>
```

**Example**

```
set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
```

**Parameter for setting weights**

**weight**

Weight to be assigned to the specified service. The minimum value is 1 and the maximum value is 100.

**To configure a virtual server to assign weights to services by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server, and then click Open.

3. On the Services tab, in the Weights spin box, type or select the weight to assign to the service (for example, 10).

4. Click OK.
Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a load balancing virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

- set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>
- show lb vserver <name>

Example

> set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
  Done
> show lb vserver myMSSQLvip
  myMSSQLvip (190.0.2.12:1433) - MSSQL  Type: ADDRESS
  . . .
  . . .
  MSsql Server Version: 2008R2
  . . .
  . . .
  Done
>

Parameters for configuring the MS SQL Server version setting

- name
  The name of the virtual server for which you want to configure the MS SQL Server version setting.
- mssqlServerVersion
The version of MS SQL Server that you are using. Following are the possible values:

- 70, for Microsoft SQL Server 7.0
- 2000, for Microsoft SQL Server 2000
- 2000SP1, for Microsoft SQL Server 2000 Service Pack 1 (SP1)
- 2005, for Microsoft SQL Server 2005
- 2008, for Microsoft SQL Server 2008
- 2008R2, for Microsoft SQL Server 2008 R2

To set the Microsoft SQL Server version parameter by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the setting, and then click Open.

3. In the Configure Virtual Server dialog box, do the following:
   a. In the advanced tab, click MsSql.
   b. In the Server Version list, select the version of your Microsoft SQL Server product.
   c. Click Create or OK, and then click Close.
Protecting the Load Balancing Configuration against Failure

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring the NetScaler appliance to redirect excess traffic to an alternate URL, configuring a backup load balancing virtual server, and configuring stateful connection failover.
Redirecting Client Requests to an Alternate URL

In the event that a load balancing virtual server of type HTTP or type HTTPS goes DOWN or is disabled, you can redirect requests to an alternate URL by using an HTTP 302 redirect. The alternate URL can provide information about the status of the server.

You can redirect to a page on the local server or a remote server. You can redirect to a relative URL or an absolute URL. If you configure a redirect to a relative URL consisting of a domain name with no path, the NetScaler appliance appends the path of the incoming URL to the domain. If you use an absolute URL, the HTTP redirect is sent to that URL with no modification.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

To configure a virtual server to redirect the client request to a URL by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -redirectURL <URLValue>
```

**Example**

```
set lb vserver Vserver-LB-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

**Parameters for Redirecting Client Requests to an Alternative URL**

**redirectURL**

URL to which traffic is redirected when the load balancing virtual server is unavailable. This URL length must not exceed 127 characters.

**Note:** The domain specified in the URL must not match the domain specified in the domain name argument of a content switching policy. If the same domain is specified in both arguments, the request is redirected continuously to the same unavailable load balancing virtual server.
To configure a virtual server to redirect the client request to a URL by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure redirect URL, and then click Open.

4. Click OK.
Configuring a Backup Load Balancing Virtual Server

You can configure the NetScaler appliance to direct requests to a backup virtual server in the event that the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you may want to configure the backup virtual server to remain in control in the event that it takes over. For example, you may want to sync updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control in the event that the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback for when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

**Note:** If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

**To set a backup virtual server by using the command line interface**

At the command prompt, type:

```
set lb vserver <vServerName> -backupVserver <BackupVServerName> [-disablePrimaryOnDown]
```

**Example**

```
set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -disablePrimaryOnDown
```
Parameters for configuring a backup load balancing virtual server

backupVserver

Name of the backup virtual server. You can create a virtual server and specify the name, IP address, port, and type as described in “Creating a Virtual Server,” on page 38. You can use the name of the virtual server as a backup virtual server.

disablePrimaryOnDown

Configures the backup virtual server to remain in control, after it takes over, until you manually reenable the primary virtual server.

To set a backup virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the backup virtual server, and then click Open.

3. On the Advanced tab, in the Backup Virtual Server list, select the backup virtual server.

4. If you want the backup virtual server to remain in control until you manually re-enable the primary virtual server even if the primary virtual server comes back up, select the Disable Primary When Down check box.

5. Click OK.
Diverting Excess Traffic to a Backup Virtual Server

In addition to taking over for a primary virtual server when it becomes unavailable, a backup load balancing virtual server can handle excess traffic when the primary virtual server reaches its limit. To set this up, you configure the spillover option to divert new connections to the backup virtual server when the number of connections to the primary virtual server exceeds the threshold. You can allow the NetScaler appliance to calculate the threshold dynamically, or you can configure the value manually.

When spillover is configured, the appliance compares the number of established TCP connections on the primary virtual server with the threshold value. When the number of connections reaches the threshold, it diverts new connections to the backup virtual server.

You can configure persistence with spillover. When persistence is configured, connections that are diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections on it drops below the threshold. Instead, the primary virtual server accepts new client connections.

If the backup virtual server reaches its own threshold and is unable to accept additional connections, the appliance diverts all requests to the redirect URL. If a redirect URL is not configured on the primary virtual server, any requests over the threshold are dropped.

Note: With RTSP virtual servers, the appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

To configure a primary virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:

`set lb vserver <vServerName> -soMethod <spillOverType> -soThreshold <positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <positiveInteger>`

Example

`set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout`
Parameters diverting excess traffic to a backup virtual server

soMethod

The spillover method to use for diverting traffic to the backup virtual server when the primary virtual server reaches the spillover threshold. Available settings function as follows:

- CONNECTION. Spillover occurs when the number of client connections at the virtual server exceeds the static threshold value (the value of the Threshold parameter).

- DYNAMICCONNECTION. Spillover occurs when the number of client connections at the virtual server exceeds a dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are up. Do not specify a spillover threshold for this setting, because the threshold is implied by the Max Clients settings of bound services.

- BANDWIDTH. Spillover occurs when the bandwidth consumed by the virtual server's incoming and outgoing traffic exceeds the static threshold value.

- HEALTH. Spillover occurs when the percentage of weights of the services that are UP drops below the static threshold value. For example, if services svc1, svc2, and svc3 are bound to a virtual server, with weights 1, 2, and 3, and the spillover threshold is 50%, spillover occurs if svc1 and svc3 or svc2 and svc3 transition to DOWN.

- NONE. Spillover does not occur.

soThreshold

Threshold at which spillover occurs. Specify an integer for the CONNECTION spillover method, a bandwidth value in kilobits per second for the BANDWIDTH method (do not enter the units), or a percentage for the HEALTH method (do not enter the percentage symbol).

soPersistence

If spillover occurs, maintain source IP address based persistence for both primary and backup virtual servers. Possible values: ENABLED, DISABLED. Default: DISABLED.

soPersistenceTimeout

To set a primary virtual server to divert new connections to a backup virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure the spillover, and then click Open.

3. On the Advanced tab, in the Method list, select the type of threshold, and in Threshold text box, type the threshold value.

4. Under Spillover, select the Persistence check box, and in Persistence Time-out (min) text box type the time-out.

5. Click OK.
Configuring Connection-Based Spillover

You can use connection-based spillover to configure a maximum threshold for the number of active client connections on a virtual server. When the client connections exceed the configured threshold limit, new client connections are diverted to the backup virtual server.

To configure connection-based spillover, see Diverting Excess Traffic to a Backup Virtual Server.

**Note:** Global Server Load Balancing (GSLB) virtual servers do not support connection-based spillover.
Configuring Dynamic Spillover

When you configure dynamic spillover, if the number of client connections to the primary load balancing virtual server exceeds the sum of the maximum client values, new connections are diverted to the backup virtual server.

To configure dynamic spillover, you must first enable it on the primary virtual server. Next, you configure each service that is bound to that virtual server with appropriate maximum client values for that service. Different services can have different maximum client values. If the value for maximum client is set to 0, the spillover limit is treated as infinity, and spillover never occurs.

**Note:** Content-based virtual servers do not support dynamic spillover.

To configure dynamic spillover, see [Diverting Excess Traffic to a Backup Virtual Server](#).
Configuring Bandwidth-Based Spillover

With bandwidth-based spillover, when the bandwidth used by the primary load balancing virtual server exceeds the specified bandwidth threshold value, the NetScaler appliance diverts new connections to the backup virtual server. You can also configure the backup virtual server with a threshold value. When the threshold for the backup virtual server is reached, the appliance diverts new client connections to the next backup virtual server.

To configure bandwidth-based spillover, see Diverting Excess Traffic to a Backup Virtual Server.
Connection Failover

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a NetScaler High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary NetScaler appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same physical server. The new primary appliance synchronizes the information with the new secondary appliance by using the SSF framework. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

**How Connection Failover Works on NetScaler Appliances**

In stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server may experience a brief disruption and retransmissions.

**Note:**

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify correct configuration of the passwords, use the show rpcnode command from command line or use the RPC option of the Network menu from the configuration utility.

A basic HA configuration with connection failover contains the entities shown in the following figure.
Supported Setup

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content-switching virtual servers.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

<table>
<thead>
<tr>
<th>Setting</th>
<th>Stateless</th>
<th>Stateful</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service type</td>
<td>ANY.</td>
<td>ANY, UDP, TCP, FTP, SSL_BRIDGE.</td>
</tr>
<tr>

Features Affected by Connection Failover

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects NetScaler Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Impact of Connection Failover</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYN protection</td>
<td>For any connection, if a failover occurs after the NetScaler issues SYN-ACK but before it receives the final ACK, the connection is not supported by connection failover. The client must reissue the request to establish the connection.</td>
</tr>
<tr>
<td>Surge protection</td>
<td>If the failover occurs before a connection with the server is established, the new primary NetScaler tries to establish the connection with the server. It also retransmits all the packets held in the course of surge protection.</td>
</tr>
<tr>
<td>Access down</td>
<td>If enabled, the access-down functionality takes precedence over connection failover.</td>
</tr>
<tr>
<td>Application Firewall™</td>
<td>The Application Firewall feature is not supported.</td>
</tr>
<tr>
<td>INC</td>
<td>Independent network configuration is not supported in the high availability (HA) mode.</td>
</tr>
<tr>
<td>TCP buffering</td>
<td>TCP buffering is not compatible with connection mirroring.</td>
</tr>
<tr>
<td>Close on response</td>
<td>After failover, the NATPCBs may not be closed on response.</td>
</tr>
<tr>
<td>IPv6 virtual servers</td>
<td>Not yet supported.</td>

</table>
Configuring Connection Failover

You can configure connection failover on a load balancing virtual server.

To configure connection failover by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -connFailover <Value>

Example

set lb vserver Vserver-LB-1 -connFailover stateful

Parameters for configuring connection failover

cconnFailover

State of connection failover on the virtual server. Valid values: STATELESS, STATEFUL, DISABLE. Default: DISABLE.

To configure connection failover by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, select the virtual server for which you want to configure connection failover, and click Open.

3. On the Advanced tab, in the Connection Failover drop-down list, select Stateful.

4. Click OK.
Disabling Connection Failover

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

To disable a connection failover by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -connFailover <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -connFailover disable
```

To disable a connection failover by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, select the virtual server for which you want to configure a connection failover and click Open.

3. On the Advanced tab, in the Connection Failover drop-down list box, select Disable.

4. Click OK.
Flush the Surge Queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

**Note:** You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

**Note:** Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:
You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.

If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.

If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.

You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.

If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.

If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-servername <servername> <port>]
```

**Examples**

1.
flush ns surgeQ -name SVC1ANZGB -servername 10.10.10.1 80
The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address 10.10.10.1 and port 80.

2.
flush ns surgeQ
The above command flushes all the surge queues on the appliance.

**Parameters for flushing a surge queue**

- **name**
  - Name of a virtual server, service or service group

- **servername**
  - Name of a service group member
To flush a surge queue by using the configuration utility

1. In the navigation pane, expand Load Balancing.

2. To select an entity, do one of the following:
   
   · To flush the surge queue of a virtual server, click Virtual Servers, and then select the virtual server.
   
   · To flush the surge queue of a service, click Services, and then select the service.
   
   · To flush the surge queue of all the members in a service group, click Service Groups, and then select the service group.
   
   · To flush the surge queue of a specific member in a service group, click Service Groups, and in the action pane, click Manage Members. In the Manage Members of a Service Group dialog box, select the service group member.

   **Note:** You can select multiple entities in any window.

   **Note:** To flush the surge queue of a content switching virtual server, in Steps 1 and 2, expand Content Switching, and then select a virtual server.

3. In the action pane, click Flush Surge Queue.

4. Click OK.

   **Note:** On the appliance, if there are other entities with the same name as you selected, you are alerted that the surge queues of those entities would also be flushed. Take an appropriate action.
Managing a Load Balancing Setup

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new NetScaler appliances, which must be configured and added to the existing setup. Old servers wear out and need to be replaced, requiring removal of some servers and addition of others. Upgrades to your networking equipment or changes to topology may also require modifications to your load balancing setup. Therefore, you will need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of a number of other features that facilitate management of the traffic through your load balancing setup.
Managing Server Objects

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not already exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the NetScaler appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

To enable a server by using the command line interface

At the command prompt, type:

```
enable server <name>@
```

Example

```
enable server 10.102.29.5
```

To disable a server object by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Servers.
2. In the details pane, select the server that you want to enable, and then click Enable.
3. In the Enable dialog box, click Yes.

To disable a server object by using the command line interface

At the command prompt, type:

```
disable server <name>@ <delay>
```
Managing Server Objects

Example

disable server 10.102.29.5 30

Wait time parameter

delay

The time, in seconds, after which the server object is marked DOWN.

To disable a server object by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Servers.
2. In the details pane, select the server that you want to disable, and then click Disable.
3. In the Wait Time dialog box, type the wait time after which the server is to be disabled (for example 30).
4. Click Enter.

To remove a server object by using the command line interface

At the command prompt, type:

rm server <name>@

Example

rm server 10.102.29.5

To remove a server object by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Servers.
2. In the details pane, select the server that you want to remove, and then click Remove.
3. In the Remove dialog box, click Yes.
Managing Services

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service’s state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the NetScaler configuration.

To enable a service by using the command line interface

At the command prompt, type:

enable service <name>

Example

enable service Service-HTTP-1

To enable a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service that you want to enable (for example, Service-HTTP-1), and click Enable.

3. In the Enable dialog box, click Yes.

To disable a service by using the command line interface

At the command prompt, type:

disable service <name>@<DelayInSeconds>

Example

disable service Service-HTTP-1 30
Wait Time Parameter

`delay`

The time, in seconds, after which the service is marked DOWN.

To disable a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service that you want to disable (for example, Service-HTTP-1), and then click Disable.

3. In the Wait Time dialog box, type the wait time after which the service is to be disabled (for example, 30).

4. Click Enter.

To remove a service by using the command line interface

At the command prompt, type:

```
rm service <name>@
```

Example

```
rm service Service-HTTP-1
```

To remove a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service that you want to remove (for example, Service-HTTP-1), and then click Remove.

3. In the Remove dialog box, click Yes.
Managing a Load Balancing Virtual Server

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual server’s state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the downStateFLush parameter. If downStateFLush is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

To enable a virtual server by using the command line interface

At the command prompt, type:

```
enable lb vserver <name>@
```

Example

```
enable lb vserver Vserver-LB-1
```

To enable a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server that you want to enable, and click Enable.
3. In the Enable dialog box, click Yes.

To disable a virtual server by using the command line interface

At the command prompt, type:
To disable a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to disable, and then click Disable.

3. In the Disable dialog box, click Yes.

Note: In the disabled state, a virtual server continues to exist on the network. The NetScaler appliance continues to respond to address resolution protocol (ARP) and Internet control message protocol (ICMP) requests directed to the IP address of the virtual server.

To unbind a service from a virtual server by using the command line interface

At the command prompt, type:

```
unbind lb vserver <name>@<serviceName>
```

Example

```
unbind lb vserver Vserver-LB-1 Service-HTTP-1
```
To unbind a service from a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server from which you want to unbind a service, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, in the Services tab, clear the Active check box next to the service that you want to unbind from the virtual server.

4. Click OK.

To remove a virtual server by using the command line interface

At the command prompt, type:

`rm lb vserver <name>@`

**Example**

```
rm lb vserver Vserver-LB-1
```

To remove a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to remove, and then click Remove.

3. In the Remove dialog box, click Yes.
The Load Balancing Visualizer

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in graphical format. Following is an example of the Visualizer display:

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.
- Load balancing virtual server statistics.
- Statistical information such as the number of requests received per second by the virtual server and the number of hits per second for rewrite, responder, and cache.
policies.

- A comparative list of all the parameters whose values either differ or are not defined across service containers.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is a set of similar services and service groups that are bound to a single load balancing virtual server. Next to the service container is a number that shows the number of services in the group. The services in the container have the same properties, with the exception of the name, IP address, and port, and their monitor bindings should have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services; otherwise, it is placed in its own container.

The service container display can help you troubleshoot your configuration if something is not functioning as you expect. More than one container for a particular virtual server is an indication that something is wrong with the configuration of that virtual server and its services. To correct the problem, you must first identify the container that has the desired configuration. You can do so by using the Service Attributes Diff feature, described below. After you identify the container, you right-click the container and click Apply Configuration.

The following procedures provide only basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all of the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

**Note:** The Visualizer requires a graphic interface, so it is available only through the configuration utility.
To view load balancing virtual server properties by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, you can adjust the viewable area as follows:

   · Click the Zoom In and Zoom Out icons to increase or decrease the size of the viewed objects. You can click and drag the viewable area if an item that you want to see disappears from view after zooming in.

   · Click the Best Fit icon to optimize the viewing area.

   · Click the Save Image icon to save the graph as an image file.

   · Click the image, hold down the mouse button, and drag the image to pan the view.

   · In the Search in text field, begin typing the name of the item you are looking for. The item’s location is then highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for
To view configuration details for services, service groups, and monitors by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:

   · To view a summary of bound services, position the cursor over the virtual server icon.

   · To view services in a service container, click the icon for a service group, click the Related Tasks tab, click Show Member Services, and then click the service group name. To view additional details about the services click Open.

   · To view common properties of services in a service group, click the icon for the service group, click the Related Tasks tab, and view the Details section of the tab.

   · To view a comparative list of the parameters whose values either differ or are not defined across service containers, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details.

   · To view the details for a monitor, position the cursor over the icon or click the icon for the monitor. For additional details, click the icon, click the Related Tasks tab, and then click View Monitor.

   · To view binding details of a monitor, click the connecting line between the monitor and its related service.
To view configuration details for policies and policy labels by using the Visualizer in the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, to view configuration details for entities that are bound to this virtual server, you can do the following:

   - To view policies that are bound to this virtual server, select one or more policy icons in the tool bar at the top of the dialog box. For example, you can select Compression, Filter, Rewrite, and Responder. If policy labels are configured, they appear in the main view area.

   - For bound policies that appear in the view pane of the Visualizer, to view a policy’s expression and actions, position the cursor over the policy icon. To view binding details, position the cursor over the line that connects the policy to the virtual server. To view these details, click the policy. The details of the policy appear in the details pane.

To view statistical information by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, to view statistical information, you can do the following:

   - To view detailed statistics for the load balancing virtual server, click the icon for the virtual server, click the Related Tasks tab, and then click Statistics.

   - To view the number of requests received per second at a given point in time by the load balancing virtual server and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time and has to be refreshed manually. To refresh this information, click Refresh Stats.

   **Note:** The Show Stats option is available only on NetScaler nCore builds.
To save configuration properties for any entity by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to view, and then click Visualizer.

3. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks.

4. In the Related Tasks tab, click Copy Properties and then paste the information into a document.

To bind a resource to a load balancing configuration by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure bindings, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, click the Available Resources tab, select a resource type in the drop-down menu, and do one or more of the following:

   · To bind a new monitor to a service, select Monitors, click a particular monitor, and then drag it to the service container icon. Use CONTROL + click to select multiple monitors and drag them to the service.

   · To bind a service or service group, select Services or Service Groups, respectively, click a particular service or service group, and then drag it to the virtual server icon. To bind multiple services or service groups at one time, press CONTROL + click to select multiple services and drag them over the virtual server.

   · To bind a policy, select one of the policy groups, click a particular policy, and then drag it to a virtual server. To bind multiple policies (classic policies only) at one time, press CONTROL + policies and drag them over the virtual server. For details on classic and advanced policies, see Policy Configuration and Reference.
To unbind a resource by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Server.

2. In the details pane, select the virtual server from which you want to unbind a service, policy, or monitor, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, on the Visualizer image, click the connecting line between the resources that you want to unbind, and then click Unbind. For example, to unbind a monitor, you would click the link between the monitor and its bound service and click Unbind.

4. In the Unbind dialog box, click Yes.

To modify a resource in a load balancing configuration by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.
   
   **Note:** Alternatively, on the Available Resources tab, select the resource type from the drop-down menu, select the particular resource that you want to configure and then click Open.

4. In the modify dialog box, enter new settings for the resource.

To add, remove, or disable a resource in a load balancing configuration by using the Visualizer

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.

3. In the Load Balancing Visualizer dialog box, right-click the icon for the resource that you want to add, remove, or disable, and then select the corresponding option from the menu.
   
   **Note:** Alternatively, on the Available Resources tab, click the resource type from the drop-down menu, and then click Add to add an entity, or select the particular resource that you want to configure and then click Open.

   **Note:** These options are not available for service groups or policies.
Managing Client Traffic

Managing client connections properly helps to ensure that your applications remain available to users even when your NetScaler appliance is experiencing high loads. A number of load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).

- **Integrated caching.** You can redirect HTTP requests to a cache.

- **Priority queuing.** You can direct requests based on priority, by integrating your configuration with the Priority Queuing feature.

- **SureConnect.** You can use load balancing with the SureConnect feature to redirect important requests to a custom Web page, insulating them from delays due to network congestion.

- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the NetScaler appliance is experiencing high loads.

- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.

- **RTSP NAT.**

- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.

- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.

- **ICMP Response.** You can configure the NetScaler to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, NetScaler always responds.

- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, NetScaler responds even if one virtual server is UP.

- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler responds even if one virtual server set to ACTIVE is UP.
Configuring Sessionless Load Balancing
Virtual Servers

When the NetScaler appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the NetScaler resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

Supported Setup

NetScaler sessionless load balancing supports the following service types and load balancing methods:

Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
Limitations

Sessionless load balancing has the following limitations:

- The NetScaler must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address will not be changed.

Note: While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.

Note: To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the NetScaler.

To add a sessionless virtual server by using the command line interface

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

- add lb vserver <name>@<serviceType> <IPAddress>@<port> -m <redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <load_balancing_method>
- show lb vserver <name>

Example

add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -lbMethod roundrobin -m ip
Done
show lb vserver sesslessv1
  sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
  State: DOWN
To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
set lb vserver <name> @ -m <redirectionMode> -sessionless <(ENABLED | DISABLED)> -lbMethod <load_balancing_method>
```

**Example**

```
set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
Done
```

**Parameters for configuring sessionless load balancing virtual servers**

- **vServerName**
  - The name of the virtual server that you are configuring.

- **m**
  - The redirection mode that you want to use. MAC, IP.

- **sessionless**
  - Perform load balancing on a per-packet basis, without establishing sessions. Possible values: ENABLED and DISABLED. Default: DISABLED.

- **lbMethod**
  - The load balancing method. See Supported Setup.
To configure a sessionless virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, do one of the following:
   - To add a sessionless virtual server, click Add.
   - To specify sessionless load balancing for an existing virtual server, select it, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for Configuring Sessionless Load Balancing Virtual Servers" as shown:
   - Service Name*-serviceName
   - Protocol*-serviceType
   - Server*-serverName
   - Port*-port
   *A required parameter

4. In the Configure Virtual Server (Load Balancing) dialog box, on the Methods and Persistence tab, in the LB Method group, select a supported load balancing method.

5. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, under Redirection Mode, select MAC Based or IP Based.

6. Select Sessionless.

7. Click Create or click OK.

8. In the details pane, click the arrow next to the name of the virtual server and verify the configuration.
Redirecting HTTP Requests to a Cache

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```bash
set lb vserver <name>@ -cacheable <Value>
```

Example

```bash
set lb vserver Vserver-LB-1 -cacheable yes
```

Parameters for configuring cache redirection

**vServerName**

The name of the virtual server that you are configuring.

**cacheable**

Virtual server requests to be routed to the cache redirection virtual server before sending them to the configured servers. Possible values: YES and NO. Default: NO.

To configure cache redirection on a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure cache redirection, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the Cache Redirection check box, and then click OK.
Redirecting HTTP Requests to a Cache
Directing Requests According to Priority

The NetScaler appliance supports prioritization of client requests with its priority queuing feature. This feature allows you to designate certain requests, such as those from important clients, as priority requests and sends them to the “front of the line,” so that the appliance responds to them first. This allows you to provide uninterrupted service to those clients through demand surges or DDoS attacks on your Web site.

To configure priority queuing on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -pq <Value>
```

Example

```
set lb vserver Vserver-LB-1 -pq yes
```

Parameter for configuring priority queuing

- **vServerName**: The name of the virtual server that you are configuring.
- **pq**: Prioritizes client requests on the specified virtual server. Possible values: ON and OFF. Default: OFF.

To configure priority queuing on a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure priority queuing, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the PQ check box, and then click OK.

*Note*: You must configure priority queuing globally for it to function correctly.
Directing Requests to a Custom Web Page

The NetScaler appliance provides the SureConnect option to ensure that web applications respond despite delays caused by limited server capacity or processing speed. SureConnect does this by displaying an alternative web page of your choice when the server that hosts the primary web page is either unavailable or responding slowly.

To configure SureConnect on a virtual server, you must first configure the alternative content. For information about configuring a SureConnect website, see SureConnect. After you configure the website, enable SureConnect on the load balancing virtual server to put your SureConnect custom web page in use.

**Note:** For SureConnect to function correctly, you must configure it globally.

To enable SureConnect on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -sc <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -sc yes
```

Parameters for configuring SureConnect

- **vServerName**
  - The name of the virtual server that you are configuring.

- **sc**
  - Assurance of a response from an application despite possible delays due to server capacity or processing speed. Possible values: ON and OFF. Default: OFF.
To enable SureConnect on a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure SureConnect, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. Select the SC check box, and then click OK.
Enabling Cleanup of Virtual Server Connections

Under certain conditions, you can configure the downStateFlush setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

You must not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with two services bound to it, Service-TCP-1 and Service-TCP-2. The virtual server intercepts two connections, C1 and C2, and redirects them to Service-TCP-1 and Service-TCP-2, respectively. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

<table>
<thead>
<tr>
<th>Vserver-LB-1</th>
<th>Service-TCP-1</th>
<th>State of connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>E</td>
<td>Both client and server connections are terminated.</td>
</tr>
<tr>
<td>E</td>
<td>D</td>
<td>Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only client connections are terminated.</td>
</tr>
</tbody>
</table>
Both client and server connections are terminated. In case of HTTP services, both client and server connections are terminated only if the transaction is active. If the transaction is not active, only server connections are terminated.

Neither client nor server connections are terminated.

**Note:** In case of HTTP services, the downStateFlush setting is effective only when the client is connected to the server.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see Graceful Shutdown of Services.

### To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```bash
set lb vserver <name>@ -downStateFlush <Value>
```

**Example**

```bash
set lb vserver Vserver-LB-1 -downStateFlush enabled
```

### Parameters for configuring down state flush

- **vServerName**
  
  The name of the virtual server that you are configuring.

- **downStateFlush**
  
  Flush all active transactions associated with a virtual server whose state transitions from UP to DOWN. Do not enable this option for applications that must complete their transactions. Possible values: ENABLED, DISABLED. Default: ENABLED
To configure the down state flush setting on a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure down state flush, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. Select the Down state flush check box, and then click OK.
Graceful Shut down of Services

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. To avoid disrupting sessions that have already been established, you can specify a wait time, which places a service in the transition out of service (TROFS) state until the specified wait time expires. The service then enters the out of service (OFS) state.

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes graceful shut down options.

Table 1. Graceful Shut down Options

<table>
<thead>
<tr>
<th>State</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graceful shutdown is enabled and a wait time is specified.</td>
<td>Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.</td>
</tr>
<tr>
<td>Graceful shutdown is disabled and a wait time is specified.</td>
<td>Service is shut down only after the wait time expires, even if all established connections are served before expiration.</td>
</tr>
<tr>
<td>Graceful shutdown is enabled and no wait time is specified.</td>
<td>Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.</td>
</tr>
<tr>
<td>Graceful shutdown is disabled and no wait time is specified.</td>
<td>No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)</td>
</tr>
</tbody>
</table>

To terminate existing connections when a service or a virtual server is marked DOWN, you can use the Down State Flush option. For more information, see Enabling Cleanup of Virtual Server Connections.
To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

- `disable service <name>@[<delay>] [-graceful (YES|NO)]`
- `show service <name>`

Example

```
> disable service svc1 6000 -graceful YES
Done
>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
Last state change was at Mon Nov 15 22:44:15 2010
Time since last state change: 0 days, 00:00:01.160
...
Down state flush: ENABLED

1 bound monitor:
1) Monitor Name: tcp-default
   State: UP               Weight: 1
   Probes: 13898   Failed [Total: 0 Current: 0]
   Last response: Probe skipped - live traffic to service.
   Response Time: N/A
Done

>show service svc1
svc1 (10.102.80.41:80) - HTTP
State: OUT OF SERVICE
Last state change was at Mon Nov 15 22:44:19 2010
Time since last state change: 0 days, 00:00:03.250
Down state flush: ENABLED

1 bound monitor:
1) Monitor Name: tcp-default
   State: UNKNOWN           Weight: 1
   Probes: 13898   Failed [Total: 0 Current: 0]
   Last response: Probe skipped - service state OFS.
   Response Time: N/A
Done
```
Parameters for configuring a graceful shutdown for a service

**serviceName**

Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

**delayInSeconds**

The time in seconds after which the service is marked as OUT OF SERVICE.

**graceFul**

Wait for all previously established connections to this service to be closed before disabling the service. Possible values: YES, NO. Default: NO.

To configure graceful shutdown for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing and then click Services.

2. In the details pane, select the service, and then click Disable.

3. To delay disabling the service, in the Wait Time dialog box, type the wait time after which the service is to be disabled.

4. To disable the service only after all previously initiated transactions have been completed, check the Graceful Shutdown check box.

5. Click Enter.

6. In the Services pane, you can verify that the service is marked as UP until the wait time expires and after that, it is marked as OUT OF SERVICE.
Rewriting Ports and Protocols for HTTP Redirection

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the NetScaler appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The redirectPortRewrite setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.
- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only SSL redirect is enabled. The virtual server can be configured on any port.</td>
<td></td>
</tr>
<tr>
<td>SSL redirect and port rewrite are enabled. The virtual server is configured on port 80.</td>
<td></td>
</tr>
<tr>
<td>SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080.</td>
<td></td>
</tr>
</tbody>
</table>
Rewriting Ports and Protocols for HTTP Redirection

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

SSL redirect and port rewrite are enabled. The virtual server is configured on port 444.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

The virtual server is configured on port 80.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
</table>

The virtual server is configured on port 8080.
Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL redirect is enabled on the virtual server. The virtual server can be configured on any port.</td>
<td></td>
</tr>
</tbody>
</table>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443.</td>
<td></td>
</tr>
</tbody>
</table>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444.

<table>
<thead>
<tr>
<th>Redirect URL from the Server</th>
<th>Redirect URL sent to the Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444.</td>
<td></td>
</tr>
</tbody>
</table>

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
```

Example

```
set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
```

Parameters for redirect port rewrite

**vServerName**

The name of the virtual server that you are configuring.
redirectPortRewrite

Rewrite the port and change the protocol to ensure successful HTTP redirects from services. Possible values: ENABLED and DISABLED. Default: DISABLED.

To configure HTTP redirection on a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure HTTP redirection, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. Select the Redirect Port Rewrite check box, and then click OK.

To configure SSL Redirect on an SSL virtual server or service by using the command line interface

At the command prompt, type:

- set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
- set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)

Example

set ssl vserver Vserver-SSL-1 -sslRedirect enabled
set ssl service service-SSL-1 -sslRedirect enabled

Parameters for SSL Redirect

vServerName

The name of the virtual server that you are configuring.

sslRedirect

State of HTTPS redirects for the SSL virtual server or service.
To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers or Services.

2. In the details pane, select the virtual server or service for which you want to configure SSL redirection, and then click Open.

3. In the Configure Virtual Server (SSL Offload) dialog box, click the SSL Settings tab, and then click SSL Parameter.

4. In the Configure SSL Params dialog box, select SSL Redirect. Optionally, select SSL Redirect Port Rewrite.

5. Click OK.

6. In the Configure Virtual Server (SSL Offload) dialog box, click OK.
Inserting the IP Address and Port of a Virtual Server in the Request Header

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

Note: This option is not supported for wild card virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

set lb vserver <name>@-insertVserverIPPort <insertVserverIPPort> [<vipHeader>]

Example

set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr

Parameters for virtual server IP port insertion

vServerName

The name of the virtual server that you are configuring.

insertVserverIPPort

Insert an HTTP header, whose value is the IP address and port number of the virtual server, before forwarding a request to the server. The format of the header is <vipHeader>: <virtual server IP address>_<port number>, where vipHeader is the name that you specify for the header. If the virtual server has an IPv6 address, the address in the header is enclosed in brackets ([ and ]) to separate it from the port number. If you have mapped an IPv4 address to a virtual server's IPv6 address, the value of this
parameter determines which IP address is inserted in the header, as follows:

VIPADDR—Insert the IP address of the virtual server in the HTTP header regardless of whether the virtual server has an IPv4 address or an IPv6 address. A mapped IPv4 address, if configured, is ignored.

V6TOV4MAPPING—Insert the IPv4 address that is mapped to the virtual server’s IPv6 address. If a mapped IPv4 address is not configured, insert the IPv6 address.

OFF—Disable header insertion.

vipHeader

Name for the inserted header. The default name is vip-header. Maximum Length: 79 characters.

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to insert the IP address and port, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. In the Vserver IP Port Insertion list, select the VIPADDR or V6TOV4MAPPING, and then type the port header in a text box next to Vserver IP Port Insertion box.

5. Click OK.
Using a Specified Source IP for Backend Communication

For communication with the physical servers or other peer devices, the NetScaler appliance uses an IP address owned by it as the source IP address. NetScaler maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, NetScaler decides which IP address to use. This address pool is used for sending traffic as well as monitor probes.

In many situations, you may want the NetScaler to use a specific IP address or any IP address from a specific set of IP addresses for backend communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.

- To improve server security, a server may be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the NetScaler can use only the IP addresses accepted by the server as the source IP address.

- The NetScaler can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the NetScaler to use a specified source IP address, create net profiles (network profiles) and configure the NetScaler entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. A net profile has NetScaler owned IP addresses (SNIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, NetScaler dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile will be used for sending traffic to all the services bound to it. If a net profile is bound to a service group, NetScaler uses the profile for all the members of the service group. If a net profile is bound to a monitor, NetScaler uses the profile for all the probes sent from the monitor.

Usage of a net profile for sending traffic:

If the Use Source IP Address (USIP) option is enabled, NetScaler uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, NetScaler selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, NetScaler uses the default method.
If there is a net profile only on the service/service group, NetScaler uses that net profile.

- If there is a net profile only on the virtual server, NetScaler uses the net profile.
- If there is a net profile both on the virtual server and service/service group, NetScaler uses the net profile bound to the service/service group.

**Usage of a net profile for sending monitor probes:**

For monitor probes, NetScaler selects the source IP in the following manner:

- If there is a net profile bound to the monitor, NetScaler uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,

  - If there is a net profile on the service/service group, NetScaler uses the net profile of the service/service group.
  
  - If there is no net profile even on the service/service group, NetScaler uses the default method of selecting a source IP.

**Note:** If there is no net profile bound to a service, NetScaler looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs owned by the NetScaler. An IP set can consist of both SNIP addresses. For instructions, see Creating IP Sets.
2. Create net profiles. For instructions, see Creating a Net Profile.
3. Bind the net profiles to NetScaler entities. For instructions, see Binding a Net Profile to a NetScaler Entity.

**Note:** A net profile can have only the IP addresses specified as SNIP on the NetScaler.

### Managing Net Profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the NetScaler appliance uses the addresses specified in the profile as the source IP address. For more information on the use of net profiles, see Using a User-specified Source IP Address for Backend Communication.

- For instructions on creating a network profile, see Creating a Network Profile.
- For instructions on binding a network profile to a NetScaler entity, see Binding a Network Profile.
Creating an IP Set

An IP set is a set of IP addresses, which are configured on the NetScaler appliance as Subnet IP addresses (SNIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set and bind NetScaler owned IP addresses to it. SNIP addresses can be present in the same IP set. For more information about the use of IP sets, see Using a User-specified Source IP Address for Backend Communication.

To create an IP set by using the command line interface

At the command prompt, type the following commands:

- add ipset <name>
- bind ipset <name> <IPAddress>@
- or
- bind ipset <name> <IPAddress>@
- show ipset [<name>]

The above command shows the names of all the IP sets on the NetScaler if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

Examples

1.  
> add ipset skpnwipset
Done
> bind ipset skpnwipset 21.21.20.1
Done

2.  
> add ipset testnwipset
Done
IPAddress "21.21.21.21" bound
IPAddress "21.21.21.22" bound
IPAddress "21.21.21.23" bound
IPAddress "21.21.21.24" bound
IPAddress "21.21.21.25" bound
Done

3.  
> bind ipset skpipset 11.11.11.101
ERROR: Invalid IP address
[This IP address could not be added because this is not an IP address owned by the NetScaler]
> add ns ip 11.11.11.101 255.255.255.0 -type SNIP
ip "11.11.11.101" added
Done
> bind ipset skpipset 11.11.11.101
IPAddress "11.11.11.101" bound
Parameters for configuring an IP set

name (Name)

The name of the IP set. The name can have up to 127 characters. It must begin with an alphanumeric character or underscore, and must contain only alphanumerics, '_', '#', ':', '@', '=' or '-'.

ipAddress (IP Address)

A SNIP address on the NetScaler.

ipAddressRange

A contiguous range of SNIP or MIP address on the NetScaler.
To create an IP set by using the configuration utility

1. In the navigation pane, expand Network, and then click IP Sets.

2. In the details pane, do one of the following:
   
   - To create a new IP set, click Add.
   
   - To modify an existing IP set, select the IP set, and then click Open.

3. In the Create IP Set dialog box, set the following parameters:
   
   - Name
   
   - IP Address (The SNIPs specified on the NetScaler are displayed. Check the IP addresses that you want to bind to the IP set. You can select more than one.)

   If you want to add an IP address to the pool, do one of the following:
   
   - To add an IPv4 address, click Add IPv4, and then in the Create IP dialog box, type the necessary details.
   
   - To add an IPv6 address, click Add IPv6, and then in the Create IPV6 dialog box, type the necessary details.

4. Click Create.

Creating a Net Profile

A net profile (network profile) consists of one or more SNIP addresses of the NetScaler. For more information about the usage of net profiles, see Using a User-specified Source IP Address for Backend Communication.

To create a net profile by using the command line interface

At the command prompt, type:

```
add netprofile <name> [-srcIp <srcIpVal>]
```

If the srcIpVal is not provided in this command, it can be provided later by using the set netprofile command.

Examples

```
> add netprofile skpnetprofile1 -srcIp 21.21.20.1
Done

> add netprofile baksnp -srcIp bakipset
Done

> set netprofile yahnp -srcIp 12.12.23.1
Done

> set netprofile citkbnp -srcIp citkbipset
Done
```
Parameters for creating a net profile

name (Name)

The name of the net profile. The name can have up to 127 characters. It must begin with an alphanumeric character or underscore, and must contain only alphanumerics, '_.', '#', '.', '/', ';', ':', '@', '=' or '-'.

srcIpVal (IP address or IP Set)

IP address or the name of an IP set.

To create a net profile by using the configuration utility

1. In the navigation pane, expand Network, and then click Net Profiles.

2. In the Create Net Profile dialog box, type a name for the net profile.

3. To specify the source IP address, do one of the following:
   - Check IP Address and select an IP address from the IP Address drop-down list.
   - Check IP Set and select the name of an IP set from the IP Set drop-down list.
     If you want to add a new IP address or IP set, click New and type the necessary details in the dialog box that is displayed. If you want to modify an entry after selecting it from the drop-down list, click Modify and change the values. To unbind an IP address or IP set from a net profile, select the blank entry from the drop down list, and then click OK.

4. Click Create.

Binding a Net Profile to a NetScalser Entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor. For more information about the effect of binding a net profile to a NetScaler entity, see Using a User-specified Source IP Address for Backend Communication.

Note: You can bind a net profile at the time of creating a NetScaler entity or bind it to an already existing entity.

To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```bash
set lb vserver <name>@ -netProfile <net_profile_name>
```

or
Using a Specified Source IP for Backend Communication

- set cs vserver <name> -netProfile <net_profile_name>

Examples

set lb vserver skpnwvs1 -netProfile gntnp
Done
set cs vserver mmdcsv -netProfile mmdnp
Done

To bind a net profile to a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing or Content Switching, and then click Virtual Servers.

2. In the details pane, select the virtual server to which you want to bind a net profile, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, or Configure Virtual Server (Content Switching) click the Profiles tab.

4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or Modify... to modify the selected net profile.

5. Click OK.

To bind a net profile to a service by using the command line interface

At the command prompt, type:

set service <name> -netProfile <net_profile_name>

Example

set service brnssvc1 -netProfile brnsnp
Done
To bind a net profile to a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service to which you want to bind a net profile, and then click Open.

3. In the Configure Service dialog box, click the Profiles tab.

4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or Modify... to modify the selected net profile.

5. Click OK.

To bind a net profile to a service group by using the command line interface

At the command prompt, type:

```
set servicegroup <serviceGroupName>@-netProfile <net_profile_name>
```

Example

```
set servicegroup ndhsvcgrp -netProfile ndhnp
Done
```

To bind a net profile to a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, select the service group to which you want to bind a net profile, and then click Open.

3. In the Configure Service Group dialog box, click the Profiles tab.

4. In the Net Profile drop-down list, select a net profile. In this dialog box, you can click New... to add a net profile or Modify... to modify the selected net profile.

5. Click OK.

To bind a net profile to a monitor by using the command line interface

At the command prompt, type:
set monitor <monitor_name> -netProfile <net_profile_name>

Example

set monitor brnsecvmon1 -netProfile brnsmonnp
Done

To bind a net profile to a monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, select the monitor to which you want to bind a net profile, and then click Open.

3. In the Configure Monitor dialog box, in the Net Profile drop-down list, select a net profile.

4. Click OK.
Setting a Timeout Value for Idle Client Connections

You can configure a virtual server to terminate any idle client connections after a configured timeout period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -cltTimeout <Value>
```

Example

```
set lb vserver Vserver-LB-1 -cltTimeout 100
```

Parameters for setting the client time-out value

`vServerName`

The name of the virtual server that you are configuring.

`cltTimeout`

Idle time (in seconds) after which the client connection is terminated. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.
To set a time-out value for idle client connections by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure a time-out value, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. In the Client Time-out (secs) text box, type the timeout value (for example, 100).

5. Click OK.
Managing RTSP Connections

The NetScaler appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see "IP Addressing."

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see "Configuring Load Balancing in Direct Server Return Mode." For more information about configuring DNS, see "Domain Name System."

In either case, when you configure RTSP load balancing, you must also configure rtspNat to match the topology of your load balancing setup.

To configure RTSP NAT by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@-RTSPNAT <ValueOfRTSPNAT>
```

Example

```
set lb vserver vserver-LB-1 -RTSPNAT ON
```

Parameters for configuring RTSP

vServerName

The name of the virtual server that you are configuring.

rtspNat

Whether the appliance is configured to use NAT or not when load balancing RTSP services. When the appliance is configured for the NAT-on mode, you must set rtspNat
ON. When the NetScaler is configured for NAT-off mode, you must set rtspNat OFF. Possible values: ON and OFF. Default value: OFF.

**To configure RTSP NAT by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server for which you want to configure RTSP NAT, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.

4. Select the RTSP Natting check box, and then click OK.
Managing Client Traffic on the Basis of Traffic Rate

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the NetScaler appliance based on the traffic rate. You can throttle the traffic flow if it is too high, cache information based on the traffic rate, and if the traffic rate is too high redirect excess traffic to a different load balancing virtual server. You can apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see Rate Limiting.
Identifying a connection with Layer 2 Parameters

Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>::<destination IP>::<destination port>) to co-exist on the NetScaler appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the NetScaler appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore NetScaler appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

To configure the L2 connection option by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@<serviceType> <IPAddress>@<port> -l2Conn ON
```

Example

```
add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
```

Parameters for configuring a virtual server

vServerName

Name of the virtual server that is associated with the service. The name must not exceed 127 characters, and the leading character must be a number or a letter. The following
Identifying a connection with Layer 2 Parameters

characters are also allowed: @ _ . (period) : (colon) # and space ( ).

ipAddress

IP address of the virtual server, in either IPv4 or IPv6 format.

serviceType

The type of services to which the virtual server distributes requests.

port

Port on which the virtual server listens for client connections.

l2Conn

The tuple used to identify a connection includes the layer 2 parameters.

To configure the L2 connection option by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the CreateVirtual Server (Load Balancing) dialog box, specify values which correspond to parameters described in "Parameters for configuring a virtual server" as shown:
   - Name*—vServerName
   - IP Address*—ipAddress
   - Protocol*—serviceType
   - Port*—port
   *A required parameter

4. On the Advanced tab, select L2 Connection.

5. Click Create.

6. Open the virtual server you configured and verify the configuration.
Configuring the Prefer Direct Route Option

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the NetScaler appliance forwards traffic according to the configured route. If you want the NetScaler to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a NetScaler appliance, the NetScaler directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, in some cases, you may want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the NetScaler appliance.

To set the prefer direct route option by using the command line interface

At the command prompt, type:

```
set lb parameter -preferDirectRoute (YES | NO)
```

Example

```
set lb parameter -preferDirectRoute YES
```

Parameter for configuring prefer direct route option

preferDirectRoute

If enabled, the NetScaler looks up for the configured route. Possible values: YES, NO. Default: YES.
To set the prefer direct route option by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. Under Settings, click Configure Load Balancing Parameters.

3. In the Configure Load Balancing Parameters dialog box, select the Prefer Direct Route check box.

4. Click OK.
Advanced Load Balancing Settings

In addition to configuring virtual servers, you can configure advanced settings for services.
Gradually Stepping Up the Load on a New Service with Virtual Server–Level Slow Start

You can configure the NetScaler appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (hereafter, the term “new service” is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

  **Note:** In automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.
Gradually Stepping Up the Load on a New Service with Virtual Server-Level Slow Start

With automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.
If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval in seconds</td>
<td>0</td>
</tr>
<tr>
<td>New service request rate</td>
<td>10, 20, 40, and 0, at intervals that you choose</td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Requests per second</td>
</tr>
</tbody>
</table>

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

<table>
<thead>
<tr>
<th></th>
<th>new service request rate = 10 req/sec</th>
<th>new service request rate = 20 req/sec</th>
<th>new service request rate = 40 req/sec</th>
<th>new service request rate = 0 req/sec</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(Service3added)</td>
<td>(Service4added)</td>
<td>(new services exit slow start mode)</td>
<td></td>
</tr>
<tr>
<td>Service1</td>
<td>115</td>
<td>110</td>
<td>80</td>
<td>60</td>
</tr>
</tbody>
</table>

Table 1. Parameter Values

Table 2. Load Distribution on Services when Manually Stepping Up the Load
## Manual Slow Start

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Service2</td>
<td>115</td>
<td>110</td>
<td>80</td>
<td>60</td>
</tr>
<tr>
<td>Service3</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>60</td>
</tr>
<tr>
<td>Service4</td>
<td>-</td>
<td>-</td>
<td>40</td>
<td>60</td>
</tr>
<tr>
<td><strong>Total req/sec (load on the virtual server)</strong></td>
<td>240</td>
<td>240</td>
<td>240</td>
<td>240</td>
</tr>
</tbody>
</table>
Automated Slow Start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving it’s full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 1. Parameter Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval in seconds</td>
<td>10</td>
</tr>
<tr>
<td>Increment value</td>
<td>4</td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Requests per second</td>
</tr>
</tbody>
</table>

With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 2. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

<table>
<thead>
<tr>
<th></th>
<th>0 sec</th>
<th>10 sec</th>
<th>20 sec</th>
<th>30 sec</th>
<th>40 sec</th>
<th>50 sec</th>
</tr>
</thead>
<tbody>
<tr>
<td>Req/sec forService1</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec forService2</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Req/sec forService3</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
<td>20</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>--------</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interval in seconds</td>
<td>5</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Increment value</td>
<td>25</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Units for the new service request rate</td>
<td>Percent</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”
Setting the Slow Start Parameters

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

**To configure stepwise load increments for a new service by using the command line interface**

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```
add lb vserver <name> <serviceType> <IPAddress> <port> [-newServiceRequest <positive_integer>] [newServiceRequestUnit] [-newServiceRequestIncrementInterval <positive_integer>]
show lb vserver <name>
```

**Example**

```
> set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -newServiceRequestIncrementInterval 10
Done
> show lb vserver BR_LB
BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
State: UP
... ...
New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
... ...
Done
>
```

**Parameters for configuring stepwise load increments for a new service**

**newServiceRequest (New Service Startup Request Rate)**

Number of requests, or percentage of the load on existing services, by which to increase the load on a new service at each interval in slow-start mode. A non-zero value indicates that slow-start is applicable. A zero value indicates that the global RR startup parameter is applied. Changing the value to zero will cause services currently in slow start to take the full traffic as determined by the LB method. Subsequently, any new services added
will use the global RR factor.

**newServiceRequestUnit**

The unit for the step increment in load. Possible values: PER_SECOND (number of requests per second), PERCENT (percentage of the load on existing services).

**newServiceRequestIncrementInterval (Increment Interval)**

The interval, in seconds, between successive increments in the load on a new service or a service whose state has just changed from DOWN to UP. A value of 0 (zero) specifies manual slow start.

**To configure stepwise load increments for a new service by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, do one of the following:

   - To configure stepwise increments for a new load balancing virtual server, click Add.
   - To configure stepwise increments for an existing load balancing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server or Configure Virtual Server dialog box, on the Method and Persistence tab, set the following parameters:

   - New Service Startup Request Rate. Also, from the list next to the text box, select the unit (PER_SECOND or PERCENT).
   - Increment Interval.

4. Click Create or OK, and then click Close.
The No-Monitor Option for Services

If you use an external system to perform health checks on the services and do not want the NetScaler appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the NetScaler continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports that a service that is DOWN, remove the service from the NetScaler configuration.

- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

To set the no-monitor option for a new service by using the command line interface

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
add service <serviceName> <IP | serverName> <serviceType> <port> -healthMonitor (YES|NO)
```

**Example**

```
>add service nomonsrvc 10.102.21.21 http 80
-healhMonitor no
Done
> show service nomonsrvc
nomonsrvc (10.102.21.21:80) - HTTP
State: UP
Last state change was at Mon Nov 15 22:41:29 2010
Time since last state change: 0 days, 00:00:00.970
```
Server Name: 10.102.21.21  
Server ID: 0 Monitor Threshold: 0

Access Down Service: NO

Down state flush: ENABLED  
Health monitoring: OFF

1 bound monitor:
1) Monitor Name: tcp-default  
State: UNKNOWN Weight: 1
Probes: 3 Failed [Total: 3 Current: 3]
Last response: Probe skipped - Health monitoring is turned off.
Response Time: N/A  
Done

To set the no-monitor option for an existing service by using the command line interface

At the command prompt, type the following command to set the health monitor option:

```
set service <name> -healthMonitor (YES|NO)
```

**Example**

By default, the state of a service and the state of the corresponding monitor are UP.

```
> show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP

1) Monitor Name: http-ecv  
State: UP Weight: 1
Probes: 99992 Failed [Total: 0 Current: 0]
Last response: Success - Pattern found in response.
Response Time: 3.76 millisec  
Done
```

When the no-monitor option is set on a service, the state of the monitor changes to UNKNOWN.

```
> set service LB-SVC1 -healthMonitor NO
Done
> show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010.
Time since last state change: 5 days, 18:55:48.710
Health monitoring: OFF

1) Monitor Name: http-ecv  
State: UNKNOWN Weight: 1
```
The No-Monitor Option for Services

Probes: 100028 Failed [Total: 0 Current: 0]
Last response: Probe skipped - Health monitoring is turned off.
Response Time: 0.0 millisec
Done
When the no-monitor option is removed, the earlier state of the monitor is resumed.
> set service LB-SVC1 -healthMonitor YES
Done
> show service LB-SVC1
LB-SVC1 (10.102.29.5:80) - HTTP
State: UP
Last state change was at Fri Dec 10 10:17:37 2010
Time since last state change: 5 days, 18:57:47.880
1) Monitor Name: http-ecv

   Done

Parameters for configuring a service

serviceName

Name of the service. The name must not exceed 127 characters, and the leading
character must be a number or letter. The following characters are also allowed: @ _ - . 
(period) : (colon) # and space ( ).

ipAddress

IP address of the server that is associated with the service, in either IPv4 or IPv6 format.

serverName

Name of the server that is associated with the service. The name must not exceed 127
characters, and the leading character must be a number or a letter. The following
characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

serviceType

Protocol supported by the service. Possible values: HTTP, FTP, TCP, UDP, SSL,
SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP,
DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDP.

port

The port number used for the service.

healthMonitor

The monitoring option for the service. Possible values: YES, NO. Default: YES.
To set the no-monitor option for a service by using the configuration utility

1. In the navigation pane, click Load Balancing and then click Services.

2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service and then click Open.

3. In the Create Service or Configure Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a service” as shown:
   - Service Name* - serviceName
   - Protocol* - serviceType
   - Server* - ipAddress
   - Port* - port
   - Health Monitor - healthMonitor
   * A required parameter

4. Click Create. The service you created appears in the Services pane.

5. From the Services pane, open the service that you added, and verify the health monitor setting.
Protecting Applications on Protected Servers Against Traffic Surges

The NetScaler provides the surge protection option to maintain the capacity of a server or cache. The NetScaler regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The NetScaler blocks any surges passed to the server, thereby preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see "Surge Protection."

To set surge protection on the service by using the command line interface

At the command prompt, type:

```
set service <name>@ -sp <Value>
```

Example

```
set service Service-HTTP-1 -sp ON
```

Parameters for configuring surge protection on the service

- **ServiceName**
  - The name of the service that you are configuring.

- **sp**
  - State of surge protection for the service. Possible values: ON and OFF. Default: OFF.
To set surge protection on the service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure surge protection, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab, scroll down, and under Others, select the Surge Protection check box.

4. Click OK.
Enabling Cleanup of Service Connections

When cleanup of service connections is enabled, the NetScaler performs a cleanup of the connections on a service that is down. This setting is described in Enabling Cleanup of Virtual Server Connections.

To set down state flush on the service by using the command line interface

At the command prompt, type:

```
set service <name> -downStateFlush <Value>
```

Example

```
set service Service-HTTP-1 -downStateFlush enabled
```

Parameters for configuring down state flush on the service

ServiceName

The name of the service that you are configuring.

downStateFlush

Flush all active transactions associated with a service whose state transitions from UP to DOWN. Do not enable this option for applications that must complete their transactions. Possible values: ENABLED and DISABLED. Default: ENABLED.
To set down state flush on the service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure down state flush, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Scroll down, and under Others, select the Down state flush check box.

5. Click OK.
Directing Requests to a Custom Web Page

For SureConnect to function correctly, you must set it globally. The NetScaler provides the SureConnect option to ensure the response from an application. For more information about the SureConnect option, see "Sure Connect."

**To set SureConnect on the service by using the command line interface**

At the command prompt, type:

```
set service <name>@ -sc <Value>
```

**Example**

```
set service Service-HTTP-1 -sc ON
```

**Parameters for configuring SureConnect on the service**

**ServiceName**

The name of the service that you are configuring.

**sc**

State of SureConnect for the service. This parameter is supported for legacy purposes only. It has no effect on the NetScaler, and its only valid value is OFF. Possible values: ON and OFF. Default: OFF.
To set SureConnect on the service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure SureConnect, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Scroll down, and under Others, select the Sure Connect check box.

5. Click OK.
Enabling Access to Services When Down

You can enable access to a service when it is disabled or in a DOWN state by configuring the NetScaler appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the Access Down setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see IP Addressing.

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the accessDown parameter.

**To enable access down on a service by using the command line interface**

At the command prompt, type:

```
set service <name> -accessDown <Value>
```

**Example**

```
set service Service-HTTP-1 -accessDown YES
```

**Parameters for configuring Access Down**

**ServiceName**

The name of the service that you are configuring.

**accessDown**

Access to disabled or DOWN services. If this option is enabled, and the service goes DOWN, all packets to the service are bridged. If this option is disabled, and the service goes DOWN, the packets are dropped. Possible values: YES and NO. Default: NO.
To enable access down on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure access down, click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Scroll down, and under Others, select the Access Down check box.

5. Click OK.
Enabling TCP Buffering of Responses

The NetScaler appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 megabytes (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting. For more information about configuring TCP buffering globally, see “TCP Buffering.”

To enable TCP Buffering on a service by using the command line interface

At the command prompt, type:

```
set service <name>@-TCPB <Value>
```

Example

```
set service Service-HTTP-1 -TCPB YES
```

Parameters for configuring TCP buffering

**ServiceName**

The name of the service that you are configuring.

**TCPB**

State of the TCP buffering feature for the service. Possible values: YES and NO. Default: NO.
To enable TCP Buffering on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure TCP buffering (for example, Service-HTTP-1), and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Scroll down, and under Settings, select the TCP Buffering check box.

5. Click OK.
Enabling Compression

The NetScaler appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

**Note:** For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see Compression.

To enable compression on a service by using the command line interface

At the command prompt, type:

```
set service <name> -CMP <YES | NO>
```

**Example**

```
set service Service-HTTP-1 -CMP YES
```

Parameters for configuring compression

**ServiceName**

The name of the service that you are configuring.

**CMP**

State of the HTTP compression feature for the service. Possible values: YES, NO. Default: NO.
To enable compression on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure compression (for example, Service-HTTP-1), and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Settings, select the Compression check box.

5. Click OK.
Maintaining Client Connection for Multiple Client Requests

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a Web site open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the NetScaler appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client will open a new connection for every request that it sends to the Web site. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see Client Keep-Alive.

To enable client keep-alive on a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -CKA <Value>
```

Example

```
set service Service-HTTP-1 -CKA YES
```

Parameters to configure client keep-alive

ServiceName

The name of the service that you are configuring.

CKA

To enable client keep-alive on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure client keep-alive, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Settings, select the Client Keep-Alive check box.

5. Click OK.
Inserting the IP Address of the Client in the Request Header

A NetScaler uses the mapped IP address (MIP) to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the NetScaler inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

To insert client IP address in the client request by using the command line interface

At the command prompt, type:

```
set service <name>@ -CIP <Value> <cipHeader>
```

Example

```
set service Service-HTTP-1 -CIP enabled X-forwarded-for
```

Parameters for inserting client IP address in the client request

**ServiceName**

The name of the service that you are configuring.

**CIP**

Client IP address header addition option for the service. Possible values: ENABLED and DISABLED. Default: DISABLED.

This option works with IPv4 and IPv6 addresses.

**cipHeader**

The name of the HTTP header that the NetScaler inserts and to which it adds the IP address of the client as the header value. If client IP insertion is enabled, and the client IP header is not specified, then the NetScaler sets the client IP header. The default is blank (NetScaler uses a blank HTTP header).
To insert client IP address in the client request by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to add the client IP address in the request, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Settings, select the Client IP check box.

5. In the Header text box, type the header tag (for example, X-Forwarded-for).

6. Click OK.
Using the Source IP Address of the Client When Connecting to the Server

You can configure the NetScaler appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see "Enabling Use Source IP Mode."

For information about using the port of the client when connecting to the server, see Using the Client Port When Connecting to the Server.

To enable USIP mode for a service by using the command line interface

At the command prompt, type:

```
set service <name>@ -usip (YES | NO)
```

Example

```
set service Service-HTTP-1 -usip YES
```

Parameters to configure USIP mode

**ServiceName**

The name of the service that you are configuring.

**usip**

Determines the source IP address used when the NetScaler appliance connects to the server. If this option is set to YES, the NetScaler uses the client IP address. Possible values: YES, NO. Default: NO.

**Note:** USIP does not work when you bind an IPv6 service with USIP enabled to an IPv4 virtual server, or when you bind an IPv4 service with USIP enabled to an IPv6 virtual server.
To enable USIP mode for a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service for which you want to enable the USIP mode, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. Under Settings, select the Use Source IP check box.
5. Click OK.
Configuring the Source Port for Server-Side Connections

When the NetScaler appliance connects to a physical server, it can use the source port from client’s request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The NetScaler appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client’s) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- Req1 is received by LBVS1 and Req2 is received by LBVS2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, they forward the response to the client.
- Consider two cases:
  - Use the client port. When the NetScaler uses the client port, both the virtual servers use the client’s IP address (because USIP is ON) and the client’s port when connecting to the server. Therefore, when the service sends the response, the NetScaler cannot determine which virtual server should receive the response.
  - Use proxy port. When the NetScaler uses a proxy port, the virtual servers use the client's IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that should receive the response.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see “Enabling Use Source IP Mode.”

You can configure the Use Proxy Port setting either globally or on a given service.

To configure the Use Proxy Port setting on a service by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -useProxyPort (YES | NO)
```

Example
Parameters for configuring proxy port mode on a service

ServiceName
The name of the service that you are configuring.

useProxyPort
If USIP is enabled, use a proxy port, instead of the source port in the client’s request, as the source port when connecting to a physical server. Possible values: YES, NO. Default: YES for TCP based service types, NO for UDP based service types.

To configure the Use Proxy Port setting on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to use the source IP address, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Others, in the Use Proxy Port drop-down list, select YES.

5. Click OK.
Setting a Limit on the Number of Client Connections

You can specify a maximum number of client connections that each load balanced server can handle. The NetScaler appliance then opens client connections to a server only until this limit is reached. When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the Maximum Client setting, see “Load Balancing Domain-Name Based Services.”

Note: Connections that are in the process of closing are not considered for this limit.

To set a limit to the number of client connections by using the command line interface

At the command prompt, type:

set service <name> -maxclient <Value>

Example

set service Service-HTTP-1 -maxClient 1000

Parameters for configuring the maximum clients setting

ServiceName

The name of the service that you are configuring.

maxClient

Maximum number of open connections to the service. The default value is 0. The maximum value is 4294967294.
To set a limit to the number of client connections by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure the maximum number of client connections (for example, Service-HTTP-1), and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Thresholds, in the Max Clients text box, type the maximum number of client connections (for example, 100).

5. Click OK.
Setting a Limit on Number of Requests Per Connection to the Server

The NetScaler appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers may have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

**Note:** You can configure the max request option for HTTP or SSL services only.

**To limit the number of client requests per connection by using the command line interface**

At the command prompt, type:

```
set service <ServiceName> -maxReq <Value>
```

**Example**

```
set service Service-HTTP-1 -maxReq 100
```

**Parameters for configuring the maximum requests setting**

**ServiceName**

The name of the service that you are configuring.

**maxReq**

Maximum number of requests that can be sent on a persistent connection to the service. The default value is 0. The minimum value is 0 and maximum value is 65535. ‘0’ specifies that there is no limit on the maximum requests that are sent on a persistent connection.
To limit the number of client requests per connection by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure the maximum number of client requests, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Thresholds, in the Max Requests text box, type the maximum number of client requests (for example, 100).

5. Click OK.
Setting a Threshold Value for the Monitors Bound to a Service

The NetScaler appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

To set the monitor threshold value on a service by using the command line interface

At the command prompt, type:

```
set service <name> -monThreshold <Value>
```

**Example**

```
set service Service-HTTP-1 -monThreshold 100
```

Parameters for configuring the monitor threshold on a service

*ServiceName*
The name of the service that you are configuring.

monThreshold

Monitoring threshold. The default value is 0. The minimum value is 0 and maximum value is 65535.

To set the monitor threshold value on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, select the service for which you want to configure monitor threshold (for example, Service-HTTP-1), and then click Open.
3. In the Configure Service dialog box, click the Advanced tab.
4. In the Monitor Threshold text box, type the monitor threshold.
5. Click OK.
Setting a Timeout Value for Idle Client Connections

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the NetScaler closes the client connection.

To set a timeout value for idle client connections by using the command line interface

At the command prompt, type:

```
set service <name> -cltTimeout <Value>
```

Example

```
set service Service-HTTP-1 -cltTimeout 100
```

Parameters for setting a timeout value for idle client connections

**ServiceName**

The name of the service that you are configuring.

**cltTimeout**

Idle time (in seconds) after which the client connection is terminated. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.
To set a timeout value for idle client connections by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure the time-out value for client connections, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Idle Time-out (secs), in the Client text box, type the timeout value.

5. Click OK.
Setting a Timeout Value for Idle Server Connections

You can configure a service with a timeout value to terminate any idle server connections when the configured time elapses. If the server is idle for the configured amount of time, the NetScaler appliance closes the server connection.

To set a timeout value for idle server connections by using the command line interface

At the command prompt, type:

```
set service <name>@ -svrTimeout <Value>
```

Example

```
set service Service-HTTP-1 -svrTimeout 100
```

Parameters for configuring idle server timeout on services

**ServiceName**

The name of the service that you are configuring.

**svrTimeout**

Idle time (in seconds) after which the server connection is terminated. The default value is 360. The maximum value is 31536000.
To set a timeout value for idle server connections by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure the timeout value for server connections (for example, Service-HTTP-1), and click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Idle Time-out (secs), in the Server text box, type a timeout value as a number of seconds (for example, 100).

5. Click OK.
Setting a Limit on the Bandwidth Usage by Clients

In some cases, servers may have limited bandwidth to handle client requests and may become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth processed by the server. The NetScaler appliance forwards requests to a load balanced server only until this limit is reached.

To set a maximum bandwidth limit on a service by using the command line interface

At the command prompt, type:

```
set service <name> -maxBandwidth <Value>
```

Example

```
set service Service-HTTP-1 -maxBandwidth 100
```

Parameters for configuring a maximum bandwidth on a service

- **ServiceName**
  The name of the service that you are configuring.

- **maxBandwidth**
  Maximum bandwidth, in Kbps, allowed for forwarding incoming requests to a service. Possible Values: 0-limit of memory. Default: limit of memory.
To set a maximum bandwidth limit on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details page, select the service for which you want to configure maximum bandwidth usage (for example, Service-HTTP-1), and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Under Thresholds, in the Max Bandwidth (kbits) text box, type the maximum bandwidth (for example, 100).

5. Click OK.
Redirecting Client Requests to a Cache

You can configure a service to redirect client requests to a cache, and forward only those requests that are cache misses to a service chosen by the configured load balancing method.

To set cache redirection on a service by using the command line interface

At the command prompt, type:

set service <name>@ -cacheable <Value>

Example

set service Service-HTTP-1 -cacheable YES

Parameters for configuring caching of client requests

ServiceName

The name of the service that you are configuring.

cacheable

Use the transparent cache redirection virtual server to forward requests to the cache server.

Note: Do not specify this parameter if you set the Cache Type parameter.

Possible values: YES and NO. Default: NO.
To set cache redirection on a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to configure cache redirection, and then click Open.

3. In the Configure Service dialog box, click the Advanced tab.

4. Scroll down, and under Cache Redirection Options, in Cache Type list, select the type of cache (for example, Regular Server).

5. Click OK.
Monitors

To manage a high-traffic load balancing setup, the NetScaler appliance needs to track the state of each load balanced server in near real time, so that it can divert traffic from any load balanced server that is not responding and send that traffic to a load balanced server that is responding. Therefore, a monitor is bound to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

The load balancing virtual server does not route requests to services that are DOWN. Those services are removed from its list of available services until they become available again and respond to monitor probes.

You can bind a single monitor or multiple monitors to the same service. If you bind multiple monitors to a service, they each evaluate responses to different types of traffic.

The NetScaler appliance supports built-in monitors to monitor common types of services. It also supports user-created monitors based on the built-in monitors, and allows you to create and configure custom monitors.
The Built-in Monitors

The NetScaler appliance contains a number of built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. You cannot modify or remove the built-in monitors; you can only bind a built-in monitor to a service and unbind it from the service.

**Note:** You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see *Configuring Monitors in a Load Balancing Setup.*
The NetScaler appliance has two built-in monitors that monitor TCP-based applications: tcp-default and ping-default. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The tcp-default monitor is bound to all TCP services; the ping-default monitor is bound to all non-TCP services.

You cannot delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

<table>
<thead>
<tr>
<th>Monitor type</th>

To configure built-in monitors for TCP-based applications, see Configuring Monitors in a Load Balancing Setup.
Monitoring SSL Services

The NetScaler appliance has built-in secure monitors, TCPS and HTTPS. You can use the secure monitors to monitor HTTP as well as non-HTTP traffic. The secure monitors work as described below:

- **TCPS.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.

- **HTTPS.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

<table>
<thead>
<tr>

Monitoring FTP Services

To monitor FTP services, the NetScaler appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected on both connections is it marked UP.

The NetScaler appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP monitor checks basic functionality; the FTP-EXTENDED monitor also verifies that the FTP server is able to transmit a file correctly.

<table>
<thead>
<tr>

</tbody>
</table>

To configure built-in monitors to check the state of FTP services, see Configuring Monitors in a Load Balancing Setup.
Monitoring SIP Services

A NetScaler ADC has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

<table>

</tbody>
</table>

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The following table summarizes the structure of SIP messages.

<table>
<thead>
<tr>
<th>Message type</th>
<th>Components</th>
<th>Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request</td>
<td>Method</td>
<td>Invite, Ack, Options, Bye, Cancel, Register</td>

</tr>
<tr>
<td>SIP version</td>
<td>SIP version</td>
<td>The SIP version being used</td>
</tr>
<tr>
<td>Response</td>
<td>SIP version</td>
<td>The SIP version that is being used.</td>
</tr>
</tbody>
</table>
The traffic in an SIP-based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages.

One of the most common uses for SIP is VoIP, where SIP is used to set up the session. The following diagram illustrates how the messages and entities in a SIP-based communication system interoperate.

![SIP Communication Diagram]

**Figure 1. How SIP Works**
The entity that initiates the call is referred to as the user agent (UA). The UA can be an SIP softphone (a PC-based application) or a SIP phone.

To initiate a call, the user agent sends an INVITE request to the previously configured SIP proxy server. The INVITE request contains the details of the destination, such as the destination uniform resource identifier (URI) and Call ID. In the diagram, the Caller A (user agent) sends an INVITE request to Proxy A.

When the proxy server receives the INVITE request, it sends a 100 (Trying) response to the user agent, Caller A. It also performs a DNS lookup to locate the SIP proxy server of the destination domain. After the SIP proxy server of the destination domain is located, the SIP proxy at the source domain sends the INVITE request to it. Here, Proxy A sends a 100 (Trying) response to Caller A and an INVITE request to Proxy B.

When the SIP proxy server of the destination domain receives the INVITE request from the SIP proxy server of the source domain, it responds with a 100 (Trying) response. It then sends the INVITE request to the destination user agent. In this case, Proxy B sends a 100 (Trying) response to Proxy A and an INVITE request to Caller B.

When the destination user agent receives the INVITE request, it alerts Caller B and responds with a 180 (ringing) response. This response is routed back to the source user agent through the proxies.

When caller B accepts the call, the destination user agent responds with a 200 (OK) response. This signifies that caller B has answered the call. This response is routed back to the source user agent through the proxies. After the call is set up, the user agents communicate directly without the proxies.

The following table describes the entities of a SIP-based communication system and their roles.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Agent (UA)</td>
<td>SIP user agents generate requests and respond to incoming requests. A user agent that generates requests is known as a User Agent Client (UAC). The user agent that responds to requests is known as the User Agent Server (UAS). In the preceding example, Caller A was the UAC and Caller B was the UAS.</td>
</tr>
<tr>
<td>Proxy Server</td>
<td>Proxies receive and route SIP requests based on the URI. They can selectively rewrite parts of the request message before forwarding it. They also handle registrations and invitations to user agents, and apply call policies.</td>
</tr>
<tr>
<td>Redirect Server</td>
<td>Redirect servers send routing information to the SIP proxy servers.</td>
</tr>
<tr>
<td>Registrar Server</td>
<td>Registrar servers provide location information to user agents and proxy servers.</td>
</tr>
<tr>
<td>Back-to-Back User Agent (B2BUA)</td>
<td>Back-to-Back User Agents (B2BUA) are combination of UAS and UAC.</td>
</tr>
</tbody>
</table>
You can configure the NetScaler appliance to load balance SIP requests to a group of SIP proxy servers. To do so, you need to create a load balancing virtual server with the load balancing method set to Call-ID hash, and then bind to it the services that are bound to the SIP proxies.

For load balancing to work, you must also configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

The NetScaler appliance can load balance SIP proxies in either a one-arm DSR configuration or an inline direct server return (DSR) configuration. In a one-arm DSR configuration, the appliance receives SIP requests from user agents and routes the requests to the appropriate SIP proxy by using the configured load balancing method. The SIP proxies send their responses to the destination SIP proxies, bypassing the appliance, as illustrated in the following diagram.

Figure 2. SIP in One-Arm Mode

The flow of requests and responses in this configuration is as follows:

- The user agent, Caller A, sends an INVITE request to the NetScaler. The NetScaler, using a load balancing method, routes the request to Proxy 2.
- Proxy 2 receives the INVITE request from the NetScaler and responds with a 100 (Trying) message.
- Proxy 2 performs a DNS lookup to obtain the IP address of the destination SIP proxy at domainB.com. It then sends the INVITE request to the destination proxy.
The destination proxy responds with a 100 (Trying) message and sends the INVITE request to the destination user agent, Caller B. The destination user agent, Caller B, begins to ring and responds with a 180 (Ringing) message. This message is sent to Caller A through the NetScaler and the Proxy 2. After the user accepts the call, Caller B responds with a 200 (OK) message that is propagated to Caller A through the NetScaler and the Proxy 2.

After Caller B accepts the call, the user agents (Caller A and Caller B) communicate independently.

In an inline DSR configuration, the appliance is placed between the router and the SIP proxy, as illustrated in the following diagram.

![Figure 3. SIP in Inline Mode](image)

The flow of requests and responses is as follows:

- The user agent, Caller A, sends an INVITE request to the appliance. The NetScaler, using a load balancing method, routes the request to Proxy 2.

- Proxy 2 receives the INVITE request from the appliance and responds with a 100 (Trying) message.

- Proxy 2 performs a DNS lookup to obtain the IP address of the destination SIP proxy at domainb.com. It then propagates the INVITE request to the destination proxy through the appliance.

- The appliance performs RNAT, and replaces the source IP address in the INVITE request with the NAT IP address, and then forwards the INVITE request to the destination SIP proxy.
The destination proxy responds with a 100 (Trying) message and sends the INVITE request to the destination user agent, Caller B. Caller B begins to ring and responds with a 180 (Ringing) message. This message is sent to Caller A through the NetScaler and the Proxy 2. After the user accepts the call, Caller B responds with a 200 (OK) message that is propagated to Caller A through the appliance and Proxy 2.

After the user accepts the call, the user agents (Caller A and Caller B) communicate independently.

<table>
<thead>
<tr>

<td>SIP method string, sent to the server. For example “OPTIONS sip:sip.test.”</td>
</tr>
<tr>
<td>sipregURI</td>
<td>SIP user to be registered.</td>
</tr>
</tbody>
</table>

To configure built-in monitors to check the state of SIP server, see Configuring Monitors in a Load Balancing Setup.
Monitoring RADIUS Services

The NetScaler appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

**Note:** RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.

- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td>radKey</td>
<td>Shared secret key value that the RADIUS server uses during client authentication.</td>
</tr>
<tr>
<td>radNASid</td>
<td>NAS-ID that is encapsulated in the payload when an access request is made.</td>
</tr>
<tr>
<td>radNASip</td>
<td>The IP address that is encapsulated in the payload when an access-request is made. When radNASip is not configured, the NetScaler sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.</td>
</tr>
</tbody>
</table>

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor will use for authentication to the RADIUS authentication database.

2. Add the IP address and secret key of the client to the appropriate RADIUS database.

3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the NetScaler appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all of the IP addresses.

**Caution:** If the IP address used by the appliance are not added to the RADIUS database, the RADIUS server will discard all packets.
To configure built-in monitors to check the state of RADIUS server, see Configuring Monitors in a Load Balancing Setup.
Monitoring DNS and DNS-TCP Services

The NetScaler appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007” If the DNS query succeeds, the service is marked as UP; otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN; otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.</td>
</tr>
<tr>
<td>queryType</td>
<td>The type of DNS query that is sent. Possible values: Address, Zone.</td>
</tr>
<tr>
<td>IPAddress</td>
<td>List of IP addresses that are checked against the response to the DNS monitoring probe.</td>
</tr>
<tr>
<td>IPv6</td>
<td>Select this check box if the IP address uses IPv6 format.</td>
</tr>
</tbody>
</table>

To configure the built-in DNS or DNS-TCP monitors, see Configuring Monitors in a Load Balancing Setup.
Monitoring LDAP Services

The NetScaler appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

You configure the LDAP monitor to define the search that it should perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server should start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDN</td>
<td>Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com.</td>
</tr>
<tr>
<td>bindDN</td>
<td>BDN name for the LDAP monitor.</td>
</tr>
<tr>
<td>filter</td>
<td>Filter for the LDAP monitor.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring LDAP servers.</td>
</tr>
<tr>
<td>attribute</td>
<td>Attribute for the LDAP monitor.</td>
</tr>
</tbody>
</table>

To configure the built-in LDAP monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring MySQL Services

The NetScaler appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Database that is used for the MySQL monitor.</td>
</tr>
<tr>
<td>sqlQuery</td>
<td>SQL query that is used for the MySQL monitor.</td>
</tr>
</tbody>
</table>

To configure built-in MySQL monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring SNMP Services

The NetScaler appliance has one built-in monitor that can be used to monitor SNMP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMPOID</td>
<td>OID that is used for the SNMP monitor.</td>
</tr>
<tr>
<td>snmpCommunity</td>
<td>Community that is used for the SNMP monitor.</td>
</tr>
<tr>
<td>snmpThreshold</td>
<td>Threshold that is used for the SNMP monitor.</td>
</tr>
<tr>
<td>snmpVersion</td>
<td>SNMP version that is used for load monitoring.  Possible Values: V1, V2.</td>
</tr>
</tbody>
</table>

To configure the built-in SNMP monitor, see Configuring Monitors in a Load Balancing Setup.
The NetScaler appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MySQL/POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MySQL/POP3/LDAP servers.</td>
</tr>
<tr>
<td>group</td>
<td>Group name to be queried for NNTP monitor.</td>
</tr>
</tbody>
</table>

To configure the built-in NNTP monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring POP3 Services

The NetScaler appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name POP3 server. This user name is used in the probe.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring POP3 servers.</td>
</tr>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
</tbody>
</table>

To configure the built-in POP3 monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring SMTP Services

The NetScaler appliance has one built-in monitor that can be used to monitor SMTP services: the SMTP monitor. It periodically checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. If the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>User name SMTP server. This user name is used in the probe.</td>
</tr>
<tr>
<td>password</td>
<td>Password used in monitoring SMTP servers.</td>
</tr>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP Address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
</tbody>
</table>

To configure the built-in SMTP monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring RTSP Servers

The NetScaler appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The NetScaler appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.
The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:

- If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.

- If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.

3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

   **Note:** The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.

4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.
The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
Monitoring RTSP Servers

2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:

   - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
   - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request may be sent to a different service.

3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.

5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtspRequest</td>
<td>The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.</td>
</tr>
<tr>
<td>respCode</td>
<td>Set of response codes that are expected from the service.</td>
</tr>
</tbody>
</table>

For instructions on configuring an RTSP monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring the XML Broker Services

The NetScaler appliance has a built-in monitor type, CITRIX-XML-SERVICE, with which you can create monitors to monitor the XML Broker services. The XML Broker services are used by Citrix XenApp. The monitor opens a connection to the service and periodically probes the XML services to which it is bound. If the server responds as expected within the configured time period, the monitor marks the service UP. If the service does not respond, or responds incorrectly, the monitor marks the service DOWN.

To configure a CITRIX-XML-SERVICE monitor, you need to specify the application name in addition to setting the standard parameters. The application name is the name of the application that has to be run to monitor the state of the XML Broker service. The default application is Notepad.

To configure monitors for XML Broker services, see "Configuring Monitors in a Load Balancing Setup."
Monitoring ARP Requests

The NetScaler appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP works with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring the Access Gateway

The NetScaler appliance has one built-in monitor that can be used to monitor a load-balanced Access Gateway: the CITRIX-AG monitor. This is in addition to two monitors for the Advanced Access Control login page and agent service page, which are described separately. The CITRIX-AG monitor periodically logs on to the Access Gateway service to which it is bound, and awaits the expected responses to its requests. If it receives the expected responses, it marks the service UP. If it receives no response or the wrong responses, it marks the service DOWN.

To configure monitoring of an Access Gateway, you must first create a local user and password for the monitor on the load balanced Access Gateway server that the service is bound to. After you configure the Access Gateway, you then configure the monitor. The monitor logs on to the Access Gateway using the realm and user name. For example, if you configured a realm of LDAP and a user name of user1, the Access Gateway logs on as LDAP/user1.

Note: RSA SecurID authentication is not supported for this monitor. RSA SecurID requires an RSA-generated token as a password, which is not supported on the NetScaler appliance.

<table>
<thead>

For instructions on configuring the CITRIX-AG monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring the Advanced Access Control Login Page

The NetScaler appliance has one built-in monitor that can be used to monitor the Advanced Access Control (AAC) login page on a load-balanced Access Gateway: the CITRIX-AAC-LOGINPAGE monitor. This monitor periodically logs on to the AAC login page via the Access Gateway service to which it is bound, and awaits the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>logonpointName</td>
<td>The URL from which users access corporate resources using the Access Gateway Advanced Edition. This setting controls access to server farms, the Access Interface configuration, and other session-specific settings. It can also be used as a filter within Access Gateway policies.</td>
</tr>
</tbody>
</table>

For instructions on configuring the CITRIX-AAC-LOGINPAGE monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring the Advanced Access Control Logon Agent Service Page

The NetScaler appliance has one built-in monitor that can be used to monitor the Advanced Access Control (AAC) agent service page on a load-balanced Access Gateway: the CITRIX-AAC-LAS monitor. The Logon Agent Service (LAS) is a service component of Advanced Access Control that requests authentication to the Authentication Service. This monitor periodically logs on to the AAC agent service page via the Access Gateway service to which it is bound, and awaits the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
<tr>
<td>lasVersion</td>
<td>The version number of the agent.</td>
</tr>
</tbody>
</table>

For instructions on configuring the CITRIX-AAC-LAS monitor, see Configuring Monitors in a Load Balancing Setup.
Monitoring the XenDesktop Delivery Controller Services

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and the XenDesktop Delivery Controller servers deployed by Citrix XenDesktop environment. The NetScaler provides a built-in monitor, CITRIX-XD-DDC monitor, which monitors the XenDesktop Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the XenDesktop Delivery Controller server.

The monitor sends a probe to the XenDesktop Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the XenDesktop Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

**Note:** Regardless of whether or not the user credentials (user name, password and domain) are specified on the CITRIX-XD-DDC monitor, the XenDesktop Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the XenDesktop servers, the CITRIX-XD-DDC monitor is automatically created and bound to the XenDesktop Delivery Controller services. If you do not use the wizard, add a monitor of the type CITRIX-XD-DDC.

- For instructions on using the wizard, see [Configuring the load balancing of XenDesktop](#).
- For instructions on adding a monitor, see [Creating Monitors](#).
- For instructions on binding a monitor to a service, see [Binding Monitors to Services](#).

**To add an XD-DDC monitor with the validate credentials option by using the command line interface**

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```
add lb monitor <monitorName> <monitorType> -userName <userName> -password <password> -ddcDomain <ddc_domain_name> -validateCred YES
```

```
show lb monitor <monitorName>
```
Monitoring the XenDesktop Delivery Controller Services

Example

> add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -password E12Dc35450a1 -ddcDomain dhop -validateCred YES
Done

> show lb monitor xdddcmon
1) Name......:xdddcmon Type......:CITRIX-XD-DDC State......: ENABLED

Standard parameters:
- Interval......:5 sec
- Retries.......:3
- Response timeout........:2 sec
- Down time........:30 sec
- Reverse.........:NO
- Transparent......:NO
- Secure.........:NO
- LRTM........:ENABLED
- Action.........:Not applicable
- Deviation......:0 sec
- Destination IP....:Bound service
- Destination port...:Bound service
- Iptunnel........:NO
- TOS........:NO
- TOS ID.........:0
- SNMP Alert Retries...:0
- Success Retries....:1
- Failure Retries....:0

Special parameters:
- User Name..........:”Administrator”
- Password...........:*****
- DDC Domain.........:”dhop”
Done

To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

set lb monitor <monitorName> <monitorType> -userName -password -ddcDomain <ddc_domain_name> -validateCred YES

Example

> set lb monitor XD_DDC_21.21.22.443_mn CITRIX-xd-ddc -userName Administrator -password D123S1R2A123 -validateCred YES
Done

Parameters for configuring a monitor

monitorName
Name to identify the monitor.

monitorType
Monitoring the XenDesktop Delivery Controller Services
Type of the monitor. For monitoring XenDesktop Delivery Controller servers, specify CITRIX-XD-DDC.

**userName**

User name of the user account authorized to log into the XenDesktop Delivery Controller server.

**password**

Password for the user account.

**ddcDomain**

Domain in which the XenDesktop Delivery Controller server is present.

**validateCred**

Verify the validity of the user credentials. Possible values: YES, NO. Default: NO

---

**To configure an XD-DDC monitor with the validate credentials option by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, do one of the following:
   - To add an XD-DDC monitor, click Add.
   - To modify an XD-DDC monitor, select the monitor, and click Open.

3. Type a name for the monitor.

4. Select the monitor type as CITRIX-XD-DDC.

5. On the Special Parameters tab, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor” as shown:
   - Validate Credentials—validateCred (To specify YES, select the check box.)
   - Name*—monitorName
   - Type*—monitorType
   - User Name*—userName
   - Password*—password
   - Domain Name*—ddcDomain
   *A required parameter

6. Click Create.

7. Select the new monitor, click Open, and verify the settings.
Monitoring Web Interface Services

In desktop virtualization, the NetScaler appliance can be used to load balance the Web Interface (WI) servers and Dynamic Desktop Controller (DDC) servers deployed in the Citrix XenApp and Citrix XenDesktop and environments. The NetScaler appliance has two built-in monitor types for monitoring the WI servers used in these environments.

A CITRIX-WEB-INTERFACE monitor can monitor the Web Interface services efficiently because it monitors a dynamic page at the location specified by the site path. The monitor checks for critical failures in resource availability.

When you configure a CITRIX-WEB-INTERFACE monitor, specify the site path to the location of the http page that displays the data collected by the monitor. To monitor the status of the service, in the specified site path, you can view the data updated dynamically by the monitoring script auth/nocookies.aspx.

**Note:** End the site path with a slash (/) to indicate that the monitored resource is dynamic.

**Note:** When you configure the WI-EXTENDED monitor, when specifying the site path, do not enter a slash (/) at the end of the path as the software internally adds a slash at the end of the path. For example, note the following command:

```
add monitor wi CITRIX-WI-EXTENDED -sitepath "/Citrix/DesktopWeb" -username aaa -password bbb -domain ccc
```

A CITRIX-WI-EXTENDED monitor verifies the logging process with the Web Interface service. This monitor accesses the login page and passes the user name, password, domain, and site path that were specified while configuring the monitor. It verifies the validity of the login credentials, correct configuration of the monitor (for example, the site path), and the connection with the IIS server.

**Note:** The CITRIX-WI-EXTENDED monitor is supported only for the .NET version of the WI servers. This monitor will not work for the JSP version of the WI servers.

If you use the wizard for configuring load balancing of the XenDesktop servers, a CITRIX-WEB-INTERFACE monitor is automatically created and bound to the WI services. The wizard adds and binds a CITRIX-WEB-INTERFACE monitor by default. If you want to add and bind a CITRIX-WI-EXTENDED monitor, select the Validate Credentials check box and type the necessary data. If you do not use the wizard, add a monitor corresponding to the WI services and bind it to each WI service that you create.

- For instructions on using the wizard, see Configuring XenDesktop for Load Balancing or Configuring XenApp for Load Balancing.
- For instructions on adding a CITRIX-WEB-INTERFACE monitor, see Creating Monitors.
- For instructions on binding a monitor to a service, see Binding Monitors to Services.
To add a WI monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> -sitePath <site_path> -dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName <username> -password <password> -domain <domain_name>
```

Examples

```
add lb monitor mwie CITRIX-WEB-INTERFACE -sitePath "/Citrix/XDWI/"

add lb monitor mwie CITRIX-WI-EXTENDED -sitePath "/Citrix/XDWI/"
-dispatcherIP 127.0.0.1 -dispatcherPort 3013 -userName administrator -password d83d154575d426 -encrypted -domain wi
```

Parameters for configuring WI monitors

- **monitorName**
  Name of the monitor.

- **monitorType**
  Type of the monitor. Type of monitor. For monitoring WI servers, specify CITRIX-WEB-INTERFACE or CITRIX_WI_EXTENDED.

- **sitePath**
  URL of the logon page.

- **password**
  Password for the user account. To view the dynamic page, this site path must end with a slash (/).

- **userName**
  User name of the user account authorized to log on to the WI server.

- **password**
  Password for the user account.

- **domain**
  Domain in which the WI server is present.
To add a WI monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, do one of the following:
   - To add a WI monitor, click Add.
   - To modify a WI monitor, select the monitor, and click Open.

3. Type a name for the monitor.

4. Select the monitor type as CITRIX-WEB-INTERFACE or CITRIX-WI-EXTENDED.

5. On the Special Parameters tab, type the site path. To configure the CITRIX-WI-EXTENDED monitor, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a monitor” as shown:
   - User Name*—userName
   - Password*—password
   - Domain Name*—domain

6. Click Create.

7. Select the new monitor, click Open, and verify the settings.
In addition to built-in monitors, you can use custom monitors to check the state of your services. The NetScaler appliance provides several types of custom monitors based on scripts that are included with NetScaler operating system that can be used to determine the state of services based on the load on the service or network traffic sent to the service. These are the inline monitors, user monitors, and load monitors.

With any of these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.
Configuring Inline Monitors

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTPINLINE and can only be configured to work with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

**Note:** Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the NetScaler appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured down time. After the DOWN time elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see Configuring Monitors in a Load Balancing Setup.
Understanding User Monitors

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the NetScaler appliance does not support. The following diagram illustrates how the user monitor works.

Figure 1. User Monitors

A user monitor requires the following components.

- **Dispatcher.** A process on the appliance that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a Web server that supports Common Gateway Interface (CGI). Such dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

  **Note:** You can configure the monitor and the dispatcher to use HTTPS instead of HTTP if you enable the “secure” option on the monitor and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

In a HA setup, the dispatcher runs on both the primary and secondary NetScaler appliances. The dispatcher remains inactive on the secondary appliance.
· **Script.** The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script may return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

The NetScaler appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the /nsconfig/monitors directory. If you want to add a new script, you add the script there. If you want to customize an existing script, you copy the script with a new name and modify the script.

For the scripts to function correctly, the name of the script file must not exceed 63 characters, and the maximum number of script arguments is 512. To debug the script, you must run it using the nsumon-debug.pl script from the NetScaler command line. You use the script name (with its arguments), IP address, and the port as the arguments of the nsumon-debug.pl script. Users must use the script name, IP address, port, time-out, and the script arguments for the nsumon-debug.pl script.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be executed. The dispatcher executes the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The appliance logs the error messages to the /var/nslog/nsumond.log file when user monitor probes fail. The following table lists the user monitors and the possible reasons for failure.

<table>
<thead>
<tr>
<th>User monitor type</th>
<th>Probe failure reasons</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SMTP</strong></td>
<td>Monitor fails to establish a connection to the server.</td>
</tr>
<tr>
<td><strong>NNTP</strong></td>
<td>Monitor fails to establish a connection to the server.</td>
</tr>
<tr>
<td></td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td></td>
<td>Monitor fails to find NNTP group.</td>
</tr>
<tr>
<td><strong>LDAP</strong></td>
<td>Monitor fails to establish a connection to the server.</td>
</tr>
<tr>
<td></td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td></td>
<td>Monitor fails to bind to the LDAP server.</td>
</tr>
<tr>
<td><strong>FTP</strong></td>
<td>Monitor fails to locate an entry for the target entity in the LDAP server.</td>
</tr>
<tr>
<td></td>
<td>The connection to the server times out.</td>
</tr>
<tr>
<td></td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td><strong>Log Item</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Login fails.</td>
<td></td>
</tr>
<tr>
<td>POP3</td>
<td>Monitor fails to establish a connection to the database.</td>
</tr>
<tr>
<td>SNMP</td>
<td>Monitor fails to establish a connection to the database.</td>
</tr>
<tr>
<td>RDP (Windows Terminal Server)</td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td>Login fails.</td>
<td></td>
</tr>
<tr>
<td>Preperation of SQL query fails.</td>
<td></td>
</tr>
<tr>
<td>Execution of SQL query fails.</td>
<td></td>
</tr>
<tr>
<td>POP3</td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td>SNMP</td>
<td>Missing or invalid script arguments, which may include an invalid number of arguments or argument format.</td>
</tr>
<tr>
<td>Preparation of SQL query fails.</td>
<td></td>
</tr>
<tr>
<td>Execution of SQL query fails.</td>
<td></td>
</tr>
</tbody>
</table>

You can view the log file from the NetScaler command line by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the NetScaler command prompt:

```bash
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
```

User monitors also have a time-out value and a retry count on failure of probes. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.
Note: If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.
How to Use a User Monitor to Check Web Sites

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

<table>
<thead>
<tr>
<th>HTTP response code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 - success</td>
<td>Probe success.</td>
</tr>
<tr>
<td>503 - service unavailable</td>
<td>Probe failure.</td>
</tr>
<tr>
<td>404 - not found</td>
<td>Script not found or cannot execute.</td>
</tr>
<tr>
<td>500 - Internal server error</td>
<td>Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.</td>
</tr>
<tr>
<td>400 - bad request</td>
<td>Error parsing HTTP request.</td>
</tr>
<tr>
<td>502 - bad gateway</td>
<td>Error decoding script's response.</td>
</tr>
</tbody>
</table>

You configure the user monitor for HTTP by using the following parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>scriptName</td>
<td>The path and name of the script to execute.</td>
</tr>
<tr>
<td>scriptArgs</td>
<td>The strings that are added in the POST data. They are copied to the request verbatim.</td>
</tr>
<tr>
<td>dispatcherIP</td>
<td>The IP address of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>dispatcherPort</td>
<td>The port of the dispatcher to which the probe is sent.</td>
</tr>
<tr>
<td>localfileName</td>
<td>The name of a monitor script file on the local system.</td>
</tr>
<tr>
<td>destPath</td>
<td>A particular location on the NetScaler appliance where the uploaded local file is stored.</td>
</tr>
</tbody>
</table>

To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.
Understanding the Internal Dispatcher

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

![Diagram of using a User Monitor with the Internal Dispatcher]

**Figure 1. Using a User Monitor with the Internal Dispatcher**

A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The NetScaler includes such a Perl script (nsftp.pl), in the `/nsconfig/monitors/` directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

**Figure 2. Using a User Monitor with an External Dispatcher**
A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.
To configure a custom user monitor, you must first write the script that performs the action that the monitor will use to check the service that is bound to it, and upload the script to the /home/user directory on the NetScaler appliance. Then you create the monitor on the appliance, as described below.

To configure a user monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> USER -scriptname <NameOfScript> -scriptargs <Arguments>
```

Example

```
add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file=/home/user/sample.txt;user=root;password=passwd"
```
Understanding Load Monitors

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The NetScaler appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

![Figure 1. Operation of Load Monitors](image)

**Note:** The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These
metrics cannot be changed.

- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

<table>
<thead>
<tr>
<th>Metric name</th>
<th>OIDs</th>
<th>Weight</th>
<th>Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>1.2.3.4</td>
<td>2</td>
<td>70</td>
</tr>
<tr>
<td>Memory</td>
<td>4.5.6.7</td>
<td>3</td>
<td>80</td>
</tr>
<tr>
<td>Connections</td>
<td>5.6.7.8</td>
<td>4</td>
<td>90</td>
</tr>
</tbody>
</table>

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.
Configuring Load Monitors

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see Creating Monitors. Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

- `add lb metricTable <metricTableName>`
- `bind lb metricTable <metricTableName> <metric> <SNMPOID>`

Example

```
add metricTable Table-Custom-1
bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

Parameters for configuring load balancing metric tables

- `metricTableName`

  Name of the metric table. This alphanumeric string is required and cannot be changed after the metric table is created. The name must not exceed 31 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

- `metric`

  The name of the metric that you are binding to the metric table.

- `SNMPOID`

  The SNMP OID for the metric that you are binding to the metric table.
To create a metric table and bind metrics to it by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Metric Tables.

2. In the details pane, click Add.

3. In the Create Metric Table dialog box, in the Metric Table Name text box, type the name of the metric table (for example, Table-Custom-1).

4. Click Create.

5. In the details pane, select the metric table that you just created (for example, Table-Custom-1), and then click Open.

6. In the Configure Metric Table dialog box, in the Metric and SNMP OID text boxes, type the metric and SNMP OID for the metric table (for example, 1.3.6.1.4.1.5951.4.1.1.41.1.5 and 11).

7. Click Add.

8. Click Close. The metric table you created appears in the Metric Tables pane.
Unbinding Metrics from a Metrics Table

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

**To unbind metrics from a metric table by using the command line interface**

At the command prompt, type:

```bash
unbind lb metricTable <metricTable> <metric>
```

**Example**

```bash
unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
```

**To unbind metrics from a metric table by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Metric Tables.

2. In the details pane, select the metric table from which you want to unbind the metrics (for example, Table-Custom-1), click Open.

3. In the Configure Metric Table dialog box, in the Bound Metrics list box, select the metric that you want to unbind from the table (for example, 1.3.6.1.4.1.5951.4.1.1.41.1.5).

4. Click Remove, and then click OK.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.
Removing a Load Monitoring Metric Table

You can remove a metric table from the NetScaler configuration.

**Note:** Before you can remove a metric table, you must unbind all metrics from it.

**To remove a metric table by using the command line interface**

At the command prompt, type:

```
rm lb metricTable <metricTable>
```

**Example**

```
rm metricTable <Table-Custom-1>
```

**To remove a metric table by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Metric Tables.

2. In the details pane, select the metric table that you want to remove (for example, Table-Custom-1), and click Remove.

3. In the Remove dialog box, and then click Yes.

You can unbind a metric from a metric table to remove that metric from consideration.
Viewing Metrics Tables

You can view a metrics table and the metrics bound to it.

To view the metric tables by using the command line interface

At the command prompt, type:

show lb metricTable <metricTable>

Example

show metricTable Table-Custom-1

To view the metric tables by using the configuration utility

1. In the navigation pane, expand Load Balancing.

2. Click Metric Tables. The details of the available metric table appear on the Metric Tables pane.
Configuring Monitors in a Load Balancing Setup

To configure monitors on a Web site, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. (For more information about creating custom monitors, see Custom Monitors.) Once you have chosen or created a monitor, you then bind it to the appropriate service. The following conceptual diagram illustrates a basic load balancing setup with monitors.

![Diagram of load balancing setup with monitors](image)

Figure 1. How Monitors Operate

As shown above, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server should fail to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.
Creating Monitors

The NetScaler appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <monitorType> [interval]
```

Example

```
add lb mon monitor-HTTP-1 HTTP
add lb mon monitor-HTTP-2 TCP 2
```

Parameters for configuring monitors

- **monitorName**
  
  Name of the monitor. This alphanumeric string is required and cannot be changed after the monitor is created. The name must not exceed 31 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

- **Type**
  
  Type of monitor. The valid options for this parameter are: PING, TCP, HTTP, TCP-ECV, HTTP-ECV, UDP-ECV, DNS, FTP, LDNS-PING, LDNS-TCP, LDNS-DNS, RADIUS, USER, HTTP-INLINE, SIP-UDP, LOAD, FTP-EXTENDED, SMTP, SNMP, NNTP, MYSQL, LDAP, POP3, CITRIX-XML-SERVICE, CITRIX-WEB-INTERFACE, DNS-TCP, RTSP, ARP, CITRIX-AG, CITRIX-AAC-LOGINPAGE, CITRIX-AAC-LAS, CITRIX-XD-DDC, ND6, MYSQL-ECV | MSSQL-ECV, CITRIX-WI-EXTENDED.

- **interval**
  
  Frequency at which the probe is sent to a service. The interval must be greater than the response time-out. Possible values: 1 millisecond-160 seconds. Default: 5 seconds.
To create a monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, click Add.

3. In the Create Monitor dialog box, in the Name and Interval text boxes type the name and interval value of the monitor.

4. In the Type list, select the type of the monitor.

5. In the list next to the Interval text box, select Seconds.

6. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.
Binding Monitors to Services

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN. If you bind multiple monitors to a service, the NetScaler appliance checks all monitors bound to that service using a calculation that you control, and marks the service UP or DOWN depending on the results.

**Note:** The destination IP address of a monitor probe can be different than the server IP address and port.

### To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

**Example**

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

### To bind a monitor to a service by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service for which you want to bind the monitor (for example, Service-HTTP-1), and then click Open.

3. On the Monitors tab, in the Available list box, select the monitor you want to bind the service (for example, monitor-HTTP-1), and then click Add.

4. In the Configured box, click OK.
Modifying Monitors

You can modify the settings for any monitor that you created.

**Note:** Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <interval> -resptimeout <resptimeout>
```

**Example**

```
set mon monitor-HTTP-1 HTTP -interval 50 milli -resptimeout 20 milli
```

Parameters for modifying monitor settings

**LRTM**

State of the response time calculation of probes. Possible values: ENABLED and DISABLED. Default: DISABLED.

**deviation**

Deviation from the learned response time for dynamic response time monitoring. The maximum value is 348 minutes.

**interval**

Duration of the interval for which the NetScaler appliance waits before it marks the probe as failed. The response time-out must be less than the value specified in the interval parameter.

The UDP-ECV monitor type does not decide the probe failure using the response time-out. The appliance considers the probe as successful for the UDP-ECV monitor type when the server response matches the criteria that the send and receive options set, or if the response is not received from the server.

The send option specifies the data that must be sent to the server in the probe, and the receive option specifies the server response criteria for the probe to succeed. The
unreachable error from the service causes probe failure. The minimum value is 10 milliseconds. The maximum value is 159 seconds. The default value is 2 seconds.

**resptimeout**

Monitor response time-out threshold. If the response time for the monitoring probes exceeds the threshold, a trap is sent. The response time-out is given as a percentage. The minimum value is 1 and the maximum value is 100.

**retries**

Number of consecutive probe failures after which the NetScaler appliance determines the service as DOWN. Possible Values: 3 - 127. Default: 3.

**successRetries**

Number of consecutive successful retries that are required to mark the state of the service as UP. For example, if you set the success retries to 3, when 3 probes succeed consecutively, the service is marked as UP. Possible Values: 1-32. Default: 1.

**failureRetries**

Number of failed probes that are required to mark the state of the service as DOWN. By default, the NetScaler appliance requires a specific number of consecutive retry failures to mark the state of the service as DOWN. The minimum value for this parameter is 0 and maximum value is 32. The default value is 0. For example, if you set the retries to 10 and the failure retries to 3, when 3 retry probes fail, the service is marked as DOWN.

**alertRetries**

The number of probe failures after which the NetScaler appliance generates an SNMP trap named MonProbeFailed. This parameter is closely linked to the Retries parameter. For example, if you set Retries to ten and SNMP Alert Retries to three, the appliance generates a MonProbeFailed trap when it detects a third probe failure. You can then take corrective action. However, if the problem is not corrected, the appliance marks the service as DOWN after the tenth probe failure.

You need to set the SNMP Alert Retries parameter to a value lower than the Retries parameter.

**Note:** The monitor probe failures need not be consecutive.

Possible Values: 0-32. Default: 0.

**downTime**

Wait duration until the next probe after the service is marked down. Possible Values: 10-160 seconds. Default: 30 seconds.

**destIP**

IP address to which the probe is sent. If the destination IP address is set to 0, the destination IP address is set to the bound service. Default: 0.0.0.0.

**destPort**
TCP/UDP port to which the probe is sent. If the destination port is set to 0, the destination port is the port of the service to which the monitor is bound. For a USER monitor, this port is the port sent in the HTTP request to the dispatcher. This option is ignored if the monitor is of the PING type. For information about user monitors, see Understanding User Monitors.

**state**

State of the monitor. If the monitor is disabled, this monitor type probe is not sent for the services. If the monitor is bound, the state of this monitor is not considered when the state of the service is determined. Possible values: ENABLED and DISABLED. Default: ENABLED.

**reverse**

Mark a service as DOWN, instead of UP, when probe criteria are satisfied, and as UP instead of DOWN when probe criteria are not satisfied. Possible values: YES, NO. Default: NO.

**transparent**

The monitor is bound to a transparent device such as a firewall or router. The state of a transparent device depends on the responsiveness of the services behind it. If a transparent device is being monitored, a destination IP address must be specified. The probe is sent to the specified IP address by using the MAC address of the transparent device. Possible values: YES, NO. Default: NO.

**secure**

State of the secure monitoring of services. SSL handshake is performed on the established TCP connection. Applicable for TCP-based monitors only. Possible values: YES and NO. Default: NO.

**application**

Name of the application that must be executed to check the state of the service.

**sitePath**

URL of the logon page.
To modify an existing monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, select the monitor that you want to modify (for example, monitor-HTTP-1), and then click Open.

3. On the Standard Parameters tab, in the Interval and Response Time-out text boxes, type the interval and response timeout values (for example, 50 and 20).

4. In the list next to Interval text box, select the interval (for example, Milli Seconds).

5. In the list next to Response Time-out text box, select the interval (for example, Milli Seconds).

6. Click OK.
Enabling and Disabling Monitors

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the command line interface

At the command prompt, type:

`enable lb monitor <monitorName>`

Example

`enable lb mon monitor-HTTP-1`

To enable a monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, select the monitor that you want to enable (for example, `monitor-HTTP-1`), and then click Enable.

3. In the Enable dialog box, click Yes.

To disable a monitor by using the command line interface

At the command prompt, type:

`disable lb monitor <monitorName>`

Example

`disable lb mon monitor-HTTP-1`
To disable a monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, select the monitor that you want to disable (for example, monitor-HTTP-1), and then click Disable.

3. In the Disable dialog box, click Yes.
Unbinding Monitors

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

**Note:** When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

**To unbind a monitor from a service by using the command line interface**

At the command prompt, type:

`unbind lb monitor <monitorName>`

**Example**

`unbind mon monitor-HTTP-1 Service-HTTP-1`

**To unbind a monitor from a service by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, select the service from that you want to unbind the monitor (for example, Service-HTTP-1), click Open.

3. In the Configure Service dialog box, under Configured, select the monitor that you want to unbind from the service (for example, monitor-HTTP-1), and then click Remove.

4. Click OK.
Removing Monitors

After you unbind a monitor that you created from its service, you can remove that monitor from the NetScaler configuration. (If a monitor is bound to a service, it cannot be removed.)

**Note:** When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

**To remove a monitor by using the command line interface**

At the command prompt, type:

```
rm lb monitor <monitorName> <type>
```

**Example**

```
rm lb monitor monitor-HTTP-1 HTTP
```

**To remove a monitor by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, select the monitor that you want to remove (for example, monitor-HTTP-1), and then click Remove.

3. In the Remove dialog box, click Yes.
Viewing Monitors

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your NetScaler configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the command line interface

At the command prompt, type:

```
show lb monbindings <MonitorName>
```

Example

```
show lb monbindings monitor-HTTP-1
```

To view monitor bindings by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, select the monitor for which you want to view the binding information (for example, monitor-HTTP-1), and then click Show Bindings. The binding information for the monitor that you selected appears in the Binding Info for Monitor: monitor-HTTP-1 dialog box.

To view monitors by using the command line interface

At the command prompt, type:

```
show lb monitor <monitorName>
```

Example

```
show lb mon monitor-HTTP-1
```
To view monitors by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors. The details of the available monitors appear on the Monitors pane.
Closing Monitor Connections

The NetScaler appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the NetScaler and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP monitors, you can configure the NetScaler to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

**Note:** The monitorConnectionClose setting is applicable to all the monitors bound to all the services configured on the NetScaler appliance.

To configure monitor-connection closure by using the command line interface

At the command prompt, type:

```
set lb parameter -monitorConnectionClose <monitor_conn_close_option>
```

**Example**

```
set lb parameter -monitorConnectionClose RESET
```

Parameter for configuring monitor-connection closure

**monitorConnectionClose**

Close (reset) a monitor-probe connection after receiving SYN-ACK from the service, or complete (finish) the handshake before closing the connection. Possible values: RESET, and FIN. Default: FIN.
To configure monitor-connection closure by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. Under Settings, click Configure Load Balancing Parameters.

3. In the Configure Load Balancing Parameters dialog box, for Connection Close for Monitor, select FIN or RESET.

4. Click OK.
Ignoring the Upper Limit on Client Connections for Monitor Probes

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the NetScaler appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the NetScaler to skip this check when it sends monitor-probe connections to a service.

**Note:** You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the NetScaler appliance.

To set the Skip MaxClients for Monitor Connections option by using the command line interface

At the command prompt, type:

```
set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
```

**Example**

```
set lb parameter -monitorSkipMaxClient enabled
```

Parameter for skipping the maximum-client-connections check

**monitorSkipMaxClient**

For monitor-probe connections, ignore any maximum-client-connections limits that have been specified for the services being monitored. Possible values: ENABLED and DISABLED. Default: DISABLED.
To set the Skip MaxClients for Monitor Connections option by using the configuration utility

1. In the navigation pane, click Load Balancing.

2. Under Settings, click Configure Load Balancing Parameters.

3. To ignore the upper limit on client connections for monitor probes, in the Configure Load Balancing Parameters dialog box, select the Skip MaxClients for Monitor Connections checkbox.

4. Click OK.
Troubleshooting

I created a user script for monitoring but it is not working.

**Resolution:** Check the number of arguments in the script. The maximum number of arguments that a script can have is 512. If the number of arguments is more than 512, the script may not work properly. Use the nsumon-debug.pl script from the NetScaler command line to debug the script.

I see a lot of monitor probes and they seem to be increasing the network traffic unnecessarily. Is there a way to turn off the monitor probes?

**Resolution:** You can turn off the monitor probe connections. To turn off the monitor probe connections, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor probe connection to go through the complete process, set the value to FIN.

I have monitors setup for services, still connections are directed to servers which are DOWN.

**Resolution:** This probably happens because the probe interval of monitors is long. If a service goes down between two probes, NetScaler appliance does not know about the state of the service and hence would still direct the connection to the service. You, can reduce the time interval for monitor probe.
Managing a Large Scale Deployment

The NetScaler appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.
Ranges of Virtual Servers and Services

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  **Note:** The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

  For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.
Creating a Range of Virtual Servers

You create a range of virtual servers as described below.

To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

- `add lb vserver <name>@<protocol> -range <rangeValue> <IPAddress> [<port>]`
- `add lb vserver <name>@[<rangeValue>] <protocol> <IPAddress[<rangeValue>]> [<port>]`

Example

```
add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
```

OR

```
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
Done
```

Parameters for configuring virtual server ranges

**vServerName**

Name of the first virtual server in the range. If you use the second form of this command, you bracket the portion of the vServerName that contains the range.

**Note:** This command returns an error if the vServerName and IPAddress ranges that you define differ in number of entities.

**protocol**

The protocol of the virtual server.

**rangeValue**

The number of entities in the range that you are creating.

**Note:** Do not use `-range` and the `[ ]` range operator in the same command.

**IPAddress**
Creating a Range of Virtual Servers

The IP address at the beginning of the range that you are defining. If you use the second form of this command, you bracket the portion of the IP address that contains the range.

**port**

The port of the virtual servers.

To create range of virtual servers by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add Range.

3. In the Create Virtual Server (Load Balancing) - Range dialog box, in the Name Prefix, IP Address Range, and Port text boxes, type the virtual server name, IP address with which to begin the range, and port.

4. Select the Network VServer check box, and in Range, type the last value of the virtual server range.

5. In the Protocol drop-down list box, select the protocol type.

6. Click Create, and then click Close. The range of virtual servers you created appears in the Load Balancing Virtual Servers pane.
Creating a Range of Services

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the command line interface

At the command prompt, type the command:

```
add service <name>@[IP]@[protocol] <port>
```

Example

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
Done
```

Parameters for configuring service ranges

**serviceName**

Name of the first service in the range. If you use the second form of this command, you bracket the portion of the serviceName that contains the range.

*Note:* This command returns an error if the serviceName and IPAddress ranges that you define differ in number of entities.

**protocol**

The protocol of the service.

**rangeValue**

The number of entities in the range that you are creating.

*Note:* Do not use `-range` and the `[ ]` range operator in the same command.

**IPAddress**

The IP address at the beginning of the range that you are defining. If you use the second form of this command, you bracket the portion of the IP address that contains the range.
Creating a Range of Services

port

The port of the services.

**To create range of services by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add Range.

3. In the Create Service (Range) dialog box, in the IP Address Range and Port text boxes, type the start value of the IP address range and the port.

4. In the text box next to the IP Address Range text box, type the last value of the last service (for example, 104).

5. In the Protocol drop-down list box, select the protocol type.

6. Click Create, and then click Close. The range of services you created appears in the Services pane.
Configuring Service Groups

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the NetScaler appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the NetScaler learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

**Note:** If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the NetScaler. A domain name will be resolved into an IP address only if the corresponding address record is present on the NetScaler or the name server.
Creating Service Groups

You can configure up to 4096 service groups on the NetScaler appliance.

To create a service group by using the command line

At the command prompt, type:

`add servicegroup <ServiceGroupName> <Protocol>`

Example

`add servicegroup Service-Group-1 HTTP`

Parameters for creating service groups

**serviceName**

Name of the service group. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

**Protocol**

Type of service in this group. The valid options are: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, RDP.

To create a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.
2. In the details pane, click Add.
3. In the Create Service Group dialog box, in the Service Group Name text box, type name of the service group.
4. In the Protocol list, select the protocol type.
5. Click Create, and then click Close. The service group you created appears in the Service Groups pane.
Binding a Service Group to a Virtual Server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name>@<serviceGroupName>
```

Example

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

To bind a service group to a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the service group, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Services Groups tab.
4. In the Active column, select check box next to the service group that you want to bind to the virtual server (for example, Service-Group-1), and then click OK.
Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
```

**Examples**

```
bind servicegroup Service-Group-1 10.102.29.30 80
bind servicegroup Service-Group-2 1000:0000:0000:0005:0600:700a:888b 80
bind servicegroup CitrixEdu s1.citrite.net
```
To add members to a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, select the service group to which you want to bind members, and then click Open.

3. In the Configure Service Group dialog box, under Specify Member(s), do one of the following:
   - To add a new IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.
     If you want to add a domain-name based service group member, select Server Based. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

4. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box.

   **Note**: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.

5. Click OK.
Binding a Monitor to a Service Group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:

`bind serviceGroup <serviceGroupName> -monitorName <string> -monState ( ENABLED | DISABLED)`

Example

`bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1`

To bind a monitor to a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.
2. In the details pane, select the service group for which you want to bind monitors, and then click Open.
3. On the Monitors tab, under Available, select a monitor name.
4. Click Add, and then click OK.
Managing Service Groups

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group.
Modifying a Service Group

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

**Note:** A parameter you set for a service group is applied to the member servers in the group, not to individual services.

**To modify a service group by using the command line interface**

At the command prompt, type the following command with one or more of the optional parameters:

```
set servicegroup <serviceGroupName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)] [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (YES|NO)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)]
```

**Example**

```
set servicegroup Service-Group-1 -type TRANSPARENT
set servicegroup Service-Group-1 -maxClient 4096
set servicegroup Service-Group-1 -maxReq 16384
set servicegroup Service-Group-1 -cacheable YES
```

**Parameters for modifying service groups**

**type**

Cache server supports the cache type option. Possible values: TRANSPARENT, REVERSE, and FORWARD.

**maxClient**

Maximum number of open connections to each service in the service group. The default value is 0. The maximum value is 4294967294.
maxReq

Maximum number of requests that can be sent over a persistent connection to a service in the service group. The default value is 0. The minimum value is 0. The maximum value is 65535.

cacheable

Whether a virtual server used for load balancing or content switching feature routes a request to the virtual server (used in transparent cache redirection) on the same appliance before sending it to the configured servers. The virtual server used for transparent cache redirection determines if the request is directed to the cache servers or the configured servers. Do not specify this argument if a cache type is specified. By default, this argument is disabled. Possible values: YES and NO. Default: NO.

cip

Enables or disables insertion of the Client IP header for services in the service group. Possible values: ENABLED and DISABLED. Default: DISABLED.

cipHeader

Client IP header. If client IP insertion is enabled and the client IP header is not specified, then the NetScaler sets the value of the Client IP header.

usip

Use of the client IP address as the source IP address while connecting to the server. By default, the appliance uses a mapped IP address for its server connection. However, with this option, you can tell the appliance to use the client's IP address when it communicates with the server. Possible values: yes and no. Default: no.

sc

The state of SureConnect on this service group. This parameter is supported for legacy purposes only; it has no effect, and the only valid value is OFF. Possible values: ON and OFF. Default: OFF.

sp

Whether surge protection needs to be enabled on this service group. Possible values: ON and OFF. Default: OFF

cltTimeout

Idle time in seconds after which the client connection is terminated. Default: 180. Maximum value: 31536000.

svrTimeout

Idle time in seconds after which the server connection is terminated. The default value is 360. The maximum value is 31536000.

CKA
State of the client keep-alive feature for the services in the service group. Possible values: YES and NO. Default: NO.

TCPB

State of the TCP Buffering feature for the services in the service group. Possible values: YES and NO. Default: NO.

CMP

State of the HTTP Compression feature for the services in the service group. Possible values: YES and NO. Default: NO.

maxBandwidth

Positive integer that identifies the maximum bandwidth in kilobits allowed for the services in the service group.

maxThreshold

Monitoring threshold. The default value is 0. The minimum value is 0 and maximum value is 65535.

state

State of the service group after it is added. Possible values: ENABLED and DISABLED. Default: ENABLED.

DownStateFlush

Delayed cleanup of connections on this service group. Possible values: ENABLED and DISABLED. Default: ENABLED.

Note: Any parameter you set on the service group is applied to the member servers in the group, not to individual services.

To modify a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, select the service group that you want to modify (for example, Service-Group-1), and then click Open.

3. Change any of the parameters described in "Parameters for modifying service groups," and then click OK.
Removing a Service Group

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the NetScaler.

To remove a service group by using the command line interface

At the command prompt, type:

```
rm servicegroup <ServiceGroupName>
```

Example

```
rm servicegroup Service-Group-1
```

To remove a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, select the service group that you want to remove (for example, Service-Group-1), and then click Remove.

3. In the Remove dialog box, click Yes.
Unbinding a Member from a Service Group

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retains its individual settings, however, and continues to exist on the NetScaler.

To unbind members from a service group by using the command line interface

At the command prompt, type:

unbind servicegroup <serviceGroupName> <IP>@ [<port>]

Example

unbind servicegroup Service-Group-1 10.102.29.30 80

To unbind members from a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.
2. In the details pane, select the service group from which you want to unbind members, and then click Open.
3. In the Configure Service Group dialog box, in the Configured Members list box, select a service.
4. Click Remove, and then click OK.
Unbinding a Service Group from a Virtual Server

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the NetScaler appliance.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

unbind lb vserver <name>@<ServiceGroupName>

Example

unbind lb vserver Vserver-LB-1 Service-Group-1

To unbind a service group from a virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the virtual server from which you want to unbind the service group, and then click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, click the Services Group tab.

4. Clear the Active check box next to the service group that you want to unbind from the virtual server (for example, Service-Group-1).

5. Click OK.
Unbinding Monitors from Service Groups

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
unbind serviceGroup <serviceGroupName> -monitorName <string>
```

Example

```
unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
```

To unbind a monitor from a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.
2. In the details pane, select the service group from which you want to unbind the monitor, click Open.
3. In the Configure Service Group dialog box, click the Monitors tab.
4. Under Configured, select the monitor that you want to unbind from the service group, and then click Remove.
5. Click OK.
Enabling or Disabling a Service Group

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

disable servicegroup <ServiceGroupName>

Example

disable servicegroup Service-Group-1

To disable a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the Service Groups pane, select the service group that you want to disable, and then click Disable.

3. In the Wait Time dialog box type the wait time value.

4. Click Enter.

To enable a service group by using the command line interface

At the command prompt, type:

enable servicegroup <ServiceGroupName>

Example
enable servicegroup Service-Group-1

To enable a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the Service Groups pane, select the service group that you want to enable (for example, Service-Group-1), and then click Enable.

3. In the Enable dialog box, click Yes.
Viewing the Properties of a Service Group

You can view the following settings of the configured service groups: name, IP address, state, protocol, maximum client connections, maximum requests per connection, maximum bandwidth, and monitor threshold. Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

- show servicegroup <ServiceGroupName>
- show servicegroup <ServiceGroupName> -includemembers

Example

show servicegroup Service-Group-1

To view the properties of a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, click the name of the service group whose properties you want to view, and then click Open.
Viewing Service Group Statistics

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The NetScaler appliance uses the statistics of a service group, such as these, to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

```
stat servicegroup <ServiceGroupName>
```

Example

```
stat servicegroup Service-Group-1
```

To view the statistics of a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, select the service group for which statistics you want to view (for example, Service-Group-1), and then click Statistics. The statistics of the service group you selected appear in a new window.
Load Balancing Virtual Servers Bound to a Service Group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
show servicegroupbindings <serviceGroupName>
```

Example

```
> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State : ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
> 
```

Parameters

- **serviceGroupName**
  
  Indicates the name of the service group whose bindings you want to view.
To display the virtual servers bound to a service group by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. Select a service group, and then click Show Bindings. The Binding details for Service Group box then displays all the load balancing virtual servers bound to the selected service group.
A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind additional domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see Adding a Name Server.
- Add a domain based server. For information about adding a domain based server, see Adding a Server.
- Add a service group and associate the domain based server to the service group, with the autoscale option set to DNS. For information about adding a service group, see Configuring Service Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name that resolved successfully in the past results in an \texttt{NXDOMAIN} response, all
the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

- bind serviceGroup <serviceGroupName> <serverName> <port> -autoScale (YES | NO)
- show serviceGroup <serviceGroupName>

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

> bind serviceGroup servGroup server1 80 -autoScale YES
Done
> sh servicegroup servGroup
servGroup - HTTP
State: ENABLED  Monitor Threshold : 0

1) 192.0.2.31:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1
    Monitor Name: tcp-default State: UP
    Probes: 2 Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.

2) 192.0.2.32:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1
    Monitor Name: tcp-default State: UP
    Probes: 2 Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.

3) 192.0.2.36:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1
    Monitor Name: tcp-default State: UP
    Probes: 2 Failed [Total: 0 Current: 0]
    Last response: Success - TCP syn+ack received.

4) 192.0.2.55:80 State: UP Server Name: server1 (Auto scale) Server ID: None Weight: 1
Configuring Automatic Domain Based Service Group Scaling

Monitor Name: tcp-default       State: UP
Probes: 2       Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

5)   192.0.2.80:80   State: UP   Server Name: server1 (Auto scale)   Server ID: None Weight: 1

Monitor Name: tcp-default       State: UP
Probes: 2       Failed [Total: 0 Current: 0]
Last response: Success - TCP syn+ack received.

Done

Parameters for configuring a service group to scale automatically

serviceGroupName

The name of the service group to which you want to bind the domain based server.

serverName

The name of the domain based server that you want to bind to the service group.

Port (Port)

The port to which clients must connect.

Autoscale (Auto Scale)

Scale the size of a service group automatically on the basis of the IP addresses that are returned by name resolution process for the domain based server.
To configure a service group to scale automatically by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Service Groups.

2. In the details pane, do one of the following:

   - To create a domain based service, click Add.
   - To bind a domain based server to an existing service group, click the name of the service group, and then click Open.

3. In the Create Service Group or Configure Service Group dialog box, set the following parameters:

   - Server Based (Specifies that you want to bind a domain based server to the service group. A list that contains all the IP addresses and servers configured on the NetScaler appliance appears. Select the domain based server that you want.)
   - Port
   - Auto Scale

   After you set the parameters, to bind the server to the service group, click Add.

4. Click Create or OK, and then click Close.
Translating the IP Address of a Domain-Based Server

To simplify maintenance on the NetScaler appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

**Note:** Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
add server <name>@<serverDomainName> -translationIp <translationIPAddress> -translationMask <netMask> -state <ENABLED|DISABLED>
```

**Example**
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -translationMask 255.255.0.0 -state ENABLED

Parameters for configuring translation IP addresses

**serverName**

Name of the domain-based server.

**serverDomainName**

Server’s domain name (for example, www.example.com).

Note that for IP address translation, the domain name is required.

**translationIP**

IP address (relevant octets only) to which the resolved IP for the server needs to be translated (for example, 11.12.0.0).

**translationMask**

Mask determines the number of bits in the translation IP address that are to be considered when applying the transformation.

For example, if you want an original server IP of 10.20.30.40 to be translated to 11.12.30.40, you could specify the mask 255.255.0.0.

To configure a translation IP address for a server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Servers.
2. In the details pane, click Add.
3. In the Create Server dialog box, in the Server Name field, enter a name.
4. In the IP Address / Domain Name field, enter the server’s domain name.
   
   **Note:** Do not enter an IP address if you are entering a mask.
5. In the Translation IP Address field, enter the IP address of a server on the same subnet.
6. In the Translation Mask field, enter a valid mask (for example, 255.255.0.0).
7. Click Create.
Masking a Virtual Server IP Address

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works somewhat differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Additionally, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

**Note:** The NetScaler appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
· Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it will be sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <ipMask> <listenPort>
```

Example

Pattern matching based on prefix octets:

```
add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask 255.255.0.0 80
```

Pattern matching based on trailing octets:

```
add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask 0.0.255.255 80
```

Modify a pattern-based virtual server:

```
set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
```

Parameters for masking virtual server IP addresses

- **name**
  
  Name of the load balancing virtual server.

- **http**
  
  Value of HTTP

- **port**
  
  Listen port for the virtual server.

- **Pattern Based**
  
  (Configuration utility only.) Option to select if the virtual server is to be pattern-based.

- **ippattern**
IP address pattern for the virtual server. You must supply either the initial or the trailing octets (for example, 11.11.00.00).

ipmask

Network mask for the IP address. Non-zero values indicate the IP address octets that are to be passed through. (For example, for an IP address pattern of 11.11.00.00, you might specify a mask of 255.255.0.0).

Note: You cannot convert a virtual server with a fixed IP address to a pattern-based virtual server, and you cannot convert a pattern-based virtual server to one with a fixed IP address.

To configure a virtual server IP address mask by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server dialog box, in the Name field, enter a name.

4. In the Protocol field, select the protocol.

5. In the Port field, enter the listen port.

6. In the IP Pattern field, enter a pattern for an IP address. The fixed part of the pattern must be entered in contiguous octets. Enter zeros for the pattern values that can vary in the IP address.

7. In the IP Mask field, enter a standard network mask. Use non-zero mask values for the portion of the IP address that constitutes the fixed part of the pattern.
Configuring Load Balancing for Commonly Used Protocols

In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your NetScaler appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.
Load Balancing for a Group of FTP Servers

The NetScaler appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

![Diagram of basic load balancing topology for FTP servers]

**Figure 1. Basic Load Balancing Topology for FTP Servers**

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client’s connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.
The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

![Load Balancing FTP Servers Entity Model](image)

Figure 2. Load Balancing FTP Servers Entity Model

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

To create FTP monitors by using the command line interface

At the command prompt, type:
add lb monitor <FTPMonitorName> -interval <Interval> -userName <UserName> -password <Password>

Example

add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password User

To create FTP monitors by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. On the Standards Parameters tab, in the Name and Interval text boxes, type the monitor name and interval.

4. In the Type list, select FTP.

5. On the Special Parameters tab, in the User Name and Password text boxes, type User.

6. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.
Load Balancing DNS Servers

When you request DNS resolution of a domain name, the NetScaler appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

![Basic Load Balancing Topology for DNS Servers](image)

In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

<table>
<thead>
<tr>

</table>
To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

**To configure DNS monitors by using the command line interface**

At the command prompt, type:

```
add lb monitor <monitorName> DNS -query <domainName> -queryType <Address|ZONE> -IPAddress <ipAddress>
```

**Example**
To configure DNS monitors by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, in the Name and Interval text boxes, type a monitor name and a monitoring interval.

4. Select the unit of time for the interval in the drop-down menu.

5. In the Type list, select DNS.

6. Click the Special Parameters tab, in the Query text box type the domain name query to send to the DNS service (for example, www.mycompany.com), and in the Query Type list box, select ADDRESS or ZONE.

7. In the text box below the Query Type list box, type an IP address that is to be checked against the response to the DNS monitoring query (for example, 10.102.29.66), and click Add.

   **Note:** If you want to enter an IPv6 address, select the IPv6 check box before entering the address.

8. Click Create, and then click Close. The monitor that you created appears in the Monitors pane.
Load Balancing Domain-Name Based Services

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the NetScaler configuration.

When you configure services with domain names instead of IPs, if you change the IP address of a server in your load balancing setup, the name server resolves the domain name to the new IP address. The monitor runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy.

**Note:** When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).
Figure 1. Basic Load Balancing Topology for DBS Servers

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server</td>
<td>Vserver-LB-1</td>

<td>10.102.29.19</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.
To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

**To add a name server by using the command line interface**

At the command prompt, type:

```
add dns nameServer <dnsVserverName>
```

**Example**

```
add dns nameServer Vserver-LB-2
```
To add a name server by using the configuration utility

1. In the navigation pane, expand DNS, and then click Name Servers.
2. In the details pane, click Add.
3. In the Create Name Server dialog box, select DNS Virtual Server.
4. In the DNS Virtual Server drop-down list, select the server name.

   **Note:** Click New if you want to create a new load balancing vserver. The Create Virtual Server (Load Balancing) dialog box appears.
5. Click Create, and then click Close.

You can also add an authoritative name server that resolves the domain name to an IP address.
Load Balancing a Group of SIP Servers

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System

A NetScaler ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the NetScaler ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the NetScaler ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.
Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the NetScaler ADC so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the NetScaler ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named `nsrnatsip-127.0.0.1-5061`.

Support for Policies and Expressions

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip_udp, sip_tcp or sip_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

For more information, see *SIP Expressions*.
In the example, the services Service-SIP-1 and Service-SIP-2 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the entities that you need to configure on the appliance in inline mode (also called two-arm mode).

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server</td>
<td>Vserver-LB-1</td>

</tr>
<tr>
<td>Services</td>
<td>Service-SIP-1</td>
<td>192.168.1.6</td>
<td>80</td>
<td>SIP-UDP</td>
</tr>
<tr>
<td></td>
<td>Service-SIP-2</td>
<td>192.168.1.5</td>
<td>80</td>
<td>SIP-UDP</td>
</tr>
<tr>
<td>Monitors</td>
<td>Default</td>
<td>None</td>
<td>80</td>
<td>SIP-UDP</td>
</tr>
</tbody>
</table>

The following diagram shows the load balancing entities and the values of the parameters to be configured on the appliance.

![Load Balancing SIP Servers Entity Model](image)

To configure a basic load balancing setup for SIP, see [Setting Up Basic Load Balancing](#). You create services and virtual servers of type SIP-UDP, naming the entities and setting the parameters as described in the previous table. You must then configure RNAT.

## Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The NetScaler ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- **SIP_UDP** - Used when SIP servers send SIP messages over UDP.
- **SIP_TCP** - Used when SIP servers send SIP messages over TCP.
SIP_SSL – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The NetScaler ADC supports the following modes:

- End-to-end TLS connection between the client, the ADC, and the SIP server.
- TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
- TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

![Figure 4. SIP Load Balancing Topology](image)

<table>

### Load Balancing a Group of SIP Servers

<table>
<thead>
<tr>
<th>Monitors</th>
<th>Default</th>
<th>None</th>
<th>80</th>
<th>SIP_UDP / SIP_TCP / SIP_SSL</th>
</tr>
</thead>
</table>

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:
   - **SIP_UDP** - If you are load balancing the SIP traffic over UDP.
   - **SIP_TCP** - If you are load balancing the SIP traffic over TCP.
   - **SIP_SSL** - If you are load balancing and securing the SIP traffic over TCP.

   Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.

3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The NetScaler ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.

4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.

5. If you are using the NetScaler ADC as the gateway for the SIP servers in your deployment, configure RNAT.

6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.
To configure a basic load balancing setup for SIP traffic by using the command line interface

1. Create one or more services. At the command prompt, type:

```bash
add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

Example

```bash
add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
```

2. Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:

```bash
add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
```

Example

```bash
add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
```

3. Bind each service to a virtual server. At the command prompt, type:

```bash
bind lb vserver <name> <serverName>
```

Example

```bash
bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
```

4. (Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```bash
add lb monitor <monitorName> <monitorType> [<interval>]
bind lb monitor <monitorName> <ServiceName>
```

Example

```bash
add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
bind monitor mon1 Service-SIP-UDP-1
```

5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:

```bash
bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
```

Example

```bash
bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
```
6. Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```plaintext
set rnat <IPAddress> <netmask>
set rnat <IPAddress> <netmask> -natip <NATIPAddress>
set rnat <aclname> [-redirectPort <port>]
set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>
```

Example

```plaintext
set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named `nsrnatsip-127.0.0.1-5061`.

```plaintext
add ssl certKey <certkeyName> -cert <string> [-key <string>]
bind ssl service <serviceName> -certkeyName <string>
```

Example

```plaintext
add ssl certKey c1 -cert cert.epm -key key.ky
bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
```

7. If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```plaintext
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort <rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -sip503RateThreshold <sip503_rate_threshold_value>
```

### Sample Configuration for load balancing the SIP traffic over UDP

```plaintext
> add service service-UDP-1 10.102.29.5 SIP_UDP 80
Done
> add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
Done
> bind lb vserver vserver-LB-1 service-UDP-1
```
Load Balancing a Group of SIP Servers

Done

> add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
Done

> bind mon mon1 service-UDP-1
Done

> set rnat 192.168.1.0 255.255.255.0
Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
Done

Sample Configuration for load balancing the SIP traffic over TCP

> add service service-TCP-1 10.102.29.5 SIP_TCP 80
Done

> add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
Done

> bind lb vserver vserver-LB-1 service-TCP-1
Done

> add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
Done

> bind mon mon1 service-TCP-1
Done

> set rnat 192.168.1.0 255.255.255.0
Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
Done
Sample Configuration for load balancing and securing SIP traffic over TCP

> add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80
Done

> add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80
Done

> bind lb vserver vserver-LB-1 service-SIP-SSL
Done

> add lb mon mon1 sip-tCP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200
Done

> bind mon mon1 service-SIP-SSL
Done

> bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
Done

> set rnat 192.168.1.0 255.255.255.0
Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000
Done
To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.

2. Click the Service section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.

3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.

4. Bind the monitor to the service, and bind the service to the virtual server.

5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.

6. Configure RNAT as required by your network topology. To configure RNAT:
   a. Navigate to System > Network > Routes.
   b. On the Routes page, click the RNAT tab.
   c. In the details pane, click Configure RNAT.
   d. In the Configure RNAT dialog box, do one of the following:
      - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
        - Network
        - Netmask
      - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
        - ACL Name
        - Redirect Port
   e. To set a MIP or SNIP address as a NAT IP address, skip to step 7.
   f. To set a unique IP address as a NAT IP, in the Available NAT IP(s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.
   g. Click Create, and then click Close.
   
   If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named nsrnatsip-127.0.0.1-5061. To bind the pair:
   a. Navigate to Traffic Management > Load Balancing > Services and click the Internal Services tab.
   b. Select nsrnatsip-127.0.0.1-5061 and click Edit.
   c. Click the Certificates section and bind a certificate key pair to the internal service.
7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings, set the various SIP parameters.

SIP Expression and Policy Example: Compression Enabled in Client Requests

A NetScaler ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with “400 Bad Request,” so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
> add responder action sipaction1 respondwith q{"SIP/2.0 400 Bad Request\r\n\r\n"}
Done.

> add responder policy sippol1

> add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.HEADER("Compression").EXISTS" sipaction1
```

To configure RNAT by using the command line interface

At the command prompt, type:

```
set rnat<network> <netmask>
```

Example

```
set rnat 192.168.1.0 255.255.255.0
```

Parameters for configuring RNAT

- **network**
  
  IPv6 address of the network on whose traffic you want the NetScaler appliance to do RNAT processing.

- **netmask**
To configure RNAT by using the configuration utility

1. In the navigation pane expand Network, expand Routing, and then click Routes.

2. On the Routes page, click the RNAT tab.

3. In the details pane, click Configure RNAT.

4. In the Configure RNAT dialog box, do one of the following:
   - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
     - Network
     - Netmask
   - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
     - ACL Name
     - Redirect Port

5. To set a MIP or SNIP address as a NAT IP address, skip to step 7.

6. To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.

7. Click Create, and then click Close.

After you configure RNAT, the appliance sends SIP responses to the IP address and port that the client uses to send the request. The appliance also adds the RPORT tag in the VIA header of the message. The appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with the RPORT setting.

You must enable this setting when RPORT is not configured on either client.

To configure SIP parameters by using the command line interface

At the command prompt, type:

```
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> - sip503RateThreshold <sip503_rate_threshold_value>
```

Example
set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 100

Parameters for configuring the SIP parameters

**rnatSrcPort**

Port number with which to match the source port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

**rnatDstPort**

Port number with which to match the destination port in server-initiated SIP traffic. The rport parameter is added, without a value, to SIP packets that have a matching source port number, and CALL-ID based persistence is implemented for the responses received by the virtual server.

**retryDur**

Time, in seconds, for which a client must wait before initiating a connection after receiving a 503 Service Unavailable response from the SIP server. The time value is sent in the "Retry-After" header in the 503 response. Minimum value: 1. Maximum Value: 32767. Default: 120.

**addRportVip**

Add the rport parameter to the VIA headers of SIP requests that virtual servers receive from clients or servers. Possible values: ENABLED, DISABLED. Default: ENABLED.

**sip503RateThreshold**

Maximum number of 503 Service Unavailable responses to generate, once every 10 milliseconds, when a SIP virtual server becomes unavailable. Maximum Value: 65535. Default: 100.

To configure SIP parameters by using the configuration utility

1. Navigate to Traffic Management > DNS > Name Servers.

2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

1. In the navigation pane, click Load Balancing.

2. On the Load Balancing landing page, under Settings, click Change SIP settings.

3. In the Set SIP Parameters dialog box, set values for the following parameters:
Load Balancing a Group of SIP Servers

- RNAT Source Port
- RNAT Destination Port
- Retry Duration (secs)
- SIP503 Rate Threshold

4. Select Enable Add Rport VIP.

5. Click OK.
Load Balancing RTSP Servers

The NetScaler appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of an load balancing setup configured to load balance a group of RTSP servers.

In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

<table>
<thead>
<tr>
<th>Entity type</th>

The following diagram shows the load balancing entities used in RTSP configuration.
To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the command line interface

At the command prompt, type:

```
add lb monitor <monitorName> <type>
```

Example

```
add lb monitor Monitor-RTSP-1 RTSP
```
To configure RTSP monitors by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, in the Name and Interval text boxes, type the name and probing interval of a monitor.
4. In the Type list, select the type of the monitor.
5. Click Create, and then click Close.
Load Balancing of Remote Desktop Protocol (RDP) Servers

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the NetScaler appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the NetScaler RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the NetScaler applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the NetScaler forwards the response to the client.

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the NetScaler, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the NetScaler reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.
Note: When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see http://technet.microsoft.com/en-us/library/cc758177(WS.10).aspx#BKMK_2

When you add an RDP service, by default, NetScaler adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, NetScaler marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the NetScaler opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the NetScaler can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the NetScaler at /nsconfig/monitors/nsrdp.pl. When you configure the user monitor, the NetScaler runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.
To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

**To configure RDP load balancing services by using the command line interface**

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```
add service <name>@<serverName> <serviceType> <port>
```

**Note:** Repeat the above command to add more services.

**Example**

```
> add service ser1 10.102.27.182 RDP 3389
Done
> add service ser2 10.102.27.183 RDP 3389
Done
> show service ser1
ser1 (10.102. 27.182:3389) - RDP
  State: UP
  ...  
    Server Name: 10.102.27.182
    Server ID : 0     Monitor Threshold : 0
    Down state flush: ENABLED
  ...
  1)  Monitor Name: tcp-default
      State: UP       Weight: 1
      ...
      Response Time: 4.152 millisec
Done
```

**Parameters for configuring a service**

- **serviceName**
  
  Name of the service. The name must not exceed 127 characters, and the leading character must be a number or a letter. The following characters are also allowed: @ _ . (period) : (colon) # and space ( ).

- **serverName**
  
  Name or IP address of the server in IPv4 format.

- **serviceType**
The service type must be RDP.

**port**

The default port, 3389, must be used.

**To configure RDP load balancing services by using the configuration utility**

1. In the navigation pane, expand Load Balancing and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring a service" as shown:
   - **Service Name**—serviceName
   - **Protocol**—serviceType
   - **Server**—servername
   - **Port**—port
   *A required parameter

4. Click Create.

5. Create all the RDP services to be load balanced.

6. From the services pane, open the service you added, and verify the addition.

**To configure an RDP load balancing virtual server by using the command line interface**

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

- `add lb vserver <name>@ <serviceType> <ipAddress> <port>`
- `bind lb vserver <name>@ <serviceName>`

Bind all the RDP services to be load balanced to the virtual server.

**Example**

This example has two RDP services bound to the RDP virtual server.

```
> add lb vs v1 rdP 10.102.27.186 3389
Done
```
> bind lb vs v1 ser1
service "ser1" bound
> bind lb vs v1 ser2
service "ser2" bound
Done

>sh lb vs v1
v1 (10.102.27.186:3389) - RDP  Type: ADDRESS
State: UP
...
No. of Bound Services :  2 (Total)       2 (Active)
Configured Method: LEASTCONNECTION
  Current Method: Round Robin, Reason: A new service is bound
Mode: IP
Persistence: NONE
  L2Conn: OFF

1) ser1 (10.102.27.182: 3389) - RDPState: UP   Weight: 1
2) ser2 (10.102.27.183: 3389) - RDPState: UP   Weight: 1
Done

Parameters for configuring a virtual server

vServerName

Name of the virtual server that is associated with the service. The name must not exceed 127 characters, and the leading character must be a number or a letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

ipAddress

IP address of the virtual server in the IPv4 format.

serviceType

The service type must be RDP.

port

The default port, 3389, must be used.
To configure an RDP load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring a virtual server” as shown:
   
   - Name*—vServerName
   - IP Address*—ipAddress
   - Protocol*—serviceType
   - Port*—port
   *A required parameter

4. In the Services tab, select the services to be bound to the virtual server by checking the service names.

5. Click Create.

6. In the Load Balancing Virtual Servers pane, select the RDP virtual server you configured, and then click Open to verify the configuration.

To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

- add lb monitor <monitorName> USER -scriptName nsrdp.pl
- bind lb monitor <monitorName> <rdpServiceName>

Example

add service ser1 10.102.27.182 RDP 3389
add lb monitor RDP_MON USER -scriptName nsrdp.pl
bind lb monitor RDP_MON ser1
Parameter for configuring RDP scripting monitor

`scriptName`

Name of the script to be run.

To configure a scripting monitor for RDP services by using the configuration utility

1. In the navigation pane, expand Load Balancing and then click Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify a name for the RDP monitor.
4. In the Type drop-down list, select USER.
5. On the Special Parameters tab, for the Script Name, click Browse and select nsrdp.pl from the default location.
6. Click Create.
7. From the Monitors pane, open the monitor you added, and verify the addition.
8. In the navigation pane, expand Load Balancing, and then click Services.
9. In the details pane, select the RDP service, and then click Open.
10. In the Configure Service dialog box, select the RDP scripting monitor that you added and click Add.
11. Click OK.
Use Cases

Certain deployment scenarios are useful to perform load balancing in a wide variety of circumstances. Several protocols benefit from a configuration that allows the server to respond directly to the client rather than through the NetScaler appliance. This is called direct server return (DSR) mode. Many deployments are faster when you connect the appliance to the network through a single interface, rather than placing it directly in the flow of traffic. This is called one-arm mode. Other deployments require that the appliance be installed in the flow of traffic, so that it transparently intercepts traffic that is sent to and from the servers that it manages. This is called inline mode or (occasionally) two-arm mode. These use cases are described in detail below.
Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called “FIX fields”). The field format is `<tag>=<value><delimiter>`. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting “Start of Header” (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

```
8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=2000426-12:05:06 98=0 108=30 10=157
```

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule
"CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T(=,'^').VALUE("49")"
```
Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the NetScaler appliance creates a persistence session based on this value.

The argument to the Payload() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```plaintext
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=', '^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression
  ```plaintext
  CLIENT.TCP.PAYLOAD(300).BEFORE_STR("^").AFTER_STR("<tag>=")
  ```

- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression
  ```plaintext
  CLIENT.TCP.PAYLOAD(100).SUBSTR(80, 20).TYPECAST_NVLIST_T('=', '^').VALUE("<tag>")
  ```

- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression
  ```plaintext
  CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T('=', '^').VALUE("<tag>", 2)
  ```

  Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the (n+1)th instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5, 10)
- CLIENT.TCP.SRC
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream

- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID
Configuring Load Balancing in Direct Server Return Mode

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the NetScaler appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYN attacks to the server. To control the rate of SYN attacks, set a threshold for the rate of SYN attacks. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the NetScaler appliance does not replace the load balancing virtual server’s IP address with the destination server’s IP address. Instead, it forwards packets to a service by using the server’s MAC address, which it obtains from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the NetScaler appliance, do not learn a server’s MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the NetScaler appliance, the ARP requests always resolve to the MAC address of the NetScaler interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the NetScaler. The following table lists the names and values of the entities configured on the NetScaler in DSR mode.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>10.102.29.94</td>
<td>ANY</td>
</tr>
<tr>
<td>Services</td>
<td>Service-ANY-1</td>
<td>10.102.29.91</td>
<td>ANY</td>
</tr>
<tr>
<td></td>
<td>Service-ANY-2</td>
<td>10.102.29.92</td>
<td>ANY</td>
</tr>
</tbody>
</table>
The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server. To enable the appliance to do this, you must enable MAC-based forwarding.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode MACbasedforwarding
```

To enable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. On the Settings pane, under Modes and Features, click Configure modes.

3. In the Configure Modes dialog box, select the MAC Based Forwarding check box, and then click OK.

4. In the Enable/Disable Mode(s)? dialog box, click Yes.
Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless enabled
```

To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server (for example, Vserver-LB-1), and then click Open.
4. On the Advanced tab, under Redirection Mode, select MAC Based.
5. Select the Sessionless check box and click OK.

To configure a service to use source IP address by using the command line interface

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

**Example**

```
set service Service-ANY-1 -usip yes
```

To configure a service to use source IP address by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. On the Services pane, click Service-ANY-1, and then click Open.

3. On the Advanced tab, under Settings, select the Use Source IP check box, and then click OK.

4. Repeat steps 1-5 for the services Service-ANY-2 and Service-ANY-3.

Some additional steps are required in certain situations, which are described in the succeeding sections.
The LINUX operating system requires that you set up a loopback interface with the NetScaler appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the NetScaler appliance’s VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
ifconfig dummy0 up
ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up
echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore
echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
```

Then, run the software that re-maps the TOS id to VIP.

**Note:** Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.
Configuring DSR Mode When Using TOS

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the TCP packet header. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the NetScaler appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the TOS field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The NetScaler Appliance in DSR mode with TOS

The TOS feature is specifically customized for a controlled environment, as described below:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
The intermediate router must not send out ICMP error messages regarding fragmentation. The client will not understand the message, as the source IP address will be the IP address of the load balanced server and not the NetScaler VIP.

TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

<table>
<thead>
<tr>
<th>Entity Type</th>
<th>Name</th>
<th>IP Address</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>10.102.33.91</td>
<td>ANY</td>
</tr>
<tr>
<td>Services</td>
<td>Service-ANY-1</td>
<td>10.102.100.44</td>
<td>ANY</td>
</tr>
<tr>
<td>Monitors</td>
<td>PING</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

DSR with TOS requires that load balancing be set up on layer 3. To configure a basic load balancing setup for Layer 3, see Setting Up Basic Load Balancing. Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

**To configure the redirection mode for the virtual server by using the command line interface**

At the command prompt, type:

```
set lb vserver <vServerName> -m <Value> -tosId <Value>
```

**Example**

```
set lb vserver Vserver-LB-1 -m TOS -tosId 3
```
To configure the redirection mode for the virtual server by using the configuration utility

1. In the left navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, select the virtual server and click Open.

3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in Redirection Mode, click TOS Based.

4. In the TOS Id box, enter a value for the TOS ID.

5. Click OK.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -tosId <Value>
```

Example

```
add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3
```

To create the transparent monitor for TOS by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. On the Monitors pane, select the monitor (for example, tcp), and click Add.

3. In the Create Monitor dialog box, in the Name and Destination IP boxes, enter the monitor name and the destination IP address (for example, PING and 10.102.33.91).

4. In the Type list, select the type of monitor (for example, PING).

5. To configure the monitor for TOS, select the TOS check box.

6. In the TOS Id box, enter the same TOS ID that you had entered for the virtual server (for example, 3.)

7. Click OK.
Configuring Load Balancing in DSR Mode for IPv6 Networks by Using the TOS Field

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the NetScaler appliance and the servers are in different networks.

**Note:** The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a NetScaler appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the NetScaler.

Consider an example where a load balancing virtual server LBVS1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The NetScaler appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

The following table lists the settings used in this example.

<table>
<thead>
<tr>
<th>Entities</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 address of client C1</td>
<td>C1_IP (for reference purposes only)</td>
</tr>
<tr>
<td>Load balancing virtual server on NS1</td>
<td>LBVS1</td>
</tr>
<tr>
<td>IPv6 address of LBVS1</td>
<td>LBVS1_VIP6 (for reference purposes only)</td>
</tr>
</tbody>
</table>
Configuring Load Balancing in DSR Mode for IPv6 Networks by Using the TOS Field

<table>
<thead>
<tr>
<th>TOS value</th>
<th>TOS_ LBVS1_VIP6 (for references purpose only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service for server S1 on NS1</td>
<td>SVC_S1</td>

<td>SVC_S3</td>
</tr>
<tr>
<td>IPv6 address for server S1</td>
<td>S3_IP (for references purpose only)</td>
</tr>
</tbody>
</table>

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.

2. LBVS1’s load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   - TOS field set to TOS_ LBVS1_VIP6.
   - Source IP address as C1_IP.

3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the NetScaler, with:
   - Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance:

1. Enable USIP mode globally.

2. Add the servers as services.

3. Configure a load balancing virtual server with a TOS value.

4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

- `enable ns mode USIP`
- `add service <serviceName> <IP> <serviceType> <port>`

Repeat the above command as many times as necessary to add each server as a service on the NetScaler appliance.
parameters for configuring a service

serviceName (Service Name)

Name of the service. This alphanumeric string is required. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

IP (Server)

IPv6 address of the server that is associated with the service.

serviceType (Protocol)

Protocol used by the service. Specify a service type of ANY.

Port (Port)

Port on which the server listens for connections. The port number must be from 1 through 65534.

parameters for configuring a load balancing virtual server

name (Name)

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

IPAddress (IP Address)

IPv6 address of the virtual server.

serviceType (Protocol)

Protocol used by the virtual server. Specify a type of ANY.

Port (Port)

Port on which the virtual server listens for client connections. The port number must be from 1 through 65534.

m (Redirection Mode)

The load balancing redirection mode. Specify TOS for this parameter.
tosId (TOS Id)

Specify a value that the appliance sets to the TOS field of the request packets before forwarding to the server. Applicable only when the redirection mode is set as TOS for this virtual server. Minimum value: 1. Maximum value: 63.

To enable USIP mode by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.
2. In the Modes and Features group, click Configure Modes.
3. In the Configure Modes dialog box, select the Use Source IP check box.

To create services by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, set the following parameters.
   - Service Name*
   - Server*
   - Protocol* (Select ANY from the drop-down list.)
   - Port*
4. Click Create.
5. Repeat steps 3-4 to create another service.
6. Click Close.
7. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.
To create a load balancing virtual server and bind services by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, click Add.

3. In the Create Virtual Servers (Load Balancing) dialog box, select IP Address Based and then select IPv6.

4. Set the following parameters.
   · Name*
   · IP Address*
   · Protocol* (Select ANY from the drop-down list.)
   · Port*
   * A required parameter

5. On the Advanced tab, under Redirection Mode, click TOS Based. In the TOS Id box, enter a value.

6. Under the Services tab, in the Active column, select the check box for the service that you want to bind to the virtual server.

7. Click Create, and then click Close. In the Load Balancing Virtual Servers tab, select the virtual server that you just created, and verify that the settings displayed in the Details pane are correct.
You can configure your NetScaler appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called IP over IP configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the NetScaler appliance, improving response times and throughput. As with standard DSR mode, the NetScaler appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the NetScaler appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the NetScaler appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your NetScaler appliance, you must do the following:

- **Create a load balancing virtual server.** Set the protocol to ANY and set the mode to IPTUNNEL.

- **Create services.** Create a service for each of your back-end applications. Bind the services that you created to the virtual server.
Configuring a Load Balancing Virtual Server

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

- add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>
- show lb vserver <name>

Example

In the following example, we have selected the load balancing method as sourceIPHash and configured sessionless load balancing.

add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -m IPTUNNEL -sessionless enabled

Parameters for configuring virtual servers

name

A name for your new virtual server. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

serviceType

The protocol that your virtual server processes. For an IP over IP DSR virtual server, set the protocol to ANY.
The IP address assigned to your virtual server. This is normally an Internet-routable IP address.

**Note:** If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format. (An IPv6 format address appears as follows: 1000:0000:0000:0000:0005:0600:700a:888b.)

**Port**

The port that your virtual server listens on for traffic. For an IP over IP DSR virtual server, set the port to *.

**Method**

The load balancing method to use for this load balancing configuration. For information about the various load balancing methods, see "Load Balancing Algorithms."

**Mode**

Redirection mode for load balancing. For an IP over IP DSR virtual server, set to IPTUNNEL to perform IP-in-IP encapsulation for client IP packets.

**sessionless**

Perform load balancing on a per-packet basis, without establishing sessions. Recommended for load balancing in scenarios involving direct server return (DSR), where session information is unnecessary.

To create and configure a load balancing virtual server for IP over IP DSR by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Create Virtual Server dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring virtual servers" as shown:

   - Name*—name
   - Protocol*—protocol
   - IP address*—IPAddress
   - Port*—port
   * A required parameter

4. On the Advanced tab, under Redirection Mode, select IP Tunnel Based.

5. Click Create, and then click Close. The virtual server that you created now appears in the Virtual Servers pane.
Configuring Services for IP over IP DSR

After creating your load-balanced server, you must configure one service for each of your applications. The service handles traffic from the NetScaler appliance to those applications, and allows the NetScaler appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

```
· add service <serviceName> <serverName> <serviceType> <port> -usip <usip>
· add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <iptunnel>
· bind service <serviceName> -monitorName <monitorName>
```

Example

In the following example, we are creating a monitor of type IPTUNNEL:

```
add monitor mon-1 PING -destip 10.102.29.60 -iptunnel yes
add service Service-DSR-1 10.102.30.5 ANY * -usip yes
bind service Service-DSR-1 -monitorName mon-1
```

Service Configuration Parameters

`serviceName`

Name for the service. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the service has been created. Maximum Length: 127

`serverName`

Name of the server that hosts the service. Maximum Length: 127

`serviceType`

Protocol in which data is exchanged with the service.
To configure a monitor by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values for the following parameters, which correspond to parameters described in "Service Configuration Parameters" as shown:

   - Monitor Name*—name
   - Type*—type
   - Destination IP—destip. Specify the IP address of the virtual server that you created earlier.
   * A required parameter

4. Select IP Tunnel.

5. Click Create, and then click Close.
To create and configure a service for IP over IP DSR by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Services.

2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters, which correspond to parameters described in “Service Configuration Parameters” as shown:
   
   - Service Name*—name
   - Protocol*—type
   - Server*—IP
   - Port*—port
   * A required parameter

4. On the Monitors tab, from the Available list, select the monitor that you created earlier and add it to the Configured list.

5. On the Advanced tab, select Use Source IP.

6. Click Create, and then click Close.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
bind lb vserver <name> <serviceName>
```

Example

```
bind lb vserver Vserver-LB-1 Service-DSR-1
```
To bind a service to a load balancing virtual server by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the load balancing virtual server that you created earlier, and then select Open.

3. In the Services tab, select the check box beside the name of the service(s) that you created earlier.

4. Click OK.
Configuring Load Balancing in One-arm Mode

In a one-arm setup, you connect the NetScaler appliance to the network through a single interface. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. The client can access the server directly, bypassing the appliance, if the client knows the IP address of the server. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure 1. Entity Model for Load Balancing in One-Arm Mode

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>10.102.29.94</td>
<td>ANY</td>
</tr>
<tr>
<td>Services</td>
<td>Service-ANY-1</td>
<td>10.102.29.91</td>
<td>ANY</td>
</tr>
<tr>
<td></td>
<td>Service-ANY-2</td>
<td>10.102.29.92</td>
<td>ANY</td>
</tr>
</tbody>
</table>
To configure a load balancing setup in one-arm mode, see "Setting Up Basic Load Balancing."
Configuring Load Balancing in the Inline Mode

In an inline mode (also called two-arm mode) setup, you deploy the NetScaler appliance to the network through more than one interface. In the two-arm setup, the appliance is connected between the servers and the client. Traffic from clients passes through the appliance to access the load balanced server. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.
The configuration and the entity diagram for inline mode are the same as described in "Configuring Load Balancing in One-arm Mode."
Load Balancing of Intrusion Detection System Servers

To enable the NetScaler appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the NetScaler appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

![Diagram of Load Balanced IDS Servers](image)

**Figure 1. Topology of Load Balanced IDS Servers**

**Note:** Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.

2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or
destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

**Note:** When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Port</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual server</td>
<td>Vserver-LB-1</td>
<td>*</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td>Services</td>
<td>Service-ANY-1</td>
<td>10.102.29.101</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td></td>
<td>Service-ANY-2</td>
<td>10.102.29.102</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td></td>
<td>Service-ANY-3</td>
<td>10.102.29.103</td>
<td>*</td>
<td>ANY</td>
</tr>
<tr>
<td>Monitors</td>
<td>Ping</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Note:** You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

**Figure 2. Entity Model for Load Balancing IDS Servers**

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.
To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
enable ns mode <ConfigureMode>
```

Example

```
enable ns mode MAC
```

To enable MAC-based forwarding by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. On the Settings landing page, under Modes and Features, click modes.

3. In the Configure Modes dialog box, select the MAC Based Forwarding check box, and then click OK.

4. In the Enable/Disable Feature(s)? dialog box, and then click Yes.

Next, see “Setting Up Basic Load Balancing”, to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

To configure LB method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

```
set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>
```

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -sessionless enabled
```

To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility

1. In the left navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the Load Balancing Virtual Servers pane, click the virtual server Vserver-LB-1, and then click Open.

4. On the Advanced tab, under Redirection Mode, click MAC Based.
5. Select the Sessionless check box, and then click OK.

**To set a service to use source IP address by using the command line interface**

At the command prompt, type:

```
set service <ServiceName> -usip <Value>
```

**Example**

```
set service Service-ANY-1 -usip yes
```

**To set a service to use source IP address by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Services.

2. On the Services pane, select the service, Service-ANY-1, and then click Open.

3. On the Advanced tab, under Settings, select the Use Source IP check box.

4. Click OK.

5. Repeat steps 1-5 for the services Service-ANY-2 and Service-ANY-3.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see "IP Addressing."
Isolating the Network Paths by Using Traffic Domains

A very common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IDP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multi-tenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a NetScaler appliance identifies network domains and controls the traffic across the domains. The NetScaler solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified traffic domain.

To isolate the traffic, listen policies can be based on a number of client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

Table 1. Client Parameters Used to Define Listen Policies

<table>
<thead>
<tr>
<th>Category</th>
<th>Parameters</th>
</tr>
</thead>

</tbody>
</table>

On the NetScaler appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to
traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

How Network Paths Are Isolated by Using NetScaler Traffic Domains

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Network Path Isolation Using Traffic Domains
Traffic within Network Domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the NetScaler for all the traffic that originates from a client.

Traffic between Network Domain 1 and Network Domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VLAN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.
Configuring Traffic Domains

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic. For more details, see “Client Parameters Used to Define Listen Policies.”

- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.
  - Enable the L2 Connection option on both the virtual servers.

  Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

- Add services representing the server pools in the domain, and bind them to the virtual server.

- Configure the firewall for each domain as a service, and bind all of the firewall services to the shadow virtual server.

To configure traffic domains by using the command line interface

At the command prompt, type the following commands:

- `add policy expression <expressionName> <listenPolicyExpression>

- `add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -listenPolicy <expressionName>

  Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

- `add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <expressionName>

  Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

Example
Parameters for configuring a service

name

Name of the service. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ).

serverName

Either the name of a previously created server object, or the IP address of the load-balanced server that hosts this service, in either IPv4 or IPv6 format. When you
provide the IP address of the service, a server object is created with this IP address as its name. You can also create a server object manually, and then select the server name instead of an IP address from the drop-down menu that is associated with this field.

If the server is not reachable from the NetScaler or is not active, the service is designated as DOWN.

**serviceType**

The type of connections that the service will handle. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, RADIUS, MYSQL, MSSQL, and RDP_HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP.

**port**

Port on which the service listens. The port number must be a positive number not greater than 65534.

### Parameters for configuring a virtual server

**name**

Name of the virtual server. The name must not exceed 127 characters, and the leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( )

**IPAddress**

IP address of the virtual server. This IP address can be an IPv4 or IPv6 address, and is usually a public IP address. Clients send connection requests to this IP address.

**serviceType**

The type of services to which the virtual server distributes requests. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, and MSSQL_HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, DNS, DHCPRA, ANY, SIP_UDP, DNS_TCP, RTSP, PUSH, SSL_PUSH, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, and SSL_DIAMETER. Default: HTTP.

**port**

Port on which the virtual server listens for client connections. The port number must be between 0-65535.

**l2conn**

The tuple used to identify a connection includes the layer 2 parameters.
To configure traffic domains by using the configuration utility

1. Add services representing the servers, as described in "Creating a Service."

2. Add each firewall as a service:
   a. In the navigation pane, expand Load Balancing, and then click Services.
   b. In the details pane, click Add.
   c. In the Create Service dialog box, specify values for the following parameters:
      - Service Name*—The name that you assign to the service.
      - Protocol*—Select ANY from the drop-down list.
      - Server*—The firewall's IP address.
      - Port*—Specify a value of 80.
      *A required parameter
   d. Click Create.
   e. From the Services pane, open the services you created and verify the settings.

3. Configure a load balancing virtual server.
   a. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
   b. In the details pane, click Add.
   c. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters, which are described in "Creating a Virtual Server."
      - Name*
      - Protocol*
      - IP Address*
      - Port*
      *A required parameter
   d. On the Services tab, select the corresponding services.
   e. On the Advanced tab, select the L2 Connection check box and, for Redirection Mode, select MAC Based. Then, click the Listen Policy link and create the listen policy for the virtual server.
   f. Click Create.

4. Configure the shadow load balancing virtual server.
   a. For the shadow virtual server, specify
Isolating the Network Paths by Using Traffic Domains

- Protocol—ANY
- IP Address*—*
- Port*—*

*A required parameter

b. Bind the firewall services to the shadow virtual server.

5. For each network domain, repeat steps 3 and 4.

6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.
For an improved performance in the delivery of virtual desktop applications, you can integrate the NetScaler appliance with Citrix XenDesktop and use the NetScaler load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a NetScaler appliance working with XenDesktop.
Figure 1. Load Balancing of XenDesktop

**Note:** Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the DDC servers even though you use the SSL protocol for communication with the client.

A wizard is available for configuring basic load balancing in a XenDesktop deployment. You can use the wizard to configure Web interface servers and a virtual server for them, and DDC servers and a virtual server for them. The virtual servers that you configure are bound to services specified as Web Interface services and DDC services. Each virtual server is configured with the default load balancing method, and the default features are enabled. A monitor is created and bound to each virtual server.

The wizard creates a basic setup, with default values for options such as the load balancing method, policies, persistence, and advanced settings. You can change any of the values if necessary.
To configure load balancing for XenDesktop by using the configuration utility

1. In the navigation pane, click Load Balancing.
2. In the Getting Started group, click Load balancing wizard for Citrix XenDesktop.
3. Follow the instructions presented by the wizard.
Configuring XenApp for Load Balancing

For efficient delivery of applications, you can integrate the NetScaler appliance with Citrix XenApp and use the NetScaler load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. Load Balancing of XenApp

The Web Interface servers provide secure access to XenApp application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.
The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user’s permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. On the basis of the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using NetScaler. Configure one virtual server to load balance all of the Web Interface servers and another for all of the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

**Note:** Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the WI servers even though you use the SSL protocol for communication with the client.

The configuration utility provides a wizard for setting up basic load balancing for XenApp.

Through this wizard, you can configure Web Interface servers and a virtual server for them, and XML Broker servers and a virtual server for them. You can also specify the site through which the status of Web Interface servers can be monitored and the software application used to monitor the status of the XML Broker servers.

When you complete the wizard, a basic load balancing setup is configured on the NetScaler. The specified virtual servers are created and bound to the services specified as Web Interface services and XML Broker services. Each virtual server is configured with the default load balancing method, and the default features are enabled. A monitor is created and bound to each virtual server.

The wizard creates a basic setup with default values for options such as the load balancing method, policies, persistence, and advanced settings. You can change any of the values if necessary.

### To configure load balancing for XenApp by using the configuration utility

1. In the navigation pane, click Load Balancing.
2. In the Getting Started group, click Load balancing wizard for Citrix XenApp.
3. Follow the instructions presented by the wizard.
Troubleshooting Common Problems

Below are a few tips for troubleshooting common problems when configuring load balancing on the NetScaler appliance.

- When a metric bound to a monitor is present in the local and custom metric tables, add the local prefix to the metric name if the metric is chosen from the local metric table. If the metric is chosen from the custom table, no prefix needs to be added.

- If the metric table is modified (for example, if the OID for the metric is changed), the change is reflected in the monitoring table. SNMP queries originating from the monitor then use the new OID.

- Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- If multiple load monitors are bound to a service, then the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.

- When you bind a service to a virtual server where the LB method is CUSTOMLOAD, and if the service is up, then the virtual server is put to initial round robin. It continues to be in round robin if the service has no custom load monitors, or if at least one of the custom load monitors is not up.

- If you disable a load monitor bound to the service, and if the service is bound to a virtual server, then the virtual server goes to round robin.

- If you disable a metric-based binding, and if this is the last active metric, then the specific virtual server goes to round robin. A metric is disabled by setting the metric threshold to zero.

- When a metric bound to a monitor crosses the threshold value, then that particular service is not considered for load balancing.

- If all the services have reached the threshold, then the virtual server goes into round robin and an error message “5xx - server busy error” is received.

- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD must have load monitors bound to them.

- The OIDs must be scalar variables.

- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.

- The CUSTOMLOAD load balancing method also follows startup round robin.

- A user cannot modify the local table.
Troubleshooting Common Problems

- A maximum of 10 metrics from a custom table can be bound to the monitor.
SSL Offload and Acceleration

A Citrix® NetScaler® appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client’s perspective, the transaction seems to be directly with the server. A NetScaler configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS NetScaler appliance stores the server’s private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Only the MPX 9700/10500/12500/15500 appliances support a FIPS card, so other NetScaler models cannot be equipped with an HSM.

Beginning with release 10.5, build 52.1115.e, all NetScaler appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect external HSM. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled NetScaler.
Configuring SSL Offloading

To configure SSL offloading, you must enable SSL processing on the NetScaler appliance and configure an SSL based virtual server that will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.
Enabling SSL Processing

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing, but they will not work until SSL processing is enabled.

To enable SSL processing by using the command line interface

At the command prompt, type:

- `enable ns feature ssl`
- `show ns feature`

Example

```
> enable ns feature SSL
Done
> show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>9) SSL Offloading</td>
<td>SSL</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Done
```
To enable SSL processing by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. Under Modes and Features, click Configure basic features.

3. Select the SSL Offloading check box, and then click OK.

4. In the Enable/Disable Feature(s)? message box, click Yes. A message appears in the status bar, stating that the feature has been enabled.
Configuring Services

On the NetScaler appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

To add a service by using the command line interface

At the command prompt, type the following commands to add a service and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port>
- show service <serviceName>

Example

> add service ssl1 10.102.29.252 HTTP 80
Done
> show service ssl1
  ssl1 (10.102.29.252:80) - HTTP
  State: UP
  Last state change was at Thu Nov 12 05:26:31 2009
  Time since last state change: 0 days, 00:00:06.750
  Server Name: 10.102.29.252
  Server ID : 0   Monitor Threshold : 0
  Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
  Use Source IP: NO
  Client Keepalive(CKA): NO
  Access Down Service: NO
  TCP Buffering(TCPB): YES
  HTTP Compression(CMP): YES
  Idle timeout: Client: 180 sec   Server: 360 sec
  Client IP: DISABLED
  Cacheable: NO
  SC: OFF
  SP: ON
  Down state flush: ENABLED

1)   Monitor Name: tcp-default
     State: UP     Weight: 1
     Probes: 2     Failed [Total: 0 Current: 0]
     Last response: Success - TCP syn+ack received.
     Response Time: N/A

Done
To modify or remove a service by using the command line interface

To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service. To remove a service, use the rm service command, which accepts only the <name> argument.

Parameters for adding a service

name (Service Name)

The name of the service you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the type of service being added. (Cannot be changed after the action has been created.)

IP (Server)

The physical IP address of the server that the service you are configuring represents. Make sure that the server is reachable by the NetScaler.

serverName

The name of the server that the service you are configuring represents.

serviceType (Protocol)

The type of data handled by the server or application that the service you are configuring represents. For example, for web traffic, add a service of type HTTP.

port (Port)

The port number on which the service sends and receives data to and from the server.
To configure a service by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Services.

2. In the Details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.

3. In the Create Service or Configure Service dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding a service” as shown:
   - Service Name*
   - Server*
   - Protocol*
   - Port*
   * A required parameter

4. Click Create or OK, and then click Close. In the Services pane, select the service that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Configuring an SSL-Based Virtual Server

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the NetScaler appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

**Note:** The SSL virtual server is marked as down on the NetScaler appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL_TCP. The load balancing feature must be enabled on the NetScaler.

**To add an SSL-based virtual server by using the command line interface**

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- add lb vs server <name> (serviceType) <IPAddress> <port>
- show lb vs server <name>

**Example**

> add lb vs server vssl SSL 10.102.29.133 443
Done
> show ssl vs server vssl

Advanced SSL configuration for VServer vssl:

- DH: DISABLED
- Ephemeral RSA: ENABLED Refresh Count: 0
- Session Reuse: ENABLED Timeout: 120 seconds
- Cipher Redirect: DISABLED
- SSLv2 Redirect: DISABLED
- ClearText Port: 0
- Client Auth: DISABLED
- SSL Redirect: DISABLED
- Non FIPS Ciphers: DISABLED
- SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias
Done
To modify or remove an SSL-based virtual server by using the command line interface

To modify the load balancing properties of an SSL virtual server, use the set lb vserver command, which is just like using the add lb vserver command, except that you enter the name of an existing vserver. To modify the SSL properties of an SSL-based virtual server, use the set ssl vserver command. For more information, see Customizing the SSL Configuration.

To remove an SSL virtual server, use the rm lb vserver command, which accepts only the <name> argument.

Parameters for adding an SSL-based virtual server

name (Name)

The name of the SSL based virtual server you are configuring. The name can begin with a letter, a number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols. You should choose a name that helps identify the server being added.

IPAddress (IP Address)

The IP address of the virtual server that you are adding.

serviceType (Protocol)

The service that you are adding can either be of type SSL to handle secure HTTP traffic or SSL_TCP to handle secure TCP traffic.

port (Port)

The port number on which the virtual server receives SSL traffic. This is usually set to 443 for all secure transactions.
To configure an SSL-based virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. In the Details pane, do one of the following:
   - To create a new virtual server, click Add.
   - To modify an existing virtual server, select the virtual server, and then click Open.

3. In the Create Virtual Server (SSL Offload) or Configure Virtual Server (SSL Offload) dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding an SSL-based virtual server” as shown:
   - Name*
   - IP Address*
   - Protocol*
   - Port*
   * A required parameter

4. Click Create or OK, and then click Close. In the SSL Offload Virtual Servers pane, select the virtual server that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Binding Services to the SSL-Based Virtual Server

For the NetScaler appliance to forward decrypted SSL data to servers in the network, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Because the link between the NetScaler and the physical server is typically secure, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to-end encryption by encrypting data transfer between the NetScaler and the server. For details, see Configuring SSL Offloading with End-to-End Encryption.

Note: The Load Balancing feature should be enabled on the NetScaler appliance before you bind services to the SSL based virtual server.

To bind a service to a virtual server by using the command line interface

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

> bind lb vserver vssl ssl1
Done
> show lb vserver vssl
  vssl (10.102.29.133:443) - SSL  Type: ADDRESS
  State: DOWN [Certkey not bound]
  Last state change was at Thu Nov 12 05:31:17 2009 (+ 485 ms)
  Time since last state change: 0 days, 00:08:52.130
  Effective State: DOWN
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services :  1 (Total)       1 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
  Vserver IP and Port insertion: OFF
  Push: DISABLED  Push VServer:
To unbind a service from a virtual server by using the command line interface

At the command prompt, type the following command:

unbind lb vserver <name> <serviceName>

Example

unbind lb vserver vssl ssl1

Parameters for binding a service to a virtual server

name

The name of the SSL based virtual server to which you are binding the service.

serviceName

The name of the service being bound to the SSL based virtual server. The service must be configured on the NetScaler before it is bound to the virtual server.

To bind a service to a virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. In the details pane, select the virtual server to which you want to bind the service, and click Open.

3. In the Configure Virtual Server (SSL Offload) dialog box, select the Services tab, and then select the check box in the Active column of the ssl service that you want to bind to the virtual server.

4. Click OK. A message appears in the status bar, stating that the service has been bound successfully
Adding or Updating a Certificate-Key Pair

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server’s public key, which is available through the server’s certificate. Decryption requires the corresponding private key.

Because the NetScaler appliance offloads SSL transactions from the server, the server’s certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must then be bound to the virtual server that processes the SSL transactions.

Both the certificate and the key must be in local storage on the NetScaler appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

**Important:** Certificates and keys are stored in the /nsconfig/ssl directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the NetScaler appliance. The NetScaler FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

On a NetScaler MPX appliance and a NetScaler FIPS appliance, only RSA private keys are supported. On a VPX virtual appliance, both RSA and DSA private keys are supported. On an SDX appliance if SSL chips are assigned to an instance, then only RSA private keys are supported. However, if SSL chips are not assigned to an instance, then both RSA and DSA private keys are supported. In all the cases, you can bind a CA certificate with either RSA or DSA keys.

Set the notification period and enable the expiry monitor to be prompted before the certificate expires.

**Note:** A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

An MPX appliance supports certificates from 512-bits up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
Adding or Updating a Certificate-Key Pair

- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A virtual appliance supports certificates from 512-bits up to the following sizes:
- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 2048-bit certificate on the back end server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

To add a certificate-key pair by using the command line interface

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password]) | -fipsKey <string>] [-inform ( DER | PEM )] [-fipsKey <string>] [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]]
- show ssl certKey [<certkeyName>]

Example

> add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -password ssl -expiryMonitor ENABLED -fipskey
Done
Note: For FIPS appliances, replace -key with -fipskey
> show ssl certKey sslckey
  Name: sslckey           Status: Valid,   Days to expiration:8418
  Version: 3
  Serial Number: 01
  Signature Algorithm: md5WithRSAEncryption
  Issuer: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
  Validity
    Not Before: Jul 15 02:25:01 2005 GMT
    Not After : Nov 30 02:25:01 2032 GMT
  Subject: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
  Public Key Algorithm: rsaEncryption
  Public Key size: 1024
Done
Adding or Updating a Certificate-Key Pair

To update or remove a certificate-key pair by using the command line interface

To modify the expiry monitor or notification period in a certificate-key pair, use the set ssl certkey command. To replace the certificate or key in a certificate-key pair, use the update ssl certkey command. The update ssl certkey command has an additional parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the rm ssl certkey command, which accepts only the <certkeyName> argument.

Parameters for adding a certificate-key pair

**certkeyName (Certificate-Key Pair Name)**

The name of the certificate-key pair added to the NetScaler. Maximum length: 31. (Cannot be changed after the certificate has been added.)

**cert (Certificate File Name)**

The file name of the valid certificate. The certificate file should be present on the NetScaler appliance's hard-disk drive. The default path for the certificate file is /nsconfig/ssl/. If the certificate is stored at any other location, the absolute path to the file must be provided. However, Citrix does not recommend storing the certificate in a location other than the default, because this may result in inconsistency during synchronization in an HA setup. Maximum length: 63 characters.

**key (Private Key File Name)**

The file name of the private key used to create the certificate. The private-key file must be present on the NetScaler appliance's hard disk drive. The default path for the key file is /nsconfig/ssl/. If the key is stored at any other location, the absolute path to the file must be provided. If you are adding a Certificate-Authority (CA) certificate file, do not add a private key. This parameter is not applicable to an SSL FIPS appliance. Maximum length: 63 characters.

**fipskey**

The name of the FIPS key used to create the certificate. The FIPS key is created and stored inside the FIPS Hardware Security Module (HSM). This option is applicable only to an SSL FIPS appliance. Maximum length: 63 characters.

**password (Password)**

The pass phrase that was used to encrypt the private key. This option can be used to load encrypted private-keys. Maximum length: 31 characters.

**Note:** Password protected private keys are supported only for the PEM format.

**inform (Certificate Format)**

The input format of the certificate and the private-key files.

The two formats supported by the system are:
Adding or Updating a Certificate-Key Pair

PEM: Privacy Enhanced Mail
DER: Distinguished Encoding Rule
Possible values: DER, PEM
Default value: PEM

**passplain**

The pass phrase that was used to encrypt the private key. This option can be used to load encrypted private keys. Maximum length: 31 characters.

**Note:** Password protected private key is supported only for the PEM format. Maximum length: 31 characters.

**expiryMonitor (Notify When Expires)**

Issue an alert when the certificate is about to expire. Possible values: ENABLED, DISABLED

**notificationPeriod (Notification Period)**

Number of days before certificate expiration, at which to generate an alert that the certificate is about to expire. Minimum value: 10. Maximum value: 100.

**noDomainCheck (No Domain Check)**

When updating a certificate-key pair, override the check for matching domain names.
To add or update a certificate-key pair by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.

2. In the Details pane, do one of the following:
   - To add a new certificate-key pair, click Add.
   - To update an existing certificate-key pair, click Update.

3. In the Install Certificate or Update Certificate dialog box, set the following parameters:
   - Certificate-Key Pair Name*
   - Certificate File Name*
   - Private Key File Name
   - Password
   - Certificate Format
   - Notify When Expires
   - Notification Period
   - No Domain Check (Available in the Update Certificate dialog box only)
   * A required parameter

4. Click Install or OK, and then click Close. In the SSL Certificates pane, select the certificate that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Binding the Certificate-Key Pair to the SSL-Based Virtual Server

An SSL certificate is an integral element of the SSL encryption and decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

You can use a valid, existing SSL certificate that you have uploaded to the NetScaler appliance. As an alternative for testing purposes, you can create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the NetScaler cannot be bound to an SSL virtual server.

For details on how to create your own certificate, see Managing Certificates.

**Note:** Citrix recommends that you use only valid SSL certificates that have been issued by a trusted certificate authority.

### To bind an SSL certificate-key pair to a virtual server by using the command line interface

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

- `bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>`
- `show ssl vserver <vServerName>`

**Example**

```
> bind ssl vserver vssl -certkeyName sslckey
Done
> show ssl vserver vssl

Advanced SSL configuration for VServer vssl:
DH: DISABLED
Ephemeral RSA: ENABLED         Refresh Count: 0
Session Reuse: ENABLED          Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
```
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1) CertKey Name: sslckey Server Certificate

1) Cipher Name: DEFAULT
  Description: Predefined Cipher Alias
  Done

To unbind an SSL certificate-key pair from a virtual server by using the command line interface

If you try to unbind a certificate-key pair from a virtual server by using the `unbind ssl certKey <certKeyName>` command, an error message appears because the syntax of the command has changed. At the command prompt, type the following command:

`unbind ssl vserver <vServerName> -certkeyName <string>

Example

unbind ssl vserver vssl -certkeyName sslckey

Parameters for binding the certificate-key pair to the virtual server

- **vServerName**
  
  The name of the SSL based virtual server to which you are binding the certificate-key pair.

- **certkeyName**
  
  The name of the certificate-key pair that you are binding to the virtual server. This certificate-key pair should already be configured on the NetScaler.
To bind an SSL certificate-key pair to a virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. Select the virtual server to bind the certificate key to, and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings.
4. In the Available pane, select a certificate.
5. Click Add to add the certificate as a server certificate. To add as an SNI certificate, in the Add drop-down list select As SNI. To add as a CA certificate, in the Add drop-down list select As CA.
6. Click OK. The certificate pair is bound to the virtual server.
Configuring an SSL Virtual Server for Secure Hosting of Multiple Sites

Virtual hosting is used by Web servers to host more than one domain name with the same IP address. The NetScaler supports hosting of multiple secure domains by offloading SSL processing from the Web servers using transparent SSL services or vserver-based SSL offloading. However, when multiple Web sites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the NetScaler cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling Server Name Indication (SNI) on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. Based on the information provided by the client in the SNI extension, the NetScaler presents the corresponding certificate to the client.

A wildcard SSL Certificate helps enable SSL encryption on multiple subdomains if the domains are controlled by the same organization and share the same second-level domain name. For example, a wildcard certificate issued to a sports network using the common name ".sports.net" can be used to secure domains, such as "login.sports.net" and "help.sports.net" but not "login.ftp.sports.net."

**Note:** On a NetScaler appliance, SNI is not supported with a Subject Alternative Name (SAN) extension certificate.

You can bind multiple server certificates to a single SSL virtual server or transparent service using the -SNICert option. These certificates are issued by the virtual server or service if SNI is enabled on the virtual server or service. You can enable SNI at any time.

### To bind multiple server certificates to a single SSL virtual server by using the command line interface

At the command prompt, type the following commands to configure SNI and verify the configuration:

- `set ssl vserver <vServerName> @ [-SNIEnable ( ENABLED | DISABLED )]`
- `bind ssl vserver <vServerName> @ -certkeyName <string> -SNICert`
- `show ssl vserver <vServerName>`

To bind multiple server certificates to a transparent service by using the NetScaler command line, replace `vserver` with `service` and `vservername` with `servicename` in the above commands.

**Note:** The SSL service should be created with `-clearTextPort 80` option.

**Example**
Parameters for configuring SNI

vServerName

The name of the SSL virtual server on which SNI is enabled.

serviceName

The name of the SSL transparent service on which SNI is enabled.

SNIEnable

State of the Server Name Indication (SNI) feature on the virtual server and service-based offload. SNI helps to enable SSL encryption on multiple domains on a single virtual server or service if the domains are controlled by the same organization and share the same second-level domain name. For example, *.sports.net can be used to secure domains such as login.sports.net and help.sports.net. Possible values: ENABLED, DISABLED

Default: DISABLED

SNICert

Name of the certificate-key pair to bind for use in SNI processing.
To bind multiple server certificates to a single SSL virtual server or transparent SSL service by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers or Services.

2. In the details pane, select the virtual server or service on which SNI is to be enabled, and then click Open.

3. In the Configure Virtual Server (SSL Offload) or Configure Service dialog box, on the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, under Others, select the SNI Enable check box.

5. Click OK.

6. On the SSL Settings tab, under Available, select a certificate.

7. In the Add drop-down list select As SNI.

8. To add more certificates, repeat step 7.

9. Under Configured, verify that the certificate is added as a server certificate for SNI.

10. Click OK.
Managing Certificates

An SSL certificate, which is an integral part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the NetScaler appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as VeriSign
- By generating a new SSL certificate and key on the NetScaler appliance

Alternately, you can use an existing SSL certificate on the appliance.

Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as VeriSign, for all your SSL transactions. Certificates generated on the NetScaler appliance should be used for testing purposes only, not in any live deployment.
Obtaining a Certificate from a Certificate Authority

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Certificates issued or signed by a CA are automatically trusted by applications, such as web browsers, that conduct SSL transactions. These applications maintain a list of the CAs that they trust. If the certificate being used for the secure transaction is signed by any of the trusted CAs, the application proceeds with the transaction.

To obtain an SSL certificate from an authorized CA, you must create a private key, use that key to create a certificate signing request (CSR), and submit the CSR to the CA. The only special characters allowed in the file names are underscore and dot.

Creating a Private Key

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and should be kept securely on the NetScaler appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The appliance supports two encryption algorithms, RSA and DSA, for creating private keys. You can submit either type of private key to the CA. The certificate that you receive from the CA is valid only with the private key that was used to create the CSR, and the key is required for adding the certificate to the NetScaler.

Caution: Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.

All SSL certificates and keys are stored in the /nsconfig/ssl folder on the appliance. For added security, you can use the Data Encryption Standard (DES) or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

Note: The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

To create an RSA private key by using the command line interface

At the command prompt, type the following command:

```
create ssl rsakey <keyFile> <bits> [-exponent ( 3 | F4 )] [-keyform ( DER | PEM )]
```

Example

```
> create ssl rsaKey Key-RSA-1 1024 -exponent F4 -keyform PEM
```
To create a DSA private key by using the command line interface

At the command prompt, type the following command:

```
create ssl dsakey <keyfile> <bits> [-keyform (DER | PEM)]
```

Example

```
> create ssl dsakey Key-DSA-1 1024 -keyform PEM
```

To create an RSA private key by using the configuration utility

1. In the navigation pane, click SSL.
2. In the details pane, under SSL Keys, click Create RSA Key.
3. In the Create RSA Key dialog box, configure the RSA key parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create, and then click Close.

To create an DSA private key by using the configuration utility

1. In the navigation pane, click SSL.
2. In the details pane, under SSL Keys, click Create DSA Key.
3. In the Create DSA Key dialog box, configure the DSA key parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
4. Click Create, and then click Close.

Creating a Certificate Signing Request

The certificate signing request (CSR) is a collection of information, including the domain name, other important company details, and the private key to be used to create the certificate. To avoid generating an invalid certificate, make sure that the details you provide are accurate.

To create a certificate signing request by using the command line interface

At the command prompt, type the following command:
Obtaining a Certificate from a Certificate Authority

Example

> create ssl certreq csreq1 -keyfile ramp -keyform PEM -countryName IN -stateName Karnataka -localityName Bangalore -organizationName Citrix -organizationUnitName DNPG

**To create a certificate signing request by using the configuration utility**

1. In the navigation pane, click SSL.

2. In the details pane, under SSL Certificates, click Create CSR (Certificate Signing Request).

3. In the Create CSR (Certificate Signing Request) dialog box, configure the CSR parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.

4. Click Create, and then click Close. The certificate signing request you created is saved on the appliance in the specified location.

**Submitting the CSR to the CA**

Most CAs accept certificate submissions by email. The CA will return a valid certificate to the email address from which you submit the CSR.
Importing Existing Certificates and Keys

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the NetScaler appliance. You might have to convert exported certificates and keys before you can import them to the NetScaler appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

**Note:** For installation on the NetScaler appliance, key and certificate names cannot contain spaces or special characters other than those supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.

A certificate and private key pair is commonly sent in the PKCS#12 format. The NetScaler supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see Converting the Format of SSL Certificates for Import or Export.

The NetScaler appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the NetScaler command line or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
leuSSZQZKrggUQ==
-----END ENCRYPTED PRIVATE KEY-----
```

**To open the OpenSSL interface from the command line interface**

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type `shell`.
4. At the shell prompt type `openssl`.
To open the SSL interface from the configuration utility

1. In the navigation pane, click SSL.
2. In the details pane, under Tools, click OpenSSL interface.

To convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type rsa or dsa:

- `rsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>`
- `dsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>`

To convert a non-supported PKCS#8 key format to an unencrypted key format by using the OpenSSL interface

At the OpenSSL prompt, type the following commands, depending on whether the non-supported key format is of type rsa or dsa:

- `rsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>`
- `dsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>`

Parameters for converting an unsupported key format to a supported key format

- `<PKCS#8 Key Filename>`
  The input file name of the incompatible PKCS#8 private key.

- `<encrypted Key Filename>`
  The output file name of the compatible encrypted private key in PEM format.

- `<unencrypted Key Filename>`
  The output file name of the compatible unencrypted private key in PEM format.
Generating a Self-Signed Certificate

The NetScaler appliance has a built in CA tools suite that you can use to create self-signed certificates for testing purposes.

**Caution:** Because these certificates are signed by the NetScaler itself, not by an actual CA, you should not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users will receive a "certificate invalid" warning each time the virtual server is accessed.

The NetScaler supports creation of the following types of certificates:

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the NetScaler CA Tools to generate a certificate.

For details on how to create a private key and a CSR, see [Obtaining a Certificate from a Certificate Authority](#).

### To create a certificate by using a wizard

1. In the navigation pane, click SSL.
2. In the details pane, under Getting Started, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

### To create a Root-CA certificate by using the command line interface

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform ( DER | PEM )] [-days <positive_integer>]
```

**Example**
To create an Intermediate-CA certificate or end-user certificate by using the command line interface

At the command prompt, type the following command:

```
create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>] [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)] [-CAkey <input_filename>] [-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]
```

Example

```
> create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -CAserial 23
Done
```

Parameters for creating a self-signed certificate

**certFile (Certificate File Name)**

The name of the generated certificate file. The newly created certificate file is stored by default in the /nsconfig/ssl/ directory.

**reqFile (Certificate Request File Name)**

The certificate signing request (CSR) file that is used to generate the certificate.

**certType (Certificate Type)**

The type of the certificate being created. You can create a Root Certificate, an Intermediate Certificate, a Client Certificate or a Server Certificate. Select one of the following options

- **ROOT_CERT**: Specifies a self-signed Root-CA certificate. If you choose this setting, you must also set the -keyFile parameter. The generated Root-CA certificate can be used for signing end-user certificates (Client/Server) or to create Intermediate-CA certificates.
- **INTM_CERT**: Specifies an Intermediate-CA certificate.
CLNT_CERT: Specifies an end-user client certificate that is used for client authentication.

SRVR_CERT: Specifies an SSL server certificate to be used on physical SSL servers for an SSL backend-encryption setup.

The parameters CAcert, CAkey, and CAserial, are mandatory when creating an intermediate, client, or server certificate.

**keyFile (Key File Name)**

The private key used to create the certificate. You can either use an existing RSA or DSA key that you own or create a new private key on the NetScaler. This file is required only when creating a self-signed Root-CA certificate. The key file is stored in the /nsconfig/ssl directory by default.

**Note:** If the input key specified is an encrypted key, the user will be prompted to enter the PEM pass-phrase that was used for encrypting the key.

**keyform (Key Format)**

The file format in which the private key is stored. Possible values: PEM, DER. Default: PEM.

**days (Validity Period)**

The number of days for which the created certificate will be valid. The certificate is valid from the time and day (system time) of its creation to the number of days specified in this field. Minimum value: 1. Maximum value: 3650. Default: 365 days.

**certForm (Certificate Format)**

The format in which to save the certificate. Possible values: PEM, DER. Default: PEM.

**CAcert (CA Certificate File Name)**

The CA certificate file that will issue and sign the Intermediate-CA certificate or the end-user certificates (Client/Server). The default input path for the CA certificate file is /nsconfig/ssl/.

**CAcertForm (CA Certificate File Format)**

The format in which to store the CA certificate. Possible values: PEM, DER. Default: PEM.

**CAkey (CA Key File Name)**

The private key associated with the CA certificate that is used to sign the Intermediate-CA certificate or the end-user certificates (Client/Server). If the CA key file is password protected, the user will be prompted to enter the pass-phrase used when encrypting the key.

**CAkeyForm (CA Key File Format)**

The file format in which the private key of the CA certificate is stored. Possible values: PEM, DER. Default: PEM.
CAserial (CA Serial Number File)

The serial number file maintained for the CA certificate. The file will contain the serial number of the next certificate to be issued/signed by the CA (-CAcert). If the specified file does not exist, a new file will be created. The NetScaler stores the newly generated file in the /nsconfig/ssl/ directory by default.

Note: Specify the proper path of the existing serial file. Otherwise, a new serial file will be created, and that can change the certificate serial numbers assigned by the CA certificate to each of the certificate it signs.

To create a Root-CA certificate by using the configuration utility

1. In the navigation pane, click SSL.

2. Under SSL Certificates, click Create Certificate.

3. In the Create Certificate dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a self-signed certificate” as shown:
   · Certificate File Name*
   · Certificate Format
   · Certificate Type
   · Certificate Request File Name*
   · Key File Name*
   · Key Format
   · PEM Passphrase (For Encrypted Key)—If the key is encrypted, you are prompted to enter the password at run-time on the CLI.
   · Validity Period (Number of Days)
   * A required parameter

   Note: Instead of typing the file name, you can use the browse button to launch the NetScaler file browser and select the file.

4. Click Create, and then click Close. The Root-CA certificate you created is saved on the NetScaler.
To create an Intermediate-CA certificate or end-user certificate by using the configuration utility

1. In the navigation pane, click SSL.

2. Under SSL Certificates, click Create Certificate.

3. In the Create Certificate dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a self-signed certificate” as shown:
   - Certificate File Name*
   - Certificate Format
   - Certificate Type
   - Certificate Request File Name*
   - PEM Passphrase (For Encrypted Key)—If the key is encrypted, you are prompted to enter the password at run-time on the CLI.
   - Validity Period (Number of Days)
   - CA Certificate File Name*
   - CA Certificate File Format
   - CA Key File Name*—CAkey
   - CA Key File Format
   - PEM Passphrase (For Encrypted CA Key)
   - CA Serial Number File*
   * A required parameter

   Note: Instead of typing the file name, you can use the browse button to launch the NetScaler file browser and select the file.

4. Click Create, and then click Close. The Intermediate-CA certificate you created is saved on the NetScaler.

Generating a Diffie-Hellman (DH) Key

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction that have no prior knowledge of each other to agree upon a shared secret over an insecure channel. This secret can then be converted into cryptographic keying material for mainly symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default and should be specifically configured to support ciphers that use DH as the key exchange algorithm.
Note: Generating a 2048-bit DH key may take a long time (up to 30 minutes).

To generate a DH key by using the command line interface

At the command prompt, type the following command:

create ssl dhparam <dhFile> [ <bits> ] [-gen (2 | 5)]

Example

create ssl dhparam Key-DH-1 512 -gen 2

Parameters for creating a DH Key

dhFile (DH File Name)

The name of the DH key that is created. The DH key is stored in the /nsconfig/ssl directory on the appliance by default.

bits (DH Parameter Size)

The size in bits of the DH key being generated.

gen (DH Generator)

The random number required for generating the DH key. This is required as part of the DH key generation algorithm. Possible Values: 2, 5. Default Value: 2

To generate a DH key by using the configuration utility

1. In the navigation pane, click SSL.

2. Under Tools, click Create Diffe-Hellman (DH) Key.

3. In the Create DH Param dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for creating a DH Key” as shown:

   - DH File Name (with path)*
   - DH Parameter Size (Bits)*
   - DH Generator
     * A required parameter

4. Click OK.
Adding a Group of SSL Certificates

If the server certificate is issued by an intermediate CA that is not recognized by standard web browsers as a trusted CA, the CA certificate(s) must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

There are two ways to add the server and intermediate certificates:

- Create a certificate set that contains the chain of certificates.
- Create a chain of certificates manually by adding and linking the certificates individually.
Adding and Linking a Certificate Set

**Note**: This feature is not supported on the NetScaler FIPS platform.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file, and then specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (should be the first certificate in the file)
  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on

  **Note**: Intermediate certificate files are created for each intermediate certificate with the name “<certificatebundlename>.pem_ic<n>” where n is between 1 and 9. For example, bundle.pem_ic1, where bundle is the name of the certificate set and ic1 is the first intermediate certificate in the set.

- Bundle option is selected.

- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates already exists on the appliance.

- The key is placed before the server certificate in the file.

- An intermediate certificate is placed before the server certificate.

- Intermediate certificates are not in placed in the file in the same order as they are created.

- No certificates are present in the file.

- A certificate is not in the proper PEM format.

- The number of intermediate certificates in the file exceeds nine.
To add a certificate set by using the command line interface

At the command prompt, type the following commands to create a certificate set and verify the configuration:

1. add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES | NO)
2. show ssl certKey
3. show ssl certlink

Example

In the following example, the certificate set (bundle.pem) contains the following files:

- server certificate (bundle) linked to bundle_ic1
- First intermediate certificate (bundle_ic1) linked to bundle_ic2
- Second intermediate certificate (bundle_ic2) linked to bundle_ic3
- Third intermediate certificate (bundle_ic3)

> add ssl certKey bundle -cert bundle.pem -key bundle.pem -bundle yes
> show ssl certkey

1) Name: bundle
Cert Path: /nsconfig/ssl/bundle.pem
Format: PEM
Status: Valid, Days to expiration: 10415
Certificate Expiry Monitor: DISABLED

2) Name: bundle_ic1
Cert Path: /nsconfig/ssl/bundle.pem_ic1
Format: PEM
Status: Valid, Days to expiration: 10415
Certificate Expiry Monitor: DISABLED

3) Name: bundle_ic2
Cert Path: /nsconfig/ssl/bundle.pem_ic2
Format: PEM
Status: Valid, Days to expiration: 10415
Certificate Expiry Monitor: DISABLED

4) Name: bundle_ic3
Cert Path: /nsconfig/ssl/bundle.pem_ic3
Format: PEM
Status: Valid, Days to expiration: 10415
Certificate Expiry Monitor: DISABLED
Done
Adding and Linking a Certificate Set

> show ssl certlink

1) Cert Name: bundle CA Cert Name: bundle_ic1
2) Cert Name: bundle_ic1 CA Cert Name: bundle_ic2
3) Cert Name: bundle_ic2 CA Cert Name: bundle_ic3
Done

Parameters for adding a certificate

certKeyName

Name of the certificate-key pair that is linked to its issuer's certificate-key pair in the chain.

cert

File name and path for the X509 certificate file. The certificate file should be present on the NetScaler appliance's hard disk drive or solid-state drive. The default input path for the certificate file is /nsconfig/ssl/.

key

File name and path for the private-key file. The private-key file should be present on the hard disk drive or solid-state drive. The default input path for the key file is /nsconfig/ssl/.

bundle

Parse the certificate chain as a single file after linking the server certificate to its issuer's certificate within the file.

To add a certificate set by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.
2. In the SSL Certificates pane, click Install.
3. In the Install Certificate dialog box, type the details, such as the certificate and key file name, and then select Certificate Bundle.
4. Click Install, and then click Close.
Creating a Chain of Certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). For this approach to work, the intermediate CA certificate file must already be installed on the NetScaler appliance, and one of the certificates in the chain must be trusted by the client application. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

Note: The NetScaler supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

To create a certificate chain by using the command line interface

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

- link ssl certkey <certKeyName> <linkCertKeyName>
- show ssl certlink

Example

> link ssl certkey siteAcertkey CAcertkey
  Done

> show ssl certlink

linked certificate:
  1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
  Done

Parameters for creating a certificate chain

certKeyName

The name of the certificate-key pair that is linked to its issuer's certificate-key pair in the chain.

linkCertKeyName
Creating a Chain of Certificates

The name of the issuer of the certificate that is being linked to.

The two certificate-key pairs are linked only if the certificate specified in the certKeyName parameter is issued by the Certificate-Authority specified in the linkCertKeyName parameter.

To create a certificate chain by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.
2. Select the server certificate you want to link, and then click Link.
3. In Link Server Certificate(s), select CA Certificate Name to be linked to.
4. Click OK. The server certificate is now linked to the intermediate certificate.
Generating a Server Test Certificate

The NetScaler appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. A server certificate is generally issued by a trusted CA and is sent out by the server to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a CA. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. It should not be used in a production environment.

You can install the server test certificate on any virtual server that uses the SSL or the SSL_TCP protocol.

To generate a server test certificate by using the configuration utility

1. In the navigation pane, click SSL.

2. Under SSL Certificates, click Create and install a Server Test Certificate.

3. In the Create and install a Server Test Certificate dialog box, specify values for the following parameters:
   - Certificate File Name—name of the server test certificate
   - Fully Qualified Domain Name—the domain for which you want to secure the connection
   - Country—the name of the country or region

4. Click OK.
Modifying and Monitoring Certificates and Keys

To avoid downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

Updating an Existing Server Certificate

When you remove or unbind a certificate from a configured SSL virtual server, or an SSL service, the virtual server or service becomes inactive until a new valid certificate is bound to it. To avoid downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service, without first unbinding the existing certificate.

To update an existing certificate-key pair by using the command line interface

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

- update ssl certkey <certkeyName> -cert <string> -key <string>
- show ssl certKey <certkeyName>

Example

> update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /nsconfig/ssl/pkey.pem
Done

> show ssl certkey siteAcertkey
Name: siteAcertkey       Status: Valid
Version: 3
Serial Number: 02
Signature Algorithm: md5WithRSAEncryption
Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
Validity
   Not Before: Nov 11 14:58:18 2001 GMT
   Not After: Aug 7 14:58:18 2004 GMT
Subject: /C=US/ST=CA/L=San Jose/O=CA OU=Security
Public Key Algorithm: rsaEncryption
Public Key size: 1024
Done

Parameters for updating an existing certificate-key pair

certkeyName

The name of the certificate key pair that you want to update with a new certificate or a new key, or both.

cert

The name of the new certificate with which you want to update the certificate key pair.

key

The name of the private with which key you want to update an existing certificate key pair.

Note: The new certificate and key should be in local storage on the NetScaler. If the files are not stored in the default /nsconfig/ssl folder, provide the absolute path to the files.

To update an existing certificate-key pair by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.

2. Select the certificate you want to update, and then click Update.

3. Use the Browse button next to the Certificate File name and the Key File name and select the new certificate and key files respectively.

4. If the key in encrypted, in the Password text box, type the password used to encrypt the key.

5. Click OK. In SSL Certificates pane, select the certificate that you just updated and verify that the settings displayed at the bottom of the screen are correct.

Disabling Domain Checks

When an SSL certificate is replaced on the NetScaler, the domain name mentioned on the new certificate should match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to now host a new domain, you can disable the domain check before updating its certificate.
To disable the domain check for a certificate by using the command line interface

At the command prompt, type the following commands to disable the domain check and verify the configuration:

- update ssl certKey <certkeyName> -noDomainCheck
- show ssl certKey <certkeyName>

Example

> update ssl certKey sv -noDomainCheck
Done
> show ssl certkey sv
  Name: sv
  Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
  Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
  Format: PEM
  Status: Valid,  Days to expiration:9349
  Certificate Expiry Monitor: DISABLED
Done

To disable the domain check for a certificate by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.
2. Select the certificate you want to update, and then click Update.
3. Select No Domain Check, and then click OK. The domain check for the certificate is now disabled.

Enabling the Expiry Monitor

An SSL certificate is valid for a specific period of time. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the NetScaler appliance creates entries in the appliance's syslog and nsaudit logs when a certificate configured on the appliance is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

For information about monitoring on the NetScaler appliance, see Monitors.
To enable an expiry monitor for a certificate by using the command line interface

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

- `set ssl certKey <certkeyName> [-expiryMonitor ( ENABLED | DISABLED ) [-notificationPeriod <positive_integer>]]`
- `show ssl certKey <certkeyName>`

**Example**

```
> set ssl certKey sv -expiryMonitor ENABLED -notificationPeriod 60
Done

> show ssl certkey sv
Name: sv
  Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
  Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
  Format: PEM
  Status: Valid, Days to expiration:9349
  Certificate Expiry Monitor: ENABLED
  Expiry Notification period: 60 days
Done
```

**Parameters for enabling an expiry monitor**

- **certKeyName**
  
  The name of the certificate-key pair whose expiry monitor is configured.

- **expiryMonitor**
  
  Enable or disable the expiry monitor for the certificate-key pair

- **notificationPeriod**
  
  The number of days in advance that the NetScaler should warn about a certificate that is about to expire.
To enable an expiry monitor for a certificate by using the configuration utility

1. In the navigation pane, expand SSL, and then click Certificates.

2. Select the certificate you want to update, and then click Update.

3. Select the Enable option.

4. In the Notification Period text box, type the required notification period value.

   Note: The notification period parameter can be set to any value between 10 and 100 days and the default notification period is 30 days.

5. Click OK. In the SSL Certificates pane, select the certificate that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Using Global Site Certificates

A global site certificate is a special-purpose server certificate whose key length is greater than 128 bits. A global site certificate consists of a server certificate and an accompanying intermediate-CA certificate. You must import the global site certificate and its key from the server to the NetScaler appliance.

How Global Site Certificates Work

Export versions of browsers use 40-bit encryption to initiate connections to SSL Web-servers. The server responds to connection requests by sending its certificate. The client and server then decide on an encryption strength based on the server certificate type:

- If the server certificate is a normal certificate and not a global site certificate, the export client and server complete the SSL handshake and uses 40-bit encryption for data transfer.

- If the server certificate is a global site certificate (and if the export client feature is supported by the browser), the export client automatically upgrades to 128-bit encryption for data transfer.

If the server certificate is a global site certificate, the server sends its certificate, along with the accompanying intermediate-CA certificate. The browser first validates the intermediate-CA certificate by using one of the Root-CA certificates that are normally included in web browsers. Upon successful validation of the intermediate-CA certificate, the browser uses the intermediate-CA certificate to validate the server certificate. Once the server is successfully validated, the browser renegotiates (upgrades) the SSL connection to 128-bit encryption.

With Microsoft’s Server Gated Cryptography (SGC), if the Microsoft IIS server is configured with an SGC certificate, export clients that receive the certificate renegotiate to use 128-bit encryption.

Importing a Global Site Certificate

To import a global site certificate, first export the certificate and server key from the Web server. Global site certificates are generally exported in some binary format, therefore, before importing the global site certificate, convert the certificate and key to the PEM format.
To import a global site certificate

1. Using a text editor, copy the server certificate and the accompanying intermediate-CA certificate into two separate files.

   The individual PEM encoded certificate will begin with the header ----- BEGIN CERTIFICATE----- and end with the trailer -----END CERTIFICATE-----.

2. Use an SFTP client to transfer the server certificate, intermediate-CA certificate, and server-key to the NetScaler.

3. Use the following OpenSSL command to identify the server certificate and intermediate-CA certificate from the two separate files.

   Note: You can launch the OpenSSL interface from the configuration utility. In the navigation pane, click SSL. In the details pane, under Tools, click Open SSL interface.

   > openssl x509 -in >path of the CA cert file< -text

   X509v3 Basic Constraints:
   CA:TRUE
   X509v3 Key Usage:
   Certificate Sign, CRL Sign
   Netscape Cert Type:
   SSL CA, S/MIME CA

   > openssl x509 -in >path of the server certificate file< -text

   X509v3 Basic Constraints:
   CA:FALSE
   Netscape Cert Type:
   SSL Server

4. At the FreeBSD shell prompt, enter the following command:

   openssl x509 -in cert.pem -text | more

   Where cert.pem is one of the two certificate files.

   Read the Subject field in the command output. For example,

   Subject: C=US, ST=Oregon, L=Portland, O=mycompany, Inc., OU=IT, CN=www.mycompany.com

   If the CN field in the Subject matches the domain-name of your Web site, then this is the server certificate and the other certificate is the accompanying intermediate-CA certificate.
5. Use the server certificate and its private key to create a certificate key pair on the NetScaler. For details on creating a certificate-key pair on the NetScaler, see Adding a Certificate Key Pair.

6. Add the intermediate-CA certificate on the NetScaler. Use the server certificate you created in step 4 to sign this intermediate certificate. For details on creating an Intermediate-CA certificate on the NetScaler, see Generating a Self-Signed Certificate.
Converting the Format of SSL Certificates for Import or Export

A NetScaler appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The NetScaler can convert the PKCS#12 format (the personal information exchange syntax standard) to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For additional security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

**Note:** If you use the configuration utility to import a PKCS#12 certificate, and the password contains a dollar sign ($), backquote (´), or escape (\) character, the import may fail. If it does, the **ERROR: Invalid password** message appears. If you must use a special character in the password, be sure to prefix it with an escape character (\) unless all imports are performed by using the NetScaler command line.

To convert the format of a certificate by using the command line interface

At the command prompt, type the following command:

```
convert ssl pkcs12 <outfile> [-import [-pkcs12File <inputFilename>]] [-des | -des3] [-export [-certFile <inputFilename>] [-keyFile <inputFilename>]]
```

During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.

**Example**

```
convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.pfx -des
convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -keyFile Key-Client-1
```

**Parameters for Converting the Format of a Certificate**

- **outfile (Output File Name)**
  
The name of, and optionally the path to, the output file that contains the certificate and the private key after converting from PKCS#12 to PEM format. The default output path for the file is `/nsconfig/ssl/`. This is a required parameter. Maximum value: 63 characters.
pkcsFile (PKCS12 File Name)

The name of, and optionally the path to, the PKCS#12 file. If the -import option is specified, this is the input file name that contains the certificate and the private key in PKCS#12 format. If the -export option is specified, this is the output file name that contains the certificate and the private key after converting from PEM to PKCS#12 format. The default input path is /nsconfig/ssl/. Maximum value: 63 characters.

import

Convert the certificate and private key from PKCS#12 format to PEM format.

des (Encoding Format)

Encrypt the private key with DES in CBC mode during the import operation.

des3 (Encoding Format)

Encrypt the private key with DES in EDE CBC mode (168 bit key) during the import operation.

export

Convert the certificate and private key from PEM format to PKCS#12 format.

certFile (Certificate File Name)

The certificate file to be converted from PEM to PKCS#12 format.

keyFile (Key File Name)

The private key file to be converted from PEM to PKCS#12 format.

Password (Import Password/Export Password)

In the CLI, you are prompted to enter the password during the import or export operation. In the configuration utility, you have to enter the password before the operation begins. The import password is the password that was entered while creating the PKCS#12 file. For the export password, you enter a new password that will be required when installing the certificate into the client browser.

PEMPassPhrase (PEM Passphrase)

In the CLI, you are prompted to enter the passphrase during the import operation if you select des or des3 for encrypting your private key or during the export operation if you select des or des3 for encrypting your PKCS#12 file. In the configuration utility, you have to enter the passphrase before the import operation if you select an encoding format, or before the export operation if you want to encrypt your PKCS#12 file.
To convert the format of a certificate by using the configuration utility

1. In the navigation pane, click SSL.

2. Under Tools, do one of the following
   - To convert a PKCS#12 certificate and key to PEM format, click Import PKCS#12.
   - To convert a certificate and key from PEM to PKCS#12 format, click Export PKCS#12.

3. In the Import PKCS12 or Export PKCS12 dialog box, set the following parameters:
   - Output File Name*
   - PKCS12 File Name*
   - Certificate File Name*
   - Key File Name*
   - Import Password*
   - Export Password*
   - Encoding Format
   - PEM Passphrase
   * A required parameter

4. Click OK.
Managing Certificate Revocation Lists

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA may revoke the issued certificate before the expiration date (for example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes).

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs on a regular basis. You can configure the NetScaler appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the NetScaler. You can configure refresh options. You can also configure the NetScaler to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The NetScaler supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the NetScaler.

If you have used the NetScaler as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the NetScaler are not used either in a production environment or beyond a particular date.

Note:

By default, CRLs are stored in the /var/netscaler/ssl directory on the NetScaler appliance.
Creating a CRL on the NetScaler

Since you can use the NetScaler appliance to act as a certificate authority and create self-signed certificates, you can also revoke certificates that you have created and certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

To revoke a certificate or create a CRL by using the command line interface

At the command prompt, type the following command:

```
create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>)
```

Example

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```

Parameters for revoking a certificate or creating a CRL on the NetScaler

**CAcertFile (CA Certificate File Name)**

Name of and, optionally, path to the CA certificate file. /nsconfig/ssl/ is the default path. Maximum value: 63.

**CAkeyFile (CA Key File Name)**

Name of and, optionally, path to the CA key file. /nsconfig/ssl/ is the default path. Maximum value: 63.

**indexFile (Index File Name)**

Name of and, optionally, path to the file containing the serial numbers of all the certificates that are revoked. Revoked certificates are appended to the file. /nsconfig/ssl/ is the default path. Maximum value: 63.
revoke (Revoke Certificate)

Name of and, optionally, path to the certificate to be revoked. /nsconfig/ssl/ is the default path. You can revoke a certificate only if the certificate and key of the CA that issued the certificate is available on the NetScaler. Maximum value: 63.

genCRL (Generate CRL)

Name of and, optionally, path to the CRL file to be generated. The list of certificates that have been revoked is obtained from the index file. /nsconfig/ssl/ is the default path. Maximum value: 63.

To revoke a certificate or create a CRL by using the configuration utility

1. In the navigation pane, click SSL.
2. Under Getting Started, click CRL Management.
3. In the CRL Management dialog box, set the following parameters:
   - CA Certificate File Name*
   - CA Key File Name*
   - CA Key File Password—the password used to encrypt the key file. On the CLI, you are prompted to enter this password at run time.
   - Index File Name*
   - Choose Operation-
     - Revoke Certificate
     - Generate CRL
   * A required parameter
4. Click Create, and then click Close.
Adding an Existing CRL to the NetScaler

Before you configure the CRL on the NetScaler appliance, make sure that the CRL file is stored locally on the NetScaler. In the case of an HA setup, the CRL file must be present on both NetScaler appliances, and the directory path to the file must be the same on both appliances.

To add a CRL on the NetScaler by using the command line

At the command prompt, type the following commands to add a CRL on the NetScaler and verify the configuration:

- `add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]`
- `show ssl crl [<crlName>]`

Example

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM
Done
> show ssl crl crl-one
   Name: crl-one   Status: Valid,  Days to expiration: 29
   CRL Path: /var/netscaler/ssl/CRL-one
   Format: PEM   CAcert: samplecertkey
   Refresh: DISABLED
   Version: 1
   Signature Algorithm: sha1WithRSAEncryption
   Issuer: C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,OU=SSL Acceleration,CN=www.ns.com/emailAddress=support@netscaler.com
   Last_update:Jun 15 10:53:53 2010 GMT
   Next_update:Jul 15 10:53:53 2010 GMT

  1)      Serial Number: 00
          Revocation Date:Jun 15 10:51:16 2010 GMT
Done
```

Parameters for adding an existing CRL

- **crlName (CRL Name)**
  
  The name of the CRL being added on the NetScaler.

- **crlPath (CRL File)**

```
The name of the CRL file being added on the NetScaler. The NetScaler looks for the CRL file in the /var/netscaler/ssl directory by default.

**inform (Format)**

The format in which the CRL file is stored on the NetScaler appliance. Possible Values: PEM, DER. Default: PEM.

**CAcert (CA Certificate)**

The corresponding CA certificate that has issued the CRL. This is the System object identifying the CA certificate that is loaded in System. Maximum Length: 31

*Note:* The CA certificate should be installed before loading the CRL.

---

### To add a CRL on the NetScaler by using the configuration utility

1. In the navigation pane, expand SSL, and then click CRL.

2. In the details pane, click Add.

3. In the Add CRL dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for adding an existing CRL” as shown:

   - CRL Name*
   - CRL File*
   - Format
   - CA Certificate

   * A required parameter

4. Click Create, and then click Close. In the CRL pane, select the CRL that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Configuring CRL Refresh Parameters

A CRL is generated and published by a Certificate Authority periodically or, in some cases, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the NetScaler appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The NetScaler can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you execute the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.

Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. You must explicitly specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

To configure CRL autorefresh by using the command line

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration the following commands to configure CRL auto refresh and verify the configuration:

- set ssl crl <crlName> [-refresh ( ENABLED | DISABLED )] [-CAcert <string>] [-url <URL | -server <ip_addr|ipv6_addr>] [-method HTTP | (LDAP [-baseDN <string>] [-bindDN <string>] [-scope ( Base | One )] [-password <string>] [-binary ( YES | NO )]) [-port <port>] [-interval <interval>]

- show ssl crl [<crlName>]

Example

Set CRL crl1 -refresh enabled -method ldap -inform DER -CAcert ca1 -server 10.102.192.192 -port 389 -scope base

Set CRL crl1 -refresh enabled -method http -cacert ca1 -port 80 -time 00:10 -url http://10.102.192.192/crl/ca1.crl

> sh crl

1)         Name: crl1        Status: Valid,     Days to expiration: 355
CRL Path: /var/netscaler/ssl/crl1
Format: PEM      CAcert: ca1
Refresh: ENABLED          Method: HTTP
URL: http://10.102.192.192/crl/ca1.crl                 Port:80
Refresh Time: 00:10
Last Update: Successful, Date:Tue Jul  6 14:38:13 2010
CRL Refresh Parameters

**crlName**

The name of the CRL being refreshed on the NetScaler.

**refresh**

Enable or disable CRL auto refresh.

**CAcert**

The certificate of the CA that has issued the CRL. This CA certificate must be installed on the appliance. The NetScaler can update CRLs only from CAs whose certificates are installed on it.

**url (URL)**

The URL for the web location from which the CRL should be fetched.

**server (Server IP)**

The IP address of the LDAP server from which the CRL should be fetched.

**method (Method)**

Protocol in which to obtain the CRL refresh from a web server (HTTP) or an LDAP server. Possible Values: HTTP, LDAP. Default: LDAP.

**baseDN (Base DN)**

The baseDN attribute used by LDAP search to query for the `certificateRevocationList` attribute.

**Note:** Citrix recommends using the `baseDN` attribute instead of the Issuer-Name from the CA certificate to search for the CRL in the LDAP server. The Issuer-Name field may not exactly match the LDAP directory structure's DN.

**bindDN (Bind DN)**

The `bindDN` attribute to be used to access the CRL object in the LDAP repository. This is required if the access to the LDAP repository is restricted, that is, anonymous access is not allowed.

**scope (Scope)**

The extent of the search operation on the LDAP server. If the scope specified is `Base`, the search is at exactly the same level as the `baseDN`. If the scope specified is `One`, the search extends to one level below the `baseDN`. 

---

1082
password (Password)

The password used to access the CRL object in the LDAP repository. This is required if the access to the LDAP repository is restricted, that is, anonymous access is not allowed.

binary (Binary)

Set the LDAP based CRL retrieval mode to binary. Possible values: YES, NO. Default: NO.

port (Port)

The port number on which the LDAP or the HTTP server should be contacted.

interval (Interval)

The interval at which the CRL refresh should be carried out. For an instantaneous CRL refresh, specify the interval as NOW. Possible values: MONTHLY, DAILY, WEEKLY, NOW, NONE.

day (Day)

The day on which CRL refresh should be carried out. The option is not available if interval is set to DAILY.

time (Time)

The exact time in 24-hour format when the CRL refresh should be carried out.
To configure CRL autorefresh using LDAP or HTTP by using the configuration utility

1. In the navigation pane, expand SSL, and then click CRL.

2. Select the configured CRL for which you want to update refresh parameters, and then click Open.

3. Select the Enable CRL Auto Refresh option.

4. In the CRL Auto Refresh Parameters group, specify values for the following parameters, which correspond to parameters described in “CRL Refresh Parameters” as shown:

   - Method
   - Binary
   - Scope
   - Server IP
   - Port*
   - URL
   - Base DN*
   - Bind DN
   - Password
   - Interval
   - Day(s)
   - Time

   * A required parameter

   **Note:** If the new CRL has been refreshed in the external repository before its actual update time as specified by the LastUpdate field of the CRL, you should immediately refresh the CRL on the NetScaler.

5. Click Create. In the CRL pane, select the CRL that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Synchronizing CRLs

The NetScaler appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the NetScaler needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the NetScaler to update CRLs automatically at a specified refresh interval.

The NetScaler maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated, connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

**Note:** If CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, all client-authentication connections with the same issuer as the CRL are rejected as REVOKED until the CRL is successfully refreshed.

You can specify the interval at which the CRL refresh should be carried out. You can also specify the exact time.

To synchronize CRL autorefresh by using the command line interface

At the command prompt, type the following command:

```bash
set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <HH:MM>]
```

**Example**

```bash
set ssl crl CRL-1 -refresh ENABLE -interval MONTHLY -days 10 -time 12:00
```

Parameters for synchronizing CRL refresh

- **interval (Interval)**
  
  The CRL refresh interval. Possible values: DAILY, WEEKLY, MONTHLY, NONE, NOW. Specify NONE to reset a previously set interval. Specify NOW for instantaneous refresh. See also day.

- **day (Day)**
  
  Behavior depends on the interval setting. If -interval is not set, -day specifies the CRL refresh interval as a number of days. If -interval is set to MONTHLY, -day specifies a day
of the month (1-30/31/28) If -interval is set to WEEKLY, -day specifies a day of the week, 1 to 7, where 1=Sunday and 7=Saturday. If -interval is DAILY, -day cannot be used.

time (Time)

The time of the day when the CRL should be refreshed. The time is specified in 24-hour HHMM format, where HH stands for Hours and MM stands for minutes.

To synchronize CRL refresh by using the configuration utility

1. In the navigation pane, expand SSL, and then click CRL.

2. Select the configured CRL for which you want to update refresh parameters, and then click Open.

3. Select the Enable CRL Auto Refresh option.

4. In the CRL Auto Refresh Parameters group, specify values for the following parameters, which correspond to parameters described in “Parameters for synchronizing CRL refresh” as shown:

   - Interval
   - Day(s)
   - Time

5. Click Create. In the CRL pane, select the CRL that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Performing Client Authentication by using a Certificate Revocation List

If a certificate revocation list (CRL) is present on a NetScaler appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional.

The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

Table 1. Result of a Handshake with a Client Using a Revoked Certificate

<table>
<thead>
<tr>
<th>Rule for CRL Check</th>
<th>Rule for Client Certificate Check</th>
<th>State of the CRL Configured for the CA certificate</th>
<th>Result of a Handshake with a Revoked Certificate</th>

</tr>
<tr>
<td>Optional/Mandatory</td>
<td>Mandatory</td>
<td>Expired</td>
<td>Failure</td>
</tr>
</tbody>
</table>

Note:

- The CRL check is optional by default. To change from optional to mandatory or vice-versa, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.

- In the output of the `sh ssl vserver` command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the `sh ssl vserver` command only if CRL check is set to mandatory. If CRL check is set to optional, the CRL check details do not appear.
To configure CRL check by using the command line interface

At the command prompt, type the following command:

```
bind ssl vserver <vServerName> -certkeyName <string> [(CA -crlCheck (Mandatory | Optional))]
```

**Example**

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
sh ssl vserver
> sh ssl vs v1

Advanced SSL configuration for VServer v1:

DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
Push Encryption Trigger: Always
Send Close-Notify: YES

1) CertKey Name: ca CA Certificate CRLCheck: Mandatory CA_Name Sent

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done
```

**Parameters for configuring a CRL check on the NetScaler**

- **vServerName**
  
  Name of the SSL virtual server.

- **crlCheck**
  
  Rule to use for the CRL corresponding to the CA certificate during client authentication.
  Available settings function as follows:
Performing Client Authentication by using a Certificate Revocation List

- **MANDATORY**—Deny SSL clients if the CRL is missing or expired, or the Next Update date is in the past, or the CRL is incomplete.

- **OPTIONAL**—Allow SSL clients if the CRL is missing or expired, or the Next Update date is in the past, or the CRL is incomplete, but deny if the client certificate is revoked in the CRL.

**To configure CRL check by using the configuration utility**

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. In the details pane, select a virtual server, and then click Open.
3. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings.
4. In the Configured pane, in the **Check** drop-down list, select CRL Mandatory.
5. Click OK.
Monitoring Certificate Status with OCSP

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. NetScaler appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. NetScaler implementation of OCSP includes request batching and response caching.
NetScaler Implementation of OCSP

OCSP validation on a NetScaler appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the NetScaler creates an OCSP request and forwards it to the OCSP responder. To do so, the NetScaler uses a locally configured URL. The transaction is in a suspended state until the NetScaler evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the NetScaler will allow the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The NetScaler supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.
OCSP Request Batching

Each time the NetScaler receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the NetScaler can query the status of more than one client certificate in the same request. For this to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.
OCSP Response Caching

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the NetScaler caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the NetScaler first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the NetScaler sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.
Configuring an OCSP Responder

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

To add an OCSP responder by using the command line interface

At the command prompt, type the following commands to configure OCSP and verify the configuration:

- `add ssl ocspResponder <name> -url <URL> [-cache ( ENABLED | DISABLED )][-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>][-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>] [-signingCert <string>][-useNonce ( YES | NO )][ -insertClientCert( YES | NO )]

- bind ssl certKey [certkeyName] [-ocspResponder <string>] [-priority <positive_integer>]

- bind ssl vserver <vServerName>@ (-certkeyName <string> ( CA [-ocspCheck ( Mandatory | Optional )]))

- show ssl ocspResponder [<name>]

Example

```
add ssl ocspResponder ocsp_responder1 -url "http://www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeOut 30 minutes -batchingDepth 8 -batchingDelay 100 mS -resptimeout 100 mS -producedAtTimeSkew 300 -signingCert sign_cert -insertClientCert YES
bind ssl certKey cA_cert -ocspResponder ocsp_responder1 -priority 1
bind ssl vserver vs1 -certkeyName cA_cert -cA -ocspCheck Mandatory

sh ocspResponder ocsp_responder1
1)Name: ocsp_responder1
Caching: Enabled  Timeout: 30 minutes
Batching: 8 Timeout: 100 mS
HTTP Request Timeout: 100mS
Request Signing Certificate: sign_cert
Response Verification: Full, Certificate: responder_cert
ProducedAt Time Skew: 300 s
Nonce Extension: Enabled
Client Cert Insertion: Enabled
Done
```
show certkey ca_cert
Name: ca_cert     Status: Valid,   Days to expiration:8907
Version: 3
...  
1) VServer name: vs1    CA Certificate
1) OCSP Responder name: ocsp_responder1    Priority: 1
Done

sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
DH: DISABLED
...  
1) CertKey Name: ca_cert CA Certificate OCSPCheck: Mandatory
1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias
Done

To modify an OCSP responder by using the command line interface

You cannot modify the responder name. All other parameters can be changed using the set ssl ocspResponder command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

   set ssl ocspResponder <name> [-url <URL>] [-cache ( ENABLED | DISABLED)]
     [-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>]
     [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [ -responderCert
     <string> | -trustResponder][-producedAtTimeSkew <positive_integer>][ -signingCert
     <string>] [-useNonce ( YES | NO )]

   unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]

   bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority
     <positive_integer>]

   show ssl ocspResponder [<name>]

Parameters for configuring an OCSP Responder

name (Name)
   The name of the OCSP responder.

url (URL)
   The URL of the OCSP responder.
Configuring an OCSP Responder

Maximum length: 128.

cache (Cache)

Enable/disable caching of OCSP.

Possible values: ENABLED, DISABLED. Default: DISABLED.

cacheTimeout (Time-out)

OCSP cache timeout, in minutes. If none is specified, the timeout provided in the OCSP response is used.

batchingDepth (Batching Depth)

Maximum number of client certificates to batch into one OCSP request. Value of 1 signifies that each request is queried independently. Range: 1-8. Default: 1.

batchingDelay (Batching Delay)

Time, in milliseconds, to wait to accumulate OCSP requests.

resptimeout (Request Time-out)

Time, in milliseconds, to wait for an OCSP response. This is a mandatory parameter. When this time elapses, an error message appears or the transaction is forwarded, depending on the settings on the virtual server. Includes batchingDelay time.

responderCert (Certificate)

responderCert specifies the certificate used to validate OCSP responses. trustResponder specifies that responses will not be verified.

producedAtTimeSkew (Produced At Time Skew)

Specifies the time, in seconds, for which the NetScaler waits before considering the response as invalid. The response is considered invalid if the ProducedAt time stamp in the OCSP response exceeds or precedes the current NetScaler clock time by the amount of time specified. Range: 0-86400. Default: 300.

signingCert (Signing Certificate)

Certificate-key pair used to sign OCSP requests. If this parameter is not set, the requests are not signed. Maximum value: 32.

insertClientCert (Client Certificate Insertion)

Include the complete client certificate in the OCSP request. Possible values: YES, NO. Default: NO.
Configuring an OCSP Responder

**useNonce (Nonce)**

Enables the OCSP nonce extension, which is designed to prevent replay attacks.

**certKey**

The name of the certificate-key pair to bind.

**ocspResponder**

The name of the OCSP responder to which the certificate-key pair is bound to.

**priority**

Priority of the OCSP responder.

Range: 0-64000.

**sslvserver**

The name of the SSL virtual server that the certificate key is bound to.

**certkeyname**

The name of the certificate.

**CA**

CA certificate.

**ocspCheck**

OCSP check is mandatory or optional.

**Note:** When both OCSP and CRL check are set to optional, OCSP check is used by default. However, if a usable OCSP responder is not available, CRL check is used.
To configure an OCSP responder by using the configuration utility

1. In the navigation pane, expand SSL, and then click OCSP Responder.

2. In the details pane, do one of the following:
   - To create a new responder, click Add.
   - To modify an existing responder, select the responder, and then click Open.

3. In the Create OCSP Responder or Configure OCSP Responder dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring an OCSP Responder" as shown:
   - Name*
   - URL*
   - Cache
   - Time-out
   - Batching—To enable batching of OCSP requests, select this check box.
   - Batching Depth
   - Batching Delay
   - Trust Responses—To disable signature checks by the OCSP responder, select this check box.
   - Certificate
   - Produced At Time Skew
   - Request Time-out
   - Signing Certificate
   - Nonce
   - Client Certificate Insertion
   * A required parameter

4. Click Create or OK, and then click Close.

5. In the OCSP Responder pane, click the responder that you just configured and verify that the settings displayed at the bottom of the screen are correct.

6. In the navigation pane, click Certificates.

7. In the details pane, select a certificate and click OCSP Bindings.
8. In the OCSP Binding Details for certificate:certkey dialog box, specify values for the following parameters, which correspond to parameters described in "Parameters for configuring an OCSP Responder" as shown:

   - OCSP Responder Name—ocspResponder. If an OCSP responder is not already bound to the certificate-key pair, click Insert OCSP Responder and select a name from the OCSP Responder Name drop-down list.

   - Priority—priority

9. To bind a different certificate-key pair, click Unbind OCSP Responder, and then click Insert OCSP Responder and select a name from the OCSP Responder Name drop-down list. Verify that the settings displayed at the bottom of the screen are correct.

10. Click OK.

11. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

12. Select the virtual server to bind the certificate key to, and click Open.

13. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings.

15. In the Add drop-down list select As CA.

16. To make OCSP check mandatory, in the Configured pane, in the Check drop-down list, select OCSP Mandatory.

17. Click OK.
Configuring Client Authentication

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server by checking the server’s certificate before initiating the SSL transaction. In some cases, however, you might want to configure the server to authenticate the client that is connecting to it.

With client authentication enabled on an SSL virtual server, the NetScaler appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

**Note:** For the NetScaler to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the NetScaler and bound to the virtual server that the client is transacting with.

If the certificate is valid, the NetScaler allows the client to access all secure resources. But if the certificate is invalid, the NetScaler drops the client request during the SSL handshake.

The NetScaler verifies the client certificate by first forming a chain of certificates, starting with the client certificate and ending with the root CA certificate for the client (for example, VeriSign). The root CA certificate may contain one or more intermediate CA certificates (if the client certificate is not directly issued by the root CA).

Before you enable client authentication on the NetScaler, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that will handle the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the NetScaler.

**Note:** The NetScaler appliance supports a certificate-key pair size of 512 to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

A NetScaler virtual appliance supports certificates of up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
Configuring Client Authentication

- 2048-bit certificate on the physical server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)
Providing the Client Certificate

Before you configure client authentication, a valid client certificate must be installed on the client. A client certificate includes details about the specific client system that will create secure sessions with the NetScaler appliance. Each client certificate is unique and should be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the NetScaler appliance, you must convert the certificate to the correct format. On the NetScaler, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client system, make sure that it is installed on that system and configured for the client application that will be part of the SSL transactions (for example, the web browser).

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Converting SSL Certificates for Import or Export.

For instructions on how to generate a client certificate, see Generating Self-Signed Certificates.
Enabling Client-Certificate-Based Authentication

By default, client authentication is disabled on the NetScaler appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional or mandatory as part of the SSL handshake.

If client authentication is optional, the NetScaler requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the NetScaler terminates the SSL handshake if the SSL client does not provide a valid certificate.

**Caution:** Citrix recommends that you define proper access control policies before changing client-certificate-based authentication check to optional.

**Note:** Client authentication is configured for individual SSL virtual servers, not globally.

To enable client-certificate-based authentication by using the command line interface

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

- set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-clientCert (MANDATORY | OPTIONAL)]
- show ssl vserver <vServerName>

**Example**

```
> set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
Done
> show ssl vserver vssl

Advanced SSL configuration for VServer vssl:
DH: DISABLED
Ephemeral RSA: ENABLED       Refresh Count: 0
Session Reuse: ENABLED       Timeout: 120 seconds
Cipher Redirect: DISABLED    SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: ENABLED         Client Cert Required: Mandatory
SSL Redirect: DISABLED      Non FIPS Ciphers: DISABLED
SSLv2: DISABLED        SSLv3: ENABLED   TLSv1: ENABLED
```
Enabling Client-Certificate-Based Authentication

Parameters for configuring client certificate-based authentication

vServerName
The name of the NetScaler virtual server through which the client will access a physical server.

clientAuth
Enable or disable client authentication. Possible values: ENABLED, DISABLED. Default: DISABLED.

clientCert
Type of client authentication. Possible values: MANDATORY, OPTIONAL.

To enable client-certificate-based authentication by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to configure client certificate-based authentication, and then click Open.

3. Click the SSL Settings tab, and then click SSL Parameters.

4. In the Others group, select the Client Authentication check box.

    Note: To configure optional client authentication in Client Certificate, click Optional.

6. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK. The virtual server is now configured for client authentication.
Binding CA Certificates to the Virtual Server

A CA whose certificate is present on the NetScaler appliance must issue the client certificate used for client authentication. You must bind this certificate to the NetScaler virtual server that will carry out client authentication.

You must bind the CA certificate to the SSL virtual server in such a way that the NetScaler can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The NetScaler forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by CA_A, where CA_A is an intermediate CA whose certificate is issued by CA_B, whose certificate is in turn issued by a trusted root CA, Root_CA, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the NetScaler.

For instructions on binding one or more certificates to the virtual server, see Binding the Certificate-key Pair to the SSL Based Virtual Server.

For instructions on creating a chain of certificates, see Creating a Chain of Certificates.
Customizing the SSL Configuration

Once your basic SSL configuration is operational, you can customize some of the parameters that are specific to the certificates being used in SSL transactions. You can also enable and disable session reuse and client authentication, and you can configure redirect responses for cipher and SSLv2 protocol mismatches.

You can also customize SSL settings for two NetScaler appliances in a High Availability configuration, and you can synchronize settings, certificates and keys across those appliances.

These settings will depend on your network deployment and the type of clients you expect will connect to your servers.
Configuring Diffie-Hellman (DH) Parameters

If you are using ciphers on the NetScaler that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the NetScaler and configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the NetScaler command line, type: `sh cipher DH`.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to Traffic Management > SSL > Cipher Groups, and double-click DH.

For details on how to enable DH key exchange, see Generating a Diffie-Hellman (DH) Key.

**To configure DH Parameters by using the command line interface**

At the command prompt, type the following commands to configure DH parameters and verify the configuration:

- `set ssl vserver <vserverName> -dh <Option> -dhCount <RefreshCountValue> -filepath <string>`
- `show ssl vserver <vServerName>`

**Example**

```
> set ssl vserver vs-server -dh ENABLED -dhFile /nsconfig/ssl/ns-server.cert -dhCount 1000
Done
> show ssl vserver vs-server

Advanced SSL configuration for VServer vs-server:
DH: ENABLED
Ephemeral RSA: ENABLED          Refresh Count: 1000
Session Reuse: ENABLED          Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1)      Cipher Name: DEFAULT
```
Parameters for configuring DH parameters

dh (Enable DH Param)

Enable or disable DH key exchange. Possible values: ENABLED, DISABLED. Default: DISABLED.

dhCount (Refresh Count)

The number of interactions, between the client and the NetScaler, after which the DH private-public pair is regenerated. A value of zero (0) specifies infinite use (no refresh). Possible values: 0, or a number greater than 500. Default: 0.

dhFile (File Path)

The absolute path and file name of the DH parameter file to be installed. The default path is /nsconfig/ssl.

To configure DH Parameters by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize SSL settings, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring DH parameters” as shown:

   - Enable DH Param*
   - Refresh Count
   - File Path*

   * A required parameter

5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK. The DH parameters are now configured.
Configuring Ephemeral RSA

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object and/or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the NetScaler appliance, with the refresh count set to zero (infinite use).

Note:

The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted but reused at a later date when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

To configure Ephemeral RSA by using the command line interface

At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

- set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <positive_integer>
- show ssl vserver <vServerName>

Example

> set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
Done
> show ssl vserver vs-server

Advanced SSL configuration for VServer vs-server:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 1000
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
Configuring Ephemeral RSA

1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias
   Done

Parameters for configuring Ephemeral RSA

eRSA (Enable Ephemeral RSA)
   The state of Ephemeral RSA key exchange support for the SSL virtual server.
   Possible values: ENABLED, DISABLED
   Default value: ENABLED

eRSACount (Refresh Count)
   The refresh count for the re-generation of RSA public-key and private-key pair. Zero means infinite usage (no refresh)

   Note:
   The ‘-eRSA’ argument must be enabled if this argument is specified.
   Default value: 0
   Minimum value: 0
   Maximum value: 65534

To configure Ephemeral RSA by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize SSL settings, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring Ephemeral RSA” as shown:

   · Enable Ephemeral RSA*

   · Refresh Count*
   * A required parameter

5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK. The ephemeral RSA parameters are now configured.
Configuring Session Reuse

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the NetScaler appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that can be supported by the server.

To configure session reuse by using the command line interface

At the command prompt, type the following commands to configure session reuse and verify the configuration:

- `set ssl vserver <vServerName> -sessReuse ( ENABLED | DISABLED ) -sessTimeout <positive_integer>`

- `show ssl vserver <vServerName>`

Example

```
> set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
Done

> show ssl vserver vs-ssl

Advanced SSL configuration for VServer vs-ssl:
DH: DISABLED
Ephemeral RSA: ENABLED          Refresh Count: 1000
Session Reuse: ENABLED          Timeout: 600 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1) CertKey Name: Auth-Cert-1       Server Certificate
1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
```
Parameters for configuring Session Reuse

**sessReuse (Enable Session Reuse)**

Enable or disable the Session Reuse feature on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: ENABLED.

**sessTimeout (Time-out)**

Time in seconds up to which the session should be kept active. Any session resumption request received after the time out period will require a fresh SSL handshake and establishment of a new SSL session.

To configure session reuse by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize SSL settings, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring Session Reuse” as shown:
   - Enable Session Reuse*
   - Time-out
   * A required parameter

5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK.
Configuring Cipher Redirection

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client do not match those configured on the SSL server, the SSL handshake fails, and the failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When SSL handshake fails, the NetScaler appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.

To configure cipher redirection by using the command line interface

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

- set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED> -cipherURL < URL>
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://redirectURL
Done
> show ssl vserver vs-ssl

Advanced SSL configuration for VServer vs-ssl:
  DH: DISABLED
  Ephemeral RSA: ENABLED       Refresh Count: 1000
  Session Reuse: ENABLED       Timeout: 600 seconds
  Cipher Redirect: ENABLED     Redirect URL: http://redirectURL
  SSLv2 Redirect: DISABLED
  ClearText Port: 0
  Client Auth: DISABLED
  SSL Redirect: DISABLED
  Non FIPS Ciphers: DISABLED
  SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1)      CertKey Name: Auth-Cert-1       Server Certificate
1)      Cipher Name: DEFAULT
```
Parameters for configuring Cipher Redirection

**vServerName**

The name of the SSL based virtual server that you are configuring cipher redirection for.

**cipherRedirect (Enable Cipher Redirect)**

Enable or disable redirection based on cipher mismatch between the client and the NetScaler. Possible values: ENABLED, DISABLED. Default: DISABLED.

**cipherURL (Redirect URL)**

The URL of the page to which the client must be redirected in case of a cipher mismatch. This is typically a page that has a clear explanation of the error or an alternate location that the transaction can continue from.

To configure cipher redirection by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
2. Select the virtual server for which you want to customize SSL settings, and then click Open.
3. On the SSL Settings tab, click SSL Parameters.
4. In the Configure SSL Params dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring cipher redirection” as shown:
   - Enable Cipher Redirect
   - Redirect URL
5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK. The NetScaler is now configured to redirect clients in case of a cipher suite mismatch.
Configuring SSLv2 Redirection

For an SSL transaction to be initiated, and for successful completion of the SSL handshake, the server and the client should agree on an SSL protocol that both of them support. If the SSL protocol version supported by the client is not acceptable to the server, the server does not go ahead with the transaction, and an error message is displayed.

You can configure the server to display a precise error message (user-configured or internally generated) advising the client on the next action to be taken. Configuring the server to display this message requires that you set up SSLv2 redirection.

To configure SSLv2 redirection by using the command line interface

At the command prompt, type the following commands to configure SSLv2 redirection and verify the configuration:

- set ssl vserver <vServerName> [-sslv2Redirect ( ENABLED | DISABLED ) [-sslv2URL <URL>]]
- show ssl vserver <vServerName>

Example

> set ssl vserver vs-ssl -sslv2Redirect ENABLED -sslv2URL http://sslv2URL
Done
> show ssl vserver vs-ssl

Advanced SSL configuration for VServer vs-ssl:
DH: DISABLED
Ephemeral RSA: ENABLED      Refresh Count: 1000
Session Reuse: ENABLED      Timeout: 600 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: ENABLED Redirect URL: http://sslv2URL
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: Auth-Cert-1       Server Certificate
1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias
Done
Parameters for configuring SSLv2 redirection

vServerName

The name of the SSL based virtual server that you are configuring SSLv2 redirection for.

sslv2Redirect (Enable SSLv2 Redirect)

Enable or disable redirection based on the SSL protocol mismatch between the client and the NetScaler. Possible values: ENABLED, DISABLED. Default: DISABLED.

sslv2URL (SSLv2 URL)

The URL of the page to which the client must be redirected in case of a protocol mismatch. This is typically a page that has a clear explanation of the error, or an alternative location from which the transaction can continue.

To configure SSLv2 redirection by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize SSL settings, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring SSLv2 redirection” as shown:

   - Enable SSLv2 Redirect
   - SSLv2 URL

5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK. The NetScaler is now configured to redirect clients that only support SSLv2 protocol.
Configuring SSL Protocol Settings

The NetScaler appliance supports the SSLv2, SSLv3, and TLSv1 protocols. Each of these can be set on the appliance as required by your deployment and the type of clients that will connect to the appliance.

**To configure SSL protocol support by using the command line interface**

At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

- set ssl vserver <vServerName> -ssl2 ( ENABLED | DISABLED ) -ssl3 ( ENABLED | DISABLED ) -tls1 ( ENABLED | DISABLED ) -tls11 ( ENABLED | DISABLED ) -tls12 ( ENABLED | DISABLED )
- show ssl vserver <vServerName>

**Example**

```bash
> set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
Done
> sh ssl vs vs-ssl
```

Advanced SSL configuration for VServer vs-ssl:

- DH: DISABLED
- Ephemeral RSA: ENABLED
- Session Reuse: ENABLED
- Cipher Redirect: DISABLED
- SSLv2 Redirect: DISABLED
- ClearText Port: 0
- Client Auth: DISABLED
- SSL Redirect: DISABLED
- Non FIPS Ciphers: DISABLED
- SNI: DISABLED
- SSLv2: DISABLED
- SSLv3: ENABLED
- TLSv1.0: ENABLED
- TLSv1.1: ENABLED
- TLSv1.2: ENABLED
- Push Encryption Trigger: Always
- Send Close-Notify: YES

1 bound certificate:
1) CertKey Name: mycert  Server Certificate

1 configured cipher:
1) Cipher Name: DEFAULT
   Description: Predefined Cipher Alias

Done
Parameters for configuring SSL protocol settings

**vServerName**

The name of the SSL based virtual server for which you are configuring SSL protocol settings.

**tls1 (TLSv1)**

Enable or disable support for the TLSv1 protocol on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: ENABLED.

**tls11 (TLSv1.1)**

Enable or disable support for the TLSv1.1 protocol on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: ENABLED.

**tls12 (TLSv1.2)**

Enable or disable support for the TLSv1.2 protocol on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: ENABLED.

**ssl2 (SSLv2)**

Enable or disable support for the SSLv2 protocol on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: DISABLED.

**ssl3 (SSLv3)**

Enable or disable support for the SSLv3 protocol on the NetScaler appliance. Possible values: ENABLED, DISABLED. Default: ENABLED.
To configure SSL protocol support by using the configuration Utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize SSL settings, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, in the SSL Protocol group, select any of the following protocol options that you want to enable:
   - TLSv1.2
   - TLSv1.1
   - TLSv1
   - SSLv3
   - SSLv2

5. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK.
Configuring Close-Notify

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see Configuring Advanced SSL Settings.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

To configure close-notify at the entity level by using the command line interface

At the command prompt, type any of the following commands to configure close-notify and verify the configuration:

1. To configure close-notify at the virtual server level, type:
   
   · set ssl vserver <vServerName> -sendCloseNotify (YES | NO)
   
   · show ssl vserver <vServerName>

2. To configure close-notify at the service level, type:
   
   · set ssl service <serviceName> -sendCloseNotify (YES | NO)

   · show ssl service <serviceName>

3. To configure close-notify at the service group level, type:
   
   · set ssl serviceGroup <serviceGroupName> -sendCloseNotify (YES | NO)

   · show ssl serviceGroup <serviceGroupName>

Example

> set ssl vserver sslsvr -sendCloseNotify YES
Done
To configure close-notify at the entity level by using the configuration utility

1. In the navigation pane, expand SSL Offload.
2. Click Virtual Servers or Services or Service Groups.
3. Select the virtual server, service, or service group for which you want to customize SSL settings, and then click Open.
4. On the SSL Settings tab, click SSL Parameter.
5. In the Configure SSL Params dialog box, select Send Close-Notify.
6. Click OK, and in the Configure Virtual Server (SSL Offload) dialog box, click OK.
Configuring Advanced SSL Settings

Advanced customization of your SSL configuration addresses specific issues. You can use the set ssl parameter command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.

Note: The time that you specify applies only if you use the set ssl vserver command or the configuration utility to set timer-based encryption.

To configure advanced SSL settings by using the command line interface

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

- set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout <positive_integer>] [-sendCloseNotify (YES | NO)] [-encryptTriggerPktCount <positive_integer>] [-denySSLReneg <denySSLReneg>] [-insertionEncoding (Unicode | UTF-8)] [-ocspCacheSize <positive_integer>] [-pushFlag <positive_integer>] [-dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <positive_integer>]

- show ssl parameter

Example

> set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks no -sslTriggerTimeout 100 -sendCloseNotify no -encryptTriggerPktCount 45 -denySSLReneg no -insertionEncoding unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES -pushEncTriggerTimeout 100 ms

Done

> show ssl parameter

Advanced SSL Parameters
---

SSL quantum size: 8 kB
Max CRL memory size: 256 MB
Strict CA checks: NO
Encryption trigger timeout: 100 mS
Send Close-Notify: NO
Encryption trigger packet count: 45
Deny SSL Renegotiation: NO
Subject/Issuer Name Insertion Format: Unicode
OCSP cache size: 10 MB
Push flag: 0x3 (On every decrypted and encrypted record)
Strict Host Header check for SNI enabled SSL sessions: YES
PUSH encryption trigger timeout: 100 ms

Done

### Parameters for configuring advanced SSL settings

**quantumSize (SSL quantum size (Kbytes))**

SSL quantum size to be used for SSL transactions on the appliance.

Possible values: 4096, 8192, 16384. Default: 8192.

**crlMemorySizeMB (Max CRL memory size (Mbytes))**

Maximum memory size to be used for certificate revocation lists.

**strictCAChecks (Strict CA checks)**

Enable strict CA certificate checks on the appliance.

Possible values: YES, NO. Default: NO.

**sslTriggerTimeout (Encryption trigger timeout (10 mS ticks))**

Encryption trigger timeout value, in milliseconds.

**Note:** There may be a delay of up to 10 ms from the specified timeout value before the packet is pushed into the queue.

**sendCloseNotify (Send Close-Notify)**

Enable sending an SSL Close-Notify message to the client at the end of a transaction.

Possible values: YES, NO. Default: YES.

**encryptTriggerPktCount (Encryption trigger packet count)**

Number of queued packets that force encryption to occur.
Configuring Advanced SSL Settings

**denySSLReneg (Deny SSL Renegotiation)**

Deny renegotiation in specified circumstances. Possible values:

NO—Allow SSL renegotiation.

FRONTEND_CLIENT—Deny secure and nonsecure SSL renegotiation initiated by the client.

FRONTEND_CLIENTSERVER—Deny secure and nonsecure SSL renegotiation initiated by the client and by the NetScaler (during policy-based clientAuth).

ALL—Deny secure and nonsecure SSL renegotiation for the above two cases and for server initiated renegotiation.

NONSECURE—Deny nonsecure SSL renegotiation, to address the vulnerability described in RFC 5746. This option is not supported on the MPX FIPS appliances.

Default: NO.

**insertionEncoding (Encoding type)**

Encoding method used to insert the subject or issuer’s name in HTTP requests to backend servers.

**ocspCacheSize (OCSP cache size(Mbytes))**

Size, per packet engine, in megabytes, of the OCSP cache. The actual maximum value for this value is clamped at 10% of packet engine memory. Maximum packet engine memory is 4GB. Therefore, if you have enough memory to give all packet engines 4GB of memory, the maximum value here would be approximately 410 MB.

**pushFlag (PUSH Flag Insertion)**

Insert PUSH flag into decrypted, encrypted, or all records. If the PUSH flag is set to a value other than 0, the buffered records are forwarded on the basis of the value of the PUSH flag. Possible values:

0—Auto (PUSH flag is not set).

1—Insert PUSH flag into every decrypted record.

2—Insert PUSH flag into every encrypted record.

3—Insert PUSH flag into every decrypted and encrypted record.

Possible values: 0, 1, 2, 3. Default: 0.

**dropReqWithNoHostHeader (Drop requests for SNI enabled SSL sessions if Host header is absent)**
Host header check for SNI enabled sessions. If this check is enabled and the HTTP request does not contain the Host header for SNI enabled session, the request is dropped.

Possible values: YES, NO. Default: NO.

`pushEncTriggerTimeout (PUSH encryption trigger timeout (msec))`

Encryption trigger timeout value. The timeout value that is applied when timer option is specified in the set ssl vserver -pushEncTrigger command.

**To configure advanced SSL settings by using the configuration utility**

1. In the navigation pane, click SSL.

2. In the details pane, under Settings, click Change advanced SSL settings.

3. In the Change advanced SSL settings dialog box, set the following parameters:
   
   - SSL quantum size (Kbytes)
   - Max CRL memory size (Mbytes)
   - Encryption trigger timeout (10 mS ticks)
   - Encryption trigger packet count
   - Deny SSL Renegotiation
   - OCSP cache size(Mbytes)
   - Encoding type
   - PUSH encryption trigger timeout (msec)
   - Strict CA checks
   - Send Close-Notify
   - PUSH Flag Insertion

4. Click OK. The parameters you selected are now enabled on the appliance.

**PUSH Flag-Based Encryption Trigger Mechanism**

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:
· Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.

· Perform timer-based encryption, in which the time-out value is set globally by using the set ssl parameter -pushEncTriggerTimeout <positive_integer> command.

To configure PUSH flag-based encryption by using the command line interface

At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

· set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]

· show ssl vserver

Example

Advanced SSL configuration for VServer v1:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DH</td>
<td>DISABLED</td>
</tr>
<tr>
<td>Ephemeral RSA</td>
<td>ENABLED</td>
</tr>
<tr>
<td>Session Reuse</td>
<td>ENABLED</td>
</tr>
<tr>
<td>Cipher Redirect</td>
<td>DISABLED</td>
</tr>
<tr>
<td>SSLv2 Redirect</td>
<td>DISABLED</td>
</tr>
<tr>
<td>ClearText Port</td>
<td>0</td>
</tr>
<tr>
<td>Client Auth</td>
<td>DISABLED</td>
</tr>
<tr>
<td>SSL Redirect</td>
<td>DISABLED</td>
</tr>
<tr>
<td>Non FIPS Ciphers</td>
<td>DISABLED</td>
</tr>
<tr>
<td>SNI</td>
<td>DISABLED</td>
</tr>
<tr>
<td>SSLv2</td>
<td>DISABLED</td>
</tr>
<tr>
<td>SSLv3</td>
<td>ENABLED</td>
</tr>
<tr>
<td>TLSv1</td>
<td>ENABLED</td>
</tr>
<tr>
<td>Push Encryption Trigger</td>
<td>Always</td>
</tr>
</tbody>
</table>

Parameters for configuring PUSH flag-based encryption

pushEncTrigger

Trigger encryption based on the value of the PUSH flag.

Possible values:

· **Always.** Any PUSH packet triggers encryption.

· **Ignore.** Ignore PUSH packet for triggering encryption.

· **Merge.** For a consecutive sequence of PUSH packets, the last PUSH packet triggers encryption.

· **Timer.** PUSH packet triggering encryption is delayed by the time defined in the set ssl parameter command. Possible values: Always, Ignore, Merge, Timer. Default:
To configure PUSH flag-based encryption by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. Select the virtual server for which you want to customize PUSH-flag based encryption, and then click Open.

3. On the SSL Settings tab, click SSL Parameters.

4. In the Configure SSL Params dialog box, select a value for the PUSH Encryption Trigger parameter. For descriptions of the values, see “Parameters for configuring PSH flag-based encryption.”

5. Click OK and, in the Configure Virtual Server (SSL Offload) dialog box, again click OK. The PSH flag-based encryption trigger is now configured.
Synchronizing Configuration Files in a High Availability Setup

In a high availability (HA) set up, the primary NetScaler appliance in the HA pair automatically synchronizes with the secondary appliance in the pair. In the synchronization process, the secondary copies the primary's /nsconfig/ssl/ directory, which is the default location for storing the certificates and keys for SSL transactions. Synchronization occurs at one-minute intervals and every time a new file is added to the directory.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type the following command:

csync HA files [<Mode>]

Example

csync HA files SSL

Parameters for synchronizing files in a high availability set up

mode

The type of synchronization to be performed. The following options are available:

- **All.** Synchronizes all data.
- **Bookmarks.** Synchronizes all Access Gateway bookmarks.
- **SSL.** Synchronizes all the SSL certificates and keys that are defined on the NetScaler appliance.
To synchronize files in a high availability setup by using the configuration utility

1. In the navigation pane, click SSL.

2. In the details pane, under Tools, click Start file synchronization.

3. In the Start file synchronization dialog box, in the Mode drop-down list, select the appropriate type of synchronization (for example, SSL certificates and Keys), and then click OK.
Managing Server Authentication

Since the NetScaler appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server’s certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the NetScaler becomes the SSL client, carries out a secure transaction with the SSL server, verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, you must first enable server authentication and then bind the certificate of the CA that signed the server’s certificate to the SSL service on the NetScaler. When binding the certificate, you must specify the bind as CA option.

**To enable (or disable) server certificate authentication by using the command line interface**

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

- set ssl service <serviceName> -serverAuth ( ENABLED | DISABLED )
- show ssl service <serviceName>

**Example**

> set ssl service ssl-service-1 -serverAuth ENABLED
Done
> show ssl service ssl-service-1

Advanced SSL configuration for Back-end SSL Service ssl-service-1:
DH: DISABLED
Ephemeral RSA: DISABLED
Session Reuse: ENABLED           Timeout: 300 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
Server Auth: ENABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1)  Cipher Name: ALL
    Description: Predefined Cipher Alias
Done
Parameters for enabling or disabling server certificate authentication

**serviceName**

The name of the service for which you are configuring server certificate authentication.

**serverAuth**

Enable or disable server authentication. This is used when you configure end-to-end SSL encryption to verify the authenticity of the server.

To enable (or disable) server certificate authentication by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Services.

2. Select the service for which you want to enable server authentication, and then click Open.

3. In Configure Service dialog box, on the SSL Settings tab, click SSL Parameters.

4. In the Others group, select Server Authentication.

5. Click OK. Server authentication is now enabled for the service.

To bind the CA certificate to the service by using the command line interface

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

- bind ssl service <serviceName> -certkeyName <string> -CA
- show ssl service <serviceName>

**Example**

> bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
Done
> show ssl service ssl-service-1

Advanced SSL configuration for Back-end SSL Service ssl-service-1:
DH: DISABLED
Ephemeral RSA: DISABLED
Session Reuse: ENABLED          Timeout: 300 seconds
Cipher Redirect: DISABLED
Managing Server Authentication

SSLv2 Redirect: DISABLED
Server Auth: ENABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: samplecertkey CA Certificate CRLCheck: Optional
   1) Cipher Name: ALL
      Description: Predefined Cipher Alias
      Done

Parameters for managing server authentication

serviceName

The name of the service for which server authentication is configured.

certkeyName

The name of the certificate key pair that is bound to the SSL service.

CA

Specifies that the certificate-key pair being bound belongs to a Certificate Authority that has signed the server certificate.
Configuring User-Defined Cipher Groups on the NetScaler Appliance

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the NetScaler appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create a SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

If you bind a cipher group to an SSL virtual server, service, or service group, the ciphers are appended to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity and then bind the specific cipher group. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.

   \texttt{unbind ssl service <service name> -cipherName ALL}

2. Bind the AES cipher group to the service

   \texttt{bind ssl service <Service name> -cipherName AE}

If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

\texttt{bind ssl service <service name> -cipherName DES}

Note: The free NetScaler virtual appliance supports only the DH cipher group.
To configure a user-defined cipher group by using the command line interface

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

- add ssl cipher <cipherGroupName>
- bind ssl cipher <cipherGroupName> -cipherName <string>
- show ssl cipher <cipherGroupName>

Example

> add ssl cipher test
Done
> bind ssl cipher test -cipherName SSLv2
Done
> show ssl cipher test
  1) Cipher Name: SSL2-RC2-CBC-MD5
     Description: SSLv2 Kx=RSA  Au=RSA  Enc=RC2(128)  Mac=MD5
  2) Cipher Name: SSL2-RC4-MD5
     Description: SSLv2 Kx=RSA  Au=RSA  Enc=RC4(128)  Mac=MD5
  3) Cipher Name: SSL2-DES-CBC3-MD5
     Description: SSLv2 Kx=RSA  Au=RSA  Enc=3DES(168) Mac=MD5
  4) Cipher Name: SSL2-DES-CBC-MD5
     Description: SSLv2 Kx=RSA  Au=RSA  Enc=DES(56) Mac=MD5
  5) Cipher Name: SSL2-RC4-64-MD5
     Description: SSLv2 Kx=RSA  Au=RSA  Enc=RC4(64) Mac=MD5
  6) Cipher Name: SSL2-EXP-RC4-MD5
     Description: SSLv2 Kx=RSA(512) Au=RSA  Enc=RC4(40)  Mac=MD5 Export
  7) Cipher Name: SSL2-EXP-RC2-CBC-MD5
     Description: SSLv2 Kx=RSA(512) Au=RSA  Enc=RC2(40)  Mac=MD5 Export

To unbind ciphers from a cipher group by using the command line interface

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

- show ssl cipher <cipherGroupName>
- unbind ssl cipher <cipherGroupName> -cipherName <string>
- show ssl cipher <cipherGroupName>

Example
To remove a cipher group by using the command line interface

**Note:** You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.

At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

- `rm ssl cipher <userDefCipherGroupName> [cipherName ...]`
- `show ssl cipher <cipherGroupName>`
> rm ssl cipher test
Done

> sh ssl cipher test
ERROR: No such resource [cipherGroupName, test]

Parameters for configuring a user-defined cipher group

userDefCipherGroupName (Cipher Group Name)

The name of the user-defined cipher group. If the cipher group does not exist on the appliance, a new group with the specified name is created, and the ciphers are added to this group. If a group identified by userDefCipherGroupName already exists, the ciphers are added to it. This is a required parameter. Maximum Length: 39 characters.

cipherName (Available/Configured Cipher Groups/Ciphers)

The individual cipher name(s), a user-defined cipher group, or a predefined (built-in) cipher alias to be added to or removed from the user-defined cipher group. This is a required parameter. Maximum Length: 39 characters.

To configure a user-defined cipher group by using the configuration utility

1. In the navigation pane, expand SSL, and then click Cipher Groups.

2. In the details pane, do one of the following:

   • To create a new cipher group, click Add.

   • To modify an existing cipher group, select the cipher group, and then click Open.

3. If creating a new cipher group, in the Create Cipher Group dialog box, in the Cipher Group Name box, type a name for the new cipher group.

4. In the Create Cipher Group or View Cipher Group dialog box, do any or all of the following:

   • Select a cipher group or alias in the Available Cipher Groups list and click Add to move the group to the Configured Cipher Groups list.

   • Select a cipher group or alias in the Available Cipher Groups list, then select ciphers from the Available Ciphers list, and then click Add to move the selected ciphers to the Configured Ciphers list.

   • To move a cipher group or cipher from the Configured list to the Available list, select the group or cipher and click Remove.

5. Click Create, and then click Close. If you created a new cipher group, it appears in the Cipher Groups pane.
To bind a cipher group to an SSL virtual server, service, or service group by using the command line interface

At the command prompt, type one of the following:

- `bind ssl vserver <vServerName> -cipherName <string>`
- `bind ssl service <serviceName> -cipherName <string>`
- `bind ssl serviceGroup <serviceGroupName> -cipherName <string>`

**Examples**

```
> bind ssl vserver ssl_vserver_test -cipherName test
Done
bind ssl service nshttps -cipherName test
Done
> bind ssl servicegroup ssl_svc -cipherName test
Done
```

**Parameters for Binding a Cipher Group to an SSL Virtual Server, Service, or Service Group**

**vServerName (Name)**

The name of the SSL virtual server to which the cipher suite is to be bound. Maximum Length: 127 characters.

**vServer**

Set the `-vServer` flag, which specifies that the cipher operation is performed on an SSL virtual server. (The configuration utility sets this parameter transparently.)

**serviceName (Service Name)**

The name of the SSL service to which the cipher suite is to be bound. Maximum Length: 127 characters.

**service**

Set the `-service` flag, which specifies that the cipher operation is performed on an SSL service or service group. (The configuration utility sets this parameter transparently.)

**serviceGroupName (Service Group Name)**

The name of the SSL service group to which the cipher suite is to be bound. Maximum Length: 127 characters.
cipherName

A cipher suite can consist of an individual cipher name, the predefined cipher-alias name, or user-defined cipher group name. This is a required parameter. Maximum Length: 39 characters.

To bind a cipher group to an SSL virtual server, service, or service group by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers, Services, or Service Groups.

2. In the details pane, select the virtual server, service, or service group to bind the cipher to, and then click Open.

3. In the Configure Virtual Server (SSL Offload), Configure Service, or Configure Service Group dialog box, on the SSL Settings tab, click Ciphers.

4. In the SSL-Offload - Configure Ciphers, Service - Configure Ciphers, or Service Group - Configure Ciphers dialog box, do one or both of the following:

   - To bind a cipher group, select a cipher group or alias from the Available Cipher Groups list, and then click Add. To unbind a group, select the cipher group or alias from the Configured Cipher Groups list, and then click Remove.

   - To bind a cipher, select a cipher group or alias from the Available Cipher Groups list, then select ciphers from the Available Ciphers list, and then click Add. To unbind a cipher, select the cipher from the Configured Ciphers list, and then click Remove.

   **Note:** To override an existing cipher or cipher group, drag and drop the configured cipher or cipher group to a new location in the Configured Ciphers list or the Configured Cipher Groups list so that it precedes the cipher or cipher group to be overridden.

5. Click OK to close the dialog box, and then click OK again.
Configuring SSL Actions and Policies

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL. For a complete description of these expressions, how they work, and how to configure them manually, see Policy Configuration and Reference.

**Note:** Users who are not experienced in configuring policies at the NetScaler command line usually find using the configuration utility to be considerably easier.

You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.

Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the NetScaler appliance.
Configuring User-Defined Actions for SSL Policies

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies. In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see Configuring Built-in SSL Actions.

To configure an SSL action by using the command line interface

At the command prompt, type the following commands to configure an action and verify the configuration:

- add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -clientCert
  (ENABLED | DISABLED) certHeader <string> -clientHeader <string>
  -clientCertSerialNumber (ENABLED | DISABLED) -certSerialHeader <string>
  -clientCertSubject (ENABLED | DISABLED) -certSubjectHeader <string> -clientCertHash
  (ENABLED | DISABLED) -certHashHeader <string> -clientCertIssuer (ENABLED |
  DISABLED) -certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -sessionIDheader
  <string> -cipher (ENABLED | DISABLED) -cipherHeader <string> -clientCertNotBefore
  (ENABLED | DISABLED) -certNotBeforeHeader <string> -clientCertNotAfter (ENABLED |
  DISABLED) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)

- show ssl action [<name>]

Example

> add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X-Client-Cert"
Done
> show ssl action Action-SSL-ClientCert
1) Name: Action-SSL-ClientCert
   Data Insertion Action:
   Cert Header: ENABLED Cert Tag: X-Client-Cert
Done

Parameters for configuring an SSL action

name (Name)

The name of the SSL action. Maximum Length: 127 characters. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-)
clientAuth (Client Authentication)

Perform client certificate authentication. Possible values: ENABLED, DISABLED.

clientCert (Client Certificate)

Insert the entire client certificate into the HTTP header of the request being sent to the web server. The certificate is inserted in the ASCII (PEM) format. Possible values: ENABLED, DISABLED.

certHeader (Certificate Tag)

The name of the header into which the client certificate is inserted.

clientCertSerialNumber (Client Certificate Serial Number)

Insert the entire client serial number into the HTTP header of the request being sent to the web server. Possible values: ENABLED, DISABLED.

certSerialHeader (Serial Number Tag)

The name of the header into which the client serial number is inserted.

clientCertSubject (Client Certificate Subject (DN))

Insert the client certificate subject, also known as the distinguished name (DN), into the HTTP header of the request being sent to the web server. Possible values: ENABLED, DISABLED.

clientSubjectHeader (Subject Tag)

The name of the header into which the client certificate subject is inserted.

clientCertHash (Client Certificate Hash)

Insert the certificate signature (hash) into the HTTP header of the request being sent to the web server. Possible values: ENABLED, DISABLED.

certHashHeader (Hash Tag)

The name of the header into which the client certificate signature (hash) is inserted.

clientCertIssuer (Client Certificate Issuer)

Insert the certificate issuer into the HTTP header of the request being sent to the web server. Possible values: ENABLED, DISABLED.

certIssuerHeader (Issuer Tag)

The name of the header into which the client certificate issuer details are inserted.

sessionId (Session ID)
Insert the SSL session ID into the HTTP header of the request being sent to the web server. Every SSL connection that the client and the NetScaler share has a unique ID that identifies the specific connection. Possible values: ENABLED, DISABLED.

**sessionIDHeader (Session ID Tag)**

The tag name to be used while inserting the Session ID into the HTTP header. Maximum length: 31 characters.

**cipher (Cipher Suite)**

Insert the cipher suite negotiated by the client and the NetScaler for the particular SSL session into the HTTP header of the request being sent to the web server. The NetScaler will insert the cipher-suite name, SSL protocol, export or non-export string, and cipher strength bit, depending on the type of browser connecting to the SSL virtual server or service (for example, Cipher-Suite: RC4- MD5 SSLv3 Non-Export 128-bit). Possible values: ENABLED, DISABLED.

**cipherHeader (Cipher Tag)**

The name of the header into which the name of the cipher suite is inserted.

**clientCertNotBefore (Client Certificate Not Before Date)**

Insert the date from which the certificate is valid into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time from which it is valid. Possible values: ENABLED, DISABLED.

**certNotBeforeHeader (Not Before Tag)**

The name of the header into which to insert the date and time from which the certificate is valid.

**clientCertNotAfter (Client Certificate Not After Date)**

Insert the date of expiry of the certificate into the HTTP header of the request being sent to the web server. Every certificate is configured with the date and time at which the certificate expires. Possible values: ENABLED, DISABLED.

**certNotAfterHeader (Not After Tag)**

The name of the header into which the certificate's expiry date is inserted.

**OWASupport (Outlook Web Access)**

If the system is in front of an Outlook Web Access (OWA) server, insert a special header field, 'FRONT-END-HTTPS: ON', into the HTTP requests going to the OWA server. Possible values: ENABLED, DISABLED.
To configure an SSL action by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.
2. On the Actions tab, in the details pane, click Add.
3. In the Create SSL Action dialog box, set the following parameters:
   - Name*
   - Client Authentication
   - Client Certificate
   - Certificate Tag
   - Client Certificate Serial Number
   - Serial Number Tag
   - Client Certificate Subject (DN)
   - Subject Tag
   - Client Certificate Hash
   - Hash Tag
   - Client Certificate Issuer
   - Issuer Tag
   - Session ID
   - Session ID Tag
   - Cipher Suite
   - Cipher Tag
   - Client Certificate Not Before Date
   - Not Before Tag
   - Client Certificate Not After Date
   - Not After Tag
   - Outlook Web Access
     * A required parameter
4. Click Create, and then click Close.
Policies on the NetScaler help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must either bind it to a virtual server on the NetScaler, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through any virtual server configured on the NetScaler.

The NetScaler SSL feature supports both classic policies and default syntax policies. For a complete description of classic and default syntax expressions, how they work, and how to configure them manually, see Policy Configuration and Reference.

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.
Configuring an SSL Default Syntax Policy

An SSL default syntax policy defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy.** A control policy uses a control action, such as forcing client authentication.

  **Note:** In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.

- **Data policy.** A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed. SSL policies use the default expression syntax or the classic expression syntax. For information about expressions and how to configure them, see Policy Configuration and Reference.

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an additional action, called an UNDEF action, to be performed in the event that applying the expression to a request has an undefined result.

To configure an SSL default syntax policy by using the command line interface

At the command prompt, type:

```
add ssl policy <name> -rule <expression> -Action <string> [-undefAction <string>] [-comment <string>]
```

**Parameters for configuring SSL default syntax policies**

- **name (Name)**

  The name of the SSL policy. Maximum Length: 127 characters. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

- **rule (Expression)**
The expression that sets the condition for application of the SSL policy. Maximum Length: 1499 characters.

Action (Request Action)

The name of the action to be performed on the request. Available built-in actions: NOOP, RESET, DROP, CLIENTAUTH, and NOCLIENTAUTH. Maximum Length: 127 characters.

undefAction (Undefined-Result Action)

The name of the action to be performed when the result of rule evaluation is undefined. Possible values for control policies: CLIENTAUTH, NOCLIENTAUTH, NOOP, RESET, DROP. Possible values for data policies: NOOP, RESET or DROP. Default: NOOP.

comment (Comments)

Comments associated with this policy. Maximum Length: 255 characters.

To configure an SSL default syntax policy by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, click Policies, and then click Add.

3. In the Create SSL Policy dialog box, set the following parameters:

   - Name*
   - Request Action*
   - Undefined-Result Action
   - Expression
   - Comments
     * A required parameter

4. Click Create, and then click Close.

5. On the Policies tab, verify that the settings displayed for the policy that you just configured are correct.
Configuring Built-in Actions for SSL Default Syntax Policies

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies, so that you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- CLIENTAUTH—Perform client certificate authentication.
- NOCLIENTAUTH—Do not perform client certificate authentication.

The built-in data actions are:

- RESET—Close the connection by sending a RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

You can create user-defined data actions. For example, if you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server. For more information about user-defined actions, see Configuring User-Defined SSL Actions.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying CLIENTAUTH or NOCLIENTAUTH.

Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the NetScaler appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction CLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction NOOP

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction DROP

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction RESET
Configuring SSL Policy Labels

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, you bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the NetScaler command line, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

To create an SSL policy label and bind policies to the label by using the command line interface

At the command prompt, type:

- add ssl policylabel <labelName> -type (CONTROL | DATA )
- bind ssl policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]

Example

add ssl policylabel cpl1 -type CONTROL
add ssl policylabel dpl1 -type DATA
bind ssl policylabel cpl1 -policyName ctrlpol -priority 1
bind ssl policylabel dpl1 -policyName datapol -priority 1

Parameters for configuring SSL policy labels

labelName (Name)

The name of the SSL policy label to be created. Maximum Length: 127 characters. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters.

Type (Type)

The type of policy that the policy label can hold. Possible values: CONTROL, DATA.
To configure an SSL policy label and bind policies to the label by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policy Labels.

2. In the details pane, click Add.

3. In the Create new SSL Policy Label dialog box, set the following parameters:
   
   - Name*
   - Type*
   * A required parameter

4. Click Insert Policy, and select from the following:
   
   - **Policy Name.** The name of an existing policy.
   - **New policy.** Invokes the policy creation editor.

5. Click Create, and then click Close.

6. On the Policies tab, verify that the settings displayed for the policy that you just configured are correct.
Configuring Per-Directory Client Authentication

If you create an action specifying client-side authentication on a per-directory basis, a client identified by a policy associated with the action is not authenticated as part of the initial SSL handshake. Instead, authentication is carried out every time the client wants to access a specific directory on the web server.

For example, if you have multiple divisions in the company, where each division has a folder in which all its files are stored, and you want to know the identity of each client that tries to access files from a particular directory, such as the finance directory, you can enable per-directory client authentication for that directory.

To enable per-directory client authentication, first configure client authentication as an SSL action, and then create a policy that identifies the directory that you want to monitor. When you create the policy, specify your client-authentication action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

To create an SSL action and a policy to enable client authentication by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable client authentication and verify the configuration:

- add ssl action <name> [-clientAuth ( DOCLIENTAUTH | NOCLIENTAUTH )]
- show ssl action [-<name>]
- add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]
- show ssl policy [-<name>]

Example

> add ssl action ssl-action-1 -clientAuth DOCLIENTAUTH
  Done
> show ssl action ssl-action-1
  1) Name: ssl-action-1
    Client Authentication Action: DOCLIENTAUTH
    Hits: 0
    Undef Hits: 0
    Action Reference Count: 1
  Done
Configuring Per-Directory Client Authentication

> add ssl policy ssl-pol-1 -rule 'REQ.HTTP.METHOD==GET' -reqaction ssl-action-1
> sh ssl policy ssl-pol-1

Name: ssl-pol-1
Rule: REQ.HTTP.METHOD == GET
Action: ssl-action-1
UndefAction: Use Global
Hits: 0
Undef Hits: 0

Done

Parameters for enabling client authentication

name (Name)

The name for the new SSL action. Maximum Length: 127

This is a mandatory argument.

clientAuth (Client Authentication)

Set action to do client certificate authentication or no authentication.

DOCLIENTAUTH: Perform client certificate authentication.

NOCLIENTAUTH: No client certificate authentication.

Possible values: DOCLIENTAUTH, NOCLIENTAUTH

To create an SSL action to enable client authentication by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, on the Actions tab, click Add.

3. In the Create SSL Action dialog box, set values for the following parameters:

   - Name*

   - Client Authentication
   * A required parameter

4. Click Create, and then click Close.
To create and bind an SSL policy to enable client authentication by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, on the Policies tab, click Add.

3. In the Create SSL Policy dialog box, set values for the following parameters:
   - Name*
   - Request Action*
   * A required parameter

4. Click Add Expression to add an expression.

5. Click Create, and then click Close.

6. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

7. In the details pane, select a virtual server, and then click Open.

8. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Policies.

9. In the Bind/Unbind SSL Policies dialog box, click Insert Policy, and from the list select the policy that you want to bind to the virtual server.
Configuring Support for Outlook Web Access

If your SSL configuration is offloading SSL transactions from an Outlook Web Access (OWA) server, you must insert a special header field, FRONT-END-HTTPS: ON, in all HTTP requests directed to the OWA servers. This is required for the OWA servers to generate URL links as https:// instead of http://.

When you enable support for OWA on the NetScaler, the header is automatically inserted into the specified HTTP traffic, and you do not need to configure a specific header insertion. Use SSL policies to identify all traffic directed to the OWA server.

**Note:** You can enable Outlook Web Access support for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services.

To enable OWA support, first configure OWA support as an SSL action, and then create a policy that identifies the virtual servers or services for which you want to enable OWA support. When you create the policy, specify your OWA support action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

**To create an SSL action and a policy to enable OWA support by using the command line interface**

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- `add ssl action <name> -OWASupport ( ENABLED | DISABLED )`
- `show ssl action [<name>]`
- `add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]`
- `show ssl policy [<name>]`

**Example**

```plaintext
> add ssl action ssl-action-2 -OWASupport ENABLED
Done
> show ssl action ssl-action-2
1) Name: ssl-action-2
   Type: Data Insertion
   OWA Support: ENABLED
   Hits: 0
```
Configuring Support for Outlook Web Access

```bash
> add ssl policy ssl-pol -rule 'REQ.HTTP.METHOD == GET' -reqaction ssl-action-2

> sh ssl policy ssl-pol

Name: ssl-pol
Rule: REQ.HTTP.METHOD == GET
Action: ssl-action-2
UndefAction: Use Global
Hits: 0
Undef Hits: 0
```

Parameters for enabling support for Outlook Web Access

**name (Name)**

The name for the new SSL action. Maximum Length: 127

**OWASupport (Outlook Web Access)**

The state of Outlook Web-Access support. If the system is in front of an Outlook Web Access (OWA) server, a special header field, 'FRONT-END-HTTPS: ON', needs to be inserted in the HTTP requests going to the OWA server.

**To create an SSL action to enable OWA support by using the configuration utility**

1. In the navigation pane, expand SSL, and then click Policies.
2. On the Actions tab, in the details pane, click Add.
3. In the Create SSL Action dialog box, set the following parameters:
   - Name*
   - Outlook Web Access
   * A required parameter
4. Click Create, and then click Close.

**Note:** Outlook Web Access support is applicable only for SSL virtual server based configurations and transparent SSL service based configurations and not for SSL configurations with back-end encryption.
To create and bind an SSL policy to enable OWA support by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, on the Policies tab, click Add.

3. In the Create SSL Policy dialog box, set values for the following parameters:
   - Name*
   - Request Action*
   * A required parameter

4. Click Add Expression to add an expression.

5. Click Create, and then click Close.

6. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

7. In the details pane, select a virtual server, and then click Open.

8. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Policies.

9. In the Bind/Unbind SSL Policies dialog box, click Insert Policy, and from the list select the policy that you want to bind to the virtual server.
Configuring SSL-Based Header Insertion

Because the NetScaler appliance offloads all SSL-related processing from the servers, the servers receive only HTTP traffic. In some circumstances, the server needs certain SSL information. For example, security audits of recent SSL transactions require the client subject name (contained in an X509 certificate) to be logged on the server.

Such data can be sent to the server by inserting it into the HTTP header as a name-value pair. You can insert the entire client certificate, if required, or only the specific fields from the certificate, such as the subject, serial number, issuer, certificate hash, SSL session ID, cipher suite, or the not-before or not-after date used to determine certificate validity.

You can enable SSL-based insertion for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services. Also, client authentication must be enabled on the SSL virtual server, because the inserted values are taken from the client certificate that is presented to the virtual server for authentication.

To configure SSL-based header insertion, first create an SSL action for each specific set of information to be inserted, and then create policies that identify the connections for which you want to insert the information. As you create each policy, specify the action that you want associated with the policy. Then, bind the policies to the SSL virtual servers that will receive the SSL traffic.

The following example uses default syntax policies. In the following example, a control policy (ctrlpol) is created to perform client authentication if a request is received for the URL /testsite/file5.html. A data policy (datapol) is created to perform an action (act1) if client authentication is successful, and an SSL action (act1) is added to insert the certificate details and issuer's name in the request before forwarding the request. For other URLs, client authentication is disabled. The policies are then bound to an SSL virtual server (ssl_vserver) that receives the SSL traffic.

Command-line example of configuring SSL-based header insertion

For descriptions of the parameters used in the following commands, see Parameters for configuring an SSL action and Parameters for configuring SSL policies:

Example

> add ssl action act1 -clientCert ENABLED -certHeader mycert -clientcertissuer ENABLED -certIssuerHeader myissuer
> add ssl policy datapol -rule HTTP.REQ.URL.EQ("/testsite/file5.html") -action act1
> add ssl policy ctrlpol -rule HTTP.REQ.URL.EQ("/testsite/file5.html") -action CLIENTAUTH
> bind ssl vserver ssl_vserver -policyName ctrlpol -priority 1
> bind ssl vserver ssl_vserver -policyName datapol -priority 1
Done
To configure SSL-based header insertion by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, on the Actions tab, click Add.

3. In the Create SSL Action dialog box, set the following parameters (for descriptions of the parameters, see Parameters for Configuring an SSL Action):
   - Name*
   - Client Certificate
   - Certificate Tag
   - Client Certificate Issuer
   - Issuer Tag
   * A required parameter

4. Click Create, and then click Close.

5. On the tab, click Add to create a control policy.

6. In the Create SSL Policy dialog box, set the following parameters (for descriptions of the parameters, see Parameters for configuring SSL policies):
   - Name*
   - Expression
   - Request Action
   * A required parameter

7. Click Create, and then click Close.

8. Create a data policy by repeating steps 5 through 7.

9. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

10. In the details pane, from the list of virtual servers, select the virtual server to which you want to bind the SSL policies, and then click Open.

11. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings, and then click SSL Policies.

12. In the Bind/Unbind SSL Policies dialog box, click Insert Policy. Under Policy Name, select the policy that you created in steps 5 through 7.

13. Click OK, and then click Close. A message appears in the status bar, stating that the policy has been bound successfully.

14. Repeat steps 12 and 13 and select the policy that you created in step 8.
Binding SSL Policies to a Virtual Server

The SSL policies that are configured on the NetScaler appliance need to be bound to a virtual server that intercepts traffic directed to the virtual server. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

You can also bind SSL policies globally or to custom bind points on the NetScaler appliance. For more information about binding policies on the appliance, see Policy Configuration and Reference.

To bind an SSL policy to a virtual server by using the command line interface

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -policyName <string> [-priority <positive_integer>]
- show ssl vserver <vServerName>

Example

> bind ssl vserver vs-server -policyName ssl-policy-1 -priority 10
Done
> show ssl vserver vs-server

Advanced SSL configuration for VServer vs-server:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 1000
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 80
Client Auth: DISABLED
SSL Redirect: ENABLED
SSL-REDIRECT Port Rewrite: ENABLED
Non FIPS Ciphers: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) Policy Name: ssl-policy-1 Priority: 10
1) Cipher Name: DEFAULT Description: Predefined Cipher Alias
Done
Parameters for binding SSL policies to a virtual server

vServerName

The name of the SSL virtual server to which the SSL policy needs to be bound.
This is a mandatory argument. Maximum Length: 127

policyName

The name of the SSL policy. Maximum Length: 127

priority

Priority. Minimum value: 0
Maximum value: 64000

To bind an SSL policy to a virtual server by using the configuration utility

1. In the navigation pane, expand SSL Offload, and then click Virtual Servers.

2. In the details pane, from the list of virtual servers, select the virtual server to which you want to bind the SSL policy, and then click Open.

3. In the Configure Virtual Server (SSL Offload) dialog box, on the Policies tab, in the details pane, click Insert Policy.

4. Under Policy Name, select the policy that you want to bind to the virtual server.

5. Click OK, and then click Close. A message appears in the status bar, stating that the policy has been bound successfully.
Binding SSL Policies Globally

Globally bound policies are evaluated after all policies bound to services, virtual servers, or other NetScaler bind points are evaluated.

To globally bind an SSL policy by using the command line interface

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

- `bind ssl global -policyName <string> [-priority <positive_integer>]`
- `show ssl global`

Example

```
> bind ssl global -policyName Policy-SSL-2 -priority 90
Done
> sh ssl global
1) Name: Policy-SSL-2 Priority: 90
2) Name: Policy-SSL-1 Priority: 100
Done
```

Parameters for globally binding an SSL policy

- **policyName (Policy Name)**
  
  The name of the SSL policy. Maximum Length: 127.

- **priority (Priority)**
  
  A numeric value that indicates when this policy is evaluated relative to others. A lower priority is evaluated before a higher one.
To bind a global SSL policy by using the configuration utility

1. In the navigation pane, expand SSL, and then click Policies.

2. In the details pane, click Global Bindings.

3. In the Bind/Unbind SSL Policies to Global dialog box, click Insert Policy.

4. In the Policy Name drop-down list, select a policy.

5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.

6. Click OK. A message appears in the status bar, stating that the policy has been bound successfully.
Commonly Used SSL Configurations

SSL deployments typically use some version of one or more of the following configurations:

- SSL Offloading with End-to-End Encryption
- Transparent SSL Acceleration
  - Service-based Transparent SSL Acceleration
  - Virtual Server-based Acceleration with a Wildcard IP Address (*:443)
- SSL VIP-based Transparent Access with End-To-End Encryption
- SSL Acceleration with HTTP on the Front-End and SSL on the Back-End
- SSL Offloading with Other-TCP Protocols
  - SSL_TCP Based Offloading with End-to-End Encryption
  - Backend Encryption for TCP Based Data
- SSL Bridging
Configuring SSL Offloading with End-to-End Encryption

A simple SSL offloading setup terminates SSL traffic (HTTPS), decrypts the SSL records, and forwards the clear text (HTTP) traffic to the back-end web servers. However, the clear text traffic is vulnerable to being spoofed, read, stolen, or compromised by individuals who succeed in gaining access to the back-end network devices or web servers.

You can, therefore, configure SSL offloading with end-to-end security by re-encrypting the clear text data and using secure SSL sessions to communicate with the back-end Web servers.

Additionally, you can configure the back-end SSL transactions so that the NetScaler appliance uses SSL session multiplexing to reuse existing SSL sessions with the back-end web servers, thus avoiding CPU-intensive key exchange (full handshake) operations. This reduces the overall number of SSL sessions on the server, and therefore accelerates the SSL transaction while maintaining end-to-end security.

To configure SSL Offloading with end-to-end encryption, add SSL based services that represent secure servers with which the NetScaler appliance will carry out end-to-end encryption. Then create an SSL based virtual server, and create and bind a valid certificate-key pair to the virtual server. Bind the SSL services to the virtual server to complete the configuration.

For details on adding SSL based services, see Configuring Services.

For details on adding an SSL virtual server, see Configuring an SSL Based Virtual Server.

For details on creating a certificate-key pair, see Adding a Certificate-Key Pair.

For details on binding a certificate-key pair to a virtual server, see Binding the Certificate Key Pair to the SSL Based Virtual Server.

For details on binding services to a virtual server, see Binding Services to the SSL Based Virtual Server.

Example

Create two SSL based services, Service-SSL-1 and Service-SSL-2, with IP addresses 10.102.20.30 and 10.102.20.31 and both using port 443.

Then create an SSL based virtual server, Vserver-SSL-2 with an IP address of 10.102.10.20.

Next, create a certificate-key pair, CertKey-1 and bind it to the virtual server.

Bind the SSL services to the virtual server to complete the configuration.

Configuring Transparent SSL Acceleration

**Note:** You need to enable L2 mode on the NetScaler appliance for transparent SSL acceleration to work.

Transparent SSL acceleration is useful for running multiple applications on a secure server with the same public IP, and also for SSL acceleration without using an additional public IP.

In a transparent SSL acceleration setup, the NetScaler appliance is transparent to the client, because the IP address at which the appliance receives requests is the same as the Web server’s IP address.

The NetScaler offloads SSL traffic processing from the Web server and sends either clear text or encrypted traffic (depending on the configuration) to the web server. All other traffic is transparent to the NetScaler and is bridged to the Web server. Therefore, other applications running on the server are unaffected.

There are three modes of transparent SSL acceleration available on the NetScaler:

- Service-based transparent access, where the service type can be SSL or SSL_TCP.
- Virtual server-based transparent access with a wildcard IP address (*:443).
- SSL VIP-based transparent access with end-to-end encryption.

**Note:** An SSL_TCP service is used for non-HTTPS services (for example SMTPS and IMAPS).

### Service-based Transparent SSL Acceleration

To enable transparent SSL acceleration using the SSL service mode, configure an SSL or an SSL_TCP service with the IP address of the actual back-end Web server. Instead of a virtual server intercepting SSL traffic and passing it on to the service, the traffic is now directly passed on to the service, which decrypts the SSL traffic and sends clear text data to the back-end server.

The service-based mode allows you to configure individual services with a different certificate, or with a different clear text port. Also, you can also select individual services for SSL acceleration.

You can apply service-based transparent SSL acceleration to data that uses different protocols, by setting the clear text port of the SSL service to the port on which the data transfer between the SSL service and the back-end server occurs.

To configure service-based transparent SSL acceleration, first enable both the SSL and the load balancing features. Then create an SSL based service and configure its clear text port. After the service is created, create and bind a certificate-key pair to this service.
For details on configuring the clear text port for an SSL based service, see "Configuring Advanced SSL Settings."

For details on creating a certificate-key pair and binding a certificate-key pair to a service, see "Adding a Certificate-Key Pair."

**Example**

Enable SSL offloading and load balancing.

Create an SSL based service, Service-SSL-1 with the IP address 10.102.20.30 using port 443 and configure its clear text port.

Next, create a certificate-key pair, CertKey-1 and bind it to the SSL service.

**Table 1. Entities in the Service-based Transparent SSL Acceleration**

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL Service</td>
<td>Service-SSL-1</td>
<td>102.20.30</td>
</tr>
<tr>
<td>Certificate - Key Pair</td>
<td>Certkey-1</td>
<td></td>
</tr>
</tbody>
</table>

**Virtual Server-based Acceleration with a Wildcard IP Address (*:443)**

You can use an SSL virtual server in the wildcard IP address mode if when you want to enable SSL acceleration for multiple servers that host the secure content of a Web site. In this mode, a single-digital certificate is enough for the entire secure Web site, instead of one certificate per virtual server. This results in significant cost savings on SSL certificates and renewals. The wildcard IP address mode also enables centralized certificate management.

To configure global transparent SSL acceleration on the NetScaler appliance, create a *:443 virtual server, which is a virtual server that accepts any IP address associated with port 443. Then, bind a valid certificate to this virtual server, and also bind all services to which the virtual server is to transfer. Such a virtual server can use the SSL protocol for HTTP-based data or the SSL_TCP protocol for non-HTTP-based data.
To configure virtual server-based acceleration with a wildcard IP address

1. Enable SSL, as described in "Enabling SSL Processing."

2. Enable load balancing, as described in "Load Balancing."

3. Add an SSL based virtual server (see "Configuring an SSL-Based Virtual Server" for the basic settings), and set the clearTextPort parameter (described in "Configuring Advanced SSL Settings").

4. Add a certificate-key pair, as described in "Adding a Certificate-Key Pair."

   **Note:** The wildcard server will automatically learn the servers configured on the NetScaler, so you do not need to configure services for a wildcard virtual server.

**Example**

After enabling SSL offloading and load balancing, create an SSL based wildcard virtual server with IP address set to * and port number 443, and configure its clear text port (optional).

If you specify the clear text port, decrypted data will be sent to the backend server on that particular port. Otherwise, encrypted data will be sent to port 443.

Next, create an SSL certificate key pair, CertKey-1 and bind it to the SSL virtual server.

**Table 2. Entities in the Virtual Server-based Acceleration with a Wildcard IP Address**

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>IP Address</th>

<tr>
<td>Certificate - Key Pair</td>
<td>Certkey-1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SSL VIP-based Transparent Access with End-To-End Encryption**

You can use an SSL virtual server for transparent access with end-to-end encryption if you have no clear text port specified. In such a configuration, the NetScaler terminates and offloads all SSL processing, initiates a secure SSL session, and sends the encrypted data, instead of clear text data, to the web servers on the port that is configured on the wildcard virtual server.

**Note:** In this case, the SSL acceleration feature runs at the back-end, using the default configuration, with all 34 ciphers available.

To configure SSL VIP based transparent access with end-to-end encryption, Follow instructions for Configuring a Virtual Server-based Acceleration with a Wildcard IP Address (*:443), but do not configure a clear text port on the virtual server.
Configuring SSL Acceleration with HTTP on the Front End and SSL on the Back End

In certain deployments, you might be concerned about network vulnerabilities between the NetScaler appliance and the backend servers, or you might need complete end-to-end security and interaction with certain devices that can communicate only in clear text (for example, caching devices).

In such cases, you can set up an HTTP virtual server that receives data from clients that connect to it at the front end and hands the data off to a secure service, which securely transfers the data to the web server.

To implement this type of configuration, you configure an HTTP virtual server on the NetScaler and bind SSL based services to the virtual server. The NetScaler receives HTTP requests from the client on the configured HTTP virtual server, encrypts the data, and sends the encrypted data to the web servers in a secure SSL session.

To configure SSL acceleration with HTTP on the front-end and SSL on the back-end, first enable the load balancing and SSL features on the NetScaler. Then, add SSL based services that represent secure servers to which the NetScaler appliance will send encrypted data. Finally, add an HTTP based virtual server and bind the SSL services to this virtual server.

Example

Enable load balancing and SSL acceleration on the NetScaler.

After enabling load balancing and SSL acceleration, create two SSL based services, Service-SSL-1 and Service-SSL-2, with IP addresses 10.102.20.30 and 10.102.20.31, and both using port 443.

Then create an HTTP based virtual server, Vserver-HTTP-1, with an IP address of 10.102.10.20.

Bind the SSL services to the virtual server to complete the configuration.

Table 1. Entities in the SSL Acceleration with HTTP on the Front End and SSL on the Back End Example

<table>
<thead>
<tr>
<th>Entity</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL Service</td>
<td>Service-SSL-1</td>
<td>10.102.20.30</td>
</tr>
<tr>
<td></td>
<td>Service-SSL-2</td>
<td>10.102.20.31</td>
</tr>
<tr>
<td>HTTP Based Virtual Server</td>
<td>Vserver-HTTP-1</td>
<td>10.102.10.20</td>
</tr>
</tbody>
</table>
In addition to the secure HTTP (HTTPS) protocol, NetScaler appliances support SSL acceleration for other TCP-based secure protocols. However, only simple requests and response-based TCP application protocols are supported. Applications such as FTPS, that insert the server’s IP address and port information in their payloads, are not currently supported.

**Note:** The STARTTLS feature for SMTP is currently not supported.

The NetScaler supports SSL acceleration for Other TCP protocols with and without end-to-end encryption.

To configure SSL offloading with Other TCP protocols, create a virtual server of type SSL_TCP, bind a certificate-key pair and TCP based services to the virtual server, and configure SSL actions and policies based on the type of traffic expected and the acceleration to be provided.

Follow the instructions in Configuring SSL Offloading, but create an SSL_TCP virtual server instead of an SSL virtual server, and configure TCP services instead of HTTP services.

### SSL_TCP Based Offloading with End-to-End Encryption

To configure SSL_TCP-based offloading with end-to-end encryption, both the virtual server that intercepts secure traffic and the services that it forwards the traffic to must be of type SSL_TCP.

Configure SSL_TCP-based offloading as described in Configuring SSL Offloading with End-to-End Encryption, but create an SSL_TCP virtual server instead of an SSL virtual server.

### Backend Encryption for TCP Based Data

Some deployments might require the NetScaler appliance to encrypt TCP data received as clear text and send the data securely to the back end servers.

To provide SSL acceleration with back-end encryption for clear text TCP traffic arriving from the client, create a TCP based virtual server and bind it to SSL_TCP based services.

To configure end-to-end encryption for TCP-based data, follow the procedure described in Configuring the SSL feature with HTTP on the Front-End and SSL on the Back-End, but create a TCP virtual server instead of an HTTP virtual server.
Configuring SSL Bridging

An SSL bridge configured on the NetScaler appliance enables the appliance to bridge all secure traffic between the SSL client and the SSL server. The appliance does not offload or accelerate the bridged traffic, nor does it perform encryption or decryption. Only load balancing is done by the appliance. The SSL server must handle all SSL-related processing. Features such as content switching, SureConnect, and cache redirection do not work, because the traffic passing through the appliance is encrypted.

Because the appliance does not carry out any SSL processing in an SSL bridging setup, there is no need for SSL certificates.

Citrix recommends that you use this configuration only if an acceleration unit (for example, a PCI-based SSL accelerator card) is installed in the web server to handle the SSL processing overhead.

Before you configure SSL bridging, first enable SSL and load balancing on the appliance. Then, create SSL_Bridge services and bind them to an SSL_Bridge virtual server. Configure the load balancing feature to maintain server persistency for secure requests.

Example

After enabling SSL and load balancing, create two servers, s1 and s2. Create two SSL_Bridge services, sc1 and src2. Create an SSL_Bridge virtual server and bind the SSL_Bridge services to the virtual server to complete the configuration. At the command line, type:

```
enable ns feature SSL LB
add server s1 10.102.1.101
add server s2 10.102.1.102
add service src1 s1 SSL_BRIDGE 443
add service src2 s2 SSL_BRIDGE 443
add lb vserver ssl_bridge_vip SSL_BRIDGE 10.102.1.200 443
bind lb vserver ssl_bridge_vip src1
bind lb vserver ssl_bridge_vip src2
```
Configuring the SSL Feature for Commonly Used Deployment Scenarios

Some of the most commonly deployed NetScaler SSL configurations are for load balancing secure data, applying content switching to secure data, and monitoring secure data:

- Configuring an SSL Virtual Server for Load Balancing.
- Configuring a Secure Content Switching Server.
- Configuring SSL Monitoring when Client Authentication is Enabled on the Backend Service.
Configuring an SSL Virtual Server for Load Balancing

A virtual server configured to load balance incoming secure data first decrypts the data and then selects a web server as determined by the configured load balancing policies. The NetScaler appliance then sends the decrypted data to the selected server, using a mapped IP address as the source IP address.

To configure load balancing on the appliance, you must first create an SSL-based load balancing virtual server and two or more HTTP-based services. You then bind the services and an SSL certificate to the virtual server. If no load balancing policy or method is configured, the default, LEASTCONNECTION, method is used.

Example

```
> add service ssl1 10.102.29.252 HTTP 80
> add service ssl2 10.102.29.253 HTTP 80
> add lb vserver vssl SSL 10.102.29.133 443
> bind lb vserver vssl ssl1
> bind lb vserver vssl ssl2
> add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -password ssl
> bind ssl vserver vssl certKeyName sslckey
> show ssl vserver vssl
```

Advanced SSL configuration for VServer vssl:

- DH: DISABLED
- Ephemeral RSA: ENABLED Refresh Count: 0
- Session Reuse: ENABLED Timeout: 120 seconds
- Cipher Redirect: DISABLED
- SSLv2 Redirect: DISABLED
- ClearText Port: 0
- Client Auth: DISABLED
- SSL Redirect: DISABLED
- Non FIPS Ciphers: DISABLED
- SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: sslckey Server Certificate

1) Cipher Name: DEFAULT Description: Predefined Cipher Alias

Done
Configuring a Secure Content Switching Server

An SSL-based content switching virtual server first decrypts the secure data and then redirects the data to appropriately configured servers as determined by the type of content and the configured content switching policies. The packets sent to the server have a mapped IP address as the source IP address.

The following example shows the steps to configure two address-based virtual servers to perform load balancing on the HTTP services. One virtual server, Vserver-LB-HTML, load balances the dynamic content (cgi, asp), and the other, Vserver-LB-Image, load balances the static content (gif, jpeg). The load-balancing method used is the default, LEASTCONNECTION. A content switching SSL virtual server, Vserver-CS-SSL, is then configured to perform SSL acceleration and switching of HTTPS requests on the basis of configured content switching policies.

Example

```bash
> enable ns feature lb cs ssl
> add lb vserver Vserver-LB-HTML http 10.1.1.2 80
> add lb vserver Vserver-LB-Image http 10.1.1.3 80
> add service s1 10.1.1.4 http 80
> add service s2 10.1.1.5 http 80
> add service s3 10.1.1.6 http 80
> add service s4 10.1.1.7 http 80
> bind lb vserver Vserver-LB-HTML s1
> bind lb vserver Vserver-LB-HTML s2
> bind lb vserver Vserver-LB-Image s3
> bind lb vserver Vserver-LB-Image s4
> add cs vserver Vserver-CS-SSL ssl 10.1.1.1 443
> add cs policy pol1 -url "*.cgi"
> add cs policy pol2 -url "*.asp"
> add cs policy pol3 -url "*.gif"
> add cs policy pol4 -url "*.jpeg"
> bind cs vserver Vserver-CS-SSL -policyName pol1 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol2 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol3 Vserver-LB-Image
> bind cs vserver Vserver-CS-SSL -policyName pol4 Vserver-LB-Image
> add certkey mykey -cert /nsconfig/ssl/ns-root.cert -key /nsconfig/ssl/ns-root.key
> bind certkey Vserver-CS-SSL mykey
>
> show cs vserver Vserver-CS-SSL
  Vserver-CS-SSL (10.1.1.1:443) - SSL Type: CONTENT
  State: UP
  Last state change was at Tue Jul 13 02:11:37 2010
  Time since last state change: 0 days, 00:02:12.440
  Client Idle Timeout: 180 sec
  Down state flush: ENABLED
```
Configuring a Secure Content Switching Server

- Disable Primary Vserver On Down: DISABLED
- State Update: DISABLED
- Default: Content Precedence: RULE
- Vserver IP and Port insertion: OFF
- Case Sensitivity: ON
- Push: DISABLED  Push VServer:
- Push Label Rule: none
Configuring SSL Monitoring when Client Authentication is Enabled on the Backend Service

Consider a scenario in which you need to load balance servers that require SSL client certificates to validate clients. For this deployment, you need to create an SSL service on the NetScaler appliance, add an HTTPS monitor, add a certificate-key pair, bind this certificate-key pair to the SSL service, and then bind the https monitor to this service. You can use this https monitor to perform health checks on the backend services.

To configure SSL monitoring with client certificate

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on the appliance by using the administrator credentials.
3. Add an SSL service. At the command prompt, type:
   ```plaintext
   add service <name> <serverName> <serviceType> <port>
   ```
4. Add an https monitor. At the command prompt, type:
   ```plaintext
   add lb monitor <name> <type>
   ```
5. Add the certificate-key pair that is going to be used as the client cert for that SSL service. At the command prompt, type:
   ```plaintext
   add ssl certKey <certKeyame> -cert <string> -key <string>
   ```
6. Bind this certkey to the SSL service. At the command prompt, type:
   ```plaintext
   bind ssl service <serviceName> -certkeyName <string>
   ```
7. Bind the https monitor to the SSL service. At the command prompt, type:
   ```plaintext
   bind lb monitor <monitorName> <serviceName>
   ```

Now, when the appliance tries to probe the backend service on which client authentication is enabled, the backend service will request a certificate as part of the SSL handshake. When the appliance returns the certificate-key bound in step 6 above, the monitor probe will succeed.

Example
add service svc_k 10.102.145.30 SSL 443
add lb monitor sslmon HTTP -respCode 200 -httpRequest "GET /testsite/file5.html" -secure YES
add ssl certKey ctest -cert client_rsa_1024.pem -key client_rsa_1024.ky
bind ssl service svc_k -certkeyName ctest
bind lb monitor sslmon svc_k
> show service svc_k
   svc_k (10.102.145.30:443) - SSL
   State: UP
   Last state change was at Tue Jan 10 13:12:24 2012
   Time since last state change: 0 days, 00:09:37.890
   Server Name: 10.102.145.30
   Server ID : 0
   Monitor Threshold : 0

Ciphers Supported by the NetScaler Appliance

Your NetScaler appliance ships with a predefined set of cipher groups. Table 1 lists the ciphers that are part of the DEFAULT cipher group and are therefore bound by default to an SSL virtual server. Table 2 lists the other ciphers currently supported by the NetScaler appliance. To use ciphers that are not part of the DEFAULT cipher group, you have to explicitly bind them to an SSL virtual server. You can also create a user-defined cipher group to bind to the SSL virtual server. For more information about creating a user-defined cipher group, see Configuring User-Defined Cipher Groups on the NetScaler Appliance.

Note:

- NetScaler MPX appliances support TLS protocol versions 1.1 and 1.2.
- Support for TLS protocol versions 1.1 and 1.2 is not available on a FIPS appliance or on a NetScaler virtual appliance.
- Support for TLS protocol versions 1.1 and 1.2 is available on an SDX appliance, but only on an instance-by-instance basis. To support TLS protocol versions 1.1 and 1.2 on an SDX appliance, you must assign at least one SSL chip to the instance when you provision it.

On a NetScaler platform that does not have N3 chips and is configured to negotiate EDH ciphers by using TLS version 1.0 with a DH key of 2048 bits, the SSL handshake fails in either of the following scenarios:

- Client authentication is enabled and the appliance receives a client certificate of 4096 bits.
End-to-end encryption is configured and the appliance receives a server certificate of 4096 bits.

Use the show ns hardware command to find out if your appliance has N3 chips.

Example

> sh hardware
    Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100
    Manufactured on: 8/19/2013
    CPU: 2900MHZ
    Host Id: 1006665862
    Serial no: ENUK6298FT
    Encoded serial no: ENUK6298FT
Done
FIPS

The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The NetScaler FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.

The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—and a Cavium CN1620-NFBE3-2.0-G on the MPX 9700/10500/12500/15500 FIPS appliances—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

The following table summarizes the differences between standard NetScaler and NetScaler FIPS appliances.

<table>
<thead>
<tr>
<th>Setting</th>
<th>NetScaler appliance</th>
<th>NetScaler FIPS appliance</th>

</tr>
<tr>
<td>Accessing keys</td>
<td>From the hard disk</td>
<td>Not accessible</td>
</tr>
</tbody>
</table>

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you should export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability (HA) setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard HA setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1, and you can reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a NetScaler FIPS appliance.
Configuring the HSM

Before you can configure the HSM of your NetScaler FIPS appliance, you must complete the initial hardware configuration. For more information, see Initial Configuration.

Configuring the HSM of your NetScaler FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser (nsroot account). The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM.

Important: Do not perform the set ssl fips command without first resetting the FIPS card and restarting the MPX FIPS appliance.

Although the FIPS appliance can be used with the default password values, you should modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

Important: Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. Should you need to reinitialize the HSM, you will need to specify this password as the old SO password.

Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see Upgrading or Downgrading the System Software.

After upgrading, verify that the /nsconfig/fips directory has been successfully created on the appliance.

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

1. show ssl fips
2. reset ssl fips
3. reboot -warm
4. set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <userPassword> [-hsmLabel <string>]
5. save ns config
6. reboot -warm
Configuring the HSM

7. show ssl fips

Example

show fips
FIPS Card is not configured
Done
reset fips
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel cavium
This command will erase all data on the FIPS card. You must save the configuration
(saveconfig) after executing this command.

Do you want to continue?(Y/N)y
Done
save ns config
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
show fips
  FIPS HSM Info:

Done

Parameters for configuring the HSM

initHSM

The FIPS initialization level. The appliance currently supports Level-2 (FIPS 140-2
Level-2). Possible value: Level 2.

hsmLabel

newSOpassword

The security officer password that will be in effect after you have configured the HSM.
Maximum length on MPX 9700/10500/12500/15500 FIPS appliances: 14 characters.
oldSOPassword

The old security office password. Default on MPX 9700/10500/12500/15500 FIPS appliances: so12345.

userPassword

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the configuration utility

1. In the navigation pane, expand SSL, and then click FIPS. In the details pane, verify that the message "FIPS card is not configured" appears.

2. In the details pane, on the FIPS Infotab, click Reset FIPS.

3. In the navigation pane, click System.

4. In the details pane, click Reboot.

5. In the details pane, on the FIPS Info tab, click Initialize HSM.

6. In the Initialize HSM dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for configuring the HSM” as shown:

   · Security Officer (SO) Password*—new SO password
   · Old SO Password*—old SO password
   · User Password*—user password
   · Level—initHSM (Currently set to Level2 and cannot be changed)
   · HSM Label—hsmLabel
   *A required parameter

7. Click OK.

8. In the details pane, click Save.

9. In the navigation pane, click System.

10. In the details pane, click Reboot.

11. Under FIPS HSM Info, verify that the information displayed for the FIPS HSM that you just configured is correct.
Creating and Transferring FIPS Keys

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance’s HSM. You can then export the FIPS key to the appliance’s CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

Note: If you are planning an HA setup, make sure that the FIPS appliances are configured in an HA setup before creating a FIPS key.
Creating a FIPS Key

Before creating a FIPS key, make sure that the HSM is configured.

To create a FIPS key by using the configuration utility

1. In the navigation pane, expand SSL, and then click FIPS.
2. In the details pane, on the FIPS Keys tab, click Add.
3. In the Create FIPS Key dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for Creating a FIPS Key” as shown:
   - FIPS Key Name*—fipsKeyName
   - Modulus*—modulus
   - Exponent*—exponent
   *A required parameter
4. Click Create, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just created are correct.

Parameters for Creating a FIPS Key

fipsKeyName
The object name for the FIPS key. Maximum Length: 31.

modulus
The modulus of the key to be created. The modulus value should be a multiple of 64. Possible values on MPX 9700/10500/12500/15500 FIPS appliances: 1024, 2048.

exponent
The exponent value for the key to be created. Possible values: 3 (Hex: 0x3), F4 (Hex: 0x00001). Default: 3.

To create a FIPS key by using the command line interface

At the command prompt, type the following commands to create a FIPS key and verify the settings:
Creating a FIPS Key

- create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent ( 3 | F4 )]
- show ssl fipsKey [<fipsKeyName>]

Example

create fipskey Key-FIPS-1 -modulus 2048 -exponent 3
show ssl fipsKey Key-FIPS-1
FIPS Key Name: Key-FIPS-1 Modulus: 2048 Public Exponent: 3 (Hex: 0x3)
Exporting a FIPS Key

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the /nsconfig/ssl folder on the appliance's CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

To export a FIPS key by using the command line interface

At the command prompt, type:

```bash
export ssl fipsKey <fipsKeyName> -key <string>
```

Example

```bash
export fipskey Key-FIPS-1 -key Key-FIPS-1.key
```

Parameters for exporting a FIPS key

- **fipsKeyName**
  
The name of the FIPS key to be exported. Maximum Length: 31.

- **key**
  
The path and file name in which to store the exported key. Maximum Length: 63. Default path: /nsconfig/ssl/.
To export a FIPS key by using the configuration utility

1. In the navigation pane, expand SSL, and then click FIPS.

2. In the details pane, on the FIPS Keys tab, click Export.

3. In the Export FIPS key to a file dialog box, specify values for the following parameters, which correspond to parameters described in “Parameters for exporting a FIPS key” as shown:
   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

   *A required parameter

4. Click Export, and then click Close.
Importing an Existing FIPS Key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

**Note:** To avoid errors when importing a FIPS key, make sure that the name of the key imported is the same as the original key name when it was created.

**To import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface**

At the command prompt, type the following commands to import a FIPS key and verify the settings:

- `import ssl fipsKey <fipsKeyName> -key <string> -inform SIM -exponent (F4 | 3)`
- `show ssl fipskey <fipsKeyName>`

**Example**

`import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4`  
`show ssl fipskey Key-FIPS-2`  
FIPS Key Name: Key-FIPS-2  
Modulus: 2048  
Public Exponent: F4 (Hex value 0x10001)

**Parameters for importing an existing FIPS key**

- **fipsKeyName (FIPS Key Name)**
  
The name of the FIPS key to be imported. Maximum Length: 31.

- **key (Key File Name)**
  
The name of the key file. By default, the file is placed in the /nsconfig/ssl/ directory. If you want to put the file in a different location, include the complete path.

- **inform (Input Format)**
  
The input format of the key file. Possible values:

  - SIM—Secure Information Management; used when a FIPS key is imported.

  - PEM—Privacy Enhanced Mail; used on the MPX 9700/10500/12500/15500 FIPS appliances when a non-FIPS key is imported.

  Default: SIM
**exponent (Exponent)**

The exponent value for the FIPS key to be imported. Possible values: 3 and F4. Default: F4. The exponent is required only on the MPX 9700/10500/12500/15500 FIPS appliances.

---

**To import a FIPS key by using the configuration utility**

1. In the navigation pane, expand SSL, and then click FIPS.

2. In the details pane, on the FIPS Keys tab, click Import.

3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   
   * FIPS Key Name*
   
   * Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.

   * Exponent*
   *A required parameter

4. Click Import, and then click Close.

5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.
Importing External Keys

In addition to transferring FIPS keys that are created within the NetScaler appliance’s HSM, you can transfer external private keys (such as those created on a standard NetScaler, Apache, or IIS) to a FIPS NetScaler appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance’s flash drive under /nsconfig/ssl.

Importing an external key as a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

On the MPX 9700/10500/12500/15500 FIPS appliances, the -exponent parameter in the import ssl fipskey command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The NetScaler FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

```
openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>
```

To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the command line interface

1. Copy the external key to the appliance’s flash drive.

2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:

   ```
   convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx file name> -password <password>
   ```

3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:

   ```
   import ssl fipsKey <fipsKeyName> - key <string> - inform PEM
   show ssl fipskey<fipsKeyName>
   ```
Importing External Keys

Example

convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx
import fipskey Key-FIPS-2 -key iis.pem -inform PEM
show ssl fipskey key-FIPS-2
FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0x10001)

Note: The modulus is incorrectly displayed as zero in the above example. The discrepancy does not affect SSL functionality.

To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the configuration utility

1. If the key is in .pfx format, you must first convert it to PEM format.
   a. In the navigation pane, click SSL.
   b. In the details pane, under Tools, click Import PKCS#12.
   c. In the Import PKCS12 File dialog box, set the following parameters:
      · Output File Name*
      · PKCS12 File Name*—Specify the .pfx file name.
      · Import Password*
      · Encoding Format
        *A required parameter
2. In the navigation pane, expand SSL, and then click FIPS.
3. In the details pane, on the FIPS Keys tab, click Import.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   · FIPS Key Name*
   · Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
     *A required parameter
5. Click Import, and then click Close.
6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.
You can configure two appliances in a high availability (HA) pair as FIPS appliances. For information about configuring an HA setup, see High Availability.

**Note:** Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause inconsistency that requires that the appliance be restarted. In addition, if you use the CLI, the create ssl fipskey command is not propagated to the secondary node. When you execute the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not identical. You have to create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).

**Important:** On the MPX 9700/10500/12500/15500 FIPS appliances, the HA setup should be completed within six minutes. If the process takes longer than six minutes, the internal timer of the FIPS card expires and the following error message appears:

ERROR: Operation timed out or repeated, please wait for 10 mins and redo the SIM/HA configuration steps.

If this message appears, restart the appliance or wait for 10 minutes, and then repeat the HA setup procedure.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.
To configure FIPS appliances in a high availability setup by using the command line interface

1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.

2. Log on to the appliance, using the administrator credentials.

3. Initialize appliance A as the source appliance. At the command prompt, type:

   ```
   init ssl fipsSIMsource <certFile>
   ```

4. Copy this `<certFile>` file to appliance B, in the `/nconfig/ssl` folder.

5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.

6. Log on to the appliance, using the administrator credentials.

7. Initialize appliance B as the target appliance. At the command prompt, type:

   ```
   init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>
   ```

8. Copy this `<targetSecret>` file to appliance A.

9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:

   ```
   enable ssl fipsSIMSource <targetSecret> <sourceSecret>
   ```

10. Copy this `<sourceSecret>` file to appliance B.

11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:

    ```
    enable ssl fipsSIMtarget <keyVector> <sourceSecret>
    ```

12. **On appliance A**, create a FIPS key, as described in Creating a FIPS Key.

13. Export the FIPS key to the appliance’s hard disk, as described in Exporting a FIPS Key.

14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.

15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in Importing an Existing FIPS Key.
To configure FIPS appliances in a high availability setup by using the configuration utility

1. On the appliance to be configured as the source appliance, in the navigation pane, expand SSL, and then click FIPS.

2. In the details pane, on the FIPS Info tab, click Enable SIM.

3. In the Enable HA Pair for SIM dialog box, in the Certificate File Name text box, type the file name, with the path to the location at which the FIPS certificate should be stored on the source appliance.

4. In the Key Vector File Name text box, type the file name, with the path to the location at which the FIPS key vector should be stored on the source appliance.

5. In the Target Secret File Name text box, type the location for storing the secret data on the target appliance.

6. In the Source Secret File Name text box, type the location for storing the secret data on the source appliance.

7. Click OK. The FIPS appliances are now configured in HA mode.

8. Create a FIPS key, as described in Creating a FIPS Key. The FIPS key is automatically transferred from the primary to the secondary.

Example

In the following example, source.cert is the certificate on the source appliance, stored in the default directory, /nsconfig/ssl. This certificate must be transferred to the same location (/nsconfig/ssl) on the target appliance. The file target.secret is created on the target appliance and copied to the source appliance. The file source.secret is created on the source appliance and copied to the target appliance.

On the source appliance

init fipsSIMsource /nsconfig/ssl/source.cert

On the target appliance

init fipsSIMtarget /nsconfig/ssl/source.cert /nsconfig/ssl/target.key /nsconfig/ssl/target.secret

On the source appliance

enable fipsSIMsource /nsconfig/ssl/target.secret /nsconfig/ssl/source.secret

On the target appliance
enable fipssMtargeta /nsconfig/ssl/target.key /nsconfig/ssl/source.secret

On the source appliance

create ssl fipskey fips1 -modulus 2048 -exponent f4
export fipskey fips1 -key /nsconfig/ssl/fips1.key

Copy this key into the hard disk of the target appliance.

On the target appliance

import fipskey fips1 -key /nsconfig/ssl/fips1.key

The following diagram summarizes the transfer process.

Figure 1. Transferring the FIPS Key-Summary
Resetting a Locked HSM

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. This is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

**Important:** To avoid this situation, save the configuration after initializing the HSM.

If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

**Caution:** Do not reset the HSM unless it has become locked.

### To reset a locked HSM by using the command line interface

At the command prompt, type the following commands to reset and re-initialize a locked HSM:

- `reset ssl fips`
- `reboot -warm`
- `set ssl fips -initHSM Level-2 <new SO password> <old SO password> <user password> [-hsmLabel <string>]`
- `save ns config`
- `reboot -warm`

**Example**

```
reset fips
reboot -warm
set fips -initHSM Level-2 newsopin123 sopin123 userpin123 -hsmLabel NSFIPS
saveconfig
reboot -warm
```

**Note:** The SO and User passwords are the default passwords.
To reset a locked HSM by using the configuration utility

1. In the navigation pane, expand SSL, and then click FIPS.
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in Configuring the HSM.
4. In the details pane, click Save.
The FIPS approved algorithms are:

Key-Exchange algorithms
- RSA

Cipher algorithms
- SSL3-DES-CBC3-SHA
- TLS1-AES-256-CBC-SHA
- TLS1-AES-128-CBC-SHA

Note: RC4 (ARC4) is not a FIPS-approved algorithm.

SSL virtual server is marked UP only when default ciphers (FIPS) are configured.
NetScaler Web 2.0 Push

Modern web applications, also referred to as web 2.0 applications, provide highly responsive interfaces that generate asynchronous updates that can impose an additional load on a server. Typically, asynchronous notifications are sent by using HTTP and server push techniques, such as long-polling and streaming response, which enable servers to push the notifications to clients. These techniques require the servers to maintain a large number of TCP/IP connections, which provides low latency but results in low bandwidth. As the number of clients increases, the servers are overloaded with connections kept open for each client. Further, the large number of connections terminating on the server requires kernel resources and memory for data structures like protocol control blocks, socket descriptors, and socket buffers.

With the NetScaler Web 2.0 push feature, you can use the NetScaler appliance as a proxy server to offload long-lived client TCP connections and maintain relatively fewer, reusable connections to the server. NetScaler Web 2.0 push is application agnostic, with the flexibility to work seamlessly with various technologies and configurations used for asynchronous messaging. It can be extended to co-exist with developing technologies, and it preserves backward compatibility. NetScaler Web 2.0 Push is also scalable, with support for multiple NetScaler appliances.

With the NetScaler Web 2.0 push feature, the NetScaler appliance multiplexes and manages the exchange of data reliably and securely, reducing the number of server-side connections across potentially millions of persistent client connections. For every HTTP, HTTPS, or SSL transaction, the appliance can de-link and rebalance the server farm to distribute client requests across multiple servers.

The NetScaler Web 2.0 Push feature reduces the number of server-side connections across millions of persistent client connections.
Web 2.0 Push Applications

With modern Web applications, termed broadly as Web 2.0 applications, servers use AJAX technologies such as polling to maintain up-to-date information about the client. Polling enables an AJAX application to periodically poll the server for updates. For example, a chat based application can poll a Web server every 10 seconds for any chat updates. To get such updates from the Web server, the client browser periodically opens a connection to the Web server.

![Figure 1. Polling Technique](image)

Such frequent polling can overload the server. Also, if you deploy the AJAX application on a Web server with low resources and a large number of simultaneous users poll the server for updates, the network can become saturated, with significant degradation in the server performance. And if there is no update from the server, the client requests overload the server for a void response.

To avoid such problems, server push technology often uses a long polling technique. Long polling enables the client application to open a persistent connection to the server and wait for the server to push updates when available.
If your server supports asynchronous request processing, long polling is a scalable technique. However, long polling can hold the server connections until updates are available. For example, if 1,000 AJAX applications open one long polled connection, 1,000 threads hold the server while waiting for updates.

Another technique, called HTTP streaming, is identical to the long polling technique except that the connection is not closed after the server pushes the updates. The AJAX application sends a single request and receives chunks of responses (partial responses) over the same connection. With HTTP streaming, the browsers and server do not open or close the connection. Therefore, HTTP streaming significantly reduces the network latency.
In HTTP streaming, as in long polling techniques, if the server frequently pushes updates, the performance of the network and the AJAX applications are significantly degraded and the client may lose the updates. If your AJAX application opens both long polling and HTTP streaming connections to the same Web server, other AJAX applications cannot open connections to the server, because the browser blocks such connections.

NetScaler Web 2.0 push uses connection labeling to overcome the limitations of long polling and HTTP streaming.
How Web 2.0 Push Works

The NetScaler Web 2.0 push feature enables the server to label a client connection and subsequently identify and send data over that labeled connection. With NetScaler Web 2.0 push enabled, the client first establishes a TCP/IP connection and connects to the NetScaler appliance. The appliance uses the configured load balancing method or content switching policy to select a Web server to which to open a connection and send the client request. The server interacts with the client and uses either authentication or a previously established cookie to identify the client.

When the NetScaler appliance receives a request with push enabled, it initiates the labeling protocol with the Web server. This protocol enables the Web server to label the connection and defer the response. The protocol also enables the server to process other requests without invoking push processing. The Web server (referred to as a notification server) uses the label to send updates to the client through the NetScaler appliance when the updates become available. Servers can choose to push multiple updates over a single TCP connection or open one connection per update.

Note: The set of Web servers that respond to requests from the NetScaler does not necessarily include the notification servers that push updates to client.

A central component of a NetScaler Web 2.0 push configuration is a push virtual server, which is a load balancing virtual server with service type PUSH or SSL_PUSH. The NetScaler appliance uses the push virtual server to expose the message push protocol to the Web servers. A server uses the protocol to push asynchronous messages to connected clients. A push virtual server exposes a simple REST interface for posting updates.

Important: For the NetScaler Web 2.0 Push feature to work correctly, you must configure the NetScaler appliance as a proxy for the traffic between the clients and servers. You can use multiple NetScaler appliances to scale up your connection management.

For each transaction, the NetScaler Web 2.0 push feature maintains a state machine, which manages the actions of the transaction. The state machine has the following states:

- Waiting for Request State (Q) - A connection has been established between the client and the NetScaler appliance. The appliance waits in this state until the client sends a request.

- Waiting for Server Response State (R) - A request has been received from the client and forwarded to a Web server. The appliance waits in this state for the server to respond.

- Waiting for Asynchronous Messages State (A) - The appliance is waiting for asynchronous messages that the notification servers push to the push virtual server.

Until the client establishes a connection with the NetScaler appliance's load balancing or content switching virtual server, the initial state of the transaction is Q. When the appliance receives a request, it forwards the request to the server, and the transaction moves to state R.

If the appliance receives a deferred response (also called a labeled response), the transaction moves to state A. In this state, if the appliance receives a push message through the message push protocol, it processes the message and forwards the message to
the client. If this message is marked as the last message, the appliance closes the
transaction and moves to state Q. If not, the transaction remains in state A.

The push virtual server can manage long-polling and streaming responses from the server.
Each update that the server sends to the push virtual server has a flag (with query
parameters) that indicates whether there are updates from the server. When the flag
indicates that the updates from the server are unavailable, the NetScaler appliance
performs one of the following functions:

1. If the client uses HTTP 1.1 protocol and multiple updates are received from the server,
   the appliance sends a chunked response to the client and appends a zero chunk to the
   final response. If the first response itself has the flag set, the content length itself is
   sent as the response.

2. If the client uses HTTP 1.0 protocol and multiple updates are received from the server,
   then just the contents of the chunked response or the body of the content length
   response is sent to the client and the connection is terminated. If the first response
   itself has the flag set then, the content length itself is sent as the response.

The appliance sends a content-length response regardless of which HTTP version the client
uses. The connection-labeling and message-push protocols, which identify the client and
the server connections, provide the basic functionality of the NetScaler Web 2.0 push
feature.
Understanding NetScaler Web 2.0 Push Protocol

For the NetScaler Web 2.0 Push feature to work correctly, the NetScaler appliance must label the client connection and then identify and send the deferred response from the server over the labeled connection. For this purpose, the Web 2.0 push feature uses the connection labeling and the message push protocols.

Connection Labeling Protocol

The connection labeling protocol is used between the server and the NetScaler appliance to label the client connection. After a label is negotiated, the Web server includes the label in the update that is sent to the client.

The appliance forwards a request to the server after adding an X-NS-PUSHVSERVER header containing the IP address and port of the push virtual server. The server either responds to this request with an HTTP response or defers the response. If the server defers the response, it labels the connection with an X-NS-DEFERRABLE header, which indicates that the connection is deferred.

A policy configured on the load balancing or content switching virtual server enables the NetScaler appliance to extract the label from the response. The appliance uses the information in the label to send the push message (update) to the push virtual server, which sends the response on the corresponding client connection.

Note: For any update from the Web server, the NetScaler does not support rewrite and compression.

When a server receives a request that it is deferrable, it sends an HTTP 200 OK response with the X-NS-DEFERRABLE header, which indicates to the NetScaler appliance that the push feature should be applied to the request. The appliance removes the X-NS-DEFERRABLE header, sends the response to the client, and waits for updates. For example:

HTTP/1.1 200 OK
Server: Apache/2.0.61 (FreeBSD) PHP/5.2.5 with Suhosin-Patch mod_ssl/2.0.61 OpenSSL/0.9.8e mod_perl/2.0.3 Perl/v5.8.8
X-NS-DEFERRABLE: YES
X-NS-SERVERLABEL: 04c2442bcb7c4b5f826d41a623e374e!
Content-Length: 0
Content-Type: text/plain;charset=UTF-8
Message Push Protocol

The message push protocol is used between a notification server and the NetScaler appliance to enable the notification server to send a notification to a previously labeled client connection.

Web servers use the message push protocol to push asynchronous messages to connected clients. The push protocol is built as a REST interface, exposed through the push virtual server on the NetScaler appliance. The server connects to the push virtual server and sends a request to the appliance. The BODY of the request contains the payload to be sent to the client. Additionally, the request identifies the label for the target client connection and the last message of the response.

When the NetScaler appliance receives the deferred response from the server, it sends the response to the client as a single HTTP chunk and sends a 200 OK response with the XML information to the server. If the message is marked as the last message of the response, the NetScaler also closes the HTTP response on the server.

**Note:** If the NetScaler is aware of the content length, it may send a response specifying the Content-Length, instead of a chunk. This enables the NetScaler to manage both HTTP streaming and long-polling responses.

Notification from Server to Push Server

POST /CLIENT/V10/04c2442bcb7c4b5f826d41a623e374e!?MSG_END=0 HTTP/1.1
Host: 10.102.80.66:8080
Content-Length: 6

Response from Push vserver to the server

HTTP/1.1 200 OK
Content-Type: text/xml; charset="UTF-8"
Content-Length: 130
<?xml version="1.0" encoding="UTF-8"?>
<CLIENTINFO>
  <CLIENT ID="04c2442bcb7c4b5f826d41a623e374e!" INFO="SUCCESS" />
</CLIENTINFO>
Configuring Web 2.0 Push

To configure NetScaler Web 2.0 push, you must first enable the feature. Then, create a push virtual server and associate it with a load balancing or content switching virtual server. Once you have a working configuration, you can customize it to suit your deployment.

You can also monitor the Web 2.0 push configuration by viewing statistics about the push virtual server and the other entities, such as the load balancing or the content switching virtual servers, that are part of the configuration.
Enabling NetScaler Web 2.0 Push

You have to enable the NetScaler Web 2.0 push feature before you can use it. Before enabling the feature, you must have the appropriate license installed on the NetScaler appliance. With the feature disabled, you can configure NetScaler Web 2.0 push entities, such as the push virtual server, but the entities will not work until the feature is enabled.

To enable NetScaler Web 2.0 push by using the command line interface

At the command prompt, type:

```plaintext
enable ns feature push
```

If NetScaler Web 2.0 Push is not licensed or disabled, the push virtual server state is DOWN.

To enable NetScaler Web 2.0 Push by using the configuration utility

1. In the navigation pane, expand System, and then click Settings.

2. In the details pane, under Modes and Features, click Change advanced features.

3. In the Configure advanced features dialog box, select the NetScaler Push check box, and then click OK.

4. At the Enable/Disable Feature(s)? prompt, click Yes.
Creating a NetScaler Web 2.0 Push Virtual Server

A push virtual server enables the NetScaler appliance to multiplex and manage the exchange of data (server push) reliably, securely, and in a scalable manner. It enables the notification server to send a notification to a previously labeled client connection by using the message push protocol. The notification servers push the out-of-band updates to the push virtual server. When the clients access the load balancing or the content switching virtual servers, the push virtual server uses the labeling protocol to label the deferred clients.

You can add, modify, and remove push virtual servers, however, you cannot bind services to the push virtual server.

To create a NetScaler Web 2.0 Push virtual server by using the command line interface

At a command prompt, type the following commands to create a push virtual server and verify the configuration:

- `add lb vserver <name> <serviceType> <IPAddress> <Port>`
- `show lb vserver <name>`

Example

```
add lb vserver Vserver-Push-1 PUSH 10.102.29.162 80
show lb vserver Vserver-Push-1
```

Parameters for creating a push virtual server

**name**

The name of the push virtual server being created. This alphanumeric string is required and cannot be changed after the virtual server is created. Must not exceed 127 characters, and leading character must be a number or letter. The following characters are also allowed: @ _ - (period) : (colon) # and space ( ).

**IPAddress**

The IP address of the push virtual server being configured. This is a mandatory parameter.
Creating a NetScaler Web 2.0 Push Virtual Server

**serviceType**

The type of data transferred between the NetScaler appliance and the client. SSL_PUSH service type encrypts the traffic between the NetScaler and the client. Use PUSH service type for HTTP requests. Possible values: PUSH, SSL_PUSH.

**Note:** For an SSL_PUSH virtual server, you need to bind a certificate-key pair. For details about binding a certificate-key pair to the virtual server, see SSL Offload and Acceleration.

**port**

The TCP port on which the virtual server listens. This is a mandatory argument. Must be a positive number not greater than 65535. Minimum value: 1.

**To create a NetScaler Web 2.0 Push virtual server by using the configuration utility**

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, click Add.

3. In the Name, Port, and IP Address text boxes, type a name for the push virtual server, a port, and an IP address (for example, Vserver-Push-1, 80, and 10.102.29.162).

4. In Protocol, select either SSL_PUSH or PUSH.

5. Click Create, and then click Close. The push virtual server you created appears in the Load Balancing Virtual Servers pane.

To remove a push virtual server, use the rm lb vserver command that takes only the name parameter.
Configuring a Load Balancing or Content Switching Virtual Server

After creating a push virtual server, you need to associate it with the load balancing or content switching virtual servers. For details about creating a load balancing virtual server, see “Creating a Virtual Server.” Also, for details about creating a content switching setup, see “Creating Content Switching Virtual Servers.”

Once you have created the load balancing or content switching virtual servers, you must associate them with the push virtual server.

To configure a load balancing virtual server or content switching virtual server for NetScaler Web 2.0 push by using the command line interface

At the command prompt, type the following commands to configure a load balancing virtual server for NetScaler Web 2.0 push. To configure a content switching virtual server, replace set lb vserver with set cs vserver.

```
set lb vserver <name> <ServiceType> <IPAddress> <Port> -push (ENABLED | DISABLED) -pushVserver <PushVservername> -pushLabel <Expression> -pushMultiClients (YES | NO)
```

Examples

```
set lb vserver Vserver-LB-1 HTTP 10.102.29.161 80 -push ENABLED -pushVserver PushVserver1 -pushLabel "HTTP.RES.HEADER("NSLABEL").VALUE(0)" –pushMultiClients YES
set cs vserver Vserver-CS-1 HTTP 10.102.29.161 80 -push ENABLED -pushVserver PushVserver1 -pushLabel "HTTP.RES.HEADER("NSLABEL").VALUE(0)" –pushMultiClients YES
```

To modify or remove a load balancing or content switching virtual server by using the command line interface

- To modify a virtual server, type the set lb vserver or set cs vserver command, the name of the virtual server, and the parameters to be changed, with their new values.

- To remove a virtual server, type the rm lb vserver or rm cs vserver command and the name of the load balancing or content switching virtual server.
Parameters for configuring a load balancing virtual server

**push**

Enable the NetScaler appliance to process traffic with the push virtual server. Possible values: ENABLED, DISABLED. Default: DISABLED

**pushVserver**

The name of the load balancing virtual server, of type PUSH or SSL_PUSH, to which the server pushes updates received on the client-facing load balancing virtual server.

**pushLabel**

An expression for extracting the label from the response from server. The string can be either an existing rule name (configured by using the add rule command) or an in-line expression with a maximum of 64 characters. Default value: NONE.

**pushMultiClients**

Allow multiple Web 2.0 connections from the same client to connect to the virtual server and expect updates. Possible values: YES, NO. Default value: NO.

To create a load balancing virtual server for NetScaler Web 2.0 Push by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure push virtual server (for example, Vserver-LB-1), and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, click the arrow next to Push to expand it. Then, in the Push VServer list, select the push virtual server and click OK.

   **Note:** To create a content switching virtual server for NetScaler Web 2.0 Push by using the configuration utility, in the navigation pane, expand Content Switching, click Virtual Servers, Then, perform steps 2 and 3.
Monitoring the Configuration

To monitor the NetScaler Web 2.0 push configuration, you need to view the statistics of the push virtual servers and load balancing entities. This is useful for troubleshooting.

For instructions on how to display statistics of load balancing entities, see "Load Balancing." Available statistics include labeled connections, push labeled connections, and deferred requests.

To view the properties of the push virtual server by using the command line interface

At the command prompt, type:

```
show lb vserver <PushVserverName>
```

**Example**

```
show lb vserver Vserver-Push-1
```
Customizing the NetScaler Web 2.0 Push Configuration

Once your basic Web 2.0 Push configuration is operational, you can customize it by setting a time-out value for idle client connections and configuring URL redirects.
Setting a Time-out Value for Idle Client Connections

Once a client connects to the push virtual server, you can configure the virtual server to close any idle client connections after a configured time period.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

To set a time out value for idle client connections by using the command line interface

At the command prompt, type:

```
set lb vserver <PushVserverName> [-cltTimeout <secs>]
```

Example

```
set lb vserver Vserver-Push-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the configuration utility

1. In the navigation pane, expand Load Balancing and click Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure virtual server port insertion (for example, Vserver-Push-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, click the Advanced tab.
4. In the Client Time-out (secs) text box, type the timeout value (for example, 100).
5. Click OK.
Redirecting Client Requests to an Alternative URL

You can configure a URL to which to redirect HTTP or HTTPS client requests when the push virtual server is down or disabled. This URL can be a local or a remote link. The NetScaler appliance uses HTTP 302 redirect to redirect client requests.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only a domain name (relative URL), the incoming URL is appended to the domain configured in the redirect URL.

The domain specified in the redirect URL must not be the same as the domain specified in the domain name argument of a content switching policy. If the same domain is specified in both arguments, the request is redirected continuously to the same unavailable virtual server in the NetScaler appliance, and the user cannot get the requested content.

To configure a virtual server to redirect the client request to a URL by using the command line interface

At the command prompt, type:

```
set lb vserver <name> -redirectURL URLValue
```

Example

```
set lb vserver Vserver-Push-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```

To configure a virtual server to redirect the client request to a URL by using the configuration utility

1. In the navigation pane, expand Load Balancing, and then click Virtual Servers.

2. In the details pane, select the push virtual server for which you want to configure redirect URL (for example, Vserver-Push-1), and then click Open.

4. Click OK.

Reference Material

You can refer to the following documentation for quick reference:

- Command Reference
- Documentation Library

**Note:** We are in the process of transitioning reference documentation to Citrix eDocs. The following reference documentation is available in Citrix Knowledge Center (http://support.citrix.com/productdocs/). When you click these links, you will leave the site. We recommend that you book mark this site so you can easily return to it.

- NetScaler Developer's Guide
- NetScaler Log Message Reference
- NetScaler SNMP OID Reference
- NetScaler Glossary
Command Reference

Provides basic information of the NetScaler command line interface and also provides the commands to configure and retrieve details of the appliance.
Command Reference

Provides basic information of the NetScaler command line interface and also provides the commands to configure and retrieve details of the appliance.
AAA Commands

This group of commands can be used to perform operations on the following entities:

- aaa
- aaa user
- aaa group
- aaa preauthenticationaction
- aaa preauthenticationpolicy
- aaa stats
- aaa session
- aaa radiusParams
- aaa ldapParams
- aaa tacacsParams
- aaa certParams
- aaa parameter
- aaa preauthenticationparameter
- aaa global
aaa

stat aaa

Synopsis
stat aaa [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description
Display aaa statistics
aaa user

[ add | rm | set | bind | unbind | show ]

add aaa user

Synopsis

add aaa user <userName> {-password }

Description

Add an AAA user.

Parameters

userName

The name of the user.

password

Enter this keyword to create or change the user's password. The entered password is not displayed. If no password is given for a new user then the user will be authenticated externally.

Example

add aaa user johndoe -password abcd
add aaa user johndoe -password
The above example adds user johndoe with password abcd for first case, password supplied on prompt for second case

Top

rm aaa user

Synopsis

rm aaa user <userName>
aaa user

Description
Remove the AAA user.

Parameters
userName
The name of the AAA user.

set aaa user

Synopsis
set aaa user <userName>

Description
Modify the parameters for the existing AAA user.

Parameters
userName
The name of the user.

password
Enter this keyword to create or change the user’s password. The entered password is not displayed. If no password is given for a new user then the user will be authenticated externally.

Example

set aaa user johndoe password abcd
The above command sets the password for johndoe to abcd

bind aaa user

Synopsis
bind aaa user <userName> [-policy <string> [-priority <positive_integer>]] [-intranetApplication <string>] [-urlName <string>] [-intranetIP <ip_addr> [netmask]]
aaa user

Description
Bind the resources (policy/intranetip/intranetapplication/url) to a user.

Parameters

userName
The user name.
policy
the policy to be bound to aaa user.
intranetApplication
The intranet vpn application.
urlName
The intranet url
intranetIP
The IP address to be bound to this user and used to access the Intranet

Example

To bind intranetip to the user joe:
bind aaa user joe -intranetip 10.102.1.123

unbind aaa user

Synopsis
unbind aaa user <userName> [-policy <string>] [-intranetApplication <string>] [-urlName <string>] [-intranetIP <ip_addr> [<netmask>]]

Description
Unbind the resource(policy/intranetip/intranetapplication/url) from an AAA user

Parameters

userName
The user name.
aaa user

policy
    The policy to be unbound to an aaa user.

intranetApplication
    The intranet vpn application.

urlName
    The intranet url

intranetIP
    The Intranet IP to be unbound

Example

unbind AAA user joe -intranetip 10.102.1.123

show aaa user

Synopsis
    show aaa user [<userName>] [-loggedIn]

Description
    Display the AAA user detail.

Parameters

    userName
        The user name.

    loggedIn
        The loggedin flag. When this flag is turned on, the system displays the names of all
        logged-in users. If a user name is included, the system displays whether the user is
        logged in or not.

Example

    Example
    > show aaa user joe
       UserName: joe           IntranetIP: 10.102.1.123
aaa user

Bound to groups:
  GroupName: engg

Done
>

Top
aaa group

[ add | rm | bind | unbind | show ]

add aaa group

Synopsis

add aaa group <groupName>

Description

Add an AAA group. To associate AAA users with an AAA group, use the command “bind AAA group ... -username ...”. You can bind different policies to each AAA group. Use the command “bind AAA group ... -policy ...”. You can also bind ranges of Intranet IP addresses to an AAA group. For example, the administrator may want to assign pools of Intranet IP addresses to groups or departments.

Parameters

groupName

The name of the group.

Example

add aaa group group_ad

Top

rm aaa group

Synopsis

rm aaa group <groupName>

Description

Remove an AAA group. To associate AAA users with an AAA group, use the command “bind AAA group ... -username ...”. You can bind different policies to each AAA group. Use the command “bind AAA group ... -policy ...”. You can also bind ranges of Intranet IP addresses to an AAA group. For example, the administrator may want to assign pools of Intranet IP addresses to groups or departments.
**Parameters**

**groupName**

The name of the group. Note: Any user sessions belonging to the group are removed. The user must log in again.

**bind aaa group**

**Synopsis**

`bind aaa group <groupName> [-userName <string>] [-policy <string> [-priority <positive_integer>]] [-intranetApplication <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>]`

**Description**

Bind the resource (User/Intranet IP /Policy/Intranet Application) to a group. To associate AAA users with an AAA group, use the command "bind AAA group ... -username ...". You can bind different policies to each AAA group. Use the command "bind AAA group ... -policy ...". You can also bind ranges of Intranet IP addresses to an AAA group. For example, the administrator may want to assign pools of Intranet IP addresses to groups or departments.

**Parameters**

**groupName**

The group name.

**userName**

The user that the group is bound to. If the user belongs to more than one group, the group expressions are evaluated at authorization to determine the appropriate action.

**policy**

The policy to be bound to an AAA group.

**intranetApplication**

The intranet vpn application.

**urlName**

The intranet url.

**intranetIP**

The ip-block or IP address to be bound with this group. This is the block or address that will be used when members of this group access Intranet resources.
To bind an Intranet IP to the group engg:
  bind aaa group engg  -intranetip 10.102.10.0 255.255.255.0

unbind aaa group

Synopsis
unbind aaa group <groupName> [-userName <string> ...] [-policy <string>]
[-intranetApplication <string>] [-urlName <string>] [-intranetIP <ip_addr> <netmask>]

Description
Unbind the resource (User/Intranet IP/Policy/Intranet Application) from a group. To associate AAA users with an AAA group, use the command "bind AAA group ... -username ...". You can bind different policies to each AAA group. Use the command "bind AAA group ... -policy ...". You can also bind ranges of Intranet IP addresses to an AAA group. For example, the administrator may want to assign pools of Intranet IP addresses to groups or departments.

Parameters

groupName
  The group name.

userName
  The user to be unbound from the group.

policy
  The policy to be unbound from the AAA group,

intranetApplication
  The intranet vpn application.

urlName
  The intranet url.

intranetIP
  The Intranet IP to be unbound from the group

Example
unbind aaa group engg -intranetip 10.102.10.0 255.255.255.0

show aaa group

Synopsis

show aaa group [<groupName>] [-loggedIn]

Description

Display details of the AAA group. To associate AAA users with an AAA group, use the command "bind AAA group ... -username ...". You can bind different policies to each AAA group. Use the command "bind AAA group ... -policy ...". You can also bind ranges of Intranet IP addresses to an AAA group. For example, the administrator may want to assign pools of Intranet IP addresses to groups or departments.

Parameters

groupName

The group name.

loggedIn

Theloggedin flag. When this flag is turned on, the system displays the names of the users in a group if at least one user in the group is logged in. When used with a group name, the system lists the users in the group who are logged in.

Example

> show aaa group engg
    GroupName: engg

    Bound AAA users:
    UserName: joe
    UserName: jane

    Intranet IP: 10.102.10.0      Netmask: 255.255.255.0

    Done
>

Top
aaa preauthenticationaction

[ add | rm | set | unset | show ]

add aaa preauthenticationaction

Synopsis
add aaa preauthenticationaction <name> [<preauthenticationaction>] [-killProcess <string>] [-deletefiles <string>]

Description
Add actions for end point analysis (EPA) clients before authentication.

Parameters
name
The name of the Preauthentication action.

preauthenticationaction
Deny or allow login after end point analysis results. Possible values: ALLOW, DENY

killProcess
Processes to be killed by the EPA tool.

deletefiles
Files to be deleted by EPA tool.

Top

rm aaa preauthenticationaction

Synopsis
rm aaa preauthenticationaction <name>
aaa preauthenticationaction

**Description**

Remove a previously created Pre-authentication action. Note that an action cannot be removed as long as it is configured in a policy.

**Parameters**

- `name`

  The name of the action to be removed.

**set aaa preauthenticationaction**

**Synopsis**

```
set aaa preauthenticationaction <name> [preauthenticationaction] [-killProcess <string>] [-deletefiles <string>]
```

**Description**

Change properties of a Pre-authentication action.

**Parameters**

- `name`

  The name of the Preauthentication action.

- `preauthenticationaction`

  Deny or allow login after end point analysis results. Possible values: ALLOW, DENY

- `killProcess`

  Processes to be killed by EPA tool.

- `deletefiles`

  Files to be deleted by EPA tool.
**unset aaa preauthenticationaction**

**Synopsis**

```
unset aaa preauthenticationaction <name> [-killProcess] [-deletefiles]
```

**Description**

Use this command to remove aaa preauthenticationaction settings. Refer to the set aaa preauthenticationaction command for meanings of the arguments.

**show aaa preauthenticationaction**

**Synopsis**

```
show aaa preauthenticationaction [<name>]
```

**Description**

Display details of the configured Pre-authentication action(s).

**Parameters**

- **name**

  The name of the RADIUS action.
aaa preauthenticationpolicy

[ add | rm | set | show ]

add aaa preauthenticationpolicy

Synopsis

add aaa preauthenticationpolicy <name> <rule> [ <reqAction> ]

Description

Add a Radius authentication policy. The policy defines expressions to be evaluated by the EPA tool.

Parameters

name

The name to assign to the new Pre-authentication policy.

rule

The name of the rule or expression that the policy will use.

reqAction

The name of the RADIUS action the policy will use.

Top

rm aaa preauthenticationpolicy

Synopsis

rm aaa preauthenticationpolicy <name>

Description

Remove a Pre-authentication policy.
aaa preauthenticationpolicy

Parameters

name

The name of the Pre-authentication policy to remove.

Top

set aaa preauthenticationpolicy

Synopsis

set aaa preauthenticationpolicy <name> [-rule <expression>] [-reqAction <string>]

Description

Change the properties of a Pre-authentication policy.

Parameters

name

The name of the policy.

rule

The new rule to be associated with the policy.

reqAction

The new Pre-authentication action to be associated with the policy.

Top

show aaa preauthenticationpolicy

Synopsis

show aaa preauthenticationpolicy [<name>]

Description

Display configured Pre-authentication policies.

Parameters

name
aaa preauthenticationpolicy

The name of the policy. If this option is not provided, all of the configured RADIUS policies will be displayed.

Top
aaa stats

show aaa stats

Synopsis

    show aaa stats - alias for 'stat aaa'

Description

    show aaa stats is an alias for stat aaa
aaa session

[ show | kill ]

show aaa session

Synopsis

show aaa session [-userName <string>] [-groupName <string>] [-intranetIP <ip_addr>] [\*\<netmask>]\]

Description

Display the connections initiated by the user

Parameters

userName

The user name.

groupName

The group name.

intranetIP

Intranet IP address.

Example

> show aaa connection

<table>
<thead>
<tr>
<th>ClintIp (ClientPort)</th>
<th>-&gt;</th>
<th>ServerIp(ServerPort)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.102.0.39 (2318)</td>
<td>-&gt;</td>
<td>10.102.4.245 (443)</td>
</tr>
<tr>
<td>10.102.0.39 (2320)</td>
<td>-&gt;</td>
<td>10.102.4.245 (443)</td>
</tr>
<tr>
<td>10.102.0.39 (2340)</td>
<td>-&gt;</td>
<td>10.102.4.245 (443)</td>
</tr>
</tbody>
</table>

Done

>
kill aaa session

Synopsis

    kill aaa session [-userName <string>] [-groupName <string>] [-intranetIP <ip_addr|*> [-<netmask>]] [-all]

Description

    Kill the user sessions

Parameters

    userName

    The user name. The system will terminate the session initiated by the named user.

    groupName

    The group name. The system will terminate the sessions of all the users within the named group.

    intranetIP

    The Intranet IP address. The system will terminate all sessions using the named intranet IP address

    all

    Terminate the sessions of all users who are currently logged in.

Example

    kill aaa session -user joe
aaa radiusParams

[ set | unset | show ]

set aaa radiusParams

Synopsis

Description

Modify the global variables for the RADIUS server. It will be used globally in SSL-VPN across all Vservers unless you create a vserver-specific configuration using authentication policies.

Parameters

serverIP

The IP address of the RADIUS server.

serverPort

The port number on which the RADIUS server is running. Default value: 1812 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the RADIUS server. Default value: 3 Minimum value: 1

radKey

The key shared between the client and the server. This information is required for the system to communicate with the RADIUS server.

radNASip

The option to send the NetScaler's IP address (NSIP) to the server as the "nasip" (Network Access Server IP) part of the Radius protocol. Possible values: ENABLED, DISABLED

radNASid

The...
The nasid (Network Access Server ID). If configured, this string will be sent to the RADIUS server as the “nasid” part of the Radius protocol.

radVendorID

The Vendor ID for Radius group extraction. Minimum value: 1

radAttributeType

The Attribute type for Radius group extraction. Minimum value: 1

radGroupsPrefix

The groups prefix string that precedes the group names within a RADIUS attribute for RADIUS group extraction.

radGroupSeparator

The group separator string that delimits group names within a RADIUS attribute for RADIUS group extraction.

passEncoding

The option to encode the password in the Radius packets traveling from the NetScaler to the Radius server. Possible values: pap, chap, mschapv1, mschapv2 Default value: AAA_PAP

ipVendorID

The vendor ID of the attribute in the RADIUS response. The vendor ID denotes the intranet IP. The value of 0 denotes that the attribute is not vendor-encoded.

ipAttributeType

The attribute type of the remote IP address attribute in a RADIUS response. Minimum value: 1

accounting

The state of the RADIUS server to receive accounting messages. Possible values: ON, OFF

pwdVendorID

Vendor ID of the attribute in the RADIUS response which will be used to extract the user Password. Minimum value: 1

Example

To configure the default RADIUS parameters:
set aaa radiusparams -serverip 192.30.1.2 -radkey sslvpn
**unset aaa radiusParams**

**Synopsis**

[-vendorID] [-attributeType] [-groupsPrefix] [-groupSeparator]
[-pwdAttributeType]

**Description**

Use this command to remove aaa radiusParams settings. Refer to the set aaa radiusParams command for meanings of the arguments.

Top

**show aaa radiusParams**

**Synopsis**

show aaa radiusParams

**Description**

Display the configured RADIUS parameters.

**Example**

```
> show aaa radiusparams
Configured RADIUS parameters
  Server IP: 127.0.0.2      Port: 1812
  key: secret     Timeout: 10

Done
```

Top
aaa ldapParams

[ set | unset | show ]

set aaa ldapParams

Synopsis

set aaa ldapParams [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] [-ldapBindDnPassword ] [-ldapLoginName <string>] [-searchFilter <string>] [-groupAttrName <string>] [-subAttributeName <string>] [-secType <secType>] [-svrType ( AD | NDS )] [-ssoNameAttribute <string>] [-passwdChange ( ENABLED | DISABLED )] [-nestedGroupExtraction ( ON | OFF )] [-maxNestingLevel <positive_integer>] [-groupNameIdentifier <string>] [-groupSearchAttribute <string>] [-groupSearchSubAttribute <string>] [-groupSearchFilter <string>]

Description

Set the global variables for the LDAP server. It is used globally in SSL-VPN across all Vservers unless you create a vserver-specific configuration using authentication policies.

Parameters

serverIP

The IP address of the LDAP server. The default value is localhost.

serverPort

The port number on which the LDAP server is running. Default value: 389 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the LDAP server. Default value: 3 Minimum value: 1

ldapBase

The base or node where the ldapsearch should start. If the LDAP server is running locally, the default value of base is dc= netscaler, dc=com.

ldapBindDn

The full distinguished name that is used to bind to the LDAP server.
aaa ldapParams

ldapBindDnPassword

The password used to bind to the LDAP server.

ldapLoginName

The name attribute used by the system to query the external LDAP server or an Active Directory.

searchFilter

The String to be combined with the default LDAP user search string to form the value. For example, vpnallowed=true with ldaploginame "samaccount" and user-supplied username "bob" would yield the LDAP search string "(&vpnallowed=true)(samaccount=bob)".

groupAttrName

The attribute name for group extraction from the LDAP server

subAttributeName

The Sub-Attribute name for group extraction from LDAP server

secType

The type of communication between the system and the LDAP server. The values are: PLAINTEXT: No encryption required. TLS: To use the TLS protocol to communicate. SSL: To use the SSL Protocol to communicate. Possible values: PLAINTEXT, TLS, SSL Default value: AAA_LDAP_PLAINTEXT

svrType

The type of LDAP server. Possible values: AD, NDS Default value: AAA_LDAP_SERVER_TYPE_DEFAULT

ssoNameAttribute

The attribute used by the system to query the external LDAP server (or an Active Directory) for an alternate username to be used in Single Sign-On.

passwdChange

Enabling this option does not block password change request. Disabling would block password change request. Possible values: ENABLED, DISABLED Default value: DISABLED

nestedGroupExtraction

Setting this option to ON enables the nested group extraction feature where the system queries the external LDAP server to determine if a group belongs to another group. Possible values: ON, OFF Default value: OFF

Example
aaa ldapParams

To configure authentication in the LDAP server running at 192.40.1.2:
set aaa ldapparams -serverip 192.40.1.2 -ldapbase "dc=netscaler,dc=com" -ldapBindDN "cn=Manager,dc=netscaler,dc=com" -ldapBindDnPassword secret -ldaploginname uid

unset aaa ldapParams

Synopsis

[-ldapBindDnPassword] [-ldapLoginName] [-searchFilter] [-groupAttrName]
[-subAttributeName] [-secType] [-svrType] [-ssoNameAttribute] [-passwdChange]
[-nestedGroupExtraction] [-maxNestingLevel] [-groupNameIdentifier]
[-groupSearchAttribute] [-groupSearchSubAttribute] [-groupSearchFilter]

Description

Use this command to remove aaa ldapParams settings. Refer to the set aaa ldapParams command for meanings of the arguments.

show aaa ldapParams

Synopsis

show aaa ldapParams

Description

Display the configured LDAP parameters.

Example

> show aaa ldapparams
Configured LDAP parameters
  Server IP: 127.0.0.1  Port: 389
  Timeout: 1  BindDn: cn=Manager,dc=florazel,dc=com
  login: uid  Base: dc=florazel,dc=com
  Secure Type: PLAINTEXT
  Done
>

Top
aaa tacacsParams

[ set | unset | show ]

set aaa tacacsParams

Synopsis

set aaa tacacsParams [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-tacacsSecret] [-authorization (ON | OFF)] [-accounting (ON | OFF)] [-auditFailed_cmds (ON | OFF)]

Description

Set the global variables for the TACACS+ server. It is used globally in SSL-VPN across all Vservers unless a vserver-specific configuration is done using authentication policies.

Parameters

serverIP

The IP address of the TACACS+ server.

serverPort

The port on which the TACACS+ server is running. Default value: 49 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the TACACS+ server. Default value: 3 Minimum value: 1

tacacsSecret

The key shared between the client and the server. This information is required for the system to communicate with the TACACS+ server.

authorization

The option for streaming authorization for the TACACS+ server. Possible values: ON, OFF

accounting

The option for sending accounting messages to the TACACS+ server. Possible values: ON, OFF

auditFailed_cmds
aaa tacacsParams

The option for sending accounting messages to the TACACS+ server. Possible values: ON, OFF

Example

To configure a TACACS+ server running at 192.168.1.20
set aaa tacacsparams -serverip 192.168.1.20 -tacacssecret secret

unset aaa tacacsParams

Synopsis

Description

Use this command to remove aaa tacacsParams settings. Refer to the set aaa tacacsParams command for meanings of the arguments.

show aaa tacacsParams

Synopsis

show aaa tacacsParams

Description

Display configured AAA TACACS+ server parameters.

Example

> sh aaa tacacsparams
Configured TACACS parameter
  Server IP: 192.168.1.20 Port: 49
  Timeout: 1 secs
Done
aaa certParams

[ set | unset | show ]

set aaa certParams

Synopsis

set aaa certParams [-userNameField <string>] [-groupNameField <string>]

Description

Set the global variables for a certificate policy. It is used globally in SSL-VPN across all Vservers unless vserver-specific configuration is done using authentication policies.

Parameters

userNameField

The field in the client certificate to extract the username from. Should be of the format <field:subfield>. Allowed values for field are “Subject” and “Issuer”.

groupNameField

The certificate field to extract the group from. Should be of the format <field:subfield>. Allowed values for field are “Subject” and “Issuer”.

Example

To configure the default certificate parameters:

set aaa certparams -userNameField “Subject:CN” -groupNameField “Subject:OU”

unset aaa certParams

Synopsis

unset aaa certParams [-userNameField] [-groupNameField]
aaa certParams

**Description**
Use this command to remove aaa certParams settings. Refer to the set aaa certParams command for meanings of the arguments.

**show aaa certParams**

**Synopsis**
show aaa certParams

**Description**
Display the configured CERT parameters.

Top
aaa parameter

[ set | unset | show ]

set aaa parameter

Synopsis

set aaa parameter [-enableStaticPageCaching ( YES | NO )] [-defaultAuthType <defaultAuthType>] [-maxAAAUsers <positive_integer>] [-aaadnatIp <ip_addr | * ]

Description

Set the global AAA parameters. This will override the default authentication server setting.

Parameters

enableStaticPageCaching

   The default state of VPN Static Page caching. If nothing is specified, the default value is set to ON. Possible values: YES, NO Default value: STATIC_PAGE_CACHING_ENABLED

defaultAuthType

   The default authentication server type. If nothing is specified, the default value is set to Local. Possible values: LOCAL, LDAP, RADIUS, TACACS, CERT Default value: LOCAL_AUTH

maxAAAUsers

   The maximum number of concurrent users allowed to login in to the system at any given time. Minimum value: 1 Maximum value: 65535

aaadnatIp

   The source ip to be used for the traffic going to authentication servers

Example

set aaa parameter -defaultAuthType RADIUS -maxAAAUsers 100

Top
**unset aaa parameter**

**Synopsis**
unset aaa parameter [-enableStaticPageCaching] [-defaultAuthType] [-maxAAAUsers] [-aaadnatIp]

**Description**
Set default aaa parameter. Refer to the set aaa parameter command for meanings of the arguments.

**show aaa parameter**

**Synopsis**
show aaa parameter

**Description**
Displays the configured AAA parameters.

**Example**

> show aaa parameter
Configured AAA parameters
   DefaultAuthType: LDAP   MaxAAAUsers: 5
Done
>

Top
aaa preauthenticationparameter

[ set | unset | show ]

set aaa preauthenticationparameter

Synopsis

set aaa preauthenticationparameter [-preauthenticationaction ( ALLOW | DENY )] [-rule <expression>] [-killProcess <string>] [-deletefiles <string>]

Description

Sets the default end point analysis (EPA) parameters before authentication.

Parameters

preauthenticationaction
Deny or allow login after end point analysis results. Possible values: ALLOW, DENY

rule
The name of the rule, or expression, to be evaluated by the EPA tool.

killProcess
Processes to be killed by the EPA tool.

deletefiles
Files to be deleted by the EPA tool.

unset aaa preauthenticationparameter

Synopsis

Description
Set default end point analysis (EPA) parameters before authentication. Refer to the set aaa preauthenticationparameter command for meanings of the arguments.

show aaa preauthenticationparameter

Synopsis
show aaa preauthenticationparameter

Description
Display details of the configured Pre-authentication parameter(s).
aaa global

[ bind | unbind | show ]

bind aaa global

Synopsis
bind aaa global (-policy <string> [-priority <positive_integer>])

Description
Binds the policy globally.

Parameters
policy
The policy to be bound globally.

Example
bind aaa global -pol pol1

unbind aaa global

Synopsis
unbind aaa global -policy <string>

Description
Unbind the policy globally

Parameters
policy
The policy to be unbound to the AAA user.
show aaa global

Synopsis

show aaa global

Description

Display details of the configured policies aaa global.
Application Commands

[ import | export ]

**import application**

**Synopsis**

import application <apptemplateFilename> [-appname <string>] [-deploymentFilename <input_filename>]

**Description**

Imports application configuration information from an AppExpert application template file. You can specify a deployment file along with the template file. A template file contains application and variable definitions. A deployment file contains information about the services, service groups, endpoints, and variables that were in the AppExpert application configuration at the time the template file was created. Template files are imported from the /nsconfig/nstemplates/applications/ directory on the appliance. Deployment files are imported from the /nsconfig/nstemplates/applications/ deployment_files directory. You cannot change the source directories, so import the template file and deployment file to their respective directories before you use the command.

**Parameters**

- **apptemplateFilename**
  The name of the AppExpert application template file.

- **appname**
  The name with which you want the AppExpert application to function on the NetScaler appliance. If you do not provide a name, the appliance assigns the application the name of the template file.

- **deploymentFilename**
  The name of the deployment file.

**Example**

import app application sampleapp -apptemplatefilename sampleapp.xml -deploymentfilename deploy.xml

Top
export application

Synopsis

    export application <appname> [-apptemplateFilename <input_filename>]
    [-deploymentFilename <input_filename>]

Description

Exports application configuration information to an AppExpert application template file. A
deployment file is created along with the template file. The template file contains
application and variable definitions. The deployment file contains information about the
services, service groups, endpoints, and variables that are in the AppExpert application
configuration. The template file is exported to the /nsconfig/nstemplates/applications/
directory on the appliance. The deployment file is exported to the
/nsconfig/nstemplates/applications/deployment_files directory.

Parameters

    appname

        The name of the AppExpert application whose configuration you want to export to a
        template file.

    apptemplateFilename

        The name with which you want to save the template file. If you do not specify a name,
        the template file is saved with the name of the AppExpert application.

    deploymentFilename

        The name with which you want to save the deployment file. If you do not specify a
        name, the string _deployment is automatically appended to the name of the template
        file to create the name of the deployment file.

Top
AppFlow Commands

This group of commands can be used to perform operations on the following entities:

- appflow
- appflow collector
- appflow action
- appflow policy
- appflow policylabel
- appflow param
- appflow global
stat appflow

Synopsis
stat appflow [-detail] [-full\Values] [-ntimes <positive\_integer>] [-logFile <input\_filename>]

Description
Display AppFlow statistics.
appflow collector

[ add | rm | rename | show ]

add appflow collector

Synopsis
add appflow collector <name> -IPAddress <ip_addr> [-port <port>] [-netProfile <string>]

Description
Add a new AppFlow collector.

Parameters
name
Name of the AppFlow collector.

IPAddress
The IPv4 address of the AppFlow collector.

port
The UDP port on which the AppFlow collector is listening. Default value: 4739

netProfile
The IP address associated with this netprofile will be used as source IP for appflow traffic to this collector

Example
add appflow collector collector1 -IPAddress 192.168.1.40 -port 2055

Top

rm appflow collector

Synopsis
rm appflow collector <name>
Description
   Remove an AppFlow collector.

Parameters
   name
      Name of an AppFlow collector.

Example
   rm appflow collector collector1

rename appflow collector

Synopsis
   rename appflow collector <name>@ <newName>@

Description
   Rename an AppFlow collector.

Parameters
   name
      The name of an AppFlow collector.

   newName
      The new name of the AppFlow collector.

Example
   rename appflow collector old_name new_name
show appflow collector

Synopsis

    show appflow collector [<name>]

Description

Display details of all the AppFlow collectors configured on the system. Alternatively, to view the details of a particular AppFlow collector, specify its name.

Parameters

name

Name of an AppFlow collector.

Example

    show appflow collector collector1

Top
appflow action

[ add | rm | set | unset | rename | show ]

add appflow action

Synopsis

add appflow action <name> -collectors <string> ... [-comment <string>]

Description

Creates an AppFlow action. The action thus created can be associated with an AppFlow policy by using the “add appflow policy” command.

Parameters

name

Name of the AppFlow action to be added.

collectors

The names of AppFlow collectors associated with the AppFlow action.

comment

Comments associated with this AppFlow action.

Example

add appflow action appflow_action_1 -collectors col1 col2

Top

rm appflow action

Synopsis

rm appflow action <name>
**appflow action**

**Description**
Remove a configured AppFlow action.

**Parameters**

- `name`
  
  Name of an AppFlow action.

**Example**

```
rm appflow action appflow_action_1
```

**set appflow action**

**Synopsis**

```
set appflow action <name> [-collectors <string> ...] [-comment <string>]
```

**Description**

Modify an AppFlow action.

**Parameters**

- `name`
  
  The name of the AppFlow action to be modified.

- `collectors`
  
  The names of AppFlow collectors associated with the AppFlow action.

- `comment`
  
  Comments associated with this AppFlow action.

**Example**

```
set appflow action appflow_action_1 -collectors col1 col2 col3
```
**unset appflow action**

**Synopsis**

unset appflow action <name> -comment

**Description**

Use this command to remove appflow action settings. Refer to the set appflow action command for meanings of the arguments.

**rename appflow action**

**Synopsis**

rename appflow action <name>@ <newName>@

**Description**

Rename an AppFlow action.

**Parameters**

- **name**
  
  The name of an AppFlow action.

- **newName**
  
  The new name of the AppFlow action.

**Example**

rename appflow action old_name new_name

**show appflow action**

**Synopsis**

show appflow action [<name>]
Description
Display configured AppFlow action(s).

Parameters
name
Name of an AppFlow action.

Example

1. show appflow action
2. show appflow action appflow_action_1

Top
appflow policy

[ add | rm | set | unset | rename | show ]

add appflow policy

Synopsis
add appflow policy <name> <rule> <action> [-comment <string>]

Description
Add an AppFlow policy.

Parameters
name
Name of the AppFlow policy.

rule
Expression to be used by the AppFlow policy. It has to be a boolean PI rule expression.

action
AppFlow action to be used by the policy.

comment
Comments associated with this AppFlow policy.

Example
add appflow policy appflow_pol "HTTP.REQ.HEADER("header").CONTAINS("qh3")" appflow_act

Top

rm appflow policy

Synopsis
rm appflow policy <name>
appflow policy

Description
Remove an AppFlow policy.

Parameters
name
Name of the AppFlow policy to be removed.

Example

rm appflow policy appflow_policy_1

set appflow policy

Synopsis
set appflow policy <name> [-rule <expression>] [-action <string>] [-comment <string>]

Description
Set a new rule and/or action for an existing AppFlow policy. The rule flow type can change only if: . action is of NEUTRAL flow type

Parameters
name
Name of an AppFlow policy.

rule
Expression to be used by the AppFlow policy. It has to be a boolean PI rule expression.

action
AppFlow action to be used by the policy.

comment
Comments associated with this AppFlow policy.

Example

set appflow policy appflow_policy -rule "HTTP.REQ.HEADER("header").CONTAINS("qh2")"
unset appflow policy

Synopsis
unset appflow policy <name> -comment

Description
Use this command to remove appflow policy settings. Refer to the set appflow policy command for meanings of the arguments.

rename appflow policy

Synopsis
rename appflow policy <name>@ <newName>@

Description
Rename an AppFlow policy.

Parameters
name
The name of an AppFlow policy.

newName
The new name of the AppFlow policy.

Example
rename appflow policy old_name new_name
show appflow policy

Synopsis

    show appflow policy [<name>]

Description

    Display all the configured AppFlow policies.

Parameters

    name

        Name of an AppFlow policy.

Example

    show appflow policy

Top
add appflow policylabel

Synopsis
add appflow policylabel <labelName> [-policylabeltype ( HTTP | OTHERTCP )]

Description
Create an AppFlow policy label.

Parameters

labelName
The name of the AppFlow policy label to be created.

policylabeltype
The type of the policy label. Possible values: HTTP, OTHERTCP Default value: NS_PLTMAP_APPFLOW_REQ

Example
add appflow policylabel appflow_pol_label

rm appflow policylabel

Synopsis
rm appflow policylabel <labelName>

Description
Remove an AppFlow policy label.
Parameters

labelName
The name of the AppFlow policy label to be removed.

Example

rm appflow policylabel appflow_pol_label

Top

bind appflow policylabel

Synopsis

bind appflow policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-invoke (<labelType> <labelName>)]

Description

Bind an AppFlow policy to an AppFlow policy label.

Parameters

labelName
Name of an AppFlow policy label.

policyName
Name of an AppFlow policy.

Example

bind appflow policylabel appflow_pol_label -policyName appflow_pol -priority 1

Top

unbind appflow policylabel

Synopsis

unbind appflow policylabel <labelName> <policyName> [-priority <positive_integer>]

appflow policylabel

**Description**
Unbind an AppFlow policy from an AppFlow policy label.

**Parameters**
- **labelName**
  Name of an AppFlow policy label.
- **policyName**
  Name of an AppFlow policy.

**Example**
unbind appflow policylabel appflow_pol_label appflow_pol

Top

rename appflow policylabel

**Synopsis**
rename appflow policylabel <labelName>@ <newName>@

**Description**
Rename an AppFlow policy label.

**Parameters**
- **labelName**
  The name of an AppFlow policy label.
- **newName**
  The new name of the AppFlow policy label.

**Example**
rename appflow policylabel old_name new_name

Top
**show appflow policylabel**

**Synopsis**

```
show appflow policylabel [<labelName>]
```

**Description**

Display all AppFlow policy labels or all policies bound to an AppFlow policy label.

**Parameters**

```
labelName
```

The name of the AppFlow policy label.

**Example**

i) show appflow policylabel appflow_pol_label
   ii) show appflow policylabel

Top
appflow param

[ set | unset | show ]

set appflow param

Synopsis

set appflow param [-templateRefresh <secs>] [-appnameRefresh <secs>]
[-flowRecordInterval <secs>] [-udpPmtu <positive_integer>] [-httpUrl ( ENABLED | DISABLED )]
[-httpCookie ( ENABLED | DISABLED )] [-httpReferer ( ENABLED | DISABLED )]
[-httpMethod ( ENABLED | DISABLED )] [-httpHost ( ENABLED | DISABLED )] [-httpUserAgent ( ENABLED | DISABLED )]
[-clientTrafficOnly ( YES | NO )] [-httpContentType ( ENABLED | DISABLED )]
[-httpAuthorization ( ENABLED | DISABLED )] [-httpVia ( ENABLED | DISABLED )]
[-httpXForwardedFor ( ENABLED | DISABLED )] [-httpLocation ( ENABLED | DISABLED )]
[-httpSetCookie ( ENABLED | DISABLED )] [-httpSetCookie2 ( ENABLED | DISABLED )]

Description

Configure AppFlow parameters.

Parameters

templateRefresh

IPFIX template refresh interval (in seconds). Default value: 600 Minimum value: 60 Maximum value: 3600

appnameRefresh

Appname refresh interval (in seconds). Default value: 600 Minimum value: 60 Maximum value: 3600

flowRecordInterval

IPFIX flow record export interval (in seconds). Default value: 600 Minimum value: 60 Maximum value: 3600

udpPmtu

MTU to be used for IPFIX UDP packets. Default value: 1472 Minimum value: 128 Maximum value: 1472

httpUrl

Enable AppFlow HTTP URL logging. Possible values: ENABLED, DISABLED Default value: DISABLED
httpCookie
Enable AppFlow HTTP cookie logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpReferer
Enable AppFlow HTTP referer logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpMethod
Enable AppFlow HTTP method logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpHost
Enable AppFlow HTTP host logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpUserAgent
Enable AppFlow HTTP user-agent logging. Possible values: ENABLED, DISABLED Default value: DISABLED

clientTrafficOnly
Control whether AppFlow records should be generated only for client-side traffic. Possible values: YES, NO Default value: NO

httpContentType
Enable AppFlow HTTP Content-Type header logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpAuthorization
Enable AppFlow HTTP Authorization header logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpVia
Enable AppFlow HTTP Via header logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpXForwardedFor
Enable AppFlow HTTP X-Forwarded-For header logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpLocation
Enable AppFlow HTTP Location header logging. Possible values: ENABLED, DISABLED Default value: DISABLED

httpSetCookie
appflow param

Enable AppFlow HTTP Setcookie header logging. Possible values: ENABLED, DISABLED
Default value: DISABLED

httpSetCookie2

Enable AppFlow HTTP Setcookie2 header logging. Possible values: ENABLED, DISABLED
Default value: DISABLED

Example

set appflow param -templateRefresh 240

unset appflow param

Synopsis

unset appflow param [-templateRefresh] [-appnameRefresh] [-flowRecordInterval]
[-httpXForwardedFor] [-httpLocation] [-httpSetCookie] [-httpSetCookie2]

Description

Use this command to remove appflow param settings. Refer to the set appflow param command for meanings of the arguments.

show appflow param

Synopsis

show appflow param

Description

Display AppFlow parameters.
**bind appflow global**

**Synopsis**

bind appflow global <policyName> <priority> [<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]

**Description**

Bind the AppFlow policy to one of the two global lists of AppFlow policies. A policy becomes active only after it is bound. All traffic will be evaluated against these two policy banks. Each bank of policies is an ordered list ordered by policies priority values. Policy Bank Evaluation The goal of evaluation is to traverse the ordered list of policies in the bank, find out which policies match and build a result set that will contain the actions of all the matching policies. While evaluating a policy if any advanced expression cannot be evaluated then UNDEF processing will get triggered. There are also other scenarios during policy traversal when UNDEF processing can get triggered. If an UNDEF event occurs while processing a policy, then (i) policy bank traversal ends, (ii) the result set of actions that was built so far is wiped out (iii) the current policy's undefAction is put in the result set and the evaluation ends.

**Parameters**

**policyName**

Name of an AppFlow policy.

**Example**

i) bind appflow global pol9 9
   ii) bind appflow global pol9 9 120
   iii) bind appflow global pol9 9 "HTTP.REQ.HEADER("qh3")\.TYPECAST_NUM_T(DECIMAL)"

**unbind appflow global**

**Synopsis**

unbind appflow global (<policyName> [-type <type>] [-priority <positive_integer>])
appflow global

Description
Unbind entities from AppFlow global.

Parameters

policyName
Name of an AppFlow policy.

Example
unbind appflow global pol9

Top

show appflow global

Synopsis
show appflow global [-type <type>]

Description
Display the AppFlow global bindings.

Parameters

type
The bindpoint to which the policy is bound. Possible values: REQ_OVERRIDE, REQ_DEFAULT, OVERRIDE, DEFAULT, OTHERTCP_REQ_OVERRIDE, OTHERTCP_REQ_DEFAULT, MSSQL_REQ_OVERRIDE, MSSQL_REQ_DEFAULT, MYSQL_REQ_OVERRIDE, MYSQL_REQ_DEFAULT

Example
show appflow global

Top
Application Firewall Commands

This group of commands can be used to perform operations on the following entities:

- appfw
- appfw fieldType
- appfw profile
- appfw policy
- appfw policylabel
- appfw confidField
- appfw stats
- appfw xmlerrorpage
- appfw htmlerrorpage
- appfw settings
- appfw global
- appfw learningsettings
- appfw learningdata
- appfw wsdl
- appfw signatures
- appfw xmlschema
- appfw XMLContentType
- appfw archive
appfw

stat appfw

Synopsis

stat appfw [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display application firewall stats.
appfw fieldType

[ add | rm | set | show ]

add appfw fieldType

Synopsis
add appfw fieldType <name> <regex> <priority> [-comment <string>]

Description
Add an application firewall field type. Field types define the type of data that can appear in a web form field. The Learning engine uses the field types list to generate appropriate field type assignments for the field formats check.

Parameters
name
The name of this field type.
regex
The regular expression that describes this field type.
priority
The priority of this field type. Maximum value: 64000
comment
Comments associated with this field type.

rm appfw fieldType

Synopsis
rm appfw fieldType <name>
**appfw fieldType**

**Description**
Remove an application firewall field type. Field types define the type of data that can appear in a web form field. The Learning engine uses the field types list to generate appropriate field type assignments for the field formats check.

**Parameters**
- name
  The name of this field type.

**set appfw fieldType**

**Synopsis**
set appfw fieldType <name> <regex> <priority> [-comment <string>]

**Description**
Modify an application firewall field type. Field types define the type of data that can appear in a web form field. The Learning engine uses the field types list to generate appropriate field type assignments for the field formats check.

**Parameters**
- name
  The name of this field type.
- regex
  The regular expression that describes this field type.

**show appfw fieldType**

**Synopsis**
show appfw fieldType [<name>]

**Description**
Display all configured application firewall form field types.
Parameters

name

The name of this field type.

Top
appfw profile

[ add | rm | set | unset | bind | unbind | show | stat | archive | restore ]

add appfw profile

Synopsis

add appfw profile <name> [-defaults ( basic | advanced )] [-startURLAction <startURLAction> ...] [-startURLClosure ( ON | OFF )] [-denyURLAction <denyURLAction> ...] [-RefererHeaderCheck <RefererHeaderCheck> -cookieConsistencyAction <cookieConsistencyAction> ...] [-cookieTransforms ( ON | OFF )] [-cookieEncryption <cookieEncryption>] [-cookieProxying ( none | sessionOnly )] [-addCookieFlags <addCookieFlags>] [-fieldConsistencyAction <fieldConsistencyAction> ...] [-CSRFtagAction <CSRFtagAction> ...] [-crossSiteScriptingAction <crossSiteScriptingAction> ...] [-crossSiteScriptingTransformUnsafeHTML ( ON | OFF )] [-crossSiteScriptingCheckCompleteURLs ( ON | OFF )] [-SQLInjectionAction <SQLInjectionAction> ...] [-SQLInjectionTransformSpecialChars ( ON | OFF )] [-SQLInjectionOnlyCheckFieldsWithSQLChars ( ON | OFF )] [-fieldFormatAction <fieldFormatAction> ...] [-defaultFieldFormatType <string>] [-defaultFieldFormatMinLength <positive_integer>] [-defaultFieldFormatMaxLength <positive_integer>] [-bufferOverflowAction <bufferOverflowAction> ...] [-bufferOverflowMaxURLLength <positive_integer>] [-bufferOverflowMaxHeaderLength <positive_integer>] [-bufferOverflowMaxCookieLength <positive_integer>] [-creditCardAction <creditCardAction> ...] [-creditCard <creditCard> ...] [-creditCardMaxAllowed <positive_integer>] [-creditCardXOut ( ON | OFF )] [-requestContentType <string>] [-responseContentType <string>] [-XMLDoSAction <XMLDoSAction> ...] [-XMLFormatAction <XMLFormatAction> ...] [-XMLSQLInjectionAction <XMLSQLInjectionAction> ...] [-XMLSQLInjectionOnlyCheckFieldsWithSQLChars ( ON | OFF )] [-XMLSQLInjectionActionParseComments <XMLSQLInjectionActionParseComments> ...] [-XMLXSSAction <XMLXSSAction> ...] [-XMLWASIAction <XMLWASIAction> ...] [-XMLAttachmentAction <XMLAttachmentAction> ...] [-XMLValidationAction <XMLValidationAction> ...] [-XMLErrorObject <string>] [-signatures <string>] [-XMLSOAPFaultAction <XMLSOAPFaultAction> ...] [-useHTMLErrorObject ( ON | OFF )] [-errorURL <expression>] [-HTTPErrorObject <string>] [-logEveryPolicyHit ( ON | OFF )] [-stripHtmlComments <stripHtmlComments>] [-stripXmlComments <stripHtmlComments>] [-stripCharSet <string>] [-fileUploadMaxNum <positive_integer>] [-canonicalizeHTMLResponse ( ON | OFF )] [-enableFormTagging ( ON | OFF )] [-sessionlessFieldConsistency <sessionlessFieldConsistency> ...] [-sessionlessURLClosure ( ON | OFF )] [-semicolonFieldSeparator ( ON | OFF )] [-excludeFileUploadFromChecks ( ON | OFF )] [-SQLInjectionParseComments <SQLInjectionParseComments> ...] [-invalidPercentHandling <invalidPercentHandling>] [-type ( HTML | XML ) ...] [-checkRequestHeaders ( ON | OFF )] [-comment <string>]
Description
Add an application firewall profile. A profile tells the application firewall how it should protect a given class of web content. Different types of content often require different protection strategies. You define these strategies in a profile. You can create profiles with basic or advanced defaults. The defaults, or predefined settings, provide solid initial protection for web content - a starting point from which you can configure additional protection for special content. Each profile is associated with a policy that tells the application firewall the content type of a request or response. When a request or response matches the policy, that profile is applied.

Parameters
name
Application firewall profile name.

defaults
Default Start URLs and Deny URLs. Possible values: basic, advanced

builtin
Indicates that a profile is a built-in entity.
builtinType
Type of built-in Profile. Possible values: APPFW_NOT_BUILTIN, APPFW_BYPASS, APPFW_BLOCK, APPFW_RESET, APPFW_DROP

startURLAction
Start URL action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. Default value: AS_DEFAULT_DISPOSITION

startURLClosure
Start URL closure. This check is applicable to Profile Type: HTML, XML. Possible values: ON, OFF Default value: OFF

denyURLAction
Deny URL action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

RefererHeaderCheck
Referer header check This check is applicable to Profile Type: HTML. Possible values: OFF, if_present, always Default value: AS_HEADER_CHECK_OFF

cookieConsistencyAction
Cookie consistency action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. Default value: AS_NONE
cookieTransforms

Enable cookie transforms: encryption, proxying, and adding cookie flags. Make sure this is turned ON if you want the transforms to happen. This check is applicable to Profile Type: HTML. XML Possible values: ON, OFF Default value: OFF

cookieEncryption

Encrypts server cookies Possible values: none, decryptOnly, encryptSessionOnly, encryptAll Default value: AS_CKI_ENCRYPT_NONE

cookieProxying

Proxy server cookies using an application firewall session Possible values: none, sessionOnly Default value: AS_CKI_PROXY_NONE

addCookieFlags

Add HttpOnly and/or Secure flags to cookies Possible values: none, httpOnly, secure, all Default value: AS_ADD_CKI_FLAGS_NONE

fieldConsistencyAction

Form Field Consistency action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_NONE

CSRFtagAction

Cross-site request forgery tag action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. LEARN is not supported. Default value: AS_NONE

crossSiteScriptingAction

Cross-site scripting action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

crossSiteScriptingTransformUnsafeHTML

Transform HTML characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF

crossSiteScriptingCheckCompleteURLs

Check complete URLs. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF

SQLInjectionAction

SQL injection action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

SQLInjectionTransformSpecialChars

Transform HTML characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF
SQLInjectionOnlyCheckFieldsWithSQLChars

Check SQL characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: ON

fieldFormatAction

Field format action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

defaultFieldFormatType

Default field type. This check is applicable to Profile Type: HTML.

defaultFieldFormatMinLength

Default field type minimum length. This check is applicable to Profile Type: HTML. Default value: AS_DEFAULTFIELDFORMAT_DEFAULT_MIN_LEN Maximum value: 65535

defaultFieldFormatMaxLength

Default field type maximum length. This check is applicable to Profile Type: HTML. Default value: AS_DEFAULTFIELDFORMAT_DEFAULT_MAX_LEN Minimum value: 1 Maximum value: 65535

bufferOverflowAction

Buffer overflow action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

bufferOverflowMaxURLLength

Maximum URL length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_URL_LEN Maximum value: 65535

bufferOverflowMaxHeaderLength

Maximum header length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_HDR_LEN Maximum value: 65535

bufferOverflowMaxCookieLength

Maximum cookie length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_COOKIE_LEN Maximum value: 65535

creditCardAction

Credit Card action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_NONE

creditCard

Credit card. This check is applicable to Profile Type: HTML, XML. Default value: AS_CCARD_DEFAULT_CARD_TYPE
creditCardMaxAllowed

Maximum number of times a credit card number may be seen before action is taken. This check is applicable to Profile Type: HTML, XML. Maximum value: 255

creditCardXOut

X-out the credit card numbers. This check is applicable to Profile Type: HTML, XML. Possible values: ON, OFF Default value: OFF

requestContentType

Default content-type for request messages. This binding is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_DEFAULT_REQUEST_CONTENT_TYPE

responseContentType

Default content-type for response messages. This binding is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_DEFAULT_RESPONSE_CONTENT_TYPE

XMLDoSAction

XML DOS action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION

XMLFormatAction

XML well-formed request action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

XMLSQLInjectionAction

XML SQL injection action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

XMLSQLInjectionOnlyCheckFieldsWithSQLChars

Check SQL characters. This check is applicable to Profile Type: XML. Possible values: ON, OFF Default value: ON

XMLSQLInjectionParseComments

Canonicalize SQL Comments in XML Data. This check is applicable to Profile Type: XML. Possible values: checkall, ansi, nested, ansinested Default value: AS_CHECKALL

XMLXSSAction

XML cross-site scripting action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

XMLWSIAction

XML WS-I action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION
**XMLAttachmentAction**

XML attachment action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION

**XMLValidationAction**

XML validation action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**XMLErrorObject**

Object name for the xml error page. This check is applicable to Profile Type: XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**customSettings**

Object name for custom settings. This check is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**signatures**

Object name for signatures. This check is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**XMLSOAPFaultAction**

XML SOAP fault filtering action types. (BLOCK | LOG | STATS | REMOVE | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**useHTMLErrorObject**

Use HTML Error object for response instead of Redirect Error URL. Possible values: ON, OFF Default value: OFF

**errorURL**

Error page. This check is applicable to Profile Type: HTML. Default value: NS_S_AS_ERROR_URL_DEFAULT

**HTMLErrorObject**

Object name for the html error page. This check is applicable to Profile Type: HTML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**logEveryPolicyHit**

Log every profile match regardless of security checks results. Possible values: ON, OFF Default value: OFF

**stripComments**

Strip HTML comments. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF
stripHtmlComments

Strip HTML comments. This check is applicable to Profile Type: HTML. Possible values:
none, all, exclude_script_tag Default value: AS_STRIP_COMMENT_NONE

stripXmlComments

Strip XML comments. This check is applicable to Profile Type: XML. Possible values: none,
all Default value: AS_STRIP_COMMENT_NONE

exemptClosureURLsFromSecurityChecks

Tells the application firewall to exempt closure URLs from security checks. This check is
applicable to Profile Type: HTML. Possible values: ON, OFF Default value: ON

defaultCharSet

Default character set. Possible values are iso-8859-1 (English US), big5 (Chinese
Traditional), gb2312 (Chinese Simplified), sjis (Japanese), euc-jp (Japanese EUC-JP),
utf-8 (Unicode), and euc-kr (Korean). This check is applicable to Profile Type: HTML.
Default value: NS_S_AS_CHARSET_DEFAULT Maximum value: 31

postBodyLimit

Maximum allowed post body size. This check is applicable to Profile Type: HTML, XML.
Default value: AS_DEFAULT_POSTBODYLIMIT Maximum value: 1000000000

fileUploadMaxNum

Maximum allowed number of file uploads per form submission request. Setting this
parameter to the maximum value of 65535 will allow an unlimited number of uploads.
Default value: AS_DEFAULT_MAX_FILE_UPLOADS Maximum value: 65535

canonicalizeHTMLResponse

Entity encoding for html special characters for attributes in the response. This check is
applicable to Profile Type: HTML. Possible values: ON, OFF Default value: ON

enableFormTagging

Enable Tagging of Forms for Field Consistency Checks. This check is applicable to Profile
Type: HTML. Possible values: ON, OFF Default value: ON

sessionlessFieldConsistency

Enable session less Field Consistency Checks. This check is applicable to Profile Type:
HTML. Possible values: OFF, ON, postOnly Default value: AS_OFF

sessionlessURLClosure

Enable session less URL Closure Checks. This check is applicable to Profile Type: HTML.
Possible values: ON, OFF Default value: OFF

semicolonFieldSeparator
appfw profile

Allow ';' as a form field separator in URL queries and POST form bodies. Possible values: ON, OFF Default value: OFF

excludeFileUploadFromChecks

Exclude Uploaded Files from Form checks. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF

SQLInjectionParseComments

Canonicalize SQL Comments in form fields. This check is applicable to Profile Type: HTML. Possible values: checkall, ansi, nested, ansinested Default value: AS_DEFAULT_SQLINJECTIONPARSECOMMENTS

invalidPercentHandling

Options for handling percent-encoded names and values. Possible values: apache_mode, asp_mode, secure_mode Default value: AS_PERCENT_DECODE_SECURE_MODE

type

Defines the type of the Application Firewall Profile. If the profile is of type XML, then you can only set security checks that are relevent to XML. Similary, if the profile type is HTML then you can set only security checks that are relevant to HTML. Composite profile types can have HTML and XML checks. Default value: AF_PROFILE_TYPE_HTML

checkRequestHeaders

Check for XSS and SQL injections in request headers. Possible values: ON, OFF Default value: OFF

comment

Comments associated with this profile.

**Description**

Modify the settings for a given application firewall profile.

**Parameters**

- **name**
  
  Application firewall profile name.
**appfw profile**

**startURLAction**

Start URL action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. Default value: AS_DEFAULT_DISPOSITION

**startURLClosure**

Start URL closure. This check is applicable to Profile Type: HTML, XML. Possible values: ON, OFF Default value: OFF

**denyURLAction**

Deny URL action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**RefererHeaderCheck**

Referer header check. This check is applicable to Profile Type: HTML. Possible values: OFF, if_present, always Default value: AS_HEADER_CHECK_OFF

**cookieConsistencyAction**

Cookie consistency action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. Default value: AS_NONE

**cookieTransforms**

Enable cookie transforms: encryption, proxying, and adding cookie flags. Make sure this is turned ON if you want the transforms to happen. This check is applicable to Profile Type: HTML, XML. Possible values: ON, OFF

**cookieEncryption**

Encrypts server cookies Possible values: none, decryptOnly, encryptSessionOnly, encryptAll Default value: AS_CKI_ENCRYPT_NONE

**cookieProxying**

Proxy server cookies using an application firewall session Possible values: none, sessionOnly Default value: AS_CKI_PROXY_NONE

**addCookieFlags**

Add HttpOnly and Secure flags to cookies Possible values: none, httpOnly, secure, all Default value: AS_ADD_CKI_FLAGS_NONE

**fieldConsistencyAction**

Form Field Consistency action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_NONE

**CSRFtagAction**

Cross-site request forgery tag action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. LEARN is not supported. Default value: AS_NONE
**crossSiteScriptingAction**

Cross-site scripting action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

**crossSiteScriptingTransformUnsafeHTML**

Transform HTML characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

**crossSiteScriptingCheckCompleteURLs**

Check complete URLs. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

**SQLInjectionAction**

SQL injection action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

**SQLInjectionTransformSpecialChars**

Transform HTML characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

**SQLInjectionOnlyCheckFieldsWithSQLChars**

Check SQL characters. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

**fieldFormatAction**

Field format action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: HTML. Default value: AS_DEFAULT_DISPOSITION

**defaultFieldFormatType**

Default field type. This check is applicable to Profile Type: HTML.

**defaultFieldFormatMinLength**

Default field type minimum length. This check is applicable to Profile Type: HTML. Default value: AS_DEFAULTFIELDFORMAT_DEFAULT_MIN_LEN Maximum value: 65535

**defaultFieldFormatMaxLength**

Default field type maximum length. This check is applicable to Profile Type: HTML. Default value: AS_DEFAULTFIELDFORMAT_DEFAULT_MAX_LEN Minimum value: 1 Maximum value: 65535

**bufferOverflowAction**

Buffer overflow action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION
bufferOverflowMaxURLLength

Maximum URL length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_URL_LEN Maximum value: 65535

bufferOverflowMaxHeaderLength

Maximum header length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_HDR_LEN Maximum value: 65535

bufferOverflowMaxCookieLength

Maximum cookie length. This check is applicable to Profile Type: HTML, XML. Default value: AS_BUFFEROVERFLOW_DEFAULT_MAX_COOKIE_LEN Maximum value: 65535

creditCardAction

Credit Card action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: HTML, XML. LEARN is not supported. Default value: AS_NONE

creditCard

Credit card. This check is applicable to Profile Type: HTML, XML. Default value: AS_CCARD_DEFAULT_CARD_TYPE

creditCardMaxAllowed

Maximum number of times a credit card number may be seen before action is taken. This check is applicable to Profile Type: HTML, XML. Maximum value: 255

creditCardXOut

X-out the credit card numbers. This check is applicable to Profile Type: HTML, XML. Possible values: ON, OFF

requestContentType

Default content-type for request messages. This binding is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_DEFAULT_REQUEST_CONTENT_TYPE

responseContentType

Default content-type for response messages. This binding is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_DEFAULT_RESPONSE_CONTENT_TYPE

XMLDoSAction

XML DOS action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION

XMLFormatAction

XML well-formed request action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION
**XMLSQLInjectionAction**

XML SQL injection action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**XMLSQLInjectionOnlyCheckFieldsWithSQLChars**

Check SQL characters. This check is applicable to Profile Type: XML. Possible values: ON, OFF

**XMLSQLInjectionParseComments**

Canonicalize SQL Comments in XML Data. This check is applicable to Profile Type: XML. Possible values: checkall, ansi, nested, ansinested Default value: AS_CHECKALL

**XMLXSSAction**

XML cross-site scripting action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**XMLWSIAction**

XML WS-I action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION

**XMLAttachmentAction**

XML attachment action types. (BLOCK | LEARN | LOG | STATS | NONE) This check is applicable to Profile Type: XML. Default value: AS_DEFAULT_DISPOSITION

**XMLValidationAction**

XML validation action types. (BLOCK | LOG | STATS | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION

**XMLErrorObject**

Object name for the xml error page. This check is applicable to Profile Type: XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**customSettings**

Object name for custom settings. This check is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**signatures**

Object name for signatures. This check is applicable to Profile Type: HTML, XML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

**XMLSOAPFaultAction**

XML SOAP fault filtering action types. (BLOCK | LOG | STATS | REMOVE | NONE) This check is applicable to Profile Type: XML. LEARN is not supported. Default value: AS_DEFAULT_DISPOSITION
appfw profile

useHTMLErrorObject

Use HTML Error object for response instead of Redirect Error URL. Possible values: ON, OFF

errorURL

Error page. This check is applicable to Profile Type: HTML. Default value: NS_S_AS_ERROR_URL_DEFAULT

HTMLErrorObject

Object name for the html error page. This check is applicable to Profile Type: HTML. Default value: NS_S_AS_ERROROBJECT_DEFAULT

logEveryPolicyHit

Log every profile match regardless of security checks results. Possible values: ON, OFF

stripComments

Strip HTML comments. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

stripHtmlComments

Strip HTML comments. This check is applicable to Profile Type: HTML. Possible values: none, all, exclude_script_tag

stripXmlComments

Strip XML comments. This check is applicable to Profile Type: XML. Possible values: none, all

exemptClosureURLsFromSecurityChecks

Tells the application firewall to exempt closure URLs from security checks. This check is applicable to Profile Type: HTML. Possible values: ON, OFF

defaultCharSet

Default character set. Possible values are iso-8859-1 (English US), big5 (Chinese Traditional), gb2312 (Chinese Simplified), sjis (Japanese), euc-jp (Japanese EUC-JP), utf-8 (Unicode), and euc-kr (Korean). This check is applicable to Profile Type: HTML. Default value: NS_S_AS_CHARSET_DEFAULT Maximum value: 31

postBodyLimit

Maximum allowed post body size. This check is applicable to Profile Type: HTML, XML. Default value: AS_DEFAULT_POSTBODYLIMIT Maximum value: 1000000000

fileUploadMaxNum

Maximum allowed number of file uploads per form submission request. Setting this parameter to the maximum value of 65535 will allow an unlimited number of uploads. Default value: AS_DEFAULT_MAX_FILE_UPLOADS Maximum value: 65535
canonicalizeHTMLResponse

Entity encoding for html special characters for attributes in the response. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: ON

enableFormTagging

Enable Tagging of Forms for Field Consistency Checks. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: ON

sessionlessFieldConsistency

Enable session less Field Consistency Checks. This check is applicable to Profile Type: HTML. Possible values: OFF, ON, postOnly Default value: AS_OFF

sessionlessURLClosure

Enable session less URL Closure Checks. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF

semicolonFieldSeparator

Allow ';' as a form field separator in URL queries and POST form bodies. Possible values: ON, OFF Default value: OFF

excludeFileUploadFromChecks

Exclude Uploaded Files from Form checks. This check is applicable to Profile Type: HTML. Possible values: ON, OFF Default value: OFF

SQLInjectionParseComments

Canonicalize SQL Comments in form fields. This check is applicable to Profile Type: HTML. Possible values: checkall, ansi, nested, ansinested Default value: AS_DEFAULT_SQLINJECTIONPARSECOMMENTS

invalidPercentHandling

Options for handling percent-encoded names and values. Possible values: apache_mode, asp_mode, secure_mode Default value: AS_PERCENT_DECODE_SECURE_MODE

type

Defines the type of the application firewall Profile. If the profile is of type XML, then you can only set security checks that are relevant to XML. Similarly, if the profile type is HTML then you can set only security checks that are relevant to HTML. Composite profile types can have HTML and XML checks. Default value: AF_PROFILE_TYPE_HTML

checkRequestHeaders

Check for XSS and SQL injections in request headers. Possible values: ON, OFF Default value: OFF

comment

Comments associated with this profile.
unset appfw profile

Synopsis

Description

Use this command to remove appfw profile settings. Refer to the set appfw profile command for meanings of the arguments.
bind appfw profile

Synopsis

bind appfw profile <name> [-startURL <expression> | -denyURL <expression> | (-fieldConsistency <string> [-isRegex ( REGEX | NOTREGEX )]) | (-cookieConsistency <string> [-isRegex ( REGEX | NOTREGEX )]) | (-SQLInjection <string> [-isRegex ( REGEX | NOTREGEX )]) | (-CSRFTag <expression> <CSRFFormActionURL> [-isRegex ( REGEX | NOTREGEX )]) | (-crossSiteScripting <string> <formActionURL> [-isRegex ( REGEX | NOTREGEX )]) | (-fieldFormat <string> [-fieldFormatMinLength <positive_integer> | -fieldFormatMaxLength <positive_integer> | -isRegex ( REGEX | NOTREGEX )]) | (-safeObject <string> <expression> [-maxMatchLength <action> ...]) | (-trustedLearningClients <ip_addr[/prefix] | ipv6_addr[/prefix]> | (-XMLDoSURL <expression> [-XMLMaxElementDepth ( ON | OFF ) [-XMLMaxElementDepth <positive_integer>]] [-XMLMaxElementNameLengthCheck ( ON | OFF ) [-XMLMaxElementNameLength <positive_integer>]] [-XMLMaxElementChildrenCheck ( ON | OFF ) [-XMLMaxElementChildren <positive_integer>]] [-XMLMaxAttributesCheck ( ON | OFF ) [-XMLMaxAttributes <positive_integer>]] [-XMLMaxAttributeNameLengthCheck ( ON | OFF ) [-XMLMaxAttributeNameLength <positive_integer>]] [-XMLMaxAttributeValueLengthCheck ( ON | OFF ) [-XMLMaxAttributeValueLength <positive_integer>]] [-XMLMaxCharDATALengthCheck ( ON | OFF ) [-XMLMaxCharDATALength <positive_integer>]] [-XMLMaxFileSizeCheck ( ON | OFF ) [-XMLMaxFileSize <positive_integer>]] [-XMLMinFileSizeCheck ( ON | OFF ) [-XMLMinFileSize <positive_integer>]] [-XMLBlockPI ( ON | OFF ) [-XMLBlockPI <positive_integer>]] [-XMLBlockDTD ( ON | OFF ) [-XMLBlockDTD <positive_integer>]] [-XMLBlockExternalEntities ( ON | OFF ) [-XMLBlockExternalEntities <positive_integer>]] [-XMLMaxEntityExpansionsCheck ( ON | OFF ) [-XMLMaxEntityExpansions <positive_integer>]] [-XMLMaxEntityExpansionDepthCheck ( ON | OFF ) [-XMLMaxEntityExpansionDepth <positive_integer>]] [-XMLMaxNamespacesCheck ( ON | OFF ) [-XMLMaxNamespaces <positive_integer>]] [-XMLMaxNamespaceUriLengthCheck ( ON | OFF ) [-XMLMaxNamespaceUriLength <positive_integer>]] [-XMLSOAPArrayCheck ( ON | OFF ) [-XMLSOAPArray <positive_integer>]] [-XMLMaxSOAPArrayRank <positive_integer>]] [-XMLWSIURL <expression> [-XMLWSIChecks <string>]] [-XMLValidationURL <expression> [-XMLAdditionalSOAPHeaders ( ON | OFF ) [-XMLAdditionalSOAPHeaders <string>]] [-XMLRequestSchema <expression> [-XMLValidateSOAPEnvelope ( ON | OFF ) [-XMLValidateSOAPEnvelope <positive_integer>]] [-XMLResponseSchema <expression> [-XMLValidateResponse ( ON | OFF )]] [-XMLAttachmentURL <expression> [-XMLAttachmentContentSizeCheck ( ON | OFF ) [-XMLAttachmentContentSize <positive_integer>]] [-XMLAttachmentContentTypeCheck ( ON | OFF ) [-XMLAttachmentContentType <expression>]] [-XMLSQLInjection ( ON | OFF ) [-isRegex ( REGEX | NOTREGEX )]] [-location ( ELEMENT | ATTRIBUTE )]] [-XMLXSS <string> [-isRegex ( REGEX | NOTREGEX )]] [-location ( ELEMENT | ATTRIBUTE )]] [-comment <string> [-isRegex ( ENABLED | DISABLED )]]

Description

Bind a security check to the application firewall profile. You can bind any number of security checks to the profile. When the profile is activated (see the add appfw global command), each security check tests the data stream for the specified condition. When a test fails, the appropriate action is determined by the action configured in the profile.
Parameters

name
Application firewall profile name.

startURL
Start URL regular expression. This binding is applicable to Profile Type: HTML, XML.

denyURL
Deny URL regular expression. This binding is applicable to Profile Type: HTML, XML.

fieldConsistency
Form field name. This binding is applicable to Profile Type: HTML.

cookieConsistency
Cookie name. This binding is applicable to Profile Type: HTML, XML.

SQLInjection
Form field, header or cookie name. This binding is applicable to Profile Type: HTML.

CSRFTag
CSRF Form Origin URL. This binding is applicable to Profile Type: HTML.

crossSiteScripting
Form field, header or cookie name. This binding is applicable to Profile Type: HTML.

fieldFormat
Field format name. This binding is applicable to Profile Type: HTML.

safeObject
Safe Object name. This binding is applicable to Profile Type: HTML, XML.

trustedLearningClients
Trusted host/network learning IP. This binding is applicable to profile Type: HTML, XML.

comment
Comments associated with this profile.

state
Enabled. Possible values: ENABLED, DISABLED Default value: ENABLED

XMLDoSURL
unbind appfw profile

Synopsis

unbind appfw profile <name> (-startURL <expression> | -denyURL <expression> | (-fieldConsistency <string> <formActionURL>) | -cookieConsistency <string> | (-SQLInjection <string> <formActionURL> [-location <location>]) | (-crossSiteScripting <string> <formActionURL> [-location <location>]) | -safeObject <string> | -trustedLearningClients <ip_addr[/prefix]|ipv6_addr[/prefix]|*> | -XMLDoSURL <expression> | -XMLWSIURL <expression> | -XMLValidationURL <expression> | -XMLAttachmentURL <expression> | (-XMLSQLInjection <string> [-location (ELEMENT | ATTRIBUTE)]) | (-XMLXSS <string> [-location (ELEMENT | ATTRIBUTE)]) | [-CSRFTag <string> <CSRFFormActionURL>]

Description

Unbind a security check from the given application firewall profile.

Parameters

name

Application firewall profile name.

startURL

Start URL regular expression.
denyURL

Deny URL regular expression.

fieldConsistency

Form field name.

cookieConsistency

Cookie name.

SQLInjection

Form field, header or cookie name.

CSRFTag

CSRF Form origin URL. This binding is applicable to Profile Type: HTML.

crossSiteScripting

Form field, header or cookie name.

fieldFormat

Field format name.

safeObject

Safe Object name.

trustedLearningClients

Trusted learning Clients IP

XMLDoSURL

XML DoS URL regular expression.

XMLWSIURL

XML WS-I URL regular expression.

XMLValidationURL

XML Message URL regular expression.

XMLAttachmentURL

XML Attachment URL regular expression.

XMLSQLInjection

XML SQL Injection exemption field, this can be an element or an attribute name.
show appfw profile

Synopsis

show appfw profile [<name>]

Description

Display all application firewall profiles that currently exist.

Parameters

name

The name of the application firewall profile.

stat appfw profile

Synopsis

stat appfw profile [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display appfw profile statistics.

Parameters

name

Application firewall profile name.

Example

stat appfw profile
archive appfw profile

Synopsis
archive appfw profile <name> <archivename> [-comment <string>]

Description
Create archive for the profile.

Parameters
- name
  Application firewall profile name.
- archivename
  Source for tar archive.
- comment
  Comments associated with this profile.

restore appfw profile

Synopsis
restore appfw profile <archivename>

Description
Restore configuration from archive file

Parameters
- archivename
  Source for tar archive.
appfw policy

[ add | rm | set | unset | show | stat | rename ]

add appfw policy

Synopsis
add appfw policy <name> <rule> <profileName> [-comment <string>] [-logAction <string>]

Description
Create an application firewall policy.

Parameters
name
Application firewall policy name.
rule
The rule associated with the policy.
profileName
Application firewall profile name.
comment
Comments associated with this application firewall policy.
logAction
The log action associated with the application firewall policy.

rm appfw policy

Synopsis
rm appfw policy <name>
Description
Remove an application firewall policy.

Parameters
name
Application firewall policy name.

Top

set appfw policy

Synopsis
set appfw policy <name> [-rule <expression>] [-profileName <string>] [-comment <string>] [-logAction <string>]

Description
Modify an application firewall policy. Set a new rule/profile/comment for existing application firewall policy.

Parameters
name
Application firewall policy name.
rule
The rule associated with the policy.
profileName
Application firewall profile name.
comment
Comments associated with this application firewall policy.
logAction
The log action associated with the application firewall policy.

Example
set transform policy pol9 -rule HTTP.REQ.HEADER("header").CONTAINS("qh2")
unset appfw policy

**Synopsis**

unset appfw policy <name> [-comment] [-logAction]

**Description**

Unset comment/logaction for existing transform policy. Refer to the set appfw policy command for meanings of the arguments.

**Example**

unset transform policy pol9 -undefAction

show appfw policy

**Synopsis**

show appfw policy [<name>]

**Description**

Display the application firewall policies.

**Parameters**

name

Application firewall policy name.

stat appfw policy

**Synopsis**

stat appfw policy [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]}
Description
Display advance application firewall policy statistics.

Parameters
name
The name of the advance application firewall policy for which statistics will be displayed. If not given statistics are shown for all advance application firewall policies.

Example
stat appfw policy

rename appfw policy

Synopsis
rename appfw policy <name>@ <newName>@

Description
Rename a application firewall policy.

Parameters
name
The name of the application firewall policy.

newName
The new name of the application firewall policy.

Example
rename appfw policy oldname newname
**add appfw policylabel**

**Synopsis**

```
add appfw policylabel <labelName> <policylabeltype>
```

**Description**

Add a application firewall policy label.

**Parameters**

- **labelName**
  
  Name of the application firewall policy label.

- **policylabeltype**
  
  The type of transformations allowed by the policies bound to the label. Possible values: http_req

**Example**

```
add appfw policylabel appfw_label http_req
```

**rm appfw policylabel**

**Synopsis**

```
rm appfw policylabel <labelName>
```

**Description**

Remove a application firewall policy label.
Parameters

**Parameters**

'labelName'

Name of the application firewall policy label.

**Example**

```
rm appfw policylabel appfw_label
```

**bind appfw policylabel**

**Synopsis**

```bind appfw policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]```

**Description**

Bind the application firewall policy to one of the labels.

**Parameters**

'labelName'

Name of the application firewall policy label.

'policyName'

The transform policy name.

**Example**

```
i)  bind appfw policylabel trans_http_url pol_1 1 2 -invoke reqvserver CURRENT
   ii) bind appfw policylabel trans_http_url pol_2 2
```

**unbind appfw policylabel**

**Synopsis**

```unbind appfw policylabel <labelName> <policyName> [-priority <positive_integer>]```
appfw policylabel

**Description**
Unbind entities from application firewall label.

**Parameters**

- **labelName**
  Name of the application firewall policy label.

- **policyName**
  The transform policy name.

- **priority**
  Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647

**Example**

unbind appfw policylabel appfw_label

Top

**show appfw policylabel**

**Synopsis**

show appfw policylabel [labelName]

**Description**
Display policy label or policies bound to application firewall policylabel.

**Parameters**

- **labelName**
  Name of the application firewall policy label.

**Example**

i) show appfw policylabel appfw_label
   ii) show appfw policylabel

Top
stat appfw policylabel

Synopsis

stat appfw policylabel [<labelName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of application firewall policylabel(s).

Parameters

labelName

The name of the application firewall label for which statistics will be displayed. If not given statistics are shown for all application firewall policylabels.

rename appfw policylabel

Synopsis

rename appfw policylabel <labelName>@ <newName>@

Description

Rename a application firewall policy label.

Parameters

labelName

The name of the application firewall policy label.

newName

The new name of the application firewall policylabel.

Example

rename appfw policylabel oldname newname

Top
appfw confidField

[ add | rm | set | unset | show ]

add appfw confidField

Synopsis

add appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX )] [-comment <string>] [-state ( ENABLED | DISABLED )]

Description

Define a form field (identified by the action URL and the field name) as confidential. These fields will have their values X'ed out in the audit logs.

Parameters

fieldName

Form field name.

url

Form action URL.

isRegex

Is field name a regular expression? Possible values: REGEX, NOTREGEX Default value: NS_NOTREGEX

comment

Comments associated with this confidential form field.

state

Enabled. Possible values: ENABLED, DISABLED Default value: ENABLED
rm appfw confidField

Synopsis

    rm appfw confidField <fieldName> <url>

Description

Remove a confidential field. The field values will be logged as-is in the audit logs.

Parameters

    fieldName
        Form field name.
    url
        Form action URL.

set appfw confidField

Synopsis

    set appfw confidField <fieldName> <url> [-comment <string>] [-state ( ENABLED | DISABLED )]

Description

Modify a confidential field setting. Confidential fields have their values X'ed out in the audit logs

Parameters

    fieldName
        Form field name.
    url
        Form action URL.
    comment
        Comments associated with this confidential form field.
unset appfw confidField

Synopsis
unset appfw confidField <fieldName> <url> [-comment] [-state]

Description
Use this command to remove appfw confidField settings. Refer to the set appfw confidField command for meanings of the arguments.

show appfw confidField

Synopsis
show appfw confidField [<fieldName> <url>]

Description
Display all configured confidential form fields.

Parameters
fieldName
Form field name.

url
Form action URL.
appfw stats

show appfw stats

Synopsis
show appfw stats - alias for 'stat appfw'

Description
show appfw stats is an alias for stat appfw
appfw xmlerrorpage

[ rm | show | import | update ]

rm appfw xmlerrorpage

Synopsis
rm appfw xmlerrorpage <name>

Description
Removes the object imported by import xmlerrorpage.

Parameters
name
Indicates name of the imported xml error page to be removed.

Example
rm xmlerrorpage <name>

Top

show appfw xmlerrorpage

Synopsis
show appfw xmlerrorpage [<name>]

Description
Displays the object imported by import xmlerrorpage.

Example
show appfw xmlerrorpage

Top
import appfw xmlerrorpage

Synopsis

import appfw xmlerrorpage <src> <name> [-comment <string>] [-overwrite]

Description

Downloads the input XML Error Page to NetScaler Box with the given object name

Parameters

src

Indicates the source of the XML error page as a URL of the form
<protocol>:<host>[:<port>]/<path> <protocol> is http or https. <host> is the DNS
name or IP address of the http or https server. <port> is the port number of the server. If
omitted, the default port for http or https will be used. <path> is the path of the file on
the server. Import will fail if an https server requires client certificate authentication.

name

Indicates name of the xml error page to import.

comment

Comments.

overwrite

Overwrites the existing file

Example

import xmlerrorpage http://www.example.com/errorpage.xml my-xml-error-page

Top

update appfw xmlerrorpage

Synopsis

update appfw xmlerrorpage <name>

Description

Reloads the XML error page of the given object name in appfw profiles
Parameters

name

Indicates name of the xml error page to update.

Example

update xmlerrorpage my-xml-error-page

Top
appfw htmlerrorpage

[ rm | show | import | update ]

rm appfw htmlerrorpage

Synopsis
   rm appfw htmlerrorpage <name>

Description
   Removes the object imported by import htmlerrorpage.

Parameters
   name
       Indicates name of the imported html error page to be removed.

Example
   rm htmlerrorpage <name>
   
Top

show appfw htmlerrorpage

Synopsis
   show appfw htmlerrorpage [ <name> ]

Description
   Displays the object imported by import htmlerrorpage.

Example
   show appfw htmlerrorpage
   
Top
import appfw htmlerrorpage

Synopsis
import appfw htmlerrorpage <src> <name> [-comment <string>] [-overwrite]

Description
Downloads the input HTML Error Page to NetScaler Box with the given object name

Parameters
src
Indicates the source of the HTML error page as a URL of the form
<protocol>://<host>::<port>/<path> <protocol> is http or https. <host> is the DNS
name or IP address of the http or https server. <port> is the port number of the server. If
omitted, the default port for http or https will be used. <path> is the path of the file on
the server. Import will fail if an https server requires client certificate authentication.

name
Indicates name of the html error page to import.

comment
Comments.

overwrite
Overwrites the existing file

Example

import htmlerrorpage http://www.example.com/errorpage.html my-html-error-page

update appfw htmlerrorpage

Synopsis
update appfw htmlerrorpage <name>

Description
Reloads the HTML error page of the given object name in appfw profiles
Parameters

name

Indicates name of the html error page to update.

Example

update htmlerrorpage my-html-error-page

Top
appfw settings

[ set | unset | show ]

set appfw settings

Synopsis

set appfw settings [-defaultProfile <string>] [-undefAction <string>] [-sessionTimeout <positive_integer>] [-learnRateLimit <positive_integer>] [-sessionLifetime <positive_integer>] [-sessionCookieName <string>] [-clientIPLoggingHeader <string>] [-importSizeLimit <positive_integer>] [-cookiePostEncryptPrefix <string>] [-logMalformedReq ( ON | OFF )] [-CEFLogging ( ON | OFF )] [-entityDecoding ( ON | OFF )] [-useConfigurableSecretKey ( ON | OFF )]

Description

Set the global settings for the application firewall module. Changes in these settings are applied to all application firewall profiles.

Parameters

defaultProfile

Application firewall global default profile. Default value:
AS_ENGINESETTINGS_DEFAULT_PROF_DEFAULT

undefAction

Application firewall global undefined profile. Default value:
AS_ENGINESETTINGS_UNDEF_PROF_DEFAULT

sessionTimeout

The user session timeout (in seconds). After this many seconds of no user activity, the session is terminated and the user must establish a new session before continuing to use the protected web site. Default value: AS_ENGINESETTINGS_SESSIONTIMEOUT_DEFAULT
Minimum value: 1 Maximum value: 65535

learnRateLimit

The AppFw learn messages rate limit value (in messages per second). The extra learn messages are dropped when the rate goes above this value. Default value: AS_ENGINESETTINGS_LEARN_RATE_LIMIT_DEFAULT
Minimum value: 1 Maximum value: 1000

sessionLifetime

The user session lifetime (in seconds). If a session has existed more than the specified number of seconds, the session can be terminated and the user must establish a new session before continuing to use the protected web site. Default value: AS_ENGINESETTINGS_SESSIONLIFETIME_DEFAULT Maximum value: 2147483647

**sessionCookieName**

The name of the session cookie set by the application firewall to track the user session. Default value: NS_S_AS_DEFAULT_COOKIE_NAME

**clientIPLoggingHeader**

The name of the header that holds downstream IP address for logging purposes.

**importSizeLimit**

Total import size limit. Default value: AS_ENGINESETTINGS_IMPORTSIZELIMIT_DEFAULT Minimum value: 1 Maximum value: 134217728

**cookiePostEncryptPrefix**

String which is prepended to all encrypted cookie values Default value: NS_S_AS_DEFAULT_CKI_POST_ENCRIPT_PREFIX

**logMalformedReq**

Log requests that are so malformed that AppFw parsing doesn't happen Possible values: ON, OFF Default value: ON

**CEFLogging**

Enable CEF formatted logging. Possible values: ON, OFF Default value: OFF

**entityDecoding**

Decode Entity-Encoded characters before doing AppFw checks. Possible values: ON, OFF Default value: OFF

**useConfigurableSecretKey**

Use configurable secret key in AppFw operations Possible values: ON, OFF Default value: OFF

## unset appfw settings

### Synopsis

```
```
appfw settings

Description
Use this command to remove appfw settings. Refer to the set appfw settings command for meanings of the arguments.

show appfw settings

Synopsis
show appfw settings

Description
Display the global settings for the application firewall module.
appfw global

[ bind | unbind | show ]

bind appfw global

Synopsis
bind appfw global <policyName> <priority> [-state ( ENABLED | DISABLED )]
[<gotoPriorityExpression>] [-type <type>] [-invoke (<labelType> <labelName>)]

Description
Activate an application firewall policy.

Parameters
policyName
Application firewall policy name.

unbind appfw global

Synopsis
unbind appfw global <policyName> [-type <type>] [-priority <positive_integer>]

Description
Deactivate an application firewall policy.

Parameters
policyName
Application firewall policy name.
priority
Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647
show appfw global

Synopsis

show appfw global [-type <type>]

Description

Display the active application firewall policies.

Parameters

type

The bindpoint to which to policy is bound. This can be used with advance application firewall policy only. Possible values: REQ_OVERRIDE, REQ_DEFAULT, NONE
appfw learningsettings

[ set | unset | show ]

set appfw learningsettings

Synopsis

Description

Set the application firewall learning settings.

Parameters

profileName

Application firewall profile name.

startURLMinThreshold

Minimum threshold to learn Start URLs. Default value:
AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

startURLPercentThreshold

Minimum threshold (in percent) to learn Start URLs. Default value:
AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

cookieConsistencyMinThreshold

Minimum threshold to learn cookie consistency information. Default value:
AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

cookieConsistencyPercentThreshold

Minimum threshold (in percent) to learn cookie consistency information. Default value:
AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100
Minimum threshold (in percent) to learn cookie consistency information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

CSRFtagMinThreshold

Minimum threshold to learn CSRF tag information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

CSRFtagPercentThreshold

Minimum threshold (in percent) to learn CSRF tag information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

fieldConsistencyMinThreshold

Minimum threshold to learn field consistency information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

fieldConsistencyPercentThreshold

Minimum threshold (in percent) to learn field consistency information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

crossSiteScriptingMinThreshold

Minimum threshold to learn cross-site scripting information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

crossSiteScriptingPercentThreshold

Minimum threshold (in percent) to learn cross-site scripting information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

SQLInjectionMinThreshold

Minimum threshold to learn SQL injection information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

SQLInjectionPercentThreshold

Minimum threshold (in percent) to learn SQL injection information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

fieldFormatMinThreshold

Minimum threshold to learn field format information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

fieldFormatPercentThreshold

Minimum threshold (in percent) to learn field format information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

XMLWSIMinThreshold
Minimum threshold to learn XML Web Services Interoperability information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

XMLWSIPercentThreshold
Minimum threshold (in percent) to learn XML Web Services Interoperability information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

XMLAttachmentMinThreshold
Minimum threshold to learn XML Attachment information. Default value: AS_LEARNINGSETTINGS_DEFAULT_MINTHRESHOLD Minimum value: 1

XMLAttachmentPercentThreshold
Minimum threshold (in percent) to learn XML Attachment information. Default value: AS_LEARNINGSETTINGS_DEFAULT_PERCENTTHRESHOLD Maximum value: 100

unset appfw learningsettings

Synopsis

Description
Use this command to remove appfw learningsettings settings. Refer to the set appfw learningsettings command for meanings of the arguments.

show appfw learningsettings

Synopsis
show appfw learningsettings [<profileName>]
appfw learningsettings

Description
Display the application firewall learning settings.

Parameters

profileName
Application firewall profile name.

Top
**appfw learningdata**

[ rm | show | reset | export ]

**rm appfw learningdata**

**Synopsis**

```
rm appfw learningdata <profileName> (-startURL <expression> | -cookieConsistency <string>
| (-fieldConsistency <string> <formActionURL>) | (-crossSiteScripting <string>
<formActionURL>) | (-SQLInjection <string> <formActionURL>) | (-fieldFormat <string>
<formActionURL>) | (-CSRFTag <expression> <CSRFFormOriginURL>) | -XMLDoSCheck
<expression> | -XMLWSICheck <expression> | -XMLAttachmentCheck <expression>)
[-TotalXMLRequests]
```

**Description**

Remove some raw application firewall learning data.

**Parameters**

- **profileName**
  - Application firewall profile name.
- **startURL**
  - Start URL configuration.
- **cookieConsistency**
  - Cookie Name.
- **fieldConsistency**
  - Form field name.
- **crossSiteScripting**
  - Cross-site scripting.
- **SQLInjection**
  - Form field name.
- **fieldFormat**
show appfw learningdata

Synopsis

show appfw learningdata <profileName> <securityCheck>

Description

Display the raw application firewall learning data.

Parameters

profileName

Application firewall profile name.

securityCheck

Security check. Possible values: startURL, cookieConsistency, fieldConsistency, crossSiteScripting, SQLInjection, fieldFormat, CSRFTag, XMLDoSCheck, XMLWSICheck, XMLAttachmentCheck, TotalXMLRequests

Top
reset appfw learningdata

Synopsis
reset appfw learningdata

Description
Remove all databases. Make transaction count zero

export appfw learningdata

Synopsis
export appfw learningdata <profileName> <securityCheck> [-target <string>]

Description
Export appfw learnt data in csv format to the location /var/learnt_data/

Parameters

profileName
Application firewall profile name.

securityCheck
Security check. Possible values: startURL, cookieConsistency, fieldConsistency, crossSiteScripting, SQLInjection, fieldFormat, CSRFtag, XMLDoSCheck, XMLWSICheck, XMLAttachmentCheck, TotalXMLRequests

target
Target filename for data to be exported.
appfw wsdl

[ rm | show | import ]

rm appfw wsdl

Synopsis

rm appfw wsdl <name>

Description

Removes the object imported by import wsdl.

Parameters

name

Indicates name of the imported wsdl to be removed.

Example

rm wsdl <name>

show appfw wsdl

Synopsis

show appfw wsdl [<name>]

Description

Displays the object imported by import wsdl.

Parameters

name

Indicates name of the imported wsdl to be displayed.
import appfw wsdl

Synopsis

import appfw wsdl <src> <name> [-comment <string>] [-overwrite]

Description

Compiles the input WSDL file into NetScaler native format.

Parameters

src

Indicates the source of the WSDL file as a URL of the form
<protocol>://<host>[:<port>]/<path> <protocol> is http or https. <host> is the DNS
name or IP address of the http or https server. <port> is the port number of the server. If
omitted, the default port for http or https will be used. <path> is the path of the file on
the server. Import will fail if an https server requires client certificate authentication. If
the path contains a '?', escape the '?' with a backslash

name

Indicates name of the wsdl to import.

comment

Comments.

overwrite

Overwrites the existing file

Example

import appfw wsdl http://www.webservicex.net/stockquote.asmx?wsdl stockquote
appfw signatures

[ rm | show | import | update ]

rm appfw signatures

Synopsis
   rm appfw signatures <name>

Description
   Removes the object imported by import signatures.

Parameters
   name
      Indicates name of signature object.

Example
   rm signatures <name>
   Top

show appfw signatures

Synopsis
   show appfw signatures [<name>]

Description
   Displays the object imported by import signatures.

Parameters
   name
      Indicates name of signature object.
import appfw signatures

Synopsis

import appfw signatures <src> <name> [-xslt <string>] [-comment <string>] [-overwrite]

Description

Downloads the application firewall signatures XML configuration to the NetScaler Box with the given object name

Parameters

src

Indicates the source of the signature file as a URL of the form <protocol>://<host>[:<port>]/<path> <protocol> is http or https. <host> is the DNS name or IP address of the http or https server. <port> is the port number of the server. If omitted, the default port for http or https will be used. <path> is the path of the file on the server. Import will fail if an https server requires client certificate authentication.

name

Indicates name of signature object.

xslt

XSLT file source.

comment

Comments.

overwrite

Overwrites the existing file

Example

import signatures http://www.example.com/ns/signatures.xml my-signature
update appfw signatures

Synopsis

update appfw signatures <name>

Description

Updates the application firewall signatures XML configuration to the NetScaler Box with the given object name

Parameters

name

Indicates name of the signature object to update.

Example

update signatures my-signatures

Top
appfw xmlschema

[ rm | show | import ]

rm appfw xmlschema

Synopsis
rm appfw xmlschema <name>

Description
Removes the object imported by import xmlschema.

Parameters
name
Indicates name of the imported xmlschema to be removed.

Example
rm xmlschema <name>

Top

show appfw xmlschema

Synopsis
show appfw xmlschema [<name>]

Description
Displays the object imported by import xmlschema.

Parameters
name
Indicates name of the imported xmlschema to be displayed.
**Example**

```
show appfw xmlschema
```

**Top**

---

**import appfw xmlschema**

**Synopsis**

```
import appfw xmlschema <src> <name> [-comment <string>] [-overwrite]
```

**Description**

Compiles the input XML Schema file into NetScaler native format.

**Parameters**

- **src**
  
  Indicates the source of the XML schema file as a URL of the form
  `<protocol>://<host>[:<port>]/<path>`
  
  `<protocol>` is http or https. `<host>` is the DNS name or IP address of the http or https server. `<port>` is the port number of the server. If omitted, the default port for http or https will be used. `<path>` is the path of the file on the server. Import will fail if an https server requires client certificate authentication.

- **name**
  
  Indicates name of the xmlschema to import.

- **comment**
  
  Comments.

- **overwrite**
  
  Overwrites the existing file

**Example**

```
import xmlschema http://schemas.xmlsoap.org/soap/envelope/ soap
```

**Top**
appfw XMLContentType

[ add | rm | show ]

add appfw XMLContentType

Synopsis
add appfw XMLContentType <XMLContenttypevalue> [-isRegex ( REGEX | NOTREGEX )]

Description
Add XML content type. This will classify a request/response with the specified content type as XML

Parameters
XMLContenttypevalue
Content type to be classified as XML

isRegex
Is field name a regular expression? Possible values: REGEX, NOTREGEX Default value: NS_NOTREGEX

Top

rm appfw XMLContentType

Synopsis
rm appfw XMLContentType <XMLContenttypevalue>

Description
Remove XML content type.

Parameters
XMLContenttypevalue
Content type to be classified as XML
show appfw XMLContentType

Synopsis

show appfw XMLContentType [XMLContentTypevalue]

Description

Display all xml content types.

Parameters

XMLContentTypevalue

Content type to be classified as XML
show appfw archive

Synopsis
    show appfw archive

Example
    show appfw archive

Top

dump appfw archive

Synopsis
    export appfw archive <name> <target>

Description
    Exports the archive file to the specified location

Parameters
    name
        Name of tar archive
    target
        Path to the file to be exported

Top
import appfw archive

Synopsis
import appfw archive <src> <name> [-comment <string>]

Description
Imports the archive file from specified location

Parameters

src
Indicates the source of the tar archive file as a URL of the form
<protocol>:<host>[:<port>][/<path>] <protocol> is http or https. <host> is the DNS
name or IP address of the http or https server. <port> is the port number of the server. If
omitted, the default port for http or https will be used. <path> is the path of the file on
the server. Import will fail if an https server requires client certificate authentication.

name
Indicates name of archive

comment
Comments associated with this archive.

Top

rm appfw archive

Synopsis
rm appfw archive <name>

Description
Removes the archive created by archive command.

Parameters
name
Indicates name of the archive to be removed.

Example
rm appfw archive <name>

Top
Audit Commands

This group of commands can be used to perform operations on the following entities:

- audit
- audit syslogAction
- audit syslogPolicy
- audit nslogAction
- audit nslogPolicy
- audit messageaction
- audit stats
- audit messages
- audit syslogParams
- audit nslogParams
audit

stat audit

Synopsis

stat audit [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display the audit statistics
add audit syslogAction

Synopsis

add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... 
[-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] 
[-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] 
[-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]

Description

Add an syslog action

Parameters

name

The name of the syslog action.

serverIP

The IP address of the syslog server.

serverPort

The port on which the syslog server is running. Minimum value: 1

logLevel

The audit log level.

dateFormat

The date format. Possible values: MMDDYYYY, DDMMYYYY

logFacility

The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, 
LOCAL5, LOCAL6, LOCAL7

tcp

Log the tcp messages Possible values: NONE, ALL
rm audit syslogAction

Synopsis

rm audit syslogAction <name>

Description

Remove a previously configured syslog action. Note that the syslog action cannot be removed if it is bound to a syslog policy.

Parameters

name

The name of the action.

set audit syslogAction

Synopsis

set audit syslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>]
[-logLevel <logLevel> ...] [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]
Description
Modify an existing syslog action.

Parameters

name
The name for the syslog action.

serverIP
The IP address of the syslog server.

serverPort
The port on which the syslog server is running. Minimum value: 1

logLevel
The audit log level.

dateFormat
The date format. Possible values: MMDDYYYY, DDMMYYYY

logFacility
The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7

tcp
Log the tcp messages Possible values: NONE, ALL

acl
Log the acl messages Possible values: ENABLED, DISABLED

timeZone
Specifies the timezone in which the timestamps in the log messages will be generated. Possible values: GMT_TIME, LOCAL_TIME

userDefinedAuditlog
Specifies whether the user configurable log messages should be done or not. Possible values: YES, NO

appflowExport
Control export of log messages to AppFlow collectors. Possible values: ENABLED, DISABLED
unset audit syslogAction

Synopsis

Description

Reset an existing syslog action. Refer to the set audit syslogAction command for meanings of the arguments.

show audit syslogAction

Synopsis

show audit syslogAction [<name>]

Description

Display details of the configured syslog action(s).

Parameters

name

The name of the syslog action. If no syslog action name is provided, all the configured syslog actions will be displayed.
audit syslogPolicy

[ add | rm | set | show ]

add audit syslogPolicy

Synopsis
add audit syslogPolicy <name> <rule> <action>

Description
Add a syslog policy. The policy defines the conditions under which the specified syslog server will be used for logging.

Parameters
name
The name of syslog policy.

rule
The name of the rule or expression that the policy will use. Currently supports only the rule "ns_true".

action
The name of the syslog action to be bound to the policy.

Top

rm audit syslogPolicy

Synopsis
rm audit syslogPolicy <name>

Description
Remove an audit syslog policy.
Parameters

name

The name of the syslog policy.

Top

set audit syslogPolicy

Synopsis

set audit syslogPolicy <name> [-rule <expression>] [-action <string>]

Description

Modify the properties of a syslog policy.

Parameters

name

The name of syslog policy.

rule

The name of the rule or expression that the policy will use. Currently supports only the rule "ns_true".

action

The name of the syslog action to be bound to the policy.

Top

show audit syslogPolicy

Synopsis

show audit syslogPolicy [<name>]

Description

Display the configured syslog policies.
Parameters

name

The name of the policy to be displayed. If the policy name is not provided, all the configured syslog policies will be displayed.
audit nslogAction

[ add | rm | set | unset | show ]

add audit nslogAction

Synopsis
add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ...
[-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logFacility <logFacility>] [-tcp ( NONE | ALL )]
[-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )]
[-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]

Description
Add an nslog action

Parameters
name
The name of the nslog action.

serverIP
The IP address of the nslog server.

serverPort
The port on which the nslog server is running. Minimum value: 1

logLevel
The audit log level.

dateFormat
The date format. Possible values: MMDDYYYY, DDMMYYYY

logFacility
The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7

tcp
Log the tcp messages Possible values: NONE, ALL
**audit nslogAction**

```markdown
acl

Log the acl messages Possible values: ENABLED, DISABLED

timeZone

Specifies the timezone in which the timestamps in the log messages will be generated Possible values: GMT_TIME, LOCAL_TIME

userDefinedAuditlog

Specifies whether the user configurable log messages should be done or not Possible values: YES, NO

appflowExport

Control export of log messages to AppFlow collectors. Possible values: ENABLED, DISABLED
```

**rm audit nslogAction**

**Synopsis**

`rm audit nslogAction <name>`

**Description**

Remove a previously configured nslog action. Note that the nslog action cannot be removed if it is bound to an nslog policy.

**Parameters**

`name`

The name of the nslog action.

**set audit nslogAction**

**Synopsis**

`set audit nslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-logLevel <logLevel> ...] [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]`
Description

Modify an existing nslog action.

Parameters

name

The name for the nslog action.

serverIP

The IP address of the nslog server.

serverPort

The port on which the nslog server is running. Minimum value: 1

logLevel

The audit log level.

dateFormat

The date format. Possible values: MMDDYYYY, DDMMYYYY

logFacility

The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7

tcp

Log the tcp messages Possible values: NONE, ALL

acl

Log the acl messages Possible values: ENABLED, DISABLED

timeZone

Specifies the timezone in which the timestamps in the log messages will be generated
Possible values: GMT_TIME, LOCAL_TIME

userDefinedAuditlog

Specifies whether the user configurable log messages should be done or not Possible values: YES, NO

appflowExport

Control export of log messages to AppFlow collectors. Possible values: ENABLED, DISABLED
unset audit nslogAction

Synopsis
[-acl] [-timeZone] [-userDefinedAuditlog] [-appflowExport]

Description
Unsets an existing nslog action. Refer to the set audit nslogAction command for meanings of
the arguments.

Top

show audit nslogAction

Synopsis
_show audit nslogAction [<name>]

Description
Display details of the configured nslog action(s).

Parameters
name

The name of the nslog action. If the nslog action name is not provided, all of the
configured nslog actions will be displayed.

Top
add audit nslogPolicy

Synopsis
add audit nslogPolicy <name> <rule> <action>

Description
Add an nslog policy. The policy defines the conditions under which the specified nslog
server will be used for logging.

Parameters

name
The name of nslog policy.

rule
The name of the rule or expression that the policy will use. Currently supports only the
rule "ns_true".

action
The name of the nslog action to be bound to the nslog policy.

rm audit nslogPolicy

Synopsis
rm audit nslogPolicy <name>

Description
Remove an nslog policy.
Parameters
name
The name of the nslog policy.

set audit nslogPolicy

Synopsis
set audit nslogPolicy <name> [-rule <expression>] [-action <string>]

Description
Modify properties of a nslog policy.

Parameters
name
The name of the nslog policy to be modified.
rule
The new rule to be associated with the policy.
action
The new nslog action to be associated with the policy.

show audit nslogPolicy

Synopsis
show audit nslogPolicy [<name>]

Description
Display configured nslog policies.

Parameters
name
audit nslogPolicy

The name of the nslog policy. If an nslog policy name is not provided, all of the configured nslog policies will be displayed.
audit messageaction

[ add | rm | set | unset | show ]

add audit messageaction

Synopsis

add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog ( YES | NO )] [-bypassSafetyCheck ( YES | NO )]

Description

Add a audit message action

Parameters

name

The name of the audit message action.

logLevel

The audit logLevel, which specifies the severity level of the log message being generated. Possible values: EMERGENCY, ALERT, CRITICAL, ERROR, WARNING, NOTICE, INFORMATIONAL, DEBUG

stringBuilderExpr

String builder expression which is a regular expression which will be used to build the log message

logtoNewnslog

The flag to control whether the message should go to the newnslog or not Possible values: YES, NO

bypassSafetyCheck

Bypass the safety check and allow unsafe expressions. Possible values: YES, NO Default value: NO

Top
**rm audit messageaction**

**Synopsis**

```
rm audit messageaction <name>
```

**Description**

Remove a previously configured audit message action

**Parameters**

- **name**
  
  The name of the action.

**set audit messageaction**

**Synopsis**

```
set audit messageaction <name> [-logLevel <logLevel>] [-stringBuilderExpr <string>] [-logtoNewnslog ( YES | NO )] [-bypassSafetyCheck ( YES | NO )]
```

**Description**

Set an audit message action

**Parameters**

- **name**
  
  The name of the audit message action

- **logLevel**
  
  Set the audit logLevel, which specifies the severity level of the log message being generated. Possible values: EMERGENCY, ALERT, CRITICAL, ERROR, WARNING, NOTICE, INFORMATIONAL, DEBUG

- **stringBuilderExpr**
  
  Set the string builder expression which is a regular expression which will be used to build the log message

- **logtoNewnslog**

- **bypassSafetyCheck**
Set the flag to control whether the message should go to the newnslog or not. Possible values: YES, NO

bypassSafetyCheck

Bypass the safety check and allow unsafe expressions. Possible values: YES, NO. Default value: NO
audit stats

**show audit stats**

**Synopsis**

show audit stats - alias for 'stat audit'

**Description**

show audit stats is an alias for stat audit
audit messages

show audit messages

Synopsis

    show audit messages [-logLevel <logLevel> ...] [-numOfMesgs <positive_integer>]

Description

    display the most recent audit log messages

Parameters

    logLevel
        The log level filter.

    numOfMesgs
        The number of log messages to be printed. Default value: 20 Minimum value: 1 Maximum value: 256
audit syslogParams

[ set | unset | show ]

set audit syslogParams

Synopsis

set audit syslogParams [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-dateFormat ( MMDDYYYY | DDMMYYYY )] [-logLevel <logLevel> ...] [-logFacility <logFacility>] [-tcp (NONE | ALL)] [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-appflowExport ( ENABLED | DISABLED )]

Description

Modify the syslog parameters.

Parameters

serverIP

The IP address of the syslog server.

serverPort

The port on which the syslog server is running. Minimum value: 1

dateFormat

The date format. Possible values: MMDDYYYY, DDMMYYYY

logLevel

The audit log level for which messages should be logged.

logFacility

The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7

tcp

Log the tcp messages Possible values: NONE, ALL

acl

Log the acl messages Possible values: ENABLED, DISABLED
unset audit syslogParams

Synopsis

Description
Unset syslog parameters. Refer to the set audit syslogParams command for meanings of the arguments.

show audit syslogParams

Synopsis
show audit syslogParams

Description
Display configured syslog params.
audit nslogParams

[ set | unset | show ]

set audit nslogParams

Synopsis

set audit nslogParams [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-dateFormat (MMDDYYYY | DDMMYYYY)] [-logLevel <logLevel> ...] [-logFacility <logFacility>] [-tcp (NONE | ALL)] [-acl (ENABLED | DISABLED)] [-timeZone (GMT_TIME | LOCAL_TIME)] [-userDefinedAuditlog (YES | NO)] [-appflowExport (ENABLED | DISABLED)]

Description

Modify the nslog parameters

Parameters

serverIP

The IP address of the nslog server.

serverPort

The port on which the nslog server is running. Minimum value: 1

dateFormat

The date format. Possible values: MMDDYYYY, DDMMYYYY

logLevel

The audit log level for which messages should be logged.

logFacility

The log facility (RFC 3164). Possible values: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7

tcp

Log the tcp messages Possible values: NONE, ALL

acl

Log the acl messages Possible values: ENABLED, DISABLED
unset audit nslogParams

Synopsis

Description

Unset nslog parameters. Refer to the set audit nslogParams command for meanings of the arguments.

show audit nslogParams

Synopsis

show audit nslogParams

Description

Display configured nslog params.
This group of commands can be used to perform operations on the following entities:

- authentication radiusAction
- authentication ldapAction
- authentication tacacsAction
- authentication negotiateAction
- authentication samlAction
- authentication certAction
- authentication localPolicy
- authentication radiusPolicy
- authentication certPolicy
- authentication ldapPolicy
- authentication tacacsPolicy
- authentication negotiatePolicy
- authentication samlPolicy
- authentication vsServer
add authentication radiusAction

Synopsis

add authentication radiusAction <name> {-serverIP <ip_addr|ipv6_addr|*>} [-serverPort <port>] [-authTimeout <positive_integer>] [-radKey] [-radNASip ( ENABLED | DISABLED )] [-radNASid <string>] [-radVendorID <positive_integer>] [-radAttributeType <positive_integer>] [-radGroupsPrefix <string>] [-radGroupSeparator <string>] [-passEncoding <passEncoding>] [-ipVendorID <positive_integer>] [-ipAttributeType <positive_integer>] [-accounting ( ON | OFF )] [-pwdVendorID <positive_integer>] [-pwdAttributeType <positive_integer>]

Description

Add a profile for a RADIUS server. The profile contains all the configuration data necessary to communicate with a RADIUS server.

Parameters

name

The name of the RADIUS action.

serverIP

The IP address of the RADIUS server.

serverPort

The port on which the RADIUS Server is running. Default value: 1812 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the RADIUS server. Default value: 3 Minimum value: 1

radKey

The key shared between the client and the server. This information is required for the system to communicate with the RADIUS server.

radNASip
If enabled, the system's IP address (NSIP) is sent to the server as the "nasip" (Network Access Server IP) in accordance with the RADIUS protocol. Possible values: ENABLED, DISABLED

radNASid

If configured, this string is sent to the RADIUS server as the "nasid" (Network Access Server ID) in accordance with the RADIUS protocol.

radVendorID

The vendor ID for using RADIUS group extraction. Minimum value: 1

radAttributeType

The Attribute type for using RADIUS group extraction. Minimum value: 1

radGroupsPrefix

The groups prefix string that precedes the group names within a RADIUS attribute for RADIUS group extraction.

radGroupSeparator

The group separator string that delimits group names within a RADIUS attribute for RADIUS group extraction.

passEncoding

This option specifies how passwords should be encoded in the radius packets traveling from the system to the RADIUS server. Possible values: pap, chap, mschapv1, mschapv2 Default value: AAA_PAP

ipVendorID

The vendor ID of the attribute in the RADIUS response which denotes the intranet IP. The value of 0 denotes that the attribute is not vendor encoded.

ipAttributeType

The attribute type of the remote IP address attribute in a RADIUS response. Minimum value: 1

accounting

The state of the RADIUS server that will receive accounting messages. Possible values: ON, OFF

pwdVendorID

Vendor ID of the attribute in the RADIUS response which will be used to extract the user Password. Minimum value: 1

pwdAttributeType
Attribute type of the vendor specific Password-Attribute in a RADIUS response. Minimum value: 1

**rm authentication radiusAction**

**Synopsis**

rm authentication radiusAction <name>

**Description**

Remove a previously created RADIUS action. Note that an action cannot be removed as long as it is configured in a policy.

**Parameters**

name

The name of the action to be removed.

**set authentication radiusAction**

**Synopsis**

**Description**

Change the profile for a RADIUS server. The profile contains all the configuration data needed to communicate with a RADIUS server.

**Parameters**

name

The name of the RADIUS action.
The IP address of the RADIUS server.

The port on which RADIUS Server is running. Default value: 1812 Minimum value: 1

The maximum number of seconds the system will wait for a response from the RADIUS server. Default value: 3 Minimum value: 1

The key shared between the client and the server. This information is required for the system to communicate with the RADIUS server.

If enabled, the system's IP address (NSIP) is sent to the server as the "nasip" (Network Access Server IP) in accordance with the RADIUS protocol. Possible values: ENABLED, DISABLED

If configured, this string is sent to the RADIUS server as the "nasid" (Network Access Server ID) in accordance with the RADIUS protocol.

The Vendor ID for using RADIUS group extraction. Minimum value: 1

The Attribute type for using RADIUS group extraction. Minimum value: 1

The groups prefix string that precedes the group names within a RADIUS attribute for RADIUS group extraction.

The group separator string that delimits group names within a RADIUS attribute for RADIUS group extraction.

This option specifies how passwords should be encoded in RADIUS packets traveling from the system to the RADIUS server. Possible values: pap, chap, mschapv1, mschapv2 Default value: AAA_PAP

The Vendor ID for using RADIUS group extraction.
authentication radiusAction

The vendor ID of the attribute in the RADIUS response which denotes the intranet IP. The value of 0 denotes that the attribute is not vendor encoded.

**ipAttributeType**

The attribute type of the remote IP address attribute in a RADIUS response. Minimum value: 1

**accounting**

The state of the RADIUS server that will receive accounting messages. Possible values: ON, OFF

**pwdVendorID**

Vendor ID of the attribute in the RADIUS response which will be used to extract the user password. Minimum value: 1

unset authentication radiusAction

**Synopsis**

**Description**

Use this command to remove authentication radiusAction settings. Refer to the set authentication radiusAction command for meanings of the arguments.

show authentication radiusAction

**Synopsis**

show authentication radiusAction [<name>]  

**Description**

Display details of the configured RADIUS action(s).
Parameters

name

The name of the RADIUS action.

Top
add authentication ldapAction

Synopsis

add authentication ldapAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] [-ldapBindDnPassword] [-ldapLoginName <string>] [-searchFilter <string>] [-groupAttrName <string>] [-subAttributeName <string>] [-secType <secType>] [-svrType ( AD | NDS )] [-ssoNameAttribute <string>] [-authentication ( ENABLED | DISABLED )] [-requireUser ( YES | NO )] [-passwdChange ( ENABLED | DISABLED )] [-nestedGroupExtraction ( ON | OFF )] [-maxNestingLevel <positive_integer>] [-groupSearchSubAttribute <string>] [-groupSearchFilter <string>] [-groupNameIdentifier <string>] [-groupSearchAttribute <string>]

Description

Add a profile for an LDAP server. This profile contains all the configuration data needed to communicate with the LDAP server.

Parameters

name

The name for the new LDAP action.

serverIP

The IP address of the LDAP server.

serverPort

The port number on which the LDAP server is running. Default value: 389 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the LDAP server. Default value: 3 Minimum value: 1

ldapBase

The base, or node where the ldapsearch should start. If the LDAP server is running locally, the default value of base is dc=netscaler, dc=com.
ldapBindDn

The full distinguished name that is used to bind to the LDAP server. The default value of the bindDN is cn=Manager,dc=netscaler,dc=com.

ldapBindDnPassword

The password that is used to bind to the LDAP server.

ldapLoginName

The name attribute used by the system to query the external LDAP server or an Active Directory.

searchFilter

The string to be combined with the default LDAP user search string to form the value. For example, vpnallowed=true with ldaploginame "samaccount" and the user-supplied username "bob" would yield the LDAP search string "(&(vpnallowed=true)(samaccount=bob)".

groupAttrName

The Attribute name for group extraction from the LDAP server.

subAttributeName

The Sub-Attribute name for group extraction from the LDAP server.

secType

This option indicates whether communication between the system and the authentication server should be encrypted. The following values are allowed: PLAINTEXT: No encryption required. TLS: Communicate using TLS protocol. SSL: Communicate using SSL Protocol. Possible values: PLAINTEXT, TLS, SSL Default value: AAA_LDAP_PLAINTEXT

svrType

The type of LDAP server. Possible values: AD, NDS Default value: AAA_LDAP_SERVER_TYPE_DEFAULT

ssoNameAttribute

The attribute used by the system to query the external LDAP server, or an Active Directory, for an alternate username to be used in Single Sign-On.

authentication

Disable authentication. If disabled this LDAP action will return authentication success if the user is found. This should only be used for authorization group extraction and in conjunction with other authentication methods. The other authentication methods should be bound to a primary list or flagged as secondary. Possible values: ENABLED, DISABLED Default value: ENABLED

requireUser
authentication ldapAction

Setting this option to NO allows failed user searches to be considered authentication successes. If you set require user to NO, you may only configure it with authentication DISABLED Possible values: YES, NO Default value: YES

passwdChange

Enabling this option does not block password change request. Disabling would block password change request. Possible values: ENABLED, DISABLED Default value: DISABLED

nestedGroupExtraction

Setting this option to ON enables the nested group extraction feature where the system queries the external LDAP server to determine if a group belongs to another group Possible values: ON, OFF Default value: OFF

maxNestingLevel

If NESTED GROUP EXTRACTION is set to ON, this option specifies the level upto which ancestors of a group/subgroup will be determined Default value: 2 Minimum value: 2

groupNameIdentifier

The group-attribute used by the system to uniquely identify a group in LDAP/AD

groupSearchAttribute

This option specifies the attribute that will be used to determine group-membership of a 'group'

groupSearchSubAttribute

This option specifies the sub-attribute that will be used to determine group-membership of a 'group'

groupSearchFilter

The string to be combined with the default LDAP group search string to form the value. For example, vpnallowed=true with groupIdentifier "samaccount" and the groupname "g1" would yield the LDAP search string "(&(vpnallowed=true)(samaccount=g1)".

Top

rm authentication ldapAction

Synopsis

rm authentication ldapAction <name>

Description

Remove an LDAP action. Note that an action cannot be removed as long as it is configured in a policy.
Parameters

name

The name of the LDAP action to be removed.

set authentication ldapAction

Synopsis

set authentication ldapAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] [-ldapBindDnPassword] [-ldapLoginName <string>] [-searchFilter <string>] [-groupAttrName <string>] [-subAttributeName <string>] [-secType <secType>] [-svrType ( AD | NDS )] [-ssoNameAttribute <string>] [-authentication ( ENABLED | DISABLED )] [-requireUser ( YES | NO )] [-passwdChange ( ENABLED | DISABLED )] [-nestedGroupExtraction ( ON | OFF )] [-maxNestingLevel <positive_integer>] [-groupNameIdentifier <string>] [-groupSearchAttribute <string>] [-groupSearchSubAttribute <string>] [-groupSearchFilter <string>]

Description

Changes the profile of an LDAP server. The profile contains all of the configuration data needed to communicate with the LDAP server.

Parameters

name

The name for the new LDAP action.

serverIP

The IP address of the LDAP server.

serverPort

The port number on which the LDAP server is running. Default value: 389 Minimum value: 1

authTimeout

The maximum number of seconds for the system will wait for a response from the LDAP server. Default value: 3 Minimum value: 1

ldapBase

The base, or node, where the ldapsearch should start. If the LDAP server is running locally, the default value of base is dc=netScaler, dc=com.
**ldapBindDn**

The full distinguished name that is used to bind to the LDAP server. The default value of the bindDN is *cn=Manager,dc=netscaler,dc=com*.

**ldapBindDnPassword**

The password that is used to bind to the LDAP server.

**ldapLoginName**

The name attribute used by the system to query the external LDAP server or an Active Directory.

**searchFilter**

The string to be combined with the default LDAP user search string to form the value. For example, *vpnallowed=true* with *ldapLoginName* "samaccount" and the user-supplied username "bob" would yield the LDAP search string "((&vpnallowed=true)(samaccount=bob)".

**groupAttrName**

The Attribute name for group extraction from the LDAP server.

**subAttributeName**

The Sub-Attribute name for group extraction from the LDAP server.

**secType**

This option indicates whether communication between the system and the authentication server should be encrypted. The following values are allowed: PLAINTEXT: No encryption required. TLS: Communicate using TLS protocol. SSL: Communicate using SSL protocol. Possible values: PLAINTEXT, TLS, SSL Default value: AAA_LDAP_PLAINTEXT

**svrType**

LDAP server type. Possible values: AD, NDS Default value: AAA_LDAP_SERVER_TYPE_DEFAULT

**ssoNameAttribute**

The attribute used by the system to query the external LDAP server, or an Active Directory, for an alternate username to be used in Single Sign-On.

**authentication**

Disable authentication. If disabled this LDAP action will return authentication success if the user is found. This should only be used for authorization group extraction and in conjunction with other authentication methods. The other authentication methods should be bound to a primary list or flagged as secondary. Possible values: ENABLED, DISABLED Default value: ENABLED

**requireUser**
This option allows failed searches to be considered authentication successes. If you set require user to NO, you may only configure it with authentication DISABLED Possible values: YES, NO Default value: YES

**passwdChange**

Enabling this option does not block password change request. Disabling would block password change request. Possible values: ENABLED, DISABLED Default value: DISABLED

**nestedGroupExtraction**

Setting this option to ON enables the nested group extraction feature where the system queries the external LDAP server to determine if a group belongs to another group Possible values: ON, OFF Default value: OFF

### unset authentication IdapAction

**Synopsis**

**Description**

Use this command to remove authentication ldapAction settings. Refer to the set authentication ldapAction command for meanings of the arguments.

### show authentication IdapAction

**Synopsis**

show authentication ldapAction [<name>]

**Description**

Display details of the configured LDAP action(s).

**Parameters**

name
The name of the LDAP action.

Top
authentication tacacsAction

[ add | rm | set | unset | show ]

add authentication tacacsAction

Synopsis

add authentication tacacsAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-tacacsSecret] [-authorization (ON | OFF)] [-accounting (ON | OFF)] [-auditFailedCmds (ON | OFF)]

Description

Add a profile for a TACACS+ server. The profile contains all of the configuration data needed to communicate with the TACACS+ server.

Parameters

name

The name for the new TACACS+ action.

serverIP

The IP address of the TACACS+ server.

serverPort

The port on which the TACACS+ server is running. Default value: 49 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the TACACS+ server. Default value: 3 Minimum value: 1

tacacsSecret

The key shared between the client and the server. This information is required for the system to communicate with the TACACS+ server.

authorization

The state of the TACACS+ server that will be used for streaming authorization. Possible values: ON, OFF

accounting
**rm authentication tacacsAction**

**Synopsis**

rm authentication tacacsAction <name>

**Description**

Remove a TACACS+ action. Note that an action cannot be removed if it is configured in a policy.

**Parameters**

name

The name of TACACS+ action to be removed.

---

**set authentication tacacsAction**

**Synopsis**

set authentication tacacsAction <name> [-serverIP <ip_addr|ipv6_addr|*>] [-serverPort <port>] [-authTimeout <positive_integer>] [-tacacsSecret ] [-authorization ( ON | OFF )] [-accounting ( ON | OFF )] [-auditFailedCmds ( ON | OFF )]

**Description**

Changes the profile for a TACACS+ server. The profile contains all the configuration data needed to communicate with the TACACS+ server.

**Parameters**

name

The name for the new TACACS+ action.
authentication tacacsAction

serverIP

The IP address of the TACACS+ server.

serverPort

The port on which the TACACS+ server is running. Default value: 49 Minimum value: 1

authTimeout

The maximum number of seconds the system will wait for a response from the TACACS+ server. Default value: 3 Minimum value: 1

tacacsSecret

The key shared between the client and the server. This information is required for the system to communicate with the TACACS+ server.

authorization

The state of the TACACS+ server to be used for streaming authorization. Possible values: ON, OFF

accounting

The state of the TACACS+ server that will receive accounting messages. Possible values: ON, OFF

auditFailedCmds

The state of the TACACS+ server that will receive accounting messages. Possible values: ON, OFF

unset authentication tacacsAction

Synopsis

Description

Use this command to remove authentication tacacsAction settings. Refer to the set authentication tacacsAction command for meanings of the arguments.
show authentication tacacsAction

Synopsis

    show authentication tacacsAction [<name>]

Description

    Display details of the configured TACACS+ action(s).

Parameters

    name

    The name of the TACACS+ action.

    Top
authentication negotiateAction

[ add | rm | set | unset | show ]

add authentication negotiateAction

Synopsis
add authentication negotiateAction <name> {-domain <string>} {-domainUser <string>} {-domainUserPasswd} {-OU <string>}

Parameters
name
The name for the new Negotiate action.

OU
organizational unit

Top

rm authentication negotiateAction

Synopsis
rm authentication negotiateAction <name>

Description
Remove a Negotiate action. Note that an action cannot be removed if it is configured in a policy.

Parameters
name
The name of Negotiate action to be removed.

Top
set authentication negotiateAction

Synopsis

set authentication negotiateAction <name> [-domain <string>] [-domainUser <string>]
[-domainUserPasswd] [-OU <string>]

Description

Changes the profile for a AD server. The profile contains all the configuration data needed
to communicate with the AD server.

Parameters

name

The name for the Negotiate action.

OU

organizational unit

unset authentication negotiateAction

Synopsis

unset authentication negotiateAction <name> [-domain] [-domainUser]
[-domainUserPasswd] [-OU]

Description

Use this command to remove authentication negotiateAction settings. Refer to the set
authentication negotiateAction command for meanings of the arguments.

show authentication negotiateAction

Synopsis

show authentication negotiateAction [<name>]
authentication negotiateAction

Description
Display details of the configured Negotiate action(s).

Parameters

name
The name of the Negotiate action.

Top
add authentication samlAction

Synopsis

add authentication samlAction <name> {-samlIdPCertName <string>} {-samlSigningCertName <string>} {-samlRedirectUrl <string>} {-samlUserField <string>} {-samlRejectUnsignedAssertion ( ON | OFF )} {-samlIssuerName <string>}

Parameters

name

The name for the new SAML action.

samlIdPCertName

The name of the certificate to be used to decrypt messages from IdP.

samlSigningCertName

The name of the certificate to be used to sign messages to IdP.

samlRedirectUrl

The URL at the IdP to which user must be redirected for authentication.

samlUserField

The field/tag from where username/id is to be extracted.

samlRejectUnsignedAssertion

The option to reject Assertions which come without Signature. Possible values: ON, OFF

Default value: ON

samlIssuerName

The name to be used in requests sent from Netscaler to IdP to uniquely identify Netscaler.
**rm authentication samlAction**

**Synopsis**

```bash
rm authentication samlAction <name>
```

**Description**

removes saml action.

**Parameters**

- **name**
  
  The name of SAML action to be removed.

**Top**

---

**set authentication samlAction**

**Synopsis**

```bash
set authentication samlAction <name> [ -samlIdPCertName <string> ] [ -samlSigningCertName <string> ] [ -samlRedirectUrl <string> ] [ -samlUserField <string> ] [ -samlRejectUnsignedAssertion ( ON | OFF ) ] [ -samlIssuerName <string> ]
```

**Description**

Modifies the parameters associated with saml action.

**Parameters**

- **name**
  
  The name for the SAML action.

- **samlIdPCertName**
  
  The name of the certificate to be used to decrypt messages from IdP.

- **samlSigningCertName**
  
  The name of the certificate to be used to sign messages to IdP.

- **samlRedirectUrl**
  
  The URL at the IdP to which user must be redirected for authentication.
unset authentication samlAction

Synopsis

unset authentication samlAction <name> [-samlIdPCertName] [-samlSigningCertName] [-samlRedirectUrl] [-samlUserField] [-samlRejectUnsignedAssertion] [-samlIssuerName]

Description

Use this command to remove authentication samlAction settings. Refer to the set authentication samlAction command for meanings of the arguments.

show authentication samlAction

Synopsis

show authentication samlAction [<name>]

Description

Display details of the configured saml action(s).

Parameters

name

The name of the saml action.
authentication certAction

[ add | rm | set | unset | show ]

add authentication certAction

Synopsis

add authentication certAction <name> [-twoFactor ( ON | OFF )] [-userNameField <string>] [-groupNameField <string>]

Description

Add a certificate action.

Parameters

name

The name of the CERT action.

twoFactor

The state of two factor authentication. Two factor authentication means client certificate authentication followed by password authentication. Possible values: ON, OFF
Default value: OFF

 userNameField

The field in the client certificate from which the username will be extracted. Should be of the format <field:subfield>. Allowed values for the field are "Subject" and "Issuer".

groupNameField

The field in the certificate from which the group will be extracted. Should be of the format <field:subfield>. Allowed values for the field are "Subject" and "Issuer".

Example

add authentication certaction -twoFactor ON -userNameField "Subject:CN" -groupNameField "Subject:OU"

Top
**rm authentication certAction**

**Synopsis**
```
rm authentication certAction <name>
```

**Description**
Remove a cert action. Note that an action cannot be removed if it is configured in a policy.

**Parameters**
- **name**
  The name of the CERT action to be removed.

**set authentication certAction**

**Synopsis**
```
set authentication certAction <name> [-twoFactor ( ON | OFF )] [-userNameField <string>] [-groupNameField <string>]
```

**Description**
Modifies the certificate action.

**Parameters**
- **name**
  The name of the CERT action.
- **twoFactor**
  The state of two factor authentication. Two factor authentication means client certificate authentication followed by password authentication. Possible values: ON, OFF
  Default value: OFF
- **userNameField**
  The field in the client certificate from which the username will be extracted. Should be of the format `<field:subfield>`. Allowed values for the field are "Subject" and "Issuer".
The field in the certificate from which the group will be extracted. Should be of the format `<field:subfield>`. Allowed values for the field are "Subject" and "Issuer".

**Example**

```bash
set authentication certaction -twoFactor ON -userNameField "Subject:CN" -groupNameField "Subject:OU"
```

**unset authentication certAction**

**Synopsis**

```
unset authentication certAction <name> [-twoFactor] [-userNameField] [-groupNameField]
```

**Description**

Use this command to remove authentication certAction settings. Refer to the set authentication certAction command for meanings of the arguments.

**show authentication certAction**

**Synopsis**

```
show authentication certAction [<name>]
```

**Description**

Display the details of configured CERT action(s).

**Parameters**

- **name**
  
  The name of the CERT action.
authentication localPolicy

[ add | rm | set | unset | show ]

add authentication localPolicy

Synopsis
add authentication localPolicy <name> <rule>

Description
Add an authentication LOCAL policy. The policy defines the conditions under which the kernel will authenticate the user.

Parameters
name
The name of the new authentication LOCAL policy.
rule
The name of the rule or expression the policy will use.

rm authentication localPolicy

Synopsis
rm authentication localPolicy <name>

Description
Remove an authentication LOCAL policy.

Parameters
name
The name of the LOCAL policy to remove.
**set authentication localPolicy**

**Synopsis**

set authentication localPolicy <name> -rule <expression>

**Description**

Change properties of a LOCAL policy.

**Parameters**

- **name**
  The name of the policy.

- **rule**
  The new rule to be associated with the policy.

**unset authentication localPolicy**

**Synopsis**

unset authentication localPolicy <name> -rule

**Description**

Use this command to remove authentication localPolicy settings. Refer to the set authentication localPolicy command for meanings of the arguments.

**show authentication localPolicy**

**Synopsis**

show authentication localPolicy [<name>]
**authentication localPolicy**

**Description**
Display configured LOCAL policies.

**Parameters**

**name**
The name of the policy. If a name is not provided, all the configured LOCAL policies will be displayed.

*Top*
authentication radiusPolicy

[ add | rm | set | unset | show ]

add authentication radiusPolicy

Synopsis

add authentication radiusPolicy <name> <rule> [ <reqAction> ]

Description

Add an authentication RADIUS policy. The policy defines the conditions under which the specified RADIUS server will be used for authentication.

Parameters

name

The name of the new authentication RADIUS policy.

rule

The name of the rule or expression the policy will use.

reqAction

The name of the RADIUS action the policy will use.

rm authentication radiusPolicy

Synopsis

rm authentication radiusPolicy <name>

Description

Remove an authentication RADIUS policy.
Parameters

name

  The name of the RADIUS policy to remove.

set authentication radiusPolicy

Synopsis

  set authentication radiusPolicy <name> [-rule <expression>] [-reqAction <string>]

Description

  Change properties of a RADIUS policy.

Parameters

name

  The name of the policy.

rule

  The new rule to be associated with the policy.

reqAction

  The new RADIUS action to be associated with the policy.

unset authentication radiusPolicy

Synopsis

  unset authentication radiusPolicy <name> [-rule] [-reqAction]

Description

  Use this command to remove authentication radiusPolicy settings. Refer to the set authentication radiusPolicy command for meanings of the arguments.
show authentication radiusPolicy

Synopsis

type show authentication radiusPolicy [ <name> ]

Description

Display configured RADIUS policies.

Parameters

name

The name of the policy. If no name is provided, all the configured RADIUS policies will be displayed.

Top
authentication certPolicy

[ add | rm | set | unset | show ]

add authentication certPolicy

Synopsis
add authentication certPolicy <name> <rule> [<reqAction>]

Description
Add an authentication cert policy. This policy defines the conditions under which the specified cert action will be used for authentication.

Parameters
name
The name for the new policy.

rule
The name of the rule or expression the policy will use.

reqAction
The cert action to associate with the policy.

rm authentication certPolicy

Synopsis
rm authentication certPolicy <name>

Description
Remove a CERT authentication policy.
### set authentication certPolicy

**Synopsis**

```
set authentication certPolicy <name> [-rule <expression>] [-reqAction <string>]
```

**Description**

Change the properties of a CERT policy.

**Parameters**

- **name**
  - The name of the policy.
- **rule**
  - The new rule to associate with the policy.
- **reqAction**
  - The new cert action to associate to the policy.

### unset authentication certPolicy

**Synopsis**

```
unset authentication certPolicy <name> [-rule] [-reqAction]
```

**Description**

Use this command to remove authentication certPolicy settings. Refer to the set authentication certPolicy command for meanings of the arguments.
**show authentication certPolicy**

**Synopsis**

```
show authentication certPolicy [<name>]
```

**Description**

Display configured CERT policies.

**Parameters**

- `name`

  The name of the policy. If a name is not provided, all of the configured policies are displayed.

  Top
authentication ldapPolicy

[ add | rm | set | unset | show ]

add authentication ldapPolicy

Synopsis
add authentication ldapPolicy <name> <rule> [ <reqAction> ]

Description
Add an authentication LDAP policy. This policy defines the conditions under which the specified LDAP server will be used for authentication.

Parameters
name
The name for the new policy.

rule
The name of the rule or expression the policy will use.

reqAction
The LDAP action to associate with the policy.

Top

rm authentication ldapPolicy

Synopsis
rm authentication ldapPolicy <name>

Description
Remove an LDAP authentication policy.
**Parameters**

**name**

The name of the LDAP policy to be removed.

set authentication ldapPolicy

**Synopsis**

```bash
set authentication ldapPolicy <name> [-rule <expression>] [-reqAction <string>]
```

**Description**

Change properties of an LDAP policy.

**Parameters**

**name**

The name of the policy.

**rule**

The new rule to associate with the policy.

**reqAction**

The new LDAP action to associate with the policy.

unset authentication ldapPolicy

**Synopsis**

```bash
unset authentication ldapPolicy <name> [-rule] [-reqAction]
```

**Description**

Use this command to remove authentication ldapPolicy settings. Refer to the set authentication ldapPolicy command for meanings of the arguments.
show authentication ldapPolicy

Synopsis

    show authentication ldapPolicy [<name>]

Description

    Display configured LDAP policies.

Parameters

    name

    The name of the policy. If a name is not provided, all of the configured policies are displayed.

    Top
authentication tacacsPolicy

[ add | rm | set | unset | show ]

add authentication tacacsPolicy

Synopsis

    add authentication tacacsPolicy <name> <rule> [<reqAction>]

Description

    Add an authentication TACACS+ policy. This policy defines the conditions under which the
    specified TACACS+ server will be used for authentication.

Parameters

    name
    
        The name of the new TACACS+ policy.

    rule

        The name of the rule or expression the policy will use.

    reqAction

        The name of the TACACS+ action to be associated with the policy.

Synopsis

    rm authentication tacacsPolicy <name>

Description

    Remove a TACACS+ policy.
set authentication tacacsPolicy

Synopsis

set authentication tacacsPolicy <name> [-rule <expression>] [-reqAction <string>]

Description

Change the properties of a TACACS+ policy.

Parameters

name

The name of the policy.

rule

The new rule to associate with the policy.

reqAction

The new TACACS+ action to associate to the policy.

unset authentication tacacsPolicy

Synopsis

unset authentication tacacsPolicy <name> [-rule] [-reqAction]

Description

Use this command to remove authentication tacacsPolicy settings. Refer to the set authentication tacacsPolicy command for meanings of the arguments.
**show authentication tacacsPolicy**

**Synopsis**

`show authentication tacacsPolicy [<name>]`

**Description**

Display the configured TACACS+ policies.

**Parameters**

- **name**
  
  The name of the TACACS+ policy. If no name is given, all of the configured TACACS+ policies are displayed.
authentication negotiatePolicy

[ add | rm | set | unset | show ]

**add authentication negotiatePolicy**

**Synopsis**

```
add authentication negotiatePolicy <name> <rule> <reqAction>
```

**Description**

Add a negotiate authentication policy. The policy defines the conditions under which the specified AD server will be used for authentication.

**Parameters**

- **name**
  
  The name for the new Negotiate policy.

- **rule**

  The name of the rule or expression the policy will use.

- **reqAction**

  The Negotiate action the policy will use.

**rm authentication negotiatePolicy**

**Synopsis**

```
rm authentication negotiatePolicy <name>
```

**Description**

Remove a Negotiate policy.
Parameters

name

The name of the Negotiate policy to remove.

Top

set authentication negotiatePolicy

Synopsis

set authentication negotiatePolicy <name> [-rule <expression>] [-reqAction <string>]

Description

Change the properties of a Negotiate policy.

Parameters

name

The name of the Negotiate policy.

rule

The name of the new rule to be associated with the policy.

reqAction

The name of the Negotiate action to be associated with the policy.

Top

unset authentication negotiatePolicy

authentication vserver

[ add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename ]

add authentication vserver

Synopsis
add authentication vserver <name> <serviceType> (<IPAddress> [-range <positive_integer>]) <port> [-state ( ENABLED | DISABLED )] [-authentication ( ON | OFF )] [-AuthenticationDomain <string>] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )]

Description
Add an authentication virtual server.

Parameters
name
The name for the new authentication vserver.

serviceType
The authentication vserver's protocol type, e.g. SSL Possible values: SSL Default value: NSSVC_SSL

IPAddress
The IP address for the authentication vserver.

port
The TCP port on which the vserver listens. Minimum value: 1

state
The intital vserver server state, e.g. ENABLED or DISABLED Possible values: ENABLED, DISABLED Default value: ENABLED

authentication
Indicates whether or not authentication is being applied to incoming users to the vserver. Possible values: ON, OFF Default value: ON

AuthenticationDomain
authentication vserver

Domain of authentication vserver FQDN

comment

Comments associated with this vserver.

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

Example

The following example creates an authentication vserver named myauthenticationvip which supports SSL protocol and with AAA functionality enabled:

vserver myauthenticationvip SSL 65.219.17.34 443 -aaa ON

Top

rm authentication vserver

Synopsis

rm authentication vserver <name>@ ...

Description

Remove a virtual server.

Parameters

name

The name of the virtual server to be removed.

Example

rm vserver authn_vip

Top

set authentication vserver

Synopsis

set authentication vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-authentication (ON | OFF)] [-AuthenticationDomain <string>] [-comment <string>] [-appflowLog (ENABLED | DISABLED)]
Description
Change the parameters of a authentication virtual server.

Parameters

**name**
The name of the vserver to be modified.

**IPAddress**
The new IP address of the virtual server.

**authentication**
Indicates whether authentication is ON/OFF on this vserver. Possible values: ON, OFF
Default value: ON

**AuthenticationDomain**
Domain of authentication vserver FQDN

**comment**
Comments associated with this vserver.

**appflowLog**
Enable logging appflow flow information Possible values: ENABLED, DISABLED
Default value: ENABLED

unset authentication vserver

Synopsis
unset authentication vserver <name> [-AuthenticationDomain] [-authentication] [-comment] [-appflowLog]

Description
Unset the parameters of an authentication virtual server. Refer to the set authentication vserver command for meanings of the arguments.
bind authentication vserver

Synopsis

bind authentication vserver <name> [-policy <string> [-priority <positive_integer>]] [-secondary]]

Description

Bind policies to a authentication vserver.

Parameters

name

The vserver to which this command shall bind parameters.

policy

The name of the policy to be bound to the vserver.

unbind authentication vserver

Synopsis

unbind authentication vserver <name> [-policy <string> [-secondary]]

Description

Unbind policies from a authentication vserver.

Parameters

name

The name of the vserver from which an attribute is to be unbound.

policy

The name of the policy to be unbound.
enable authentication vserver

Synopsis

enable authentication vserver <name>@

Description

Enable a virtual authentication server. Note: Virtual servers, when added, are enabled by default.

Parameters

name

The name of the virtual server to be enabled.

Example

enable vserver authentication1

Top

disable authentication vserver

Synopsis

disable authentication vserver <name>@

Description

Disable (take out of service) a virtual server.

Parameters

name

The name of the virtual server to be disabled. Notes: 1. The system still responds to ARP and/or ping requests for the IP address of this virtual server. 2. As the virtual server is still configured in the system, you can enable the virtual server using ###enable vserver### command.

Example

disable vserver authn_vip
show authentication vserver

Synopsis

    show authentication vserver [<name>] show authentication vserver stats - alias for 'stat authentication vserver'

Description

Display all of the configured Authentication virtual servers.

Parameters

    name

    The name of the authentication vserver.

Example

    show authentication vserver

stat authentication vserver

Synopsis

Description

Display authentication vserver statistics.

Parameters

    name

    The name of the vserver for which statistics will be displayed. If not given statistics are shown for all authentication vservers.
rename authentication vserver

Synopsis

rename authentication vserver <name>@ <newName>@

Description

Rename an authentication virtual server.

Parameters

name

The name of the authentication virtual server.

newName

The new name of the authentication virtual server.

Example

rename authentication vserver av1 av_new

Top
Authorization Commands

This group of commands can be used to perform operations on the following entities:

- authorization policy
- authorization policylabel
authorization policy

[ add | rm | set | show ]

add authorization policy

Synopsis

add authorization policy <name> <rule> <action>

Description

Add an authorization policy. Authorization policies allow AAA users and AAA groups to access resources through the SSL VPN/AAA enabled vservers. By default, the SSLVPN is configured to deny access to all resources. You can alter this default action by configuring authorization policies. (You can modify the default for a SSLVPN session with a vpn session policy. See “add vpn sessionpolicy”). You can selectively alter access to some resources to DENY by binding one or more authorization policies to the AAA user or AAA group. Once bound, an authorization policy acts on all incoming AAA user resource requests. If an authorization policy rule evaluates to TRUE, the specified action (ALLOW/DENY) is applied. If the rule evaluates to FALSE, the action is not applied. You can also bind multiple authorization policies to AAA users/groups and give them different priorities. (See “bind aaa user/group”). Policies with different priorities are sorted in descending order. The following principles are applied when policies are evaluated: 1. DENY has the highest priority and takes effect immediately. 2. ALLOW has the next-highest priority. It waits for any other DENY policy in an authorization policy that has the same priority. 3. Implicit DENY has the third-highest priority. It waits for an explicit ALLOW/DENY of *any* priority. 4. Implicit ALLOW has the lowest priority. It waits for an explicit ALLOW/DENY with any priority and an Implicit DENY with the same priority.

Parameters

name

The name for the new authorization policy.

rule

The rule or expression for conditional evaluation of the policy. This rule can be an expression specified by “add policy expression.” or it may be an inline expression.

action

The action to be taken when the expression is satisfied. The allowed actions are ALLOW or DENY.

Example
Example: Consider the following authorization policy, "author-policy",

```bash
add authorization policy author-policy "URL == /*.gif" DENY
bind aaa user foo -policy author-policy
```

If the user "foo" now logs in through the SSL VPN and makes any other request except "gif", the rule will be evaluated to deny access to "foo". However, if "foo" makes a request to "*.gif", all those resource will implicitly be allowed to access. If "foo" tries to access "abc.gif" this access will be denied.

---

### rm authorization policy

**Synopsis**

```bash
rm authorization policy <name>
```

**Description**

Remove a configured authorization policy.

**Parameters**

- `name`
  
  The name of the authorization policy to be removed.

---

### set authorization policy

**Synopsis**

```bash
set authorization policy <name> [-rule <expression>] [-action <string>]
```

**Description**

Modify the rule or action value of a configured authorization policy.

**Parameters**

- `name`
  
  The name of the authorization policy to be modified.

- `rule`
  
  The new rule to be associated with the authorization policy.
action

The new action to be associated with the authorization policy.

Top

show authorization policy

Synopsis

show authorization policy [<name>]

Description

Display all configured authorization policies.

Parameters

name

The name of the authorization policy.
authorization policylabel

[ add | rm | bind | unbind | show | stat ]

add authorization policylabel

Synopsis
add authorization policylabel <labelName>

Description
Add a authorization policy label.

Parameters
labelName
Name of the authorization policy label.

Example
add authorization policylabel trans_http_url

Top

rm authorization policylabel

Synopsis
rm authorization policylabel <labelName>

Description
Remove a authorization policy label.

Parameters
labelName
Name of the authorization policy label.
### bind authorization policylabel

#### Synopsis

```
bind authorization policylabel <labelName> <policyName> <priority>
[<gotoPriorityExpression>] [-invoke (<labelType> <labelName>) ]
```

#### Description

Bind the authorization policy to one of the labels.

#### Parameters

- **labelName**
  
  Name of the authorization policy label.

- **policyName**
  
  The authorization policy name.

#### Example

i)  `bind authorization policylabel trans_http_url pol_1 1 2 -invoke reqvserver CURRENT`

ii) `bind authorization policylabel trans_http_url pol_2 2`

### unbind authorization policylabel

#### Synopsis

```
unbind authorization policylabel <labelName> <policyName> [-priority <positive_integer>]
```

#### Description

Unbind entities from authorization label.
Parameters

labelName

Name of the authorization policy label.

policyName

The authorization policy name.

priority

Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647

Example

unbind authorization policylabel trans_http_url pol_1

show authorization policylabel

Synopsis

show authorization policylabel [<labelName>]

Description

Display policy label or policies bound to authorization policylabel.

Parameters

labelName

Name of the authorization policy label.

Example

i) show authorization policylabel trans_http_url
    ii) show authorization policylabel

Top
stat authorization policylabel

Synopsis

stat authorization policylabel [<labelName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of authorization policylabel(s).

Parameters

labelName

The name of the authorization policy label for which statistics will be displayed. If not given statistics are shown for all authorization policylabels.
Basic Commands

This group of commands can be used to perform operations on the following entities:

- location
- locationFile
- server
- service
- serviceGroup
- dbsMonitors
- locationData
- svcbindings
- servicegroupbindings
- serviceGroupMember
- configstatus
- locationParameter
- vserver
- uiinternal
- reporting
- nstrace
location

[ add | rm | show ]

add location

Synopsis

add location <IPfrom> <IPto> <preferredLocation> [-longitude <integer> [-latitude <integer>]]

Description

Add Custom Location entries in the system.

Parameters

IPfrom

The start of the IP address range in dotted notation.

IPto

The end of the IP address range in dotted notation.

preferredLocation

The qualifiers in dotted notation for the ipaddress range mentioned.

longitude

Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range. Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location. Minimum value: -180 Maximum value: 180

latitude

Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range. Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location. Minimum value: -90 Maximum value: 90

Example
Add location 192.168.100.1 192.168.100.100 *.us.ca.san jose

Top

**rm location**

**Synopsis**

```
rm location <IPfrom> <IPto>
```

**Description**

Remove a custom location entry configured in system

**Parameters**

- **IPfrom**
  
  The start of the IP address range in dotted notation.

- **IPto**
  
  The end of the IP address range in dotted notation.

**Example**

```
rm location 192.168.100.1 192.168.100.100
```

Top

**show location**

**Synopsis**

```
show location [<IPfrom>]
```

**Description**

Display custom location entries configured in the system.

**Parameters**

- **IPfrom**
  
  The qualifiers in dotted notation for the ipaddress. If this value is not specified, all custom entries are displayed.
Example

show location

Top
locationFile

[ add | rm | show ]

add locationFile

Synopsis

add locationFile <locationFile> [-format <format>]

Description

load static database from the specified file into the system.

Parameters

locationFile

The name of the location file. The file name must include the full path. If the full path is not given, the default path /var/netscaler/locdb will be assumed. In high-availability mode, the static database should be stored in the same location on both systems.

format

The format of the location file. This optional argument is used to tell the system how to understand the file. The allowable values are: format = netscaler, ip-country, ip-country-isp, ip-country-region-city, ip-country-region-city-isp, geoip-country, geoip-region, geoip-city, geoip-country-org, geoip-country-isp, geoip-city-isp-org. Possible values: netscaler, ip-country, ip-country-isp, ip-country-region-city, ip-country-region-city-isp, geoip-country, geoip-region, geoip-city, geoip-country-org, geoip-country-isp, geoip-city-isp-org Default value: NSMAP_FORMAT_NETSCALER

Example

add locationfile /var/nsmap/locationdb -format netscaler

Top

rm locationFile

Synopsis

rm locationFile
locationFile

**Description**
Remove the location file loaded into the system.

**Example**

```
rm locationfile
```

**show locationFile**

**Synopsis**
```
show locationFile
```

**Description**
Display the location file loaded in the system.

**Example**

```
show locationfile
```

**Top**
server

[ add | rm | set | unset | enable | disable | show | rename ]

add server

Synopsis

add server <name>@ (<IPAddress>@ | (<domain>@ [-domainResolveRetry <integer>]) [-IPv6Address ( YES | NO )]) | (-translationIp <ip_addr> -translationMask <netmask>)) [-state ( ENABLED | DISABLED )) [-comment <string>]

Description

Add a physical server to the system.

Parameters

name

The server's name.

IPAddress

The IP address of the server.

domain

The domain name of the server for which a service needs to be added. If an IP Address has been specified, the domain name does not need to be specified.

translationIp

The IP address used for translating dns obtained ip.

domainResolveRetry

The duration in seconds for which NetScaler system waits to send the next dns query to resolve the domain name, in case the last query failed. If last query succeeds, the netscaler system waits for TTL time in the response. Default value: 5 Minimum value: 5 Maximum value: 20939

state

The initial state of the service. Possible values: ENABLED, DISABLED Default value: ENABLED
server

IPv6Address

Defines whether server is of type ipv6 or not for DBS services Possible values: YES, NO
Default value: NO

comment

Comments associated with this server.

Example

add server web_serv 10.102.27.150
To add multiple servers you can use the following command:
add server serv[1-3] 10.102.27.[151-153]
The above command adds three servers: serv1 with IP 10.102.27.151, serv2 with IP 10.102.27.152 and serv3 with IP 10.102.27.153.

Top

rm server

Synopsis

rm server <name>@ ...

Description

Remove a server entry from the system.

Parameters

name

The name of the server.

Example

rm server web_svr
To remove the servers named serv1, serv2 and serv3 at once you can use the following command:
rm server serv[1-3]
**set server**

**Synopsis**

```bash
set server <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@ | -domainResolveRetry <integer> | -translationIp <ip_addr> | -translationMask <netmask> | -domainResolveNow] [-comment <string>]
```

**Description**

Set server attributes.

**Parameters**

- **name**
  - The name of the server.
- **IPAddress**
  - The new IP address of the server.
- **domainResolveRetry**
  - The duration in seconds for which NetScaler system waits to send the next dns query to resolve the domain name, in case the last query failed. If last query succeeds, the netscaler system waits for TTL time in the response. Default value: 5 Minimum value: 5 Maximum value: 20939
- **translationIp**
  - The IP address used for translating dns obtained ip.
- **translationMask**
  - The netmask of the translation ip
- **domainResolveNow**
  - Restart the probe for this domain based server, immediately
- **comment**
  - Comments associated with this server.

**Example**

```bash
set server http_svr -IPAddress 10.102.1.112
```

To set multiple servers IP addresses at once you can use the following command:

```bash
setserver serv[1-3] -IPAddress 10.102.27.[1-3]
```

The above command sets the IP address of serv1 to 10.102.27.1, serv2 to 10.102.27.2 and serv3 to 10.102.27.3.
unset server

Synopsis

    unset server <name>@ -comment

Description

Use this command to remove server settings. Refer to the set server command for meanings of the arguments.

enable server

Synopsis

    enable server <name>@

Description

Enable all the services under the specified server. Note: A server is enabled by default when it is added to the system. When a server is disabled, all services under the server are disabled.

Parameters

name

The server name.

Example

enable server web_serv
To enable all the services configured on servers named serv1, serv2 and serv3 at once, use the following command:

    enable server serv[1-3]
disable server

Synopsis

disable server <name>@ [<delay>] [-graceFul ( YES | NO )]

Description

Disable all services (that have been configured in the system) for the specified server.

Parameters

name

The name of the server (created with the add server command) for which services will be disabled.

delay

The time in seconds after which all services in this server are brought down.

graceFul

Indicates graceful shutdown of the service. System will wait for all outstanding connections to this service to be closed before disabling the service. Possible values: YES, NO Default value: NO

Example

disable server web_svr 30

To disable all the services configured on servers named serv1, serv2 and serv3 at once, use the following command:

disable server serv[1-3]

show server

Synopsis

show server [<name> | -internal]

Description

View the attributes of a particular physical server.
### Parameters

**name**

The name of the server. When a servername is specified, all services under the server are displayed.

**internal**

Display internally created named servers.

### Example

```
> show server web_svr1
  Name:   web_svr1      State:ENABLED
  IPAddress:   10.102.27.154

> show server web_svr1
  Name:   web_svr2      State:ENABLED
  Domain: www.abc.com      Resolve Retry: 30 Secs
  Translation IP:   10.102.27.153  Translation Mask:   255.255.255.0
```

### rename server

**Synopsis**

```
rename server <name>@ <newName>@
```

**Description**

Rename a server.

**Parameters**

**name**

The name of the server.

**newName**

The new name of the server.

**Example**

```
rename server s1 s1-new
```
server
service

[ add | rm | set | unset | bind | unbind | enable | disable | show | rename | stat ]

add service

Synopsis

add service <name>@ (<IP>@ | <serverName>@) <serviceType> <port> [-clearTextPort <port>] [-cacheType <cacheType>] [-maxClient <positive_integer>] [-healthMonitor ( YES | NO )] [-maxReq <positive_integer>] [-cacheable ( YES | NO )] [-clip ( ENABLED | DISABLED )] [-<cipHeader>] [-usip ( YES | NO )] [-pathMonitor ( YES | NO )] [-pathMonitorIndv ( YES | NO )] [-useproxyport ( YES | NO )] [-sc ( ON | OFF )] [-sp ( ON | OFF )] [-rtspSessionidRemap ( ON | OFF )] [-cltTimeout <secs>] [-svrTimeout <secs>] [-CustomServerID <string>] [-CKA ( YES | NO )] [-TCPB ( YES | NO )] [-CMP ( YES | NO )] [-maxBandwidth <positive_integer>] [-accessDown ( YES | NO )] [-monThreshold <positive_integer>] [-state ( ENABLED | DISABLED )] [-downStateFlush ( ENABLED | DISABLED )] [-tcpProfileName <string>] [-httpProfileName <string>] [-hashId <positive_integer>] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>]

Description

Add a service to the system. Each server can have multiple services. Note: Each time you add a service for the same server, you must specify a unique port number for the service.

Parameters

name

The name of the service.

IP

The IP address of the server for which a service will be added.

serverName

The name of the server for which a service will be added.

serviceType

The type of service. The supported protocols are: HTTP - To load balance web servers and provide connection multiplexing, latency improvement, and other content and TCP protection benefits for HTTP traffic. FTP - To load balance FTP servers. In FTP mode, the system provides TCP protection benefits, protection against SYN attacks, and surge protection. TCP - To host any other TCP protocols that are not HTTP, FTP, NNTP, or SSL. In TCP mode, the system provides TCP protection benefits, protection against SYN
attack, and surge protection. UDP - To load balance servers with UDP-based services (other than DNS). SSL - To provide end-to-end encryption and SSL acceleration. SSL_BRIDGE - To load balance SSL servers. SSL_TCP - To offload SSL traffic for TCP applications. NNTP - To load balance NNTP servers. DNS - To load balance DNS servers. ADNS: To create an authoritative DNS service. ANY - To load balance a service type not listed above (for example, for IP traffic when load balancing firewalls). Note: The NNTP service is for cache redirection. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSVR, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, MYSQL, MSSQL, RADIUS, RDP, DIAMETER, SSL_DIAMETER

**port**

The port number to be used for the service.

**clearTextPort**

The clear text port number where clear text data is sent. Used with SSL offload service. Minimum value: 1

**cacheType**

The cache type option supported by the cache server. Possible values: TRANSPARENT, REVERSE, FORWARD

**maxClient**

The maximum number of open connections to the service. Maximum value: 4294967294

**healthMonitor**

Health monitoring state of the service. Possible values: YES, NO Default value: YES

**maxReq**

The maximum number of requests that can be sent on a persistent connection to the service. Maximum value: 65535

**cacheable**

The virtual server (used in load balancing or content switching) routes a request to the virtual server (used in transparent cache redirection) on the same system before sending it to the configured servers. The virtual server used for transparent cache redirection determines if the request is directed to the cache servers or configured servers. Note: This argument is disabled by default. Do not specify this argument if a -cacheType cacheType is specified. Possible values: YES, NO Default value: NO

**cip**

The Client IP header insertion option for the service. Possible values: ENABLED, DISABLED

**cipHeader**

The client IP header. If client IP insertion is enabled and the client IP header is not specified, then the value set by the ###set ns param### command will be used as the Client IP header.
**usip**

The use of client's IP Address option to the source IP Address while connecting to this server. By default, the system uses a mapped IP address for its server connection; however, you can use this option to tell the system to use the client’s IP address when it communicates with the server. Possible values: YES, NO

**pathMonitor**

Path monitoring for clustering Possible values: YES, NO

**pathMonitorIndv**

Individual Path monitoring decisions Possible values: YES, NO

**useproxyport**

When USIP is enabled, based on the setting of this variable proxy port or the client port will be used as the source port for the backend connection. Possible values: YES, NO

**sc**

The state of SureConnect for the service. Note: This parameter is supported for legacy purposes only. It has no effect on this system, and its only valid value is OFF. Possible values: ON, OFF Default value: OFF

**sp**

The state of Surge protection for the service. Possible values: ON, OFF

**rtspSessionidRemap**

Use this parameter to enable mapping of RTSP sessionid. Possible values: ON, OFF Default value: OFF

**cltTimeout**

The idle time (in seconds) after which the client connection is terminated. Maximum value: 31536000

**svrTimeout**

The idle time (in seconds) after which the server connection is terminated. Maximum value: 31536000

**CustomServerID**

The identifier for the service. This is used when the persistency type is set to Custom Server ID. Default value: “None”

**serverID**

The identifier for the service. This is used when the persistency type is set to Custom Server ID.
service

The state of the Client Keep-Alive feature for the service. Possible values: YES, NO

TCPB

The state of the TCP Buffering feature for the service. Possible values: YES, NO

CMP

The state of the HTTP Compression feature for the service. Possible values: YES, NO

maxBandwidth

The maximum bandwidth in kbps allowed for the service. Maximum value: 4294967287

accessDown

The option to allow access to disabled or down services. If enabled, all packets to this service are bridged. If disabled, they are dropped. Possible values: YES, NO Default value: NO

monThreshold

The monitoring threshold. Maximum value: 65535

state

The state of the service after it is added. Possible values: ENABLED, DISABLED Default value: ENABLED

downStateFlush

Perform delayed clean up of connections on this service. Possible values: ENABLED, DISABLED Default value: ENABLED

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

hashId

The hash identifier for the service. This must be unique for each service. This parameter is used by hash based load balancing methods. Minimum value: 1

comment

Comments associated with this server.

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED
netProfile

The name of the network profile.

Example

add service http_svc 10.102.1.112 http 80
The below command adds the service web_svc1 for the server web_serv1, web_svc2 for web_serv2 and web_svc3 for web_serv3.

rm service

Synopsis

rm service <name>@

Description

Remove a service from the system.

Parameters

name

The name of the service.

Example

rm service http_svc
To remove services svc1, svc2 and svc3 in one go use the following command:
rm service svc[1-3]
set service

Synopsis

set service <name>@ [-IPAddress <ip_addr|ipv6_addr|*>@] [-maxClient <positive_integer>] [-maxReq <positive_integer>] [-cacheable ( YES | NO )] [-cip ( ENABLED | DISABLED ) [-cipHeader>] [-usip ( YES | NO )] [-pathMonitor ( YES | NO )] [-pathMonitorIndv ( YES | NO )] [-useproxyport ( YES | NO )] [-sc ( ON | OFF )] [-sp ( ON | OFF )] [-rtspSessionIdRemap ( ON | OFF )] [-healthMonitor ( YES | NO )] [-cltTimeout <secs>] [-svrTimeout <secs>] [-maxBandwidth <positive_integer>] [-accessDown ( YES | NO )] [-monThreshold <positive_integer>] [-weight <positive_integer> <monitorName>] [-downStateFlush ( ENABLED | DISABLED )] [-tcpProfileName <string>] [-httpProfileName <string>] [-hashId <positive_integer>] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>]

Description

Use this command to modify the attributes of an existing service.

Parameters

name

The name of the service.

IPAddress

The new IP address of the service.

maxClient

The maximum number of open connections to the service. Maximum value: 4294967294

maxReq

The maximum number of requests that can be sent on a persistent connection to the service. Maximum value: 65535

cacheable

The state of cache on the service. Possible values: YES, NO Default value: NO

cip

The Client IP header insertion option for the service. Possible values: ENABLED, DISABLED

usip

The usage of Client IP Address. Possible values: YES, NO

pathMonitor
Path monitoring for clustering Possible values: YES, NO

pathMonitorIndv

Individual Path monitoring decisions Possible values: YES, NO

useproxyport

The usage of Client Port. Possible values: YES, NO

sc

The state of SureConnect for the service. Possible values: ON, OFF Default value: OFF

sp

The state of surge protection for the service. Possible values: ON, OFF

rtspSessionidRemap

Use this parameter to enable mapping of RTSP sessionid. Possible values: ON, OFF Default value: OFF

healthMonitor

Health monitoring state of the service. Possible values: YES, NO Default value: YES

cltTimeout

The idle time in seconds after which the client connection is terminated. Maximum value: 31536000

svrTimeout

The idle time in seconds after which the server connection is terminated. Maximum value: 31536000

CustomServerID

The identifier for the service. Used when the persistency type is set to Custom Server ID. Default value: "None"

serverID

The identifier for the service. This is used when the persistency type is set to Custom Server ID.

CKA

The state of the Client Keep-Alive feature for the service. Possible values: YES, NO

TCPB

The state of the TCP Buffering feature for this service. Possible values: YES, NO

CMP
The state of the HTTP Compression feature for this service. Possible values: YES, NO

maxBandwidth

The maximum bandwidth in kbps allowed for this service. Maximum value: 4294967287

accessDown

The option to allow access to disabled or down services. Possible values: YES, NO Default value: NO

monThreshold

The monitoring threshold. Maximum value: 65535

weight

The weight for the specified monitor. Minimum value: 1 Maximum value: 100

downStateFlush

Perform delayed clean up of connections on this service. Possible values: ENABLED, DISABLED Default value: ENABLED

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

hashId

The hash identifier for the service. This must be unique for each service. This parameter is used by hash based load balancing methods. Minimum value: 1

comment

Comments associated with this service.

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

netProfile

The name of the network profile.

Example

set service http_svc -maxClient 100
The following command sets IP address 10.102.27.53 for service svc1, 10.102.27.54 for svc2 and 10.102.27.55 for svc3.
set service svc[1-3] -IPAddress 10.102.27.[53-55]
unset service

Synopsis

unset service <name>@ [-maxClient] [-maxReq] [-cacheable] [-cip] [-usip] [-pathMonitor]
[-svrTimeout] [-tcpProfileName] [-httpProfileName] [-hashId] [-appflowLog] [-netProfile]
[-cipHeader] [-healthMonitor] [-monitorName] [-downStateFlush] [-comment]

Description

Use this command to unset the attributes of an existing service. Refer to the set service
command for meanings of the arguments.

Example

unset service http_svc -maxClient
To unset maxclients for services svc1, svc2 and svc3, the following command can be used:
unset service svc[1-3] -maxClient

bind service

Synopsis

bind service <name>@ (-policyName <string> | (-monitorName <string>@ [-monState (ENABLED | DISABLED)]) [-weight <positive_integer>]})

Description

Use this command to bind a policy to a service. Notes: 1. This command does not support
SureConnect policies. 2. This command only works for services that are not bound to virtual
servers. If you attempt to bind a policy to a service that is already bound to a virtual
server, the error message “Binding invalid policy” is displayed.

Parameters

name

The name of the service to which the policy will be bound.

policyName
The DoS protection policy name must be bound to the service. Also, for DoS protection to work on a service, an appropriate policy must be bound to the service.

monitorName

The name of the service or a service group to which the monitor is to be bound.

Example

bind service svc1 -policyName pol1
To bind svc1, svc2 and svc3 to the policy pol1 you can use the following command:
bind service svc[1-3] -policyName pol1

unbind service

Synopsis
unbind service <name> ( -policyName <string> | -monitorName <string>@ )

Description
Unbind a policy from a service.

Parameters
name
The name of the service.

policyName
Name of the policy to be unbound.

monitorName
The monitor Names.

Example

unbind service http_svc -policyName pol1
To unbind a policy called pol1 on services svc1, svc2 and svc3, use the following command:
unbind service svc[1-3] -policyName pol1
enable service

Synopsis
   enable service <name>@

Description
   Enable a service.

Parameters
   name
       The name of the service.

Example

   enable service http_svc
       To enable svc1, svc2 and svc3 in one go use the following command:
       enable service svc[1-3]

disable service

Synopsis
   disable service <name>@ [<delay>] [.-graceful ( YES | NO )]

Description
   Disable a service.

Parameters
   name
       The name of the service that needs to be disabled.

   delay
       The time allowed (in seconds) for a graceful shutdown. During this period, new
       connections and requests continue to be sent to the service for clients who already have
       persistent sessions on the system. Connections or requests from fresh or new clients who
       do not yet have a persistence sessions on the NetScaler system are not sent to the
       service. Instead, they are load balanced among other available services. After the delay
time has passed, no new requests or connections are sent to the service.

graceFul

Indicates graceful shutdown of the service. System will wait for all outstanding connections to this service to be closed before disabling the service. Possible values: YES, NO Default value: NO

Example

disable service http_svc 10
To disable svc1, svc2 and svc3 in one go use the following command:
disable service svc[1-3] 10

show service

Synopsis

show service [<name> | -all | -internal] show service bindings - alias for 'show svcbindings'

Description

Display the services configured on the system. This command either lists all services or displays complete information about a particular service.

Parameters

name

The name of the service.

all

Display both configured and dynamically learned services. If you do not use this option, only the configured services are displayed.

internal

Display internally created named services.

Example

The following is sample output of the show service -all command:
4 configured services:
1) svc1 (10.124.99.12:80) - HTTP State: UP
   Max Conn: 0   Max Req: 0   Use Source IP: NO
   Client Keepalive(CKA): NO
   TCP Buffering(TCPB): NO
rename service

Synopsis

rename service <name>@ <newName>@

Description

Rename a service.

Parameters

name

The name of the service.

newName

The new name of the service.

Example

rename service svc1 svcnew
stat service

Synopsis

stat service [name] [-detail] [-fullValues] [-times <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of a service.

Parameters

name

Name of the service
serviceGroup

[ add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename ]

add serviceGroup

Synopsis

add serviceGroup <serviceGroupName>@ <serviceType> [-cacheType <cacheType>] [-maxClient <positive_integer>] [-maxReq <positive_integer>] [-cacheable ( YES | NO )] [-cip ( ENABLED | DISABLED ) [-cipHeader]] [-usip ( YES | NO )] [-pathMonitor ( YES | NO )] [-pathMonitorIndv ( YES | NO )] [-useproxyport ( YES | NO )] [-healthMonitor ( YES | NO )] [-sc ( ON | OFF )] [-sp ( ON | OFF )] [-rtspSessionidRemap ( ON | OFF )] [-cltTimeout <secs>]] [-svrTimeout <secs>] [-CKA ( YES | NO )] [-TCPB ( YES | NO )] [-CMP ( YES | NO )] [-maxBandwidth <positive_integer>] [-monThreshold <positive_integer>] [-state ( ENABLED | DISABLED )] [-downStateFlush ( ENABLED | DISABLED )] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>] [-autoScale ( DISABLED | DNS )]

Description

Add a service group to the system.

Parameters

serviceGroupName

The name of the service group.

serviceType

The type of service group that is being added. Supported protocols are: HTTP - To load balance web servers and provide connection multiplexing, latency improvement, and other content and TCP protection benefits for HTTP traffic. FTP - To load balance FTP servers. In FTP mode, the NetScaler 9000 system provides TCP protection benefits, protection against SYN attacks, and surge protection. TCP - To host any other TCP protocols that are not HTTP, FTP, NNTP, or SSL. In TCP mode, the NetScaler 9000 system provides TCP protection benefits, protection against SYN attack, and surge protection. UDP - To load balance servers with UDP-based service groups (other than DNS) SSL - To provide end-to-end encryption and SSL acceleration. SSL_BRIDGE - To load balance SSL servers. SSL_TCP - To offload SSL traffic for TCP applications. NNTP - To load balance NNTP servers. DNS - To load balance DNS servers. ANY - To load balance a service group type not listed above (for example, for IP traffic when load balancing firewalls). Note: The NNTP service group is for cache redirection. Possible values: HTTP, FTP, TCP, UDP, SSL, SSL_BRIDGE, SSL_TCP, NNTP, RPCSRV, DNS, ADNS, SNMP, RTSP, DHCPRA, ANY, SIP_UDP, DNS_TCP, ADNS_TCP, MYSQL, MSSQL, RADIUS, RDP, DIAMETER, SSL_DIAMETER
cacheType

The cache type option supported by the cache server. The options are: TRANSPARENT, REVERSE, and FORWARD. Possible values: TRANSPARENT, REVERSE, FORWARD

maxClient

The maximum number of open connections to each service in the service group. Maximum value: 4294967294

maxReq

The maximum number of requests that can be sent over a persistent connection to a service in the service group. Maximum value: 65535

cacheable

Whether a virtual server (used in the NetScaler 9000 system's load balancing or content switching feature) routes a request to the virtual server (used in transparent cache redirection) on the same NetScaler 9000 system before sending it to the configured servers. The virtual server used for transparent cache redirection determines if the request is directed to the cache servers or configured servers. Note: Do not specify this argument if a cache type is specified. This argument is disabled by default. Possible values: YES, NO Default value: NO

cip

Enables or disables insertion of the Client IP header for services in the service group. Possible values: ENABLED, DISABLED

cipHeader

The client IP header. If client IP insertion is enabled and the client IP header is not specified, then the value set by the `###set ns param###` command will be used as the Client IP header.

usip

Enables or disables use of client's IP Address as the source IP Address while connecting to the server. By default, the system uses a mapped IP address for its server connection. However, with this option, you can tell the NetScaler 9000 system to use the client's IP address when it communicates with the server. Possible values: YES, NO

pathMonitor

Path monitoring for clustering Possible values: YES, NO

pathMonitorIndv

Individual Path monitoring decisions. Possible values: YES, NO

useproxyport

When USIP is enabled, based on the setting of this variable proxy port or the client port will be used as the source port for the backend connection. Possible values: YES, NO
serviceGroup

healthMonitor

Health monitoring state of the all service group members. Possible values: YES, NO
Default value: YES

sc

The state of SureConnect on this service group. Note: This parameter is supported for
legacy purposes only; it has no effect, and the only valid value is OFF. Possible values:
ON, OFF Default value: OFF

sp

Whether surge protection needs to be enabled on this service group. Possible values: ON,
OFF Default value: OFF

rtspSessionidRemap

Use this parameter to enable mapping of RTSP sessionid. Possible values: ON, OFF
Default value: OFF

cltTimeout

The idle time in seconds after which the client connection is terminated. Maximum
value: 31536000

svrTimeout

The idle time in seconds after which the server connection is terminated. Maximum
value: 31536000

CKA

The state of the Client Keep-Alive feature for the services in the service group. Possible
values: YES, NO

TCPB

The state of the TCP Buffering feature for the services in the service group. Possible
values: YES, NO

CMP

The state of the HTTP Compression feature for the services in the service group. Possible
values: YES, NO

maxBandwidth

A positive integer that identifies the maximum bandwidth in kbps allowed for the
services in the service group. Maximum value: 4294967287

monThreshold

The monitoring threshold. Maximum value: 65535

state
The state of the service group after it is added. Possible values: ENABLED, DISABLED
Default value: ENABLED

downStateFlush

Perform delayed clean up of connections on this service group. Possible values: ENABLED, DISABLED
Default value: ENABLED

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

comment

Comments associated with this servicegroup.

appflowLog

Enable logging appflow flow information
Possible values: ENABLED, DISABLED
Default value: ENABLED

netProfile

The name of the network profile.

autoScale

Auto scale option for a domain based server when bound to a servicegroup
Possible values: DISABLED, DNS
Default value: DISABLED

Example

add servicegroup http_svc_group http
To add service groups sgrp1, sgrp2 and sgrp3 at one go use the following command:
add servicegroup sgrp[1-3] http

rm serviceGroup

Synopsis

rm serviceGroup <serviceGroupName>@

Description

Remove a service group.
Parameters

`serviceGroupName`

The name of the service group that will be removed.

Example

```
rm servicegroup http_svc_group
```
To remove multiple servicegroups at once, the following command can be used:
```
rm servicegroup http_svc_group[1-3]
```

Top

set serviceGroup

Synopsis

```
set serviceGroup <serviceGroupName>@ [(<serverName>@ <port> [-weight <positive_integer>] [-CustomServerID <string>] [-hashId <positive_integer>]) | -maxClient <positive_integer> | -maxReq <positive_integer> | -cacheable ( YES | NO ) | -cip ( ENABLED | DISABLED ) | -cipHeader | -usip ( YES | NO ) | -useproxyport ( YES | NO ) | -sc ( ON | OFF ) | -sp ( ON | OFF ) | -rtspSessionidRemap ( ON | OFF ) | -cltTimeout <secs> | -svrTimeout <secs> | -CKA ( YES | NO ) | -TCPB ( YES | NO ) | -CMP ( YES | NO ) | -maxBandwidth <positive_integer> | -monThreshold <positive_integer> | -downStateFlush ( ENABLED | DISABLED ) [-monitorName <string> -weight <positive_integer>] [-healthMonitor ( YES | NO )] [-pathMonitor ( YES | NO )] [-pathMonitorIndv ( YES | NO )] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>]]
```

Description

Modify the attributes of an existing service group.

Parameters

`serviceGroupName`

The name of the service group whose attributes will be changed.

`serverName`

The name of the server to be changed.

`monitorName`

Name of monitor bound to servicegroup, it is used in setting weight bound to monitor.

`maxClient`
The maximum number of open connections to each service in the service group. Maximum value: 4294967294

**maxReq**

The maximum number of requests that can be sent on a persistent connection to a service. Maximum value: 65535

**healthMonitor**

Health monitoring state of the all service group members. Possible values: YES, NO
Default value: YES

**cacheable**

The state of cache on the service group. Possible values: YES, NO
Default value: NO

**cip**

The state of insertion of the Client IP header for a service. Possible values: ENABLED, DISABLED

**usip**

The usage of client's IP Address. Possible values: YES, NO

**pathMonitor**

Path monitoring for clustering. Possible values: YES, NO

**pathMonitorIndv**

Individual Path monitoring decisions. Possible values: YES, NO

**useproxyport**

When USIP is enabled, based on the setting of this variable proxy port or the client port will be used as the source port for the backend connection. Possible values: YES, NO

**sc**

Whether SureConnect will be enabled on this service. Possible values: ON, OFF
Default value: OFF

**sp**

The state of surge protection on this service group. Possible values: ON, OFF
Default value: OFF

**rtspSessionidRemap**

Use this parameter to enable mapping of RTSP sessionid. Possible values: ON, OFF
Default value: OFF

**cltTimeout**
The idle time (in seconds) after which the client connection is terminated. Maximum value: 31536000

svrTimeout

The idle time in seconds after which the server connection is terminated. Maximum value: 31536000

CKA

The state of the Client Keep-Alive feature for the service. Possible values: YES, NO

TCPB

The state of the TCP Buffering feature for this service. Possible values: YES, NO

CMP

The state of the HTTP Compression feature for this service. Possible values: YES, NO

maxBandwidth

A positive integer that identifies the maximum bandwidth in kbps allowed for this service. Maximum value: 4294967287

monThreshold

The monitoring threshold. Maximum value: 65535

downStateFlush

Perform delayed cleanup of connections on this service group. Possible values: ENABLED, DISABLED Default value: ENABLED

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

comment

Comments associated with this servicegroup.

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

netProfile

The name of the network profile.

Example
set servicegroup http_svc_group -maxClient 100
   To set the attribute maxclient for multiple servicegroups at once, use the following command:
   set servicegroup http_svc_group[1-3] -maxClient 100

Top

unset serviceGroup

Synopsis

Description

Use this command to unset the attributes of an existing service group. Refer to the set serviceGroup command for meanings of the arguments.

Example

unset servicegroup http_svc_group -maxClient

Top

bind serviceGroup

Synopsis

bind serviceGroup <serviceGroupName> ((<IP>@ <port>) | <serverName>@ | ((-monitorName <string>@ [-monState ( ENABLED | DISABLED )]) | -CustomServerID <string> | -state ( ENABLED | DISABLED ) | -hashId <positive_integer> | |) [-weight <positive_integer>])

Description

Bind a service to a service group.

Parameters

serviceGroupName

The name of the service group to which the service will be bound.
**serviceGroup**

**IP**

The IP address of a member to be added.

**servername**

The name of the server that hosts the member.

**port**

The port number of a service to be added.

**monitorName**

The name of the service or a service group to which the monitor is to be bound.

**weight**

Weight for this service. This weight is used when the system performs load balancing. It is useful to specify weights when services bound to the service group have different capacities. Default value: 1 Minimum value: 1 Maximum value: 100

**CustomServerID**

A positive integer that will identify the service. Used when the persistency type is set to Custom Server ID. Default value: “None”

**serverID**

The identifier for the service. This is used when the persistency type is set to Custom Server ID.

**state**

The state of the IP/Port after binding. Possible values: ENABLED, DISABLED Default value: ENABLED

**hashId**

The hash identifier for the service. This must be unique for each service. This parameter is used by hash based load balancing methods. Minimum value: 1

**Example**

bind servicegroup http_svc_group 10.102.27.153 80

To bind multiple servers to a servicegroup, following command can be used:
bind servicegroup http_svc_group 10.102.27.[153-155] 80
unbind serviceGroup

Synopsis
unbind serviceGroup <serviceGroupName> ((<IP>@ <port>) | <serverName>@ | -monitorName <string>@)

Description
Unbind a service from a service group.

Parameters

- serviceNameGroup
  The name of the service group.
- IP
  The IP address of a member to be removed.
- serverName
  The name of the server that hosts the member to be unbound from the service group.
- port
  The port number of a service to be unbound from the service group.
- monitorName
  Monitor name.

Example
unbind servicegroup http_svc_group 10.102.27.153 80
To unbind multiple servers following command can be used:
unbind servicegroup http_svc_group 10.102.27.[153-155] 80

enable serviceGroup

Synopsis
enable serviceGroup <serviceGroupName>@ [<serverName>@ <port>]
Description

Use this command to enable a service group.

Parameters

serviceGroupName

The name of the service group to be enabled.

serverName

The name of the server that hosts the member to be enabled from the service group.

port

The port number of the service to be enabled.

Example

enable servicegroup http_svc_group

To enable multiple service groups at one go use the following command:

enable servicegroup http_svc_group[1-3]

disable serviceGroup

Synopsis

disable serviceGroup <serviceGroupName>@ [<serverName>@ <port>] [-delay <secs>] [-graceFul ( YES | NO )]

Description

Use this command to disable a service group.

Parameters

serviceGroupName

The name of the service group that needs to be disabled.

serverName

The name of the server that hosts the member to be disabled from the service group.

port

The port number of the service to be disabled.
**delay**

The time allowed (in seconds) for a graceful shutdown. During this period, new connections or requests will continue to be sent to this service for clients who already have a persistent session on the system. Connections or requests from fresh or new clients who do not yet have a persistence sessions on the system will not be sent to the service. Instead, they will be load balanced among other available services. After the delay time expires, no new requests or connections will be sent to the service.

**graceful**

Indicates graceful shutdown of the service. System will wait for all outstanding connections to this service to be closed before disabling the service. Possible values: YES, NO Default value: NO

**Example**

disable servicegroup http_svc_group 10.102.27.153 80 -delay 10
To disable multiple servicegroups use the following command:
disable servicegroup http_svc_group[1-3] 10.102.27.[153-155] 80 -delay 30

**show serviceGroup**

**Synopsis**

show serviceGroup [<-serviceGroupName> | -includeMembers]

**Description**

Display the configured service groups. This command either lists all service groups or displays complete information about a particular service group.

**Parameters**

  **serviceGroupName**

  The name of the service group.

  **includeMembers**

  Include a summary of the members in a group too.
stat serviceGroup

Synopsis

stat serviceGroup [<serviceGroupName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of service group(s).

Parameters

serviceGroupName

The name of a service group

Top

rename serviceGroup

Synopsis

rename serviceGroup <serviceGroupName> @ <newName>@

Description

Rename a service group.

Parameters

serviceGroupName

The name of the service group.

newName

The new name of the service group.

Example

rename service svcgrp1 svcgrp-new1

Top
dbsMonitors

restart dbsMonitors

Synopsis
restart dbsMonitors

Description
Use this command to clear/flush all learnt ip addresses for domain based servers

Example
restart dbsMonitors
locationData

clear locationData

Synopsis
  clear locationData

Description
  Clear all location information, including custom entries and static database entries.

Example

clear locationdata
svcbindings

show svcbindings

Synopsis

    show svcbindings <serviceName>

Description

    Displays service information followed by vservers bound to it.

Parameters

    serviceName

    The name of the service.
servicegroupbindings

show servicegroupbindings

Synopsis

    show servicegroupbindings <serviceGroupName>

Description

    Displays servicegroup information followed by vservers bound to it.

Parameters

    serviceGroupName

    The name of the service.
serviceGroupMember

stat serviceGroupMember

Synopsis

stat serviceGroupMember <serviceGroupName> (<IP> | <serverName>) <port> [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of a service group member.

Parameters

serviceGroupName

The name of a service group

IP

The IP address of the member

serverName

The name of the Domain based server for which stats are required

port

The port number of the member
show configstatus

Synopsis
  show configstatus

Description
  Display status of packet engines.

Example

  show configstatus
locationParameter

[ set | unset | show ]

set locationParameter

Synopsis

set locationParameter [-context ( geographic | custom )] [-q1label <string>] [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]

Description

This command specifies the location parameters used for static proximity based load balancing.

Parameters

context

The context in which a static proximity decision has to be made. Possible values: geographic, custom

q1label

The label for the 1st qualifier. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

q2label

The label for the 2nd qualifier. These qualifier labels characterize the locations mapped with the IP addresses used to make static proximity decisions.

q3label

The label for the 3rd qualifier. These qualifier labels characterize the locations mapped with the IP addresses used to make static proximity decisions.

q4label

The label for the 4th qualifier. These qualifier labels characterize the locations mapped with the IP addresses used to make static proximity decisions.

q5label

The label for the 5th qualifier. These qualifier labels characterize the locations mapped with the IP addresses used to make static proximity decisions.
locationParameter

q6label

The label for the 6th qualifier. These qualifier labels characterize the locations mapped with the IP addresses used to make static proximity decisions.

Example

set locationparameter -context custom

unset locationParameter

Synopsis

unset locationParameter [-context] [-q1label] [-q2label] [-q3label] [-q4label] [-q5label] [-q6label]

Description

Use this command to remove locationParameter settings. Refer to the set locationParameter command for meanings of the arguments.

show locationParameter

Synopsis

show locationParameter

Description

Display information about the context and qualifier labels used for static proximity based load balancing.

Example

show locationparameter
vserver

show vserver

Synopsis

    show vserver

Description

Use this command to display all virtual servers configured on the NetScaler system. The information displayed includes the virtual server name, IP address, port number, service type, virtual server state and virtual server type.

Example

    show vserver lb_vip
uiinternal

[ set | unset | show ]

set uiinternal

Synopsis

set uiinternal <entityType> <name> [-template <string>] [-comment <string>] [-rule <string>]

Description

set uiinternal data for the entities

Parameters

entityType

The entity type of UI internal data Possible values: LBVSERVER, GSLBVSERVER, CRVSERVER, VPNVSERVER, CSVSERVER, AUTHENTICATIONVSERVER, SERVER, SERVICE, SERVICEGROUP, GSLBSERVICE, EXPRESSION, VPNURL

name

The entity name

template

The application template associated with entity

comment

The application template associated with entity

rule

rules associated with entity

Example

set uiinternal lbvserver v1 -template app1

Top
**unset uiinternal**

**Synopsis**

```
unset uiinternal <entityType> <name> [-template] [-comment] [-rule] [-all]
```

**Description**

unset uiinternal for the entities. Refer to the set uiinternal command for meanings of the arguments.

**Example**

```
unset uiinternal lbvserver v1 -template app1
```

**show uiinternal**

**Synopsis**

```
show uiinternal [<entityType>] [<name>]
```

**Description**

display all UI internal data information for the entities

**Parameters**

- **entityType**
  
The entity type of UI internal data Possible values: LBVSERVER, GSLBVSERVER, CRVSERVER, VPNVSERVER, CSVSERVER, AUTHENTICATIONVSERVER, SERVER, SERVICE, SERVICEGROUP, GSLBSERVICE, EXPRESSION, VPNURL

- **name**
  
The entity name

**Example**

```
show uiinternal LBVSERVER v1
```

reporting

[ enable | disable | show ]

enable reporting

Synopsis
   enable reporting

Description
   Enable the data collection for reporting module.

Example

   enable reporting

Top

disable reporting

Synopsis
   disable reporting

Description
   Disable the data collection for reporting module.

Example

   disable reporting

Top
show reporting

Synopsis

show reporting

Description

show the state of data collection for reporting module.

Example

show reporting

Top
nstrace

[ start | stop | show ]

start nstrace

Synopsis

start nstrace [-nf <positive_integer>] [-time <positive_integer>] [-size <positive_integer>] [-mode <mode> ...] [-tcpdump ( ENABLED | DISABLED )] [-perNIC ( ENABLED | DISABLED )] [-fileName <string>] [-fileId <string>] [-filter <expression>] [-link ( ENABLED | DISABLED )] [-nodes <positive_integer> ...]

Description

Start NetScaler packet capture tool.

Parameters

nf

Number of files to be generated in cycle. Default value: 24 Minimum value: 1 Maximum value: 100

time

Time per file (sec). Default value: 3600 Minimum value: 1

size

Size of the captured data. Set 0 for full packet trace. Default value: 164 Maximum value: 1514

mode

Capturing mode for trace. Mode can be any of the following values or combination of these values: RX Received packets before NIC pipelining NEW_RX Received packets after NIC pipelining TX Packets TXB Packets buffered for transmission IPV6 Translated IPv6 packets C2C Capture C2C message NS_FR_TX TX/TXB packets are not captured in flow receiver. Default mode: NEW_RX TXB Default value: DEFAULT_MODE

tcpdump

Trace is captured in TCPDUMP(.pcap) format. Default capture format is NSTRACE(.cap). Possible values: ENABLED, DISABLED Default value: DISABLED

perNIC
Use separate trace files for each interface. Works only with tcpdump format. Possible values: ENABLED, DISABLED Default value: DISABLED

**fileName**

Name of the trace file.

**fileId**

ID for the trace file name for uniqueness. Should be used only with -name option.

**filter**

Filter expression for nstrace. Maximum length of filter is 255 and it can be of following format: `<expression> [ <relop> <expression> ] <relop> = ( & | | )` nstrace supports two types of filter expressions: Classic Expressions: `<expression> =` the expression string in the format: `<qualifier> <operator> <qualifier-value> <qualifier> = SOURCEIP. <qualifier-value> = A valid IP address <qualifier> = SOURCEPORT. <qualifier-value> = A valid port number. <qualifier> = DESTIP. <qualifier-value> = A valid IP address. <qualifier> = DESTPORT. <qualifier-value> = A valid port number. <qualifier> = IP. <qualifier-value> = A valid IP address. <qualifier> = PORT. <qualifier-value> = A valid port number. <qualifier> = SVCNAME. <qualifier-value> = The name of a service. <qualifier> = VSVRNAME. <qualifier-value> = The name of a vserver. <qualifier> = CONNID <qualifier-value> = A valid PCB dev number. <qualifier> = VLAN <qualifier-value> = A valid VLAN ID. <qualifier> = INTF <qualifier-value> = A valid interface id in the form of x/y (n/x/y in case of cluster interface). <operator> = ( == | eq | != | neq | > | gt | < | lt | >= | ge | <= | le | BETWEEN ) eg: start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 & SOURCEPORT > 80)" The filter expression should be given in double quotes. Default Expressions: `<expression> =:

- CONNECTION.<qualifier>.<qualifier-method>.(<qualifier-value>)
- CONNECTION.SRCIP.EQ(127.0.0.1)
- CONNECTION.DSTIP.EQ(127.0.0.1)
- CONNECTION.IP.EQ(127.0.0.1)
- CONNECTION.SRCIPv6.EQ(2001:db8:0:0:1::1)
- CONNECTION.DSTIPv6.EQ(2001:db8:0:0:1::1)
- CONNECTION.IPv6.EQ(2001:db8:0:0:1::1)
- CONNECTION.SRCPORT.EQ(80)
- CONNECTION.DSTPORT.EQ(80)
- CONNECTION.PORT.EQ(1)
- CONNECTION.VLANID.EQ(0)
- CONNECTION.CONNID.EQ(0)
- CONNECTION.PPEID.EQ(0)
- CONNECTION.STARTSWITH.EQ("name")
- CONNECTION.ENDSWITH.EQ("name")
- CONNECTION.INTF.EQ("x/y")

eg: start nstrace -filter "CONNECTION.SRCIP.EQ(127.0.0.1)"
nstrace

|| (CONNECTION.SVCNAME.NE("s1") & & CONNECTION.SRCPORT.EQ(80))" The filter expression should be given in double quotes. Common use cases: Trace capturing full sized traffic from/to IP 10.102.44.111, excluding loopback traffic start nstrace -size 0 -filter "CONNECTION.IP.NE(127.0.0.1) & & CONNECTION.IP.EQ(10.102.44.111)" Trace capturing all traffic to (terminating at) port 80 or 443 start nstrace -size 0 -filter "CONNECTION.DSTPORT.EQ(443) || CONNECTION.DSTPORT.EQ(80)" Trace capturing all backend traffic specific to service service1 along with corresponding client side traffic start nstrace -size 0 -filter "CONNECTION.SVCNAME.EQ("service1")" -link ENABLED Trace capturing all traffic through NS interface 1/1 start nstrace -filter "CONNECTION.INTF.EQ("1/1")" Trace capturing all traffic specific through VLAN 2 start nstrace -filter "CONNECTION.VLANID.EQ(2)" Trace capturing all frontend (client side) traffic specific to lb vserver vserver1 along with corresponding server side traffic start nstrace -size 0 -filter "CONNECTION.LB_VSERVER.NAME.EQ("vserver1")" -link ENABLED

link

Includes filtered connection's peer traffic. Possible values: ENABLED, DISABLED Default value: DISABLED

nodes

Nodes on which tracing is started. Maximum value: 32

Example

start nstrace -time 10

stop nstrace

Synopsis

stop nstrace

Description

Stop running NetScaler packet capture tool.

Example

stop nstrace
**show nstrace**

**Synopsis**

```
show nstrace
```

**Description**

Display nstrace parameters set through 'start nstrace' command.

**Example**

```
show nstrace
```

Top
Cache Commands

This group of commands can be used to perform operations on the following entities:

- cache
- cache policy
- cache policylabel
- cache contentGroup
- cache forwardProxy
- cache selector
- cache object
- cache stats
- cache global
- cache parameter
stat cache

Synopsis
  stat cache [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description
  Display the Integrated Cache statistics.
cache policy

[ add | rm | set | unset | show | stat | rename ]

add cache policy

Synopsis

add cache policy <policyName> -rule <expression> -action <action> [-storeInGroup <string>] [-invalGroups <string> ...] [-invalObjects <string> ...] [-undefAction ( NOCACHE | RESET )]

Description

Create Integrated Cache policies. The newly created policy is in the inactive state. To activate the policy, use the ###bind cache global### command. The type of the policy depends on whether it is a request policy or a response policy, and the type of the specified action, as follows: CACHE or MAY_CACHE action: positive cachability policy NOCACHE or MAY_NOCACHE action: negative cachability policy INVAL action: Dynamic Invalidation Policy The order in which the policies are configured is significant. For a detailed discussion of the significance of the order, see the System Installation and Configuration Guide.

Parameters

policyName

The name of the new Integrated Cache policy.

rule

The request/response rule that will trigger the given action. The only actions you can specify with a request rule are: MAY_CACHE, MAY_NOCACHE, and INVAL. You specify a rule using a single expression or a logical combination of expressions (called a compound expression). You can combine expressions using the && and || operators. For more information on creating expressions, refer to the add expression CLI command. Note: If a compound expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following are examples of valid expressions: ns_ext_cgi||ns_ext_asp "ns_non_get && (ns_header_cookie || ns_headerPragma)"

action

The integrated cache action to be applied when the system finds content that matches the rules. Possible values: CACHE, NOCACHE, MAY_CACHE, MAY_NOCACHE, INVAL

storeInGroup

The content group where the object will be stored when the action directive is CACHE
invalGroups
The content group(s) to be invalidated when the action directive is INVAL

invalObjects
The content group(s) where the objects will be invalidated when the action directive is INVAL

undefAction
A CACHE action, which is used by the policy when the rule evaluation is undefined. The undef action can be NOCACHE or RESET. Possible values: NOCACHE, RESET

set cache policy

Synopsis
set cache policy <policyName> [-rule <expression>] [-action <action>] [-storeInGroup <string>] [-invalGroups <string>] [-invalObjects <string>] [-undefAction ( NOCACHE | RESET )]

Description
Set a new rule/action/storeInGroup/invalGroups/invalObjects/undefAction for existing cache policy. The rule flow type can change only if action and undefAction(if present) are of NEUTRAL flow type
**Parameters**

**policyName**

The name of the new Integrated Cache policy.

**rule**

The request/response rule that will trigger the given action. The only actions you can specify with a request rule are: MAY_CACHE, MAY_NOCACHE, and INVAL. You specify a rule using a single expression or a logical combination of expressions (called a compound expression). You can combine expressions using the && and || operators. For more information on creating expressions, refer to the add expression CLI command. Note: If a compound expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following are examples of valid expressions: ns_ext_cgi||ns_ext_asp "ns_non_get && (ns_header_cookie||ns_headerPragma)"

**action**

The integrated cache action to be applied when the system finds content that matches the rules. Possible values: CACHE, NOCACHE, MAY_CACHE, MAY_NOCACHE, INVAL

**storeInGroup**

The content group where the object will be stored when the action directive is CACHE

**invalGroups**

The content group(s) to be invalidated when the action directive is INVAL

**invalObjects**

The content group(s) where the objects will be invalidated when the action directive is INVAL

**undefAction**

A CACHE action, to be used by the policy when the rule evaluation turns out to be undefined. The undef action can be NOREWRITE or RESET. Possible values: NOCACHE, RESET

**Example**

set cache policy pol9 -rule "http.req.HEADER(\"header\").CONTAINS(\"qh2\")"

Top
unset cache policy

Synopsis
unset cache policy <policyName> [-storeInGroup] [-invalGroups] [-invalObjects] [-undefAction]

Description
Use this command to remove cache policy settings. Refer to the set cache policy command for meanings of the arguments.

show cache policy

Synopsis
show cache policy [<policyName>] show cache policy stats - alias for 'stat cache policy'

Description
Display all configured cache policies. To display a single cache policy, specify the name of the policy. When all Integrated Cache policies are displayed, the order of the displayed policies within each group is the same as the evaluation order of the policies. There are three groups: request policies, response policies, and dynamic invalidation policies.

Parameters

policyName
The name of the cache policy to be displayed.

stat cache policy

Synopsis
stat cache policy [<policyName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description
Display cache policy statistics.
Parameters

policyName

The name of the cache policy for which statistics will be displayed. If not given statistics are shown for all cache policies.

Example

stat cache policy

Top

rename cache policy

Synopsis

rename cache policy <policyName>@ <newName>@

Description

Rename a cache policy.

Parameters

policyName

The name of the cache policy.

newName

The new name of the cache policy.

Example

rename cache policy oldname newname

Top
add cache policylabel

Synopsis
add cache policylabel <labelName> -evaluates <evaluates>

Description
Add a cache policy label.

Parameters
- labelName
  Name of the cache policy label.
- evaluates
  Gives when policies bound to this label get executed. Possible values: REQ, RES, MSSQL_REQ, MSSQL_RES, MYSQL_REQ, MYSQL_RES

Example
add cache policylabel cache_http_url -evaluates REQ

rm cache policylabel

Synopsis
rm cache policylabel <labelName>

Description
Remove a cache policy label.
Parameters

labelName
Name of the cache policy label.

Example

`rm cache policylabel cache_http_url`

bind cache policylabel

Synopsis

`bind cache policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-invoke (<labelType> <labelName>) ]`

Description
Bind the cache policy to one of the labels.

Parameters

labelName
Name of the cache policy label.

policyName
The cache policy name.

Example

i) bind cache policylabel cache_http_url pol_1 1 2 -invoke reqvserver CURRENT
   ii) bind cache policylabel cache_http_url pol_2 2

unbind cache policylabel

Synopsis

`unbind cache policy label <labelName> -policyName <string> [-priority <positive_integer>]`
**Description**

Unbind entities from cache label.

**Parameters**

- **labelName**
  Name of the cache policy label.

- **policyName**
  The cache policy name.

- **priority**
  Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647

**Example**

unbind cache policylabel cache_http_url pol_1

**show cache policylabel**

**Synopsis**

show cache policylabel [<labelName>]

**Description**

Display policy label or policies bound to cache policylabel.

**Parameters**

- **labelName**
  Name of the cache policy label.

**Example**

i)  show cache policylabel cache_http_url
ii) show cache policylabel
stat cache policylabel

Synopsis

stat cache policylabel ['labelName'] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display statistics of cache policylabel(s).

Parameters

labelName

The name of the cache policy label for which statistics will be displayed. If not given statistics are shown for all cache policylabels.

rename cache policylabel

Synopsis

rename cache policylabel <labelName>@ <newName>@

Description

Rename a cache policy label.

Parameters

labelName

The name of the cache policy label.

newName

The new name of the cache policy label.

Example

rename cache policylabel oldname newname
cache contentGroup

[ add | rm | set | unset | show | expire | flush ]

add cache contentGroup

Synopsis

add cache contentGroup <name> [-weakPosRelExpiry <secs> | -relExpiry <secs> | -relExpiryMilliSec <msecs> | -absExpiry <HH:MM> ... | -absExpiryGMT <HH:MM> ...] [-heurExpiryParam <positive_integer>] [-weakNegRelExpiry <secs>] [-hitParams <string> ... [-ignoreParamValueCase ( YES | NO ) | -hitSelector <string> | -invalSelector <string>] [-matchCookies ( YES | NO )]] [-invalParams <string> ... [-invalRestrictedToHost ( YES | NO )]] [-pollEveryTime ( YES | NO )] [-ignoreReloadReq ( YES | NO )] [-removeCookies ( YES | NO )] [-prefetch ( YES | NO ) | -prefetchPeriod <secs> | -prefetchPeriodMilliSec <msecs>]] [-prefetchMaxPending <positive_integer>] [-flashCache ( YES | NO )] [-expireAtLastByte ( YES | NO )] [-insertVia ( YES | NO )] [-insertAge ( YES | NO )] [-insertETag ( YES | NO )] [-cacheControl <string>] [-quickAbortSize <KBytes>] [-minResSize <KBytes>] [-maxResSize <KBytes>] [-memLimit <MBytes>] [-ignoreReqCachingHdrs ( YES | NO )] [-minHits <integer>] [-alwaysEvalPolicies ( YES | NO )] [-pinned ( YES | NO )] [-lazyDnsResolve ( YES | NO )] [-type <type>]

Description

Create a new content group.

Parameters

name

The name of the content group to be created

weakPosRelExpiry

Use this parameter for responses with response codes between 200 and 399. (Similar to -relExpiry but has lesser precedence.) Default value: VAL_NOT_SET Maximum value: 31536000

heurExpiryParam

The heuristic expiry time, in percent of the duration since the object was last modified Default value: VAL_NOT_SET Maximum value: 100

relExpiry

The relative expiry time in seconds Default value: VAL_NOT_SET Maximum value: 31536000
relExpiryMilliSec

The relative expiry time in milliseconds. Default value: VAL_NOT_SET Maximum value: 86400000

absExpiry

Up to 4 times a day (local time) when all objects in the content group must expire.

absExpiryGMT

Up to 4 times a day (GMT), when all objects in the content group must expire.

weakNegRelExpiry

Use this parameter for all negative responses. This value will be used only if the expiry time cannot be determined from any other source. Default value: VAL_NOT_SET Maximum value: 31536000

hitParams

Use these parameters for parameterized hit evaluation of an object. Up to 128 parameters can be configured.

invalParams

Use these parameters for parameterized invalidation of an object. Up to 8 parameters can be configured.

ignoreParamValueCase

Use this parameter to specify whether to ignore case when comparing parameter values during parameterized hit evaluation. (Parameter value case is always ignored during parameterized invalidation.) Possible values: YES, NO Default value: VAL_NOT_SET

matchCookies

Use this parameter to specify whether to look for parameters also in the cookie header. Possible values: YES, NO Default value: VAL_NOT_SET

invalRestrictedToHost

Use this parameter to specify whether the host header should be taken into account during parameterized invalidation. Possible values: YES, NO Default value: VAL_NOT_SET

pollEveryTime

Use this parameter to specify whether to poll every time for the objects in this content group Possible values: YES, NO Default value: NO

ignoreReloadReq

Use this parameter to specify whether a request can force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you should set this flag to YES. To get RFC-compliant behavior you should set it to NO. Possible values: YES, NO Default value: YES
removeCookies

Use this parameter to specify whether to remove cookies from a response. Possible values: YES, NO Default value: YES

prefetch

Use this parameter to specify whether Integrated Cache should attempt to refresh an object immediately before it is about to go stale. Possible values: YES, NO Default value: YES

prefetchPeriod

The duration in seconds of the period during which prefetch should be attempted, immediately before the object’s calculated expiry time. Default value: VAL_NOT_SET
Maximum value: 4294967294

prefetchPeriodMilliSec

The duration in milliseconds of the period during which prefetch should be attempted, immediately before the object’s calculated expiry time. Default value: VAL_NOT_SET
Maximum value: 4294967290

prefetchMaxPending

The maximum number of outstanding prefetches on the contentgroup Default value: VAL_NOT_SET

flashCache

Use this parameter to specify whether Integrated Cache should do flash cache. Possible values: YES, NO Default value: NO

expireAtLastByte

Use this parameter to specify whether Integrated Cache should expire the content immediately after receiving the last body byte. Possible values: YES, NO Default value: NO

insertVia

Use this parameter to specify whether Integrated Cache should insert a Via header. Possible values: YES, NO Default value: YES

insertAge

Use this parameter to specify whether Integrated Cache should insert an Age header. Possible values: YES, NO Default value: YES

insertETag

Use this parameter to specify whether Integrated Cache should insert an ETag header. Possible values: YES, NO Default value: YES

cacheControl
Use this parameter to specify the Cache-Control header to be inserted.

**quickAbortSize**

If the client aborts when the downloaded response size is less than or equal to quick-abort-size, then Integrated Cache will stop downloading the response. Default value: 4194303 Maximum value: 4194303

**minResSize**

The minimum size of the response. Maximum value: 2097151

**maxResSize**

The maximum size of the response Default value: 80 Maximum value: 2097151

**memLimit**

The memory limit for the content group, in MB. The limit is not exact. At times, a group’s memory utilization may overshoot the limit, only to stabilize later. Default value: 65536

**ignoreReqCachingHdrs**

Use this parameter to specify whether to ignore the Cache-control and Pragma headers in the incoming request. Possible values: YES, NO Default value: YES

**minHits**

Specify the minimum number of accesses for an object to be stored in Cache.

**alwaysEvalPolicies**

Forces policy evaluation for each response arriving from origin. Possible values: YES, NO Default value: NO

**pinned**

Setting pinned to YES prevents IC from flushing objects from this contentgroup under memory pressure. Possible values: YES, NO Default value: NO

**lazyDnsResolve**

Setting this parameter to NO causes DNS resolution for every response. Setting this parameter to YES causes DNS resolution only when the destination IP in the request does not match the destination IP of the stored object. Possible values: YES, NO Default value: YES

**hitSelector**

The selector used for hit selection.

**invalSelector**

The selector used for invalidation.

**type**

"cache contentGroup"
This parameter will specify the type of content group. Possible values: HTTP, MYSQL, MSSQL. Default value: NSSVC_HTTP

**rm cache contentGroup**

**Synopsis**

`rm cache contentGroup <name>`

**Description**

Remove the specified content group.

**Parameters**

- `name`
  
  The name of the content group to be removed.

**set cache contentGroup**

**Synopsis**

`set cache contentGroup <name> [-weakPosRelExpire <secs> | -relExpire <secs> | -relExpireMilliSec <msecs> | -absExpire <HH:MM> ... | -absExpireGMT <HH:MM> ...] [-heurExpireParam <positive_integer>] [-weakNegRelExpire <secs>] [-hitParams <string> ... | -hitSelector <string> | -invalSelector <string>] [-invalParams <string> ...] [-ignoreParamValueCase ( YES | NO )] [-matchCookies ( YES | NO )] [-invalRestrictedToHost ( YES | NO )] [-pollEveryTime ( YES | NO )] [-ignoreReloadReq ( YES | NO )] [-removeCookies ( YES | NO )] [-prefetch ( YES | NO )] [-prefetchPeriod <secs> | -prefetchPeriodMilliSec <msecs>] [-prefetchMaxPending <positive_integer>] [-flashCache ( YES | NO )] [-expireAtLastByte ( YES | NO )] [-insertVia ( YES | NO )] [-insertAge ( YES | NO )] [-cacheControl <string>] [-quickAbortSize <KBytes>] [-minResSize <KBytes>] [-maxResSize <KBytes>] [-minHits <integer>] [-alwaysEvalPolicies ( YES | NO )] [-pinned ( YES | NO )] [-lazyDnsResolve ( YES | NO )]

**Description**

Modify attributes of the content group.
Parameters

name

The name of the content group whose attributes will be changed.

weakPosRelExpiry

Responses with response codes between 200 and 399. (Similar to -relExpiry, but has lesser precedence.) Maximum value: 31536000

heurExpiryParam

The heuristic expiry time, in percentage of the elapsed time since the object was last modified. Maximum value: 100

relExpiry

The relative expiry time in seconds. Default value: VAL_NOT_SET Maximum value: 31536000

relExpiryMilliSec

The relative expiry time in milliseconds. Default value: VAL_NOT_SET Maximum value: 86400000

absExpiry

Expiry time for all objects in the content group(up to 4 times a day [local time]).

absExpiryGMT

Expiry time for all objects in the content group(up to 4 times a day [GMT]).

weakNegRelExpiry

All negative responses. This value is used only if the expiry time cannot be determined from any other source. Maximum value: 31536000

hitParams

Parameterized hit evaluation of an object. Up to 128 parameters can be configured.

invalParams

Parameterized invalidation of an object. Up to 8 parameters can be configured.

ignoreParamValueCase

The option to ignore case while comparing parameter values during parameterized hit evaluation. The case of the parameter value is always ignored during parameterized invalidation. Possible values: YES, NO

matchCookies

The option to look for parameters in the cookie header. Possible values: YES, NO
invalRestrictedToHost

The option to consider the Host header during parameterized invalidation. Possible values: YES, NO

pollEveryTime

The option to poll every time for the objects in this content group. Possible values: YES, NO Default value: NO

ignoreReloadReq

For a request, the option to force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you should set this flag to YES. To get RFC-compliant behavior, you should set it to NO. Possible values: YES, NO Default value: YES

removeCookies

The option to remove cookies from response. Possible values: YES, NO Default value: YES

deprecated

The option to refresh an object immediately before it goes stale. Possible values: YES, NO Default value: YES

prefetchPeriod

The duration in seconds of the period during which prefetch should be attempted, immediately before the object’s calculated expiry time. Default value: VAL_NOT_SET Maximum value: 4294967294

prefetchPeriodMilliSec

The duration in milliseconds of the period during which prefetch should be attempted, immediately before the calculated expiry time. Default value: VAL_NOT_SET Maximum value: 4294967290

prefetchMaxPending

The maximum number of outstanding prefetches on the contentgroup.

flashCache

The option to do flash cache on Integrated caching. Possible values: YES, NO Default value: NO

expireAtLastByte

The option to expire the content immediately after receiving the last body byte. Possible values: YES, NO Default value: NO

insertVia

The option to insert a Via header. Possible values: YES, NO Default value: YES
insertAge

The option to insert an Age header. Possible values: YES, NO Default value: YES

insertETag

The option to insert an ETag header. Possible values: YES, NO Default value: YES

cacheControl

The option to insert a Cache-Control header.

quickAbortSize

The quick abort size. If the client aborts when the downloaded response size is less than or equal to the quick-abort-size, then the Integrated Cache will stop downloading the response. Maximum value: 4194303

minResSize

The minimum size of the response. Maximum value: 2097151

maxResSize

The maximum size of the response. Default value: 80 Maximum value: 2097151

memLimit

The memory limit in MB for the content group. The limit is not exact - a group's memory utilization may overshoot the limit, only to stabilize later. Default value: 65536

ignoreReqCachingHdrs

The option to ignore the Cache-control and Pragma headers in the incoming request. Possible values: YES, NO Default value: YES

minHits

The minimum number of accesses for an object to be stored in Cache.

alwaysEvalPolicies

The option to force policy evaluation for each response arriving from the origin. Possible values: YES, NO Default value: NO

pinned

The option for IC from flushing objects from this content group under memory pressure. Set YES for IC to take this state. Possible values: YES, NO Default value: NO

lazyDnsResolve

Setting this parameter to NO causes DNS resolution for every response. Setting this parameter to YES causes DNS resolution only when the destination IP in the request does not match the destination IP of the stored object. Possible values: YES, NO Default value: YES
**hitSelector**

The selector used for hit selection.

**invalSelector**

The selector used for invalidation.

---

**unset cache contentGroup**

### Synopsis

```
unset cache contentGroup <name> [-weakPosRelExpiry] [-heurExpiryParam] [-relExpiry]
[relExpiryMilliSec] [-absExpiry] [-absExpiryGMT] [-weakNegRelExpiry] [-hitParams]
[-invalParams] [-ignoreParamValueCase] [-matchCookies] [-invalRestrictedToHost]
[-pollEveryTime] [-ignoreReloadReq] [-removeCookies] [-prefetch] [-prefetchPeriod]
[prefetchPeriodMilliSec] [-prefetchMaxPending] [-flashCache] [-expireAtLastByte]
[-pinned] [-lazyDnsResolve] [-hitSelector] [-invalSelector]
```

### Description

Use this command to remove cache contentGroup settings. Refer to the set cache contentGroup command for meanings of the arguments.

---

**show cache contentGroup**

### Synopsis

```
show cache contentGroup <name>
```

### Description

Display all content groups. To display a single content group, specify the name of the content group.

### Parameters

- **name**
  
  The name of the content group.
expire cache contentGroup

Synopsis
   expire cache contentGroup <name>

Description
   Expire the objects in the specified content group.

Parameters
   name
       The name of the content group whose objects are to be expired.

flush cache contentGroup

Synopsis
   flush cache contentGroup <name> [-query <string> | -selectorValue <string>] [-host <string>]

Description
   Flush the objects in the specified content group.

Parameters
   name
       The name of the content group whose objects are to be flushed.

   query
       If a query string is specified, then the selected objects in this group will be flushed using parameterized invalidation. Otherwise, all objects in the group will be flushed.

   host
       To be set only if parameterized invalidation is being done. Objects belonging only to the specified host will be flushed. The host argument can be provided if and only if -invalRestrictedToHost is set to YES for the given group.

   selectorValue
cache contentGroup

The value of the selector to be used for flushing objects in the contentgroup.

Top
cache forwardProxy

[ add | rm | show ]

add cache forwardProxy

Synopsis
add cache forwardProxy <IPAddress> <port>

Description
Add a forward proxy known to Integrated cache.

Parameters

IPAddress
The IP address of the forward proxy.

port
The port of the forward proxy. Minimum value: 1

Top

rm cache forwardProxy

Synopsis
rm cache forwardProxy <IPAddress> <port>

Description
Remove a forward proxy known to Integrated cache.

Parameters

IPAddress
The IP address of the forward proxy.

port
show cache forwardProxy

Synopsis

text

Description

Display all forward proxies known to Integrated cache.

Text
cache selector

[ add | rm | set | show ]

add cache selector

Synopsis
add cache selector <selectorName> <rule> ...

Description
Create Integrated Cache selectors. A selector is an abstraction for a collection of PIXL expressions. After creating a selector, you can use it as either a hitSelector (for doing hit selection) or as an invalSelector (for invalidating cached objects), or both. You need to specify at least one expression when you create a selector.

Parameters
selectorName
The name of the Integrated Cache selector.

rule
The set of PIXL expressions.

Top

rm cache selector

Synopsis
rm cache selector <selectorName>

Description
Use this command to remove Integrated Cache selectors.

Parameters
selectorName
set cache selector

Synopsis

set cache selector <selectorName> <rule> ...

Description

Change the set of expressions associated with Integrated Cache selectors.

Parameters

selectorName

The name of the Integrated Cache selector.

rule

The PIXL expressions.

show cache selector

Synopsis

show cache selector [<selectorName>]

Description

Display Integrated Cache selectors.

Parameters

selectorName

The name of the Integrated Cache selector.
cache object

[ show | expire | flush ]

show cache object

Synopsis

show cache object [(url <URL> [-host <string> [-port <port>]] [-groupName <string>] [-httpMethod ( GET | POST )]) | -locator <positive_integer> | -httpStatus <positive_integer> | -group <string> | -ignoreMarkerObjects ( ON | OFF ) | -includeNotReadyObjects ( ON | OFF )]

Description

Show a list of all cached objects, or the properties of a particular cache object.

Parameters

url

The URL of the object.

locator

The id of the cached object.

httpStatus

HTTP status of the object.

host

The hostname of the object.

port

The host port of the object. Default value: 80 Minimum value: 1

groupName

The name of the content group to be in which the cell is present

httpMethod

The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET
expire cache object

Synopsis

expire cache object (-locator <positive_integer> | (-url <URL> (-host <string> [-port <port>] [-groupName <string>] [-httpMethod ( GET | POST )])))

Description

Expire a cached object.

Parameters

locator

The id of the cached object.

url

The URL of the object to be expired.

host

The host of the object to be expired.

port

The host port of the object to be expired. Default value: 80 Minimum value: 1

groupName

The name of the content group to be in which the cell is present.

httpMethod

The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET
flush cache object

Synopsis
flush cache object (-locator <positive_integer> | (-url <URL> (-host <string> [-port <port>] [-groupName <string>] [-httpMethod (GET | POST)])))

Description
Flush a cached object.

Parameters
locator
- The ID of the cached object.

url
- The URL of the object to be flushed.

host
- The host of the object to be flushed.

port
- The host port of the object to be flushed. Default value: 80 Minimum value: 1

groupName
- The name of the content group to be in which the cell is present.

httpMethod
- The HTTP request method that caused the object to be stored. Possible values: GET, POST Default value: NS_HTTP_METHOD_GET
cache stats

**show cache stats**

**Synopsis**

show cache stats - alias for 'stat cache'

**Description**

show cache stats is an alias for stat cache
bind cache global

Synopsis

bind cache global <policy> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-type <type>] [-invoke (<labelType> <labelName>)]

Description

Bind the cache policy to one of the two global lists of cache policies. A policy becomes active only after it is bound. All HTTP traffic will be evaluated against these two policy banks. There is a request time policy bank and a response time policy bank. The flow type of the policy implicitly determines which bank it gets bound to. Each bank of policies is an ordered list ordered by policies priority values. Policy Bank Evaluation The goal of evaluation is to traverse the ordered list of policies in the bank, find out which policies match and build a result set that will contain the actions of all the matching policies. While evaluating a policy if any PIXL expression cannot be evaluated then UNDEF processing will get triggered. There are also other scenarios during policy traversal when UNDEF processing can get triggered. If an UNDEF event occurs while processing a policy, then (i) policy bank traversal ends, (ii) the result set of actions that was built so far is wiped out (iii) the current policy's undefAction is put in the result set and the evaluation ends.

Parameters

gallery

Top

unbind cache global

Synopsis

unbind cache global <policy> [-type <type>] [-priority <positive_integer>]

Description

Inactivate the policy.
**Parameters**

- **policy**
  
  The name of the Integrated Cache policy to unbind

- **priority**

  Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647

**show cache global**

**Synopsis**

`show cache global [-type <type>]`

**Description**

Display the cache global bindings.

**Parameters**

- **type**

  The bindpoint to which policy is bound. Possible values: `REQ_OVERRIDE`, `REQ_DEFAULT`, `RES_OVERRIDE`, `RES_DEFAULT`

**Example**

`show cache global`

Top
cache parameter

[ set | unset | show ]

set cache parameter

Synopsis

Description

Modify the global configuration of the Integrated Cache.

Parameters

memLimit

The memory limit for Integrated Cache.

via

The string to be inserted in the "Via" header. A Via header is inserted in all responses served from a content group if its insertVia flag is set.

verifyUsing

The criteria for deciding whether a cached object can be served for an incoming HTTP request. a. If the value of this attribute is set to HOSTNAME, then URL, host name and host port values in the incoming HTTP request header must match before a cached object can be served. The IP address and the TCP port of the destination host are not matched. For certain deployments the HOSTNAME setting can be a security risk. A rogue client can access a rogue server via the Integrated Cache using the following HTTP request: GET / HTTP/1.1 Host: sensitive.foo.com Integrated Cache will store the rogue page served by the rogue server. Any subsequent client trying to access the root page from sensitive.foo.com will be served the rogue page. The HOSTNAME setting should only be set if it is certain that no rogue client can access a rogue server via the integrated Cache. The YES setting can lead to more hits if DNS-based load balancing is in use and the same content can be served by multiple backend servers. b. If the attribute is set to HOSTNAME_AND_IP, then the following items must match: URL, host name, host port in the incoming HTTP request header, and the IP address and TCP port of the destination server. c. If the attribute is set to DNS, then the following items should match: URL, host name and host port in the incoming HTTP request, and the TCP port. The hostname is used to do a DNS lookup of the destination server's IP address, and is compared with the set of addresses returned by the DNS lookup. The default value of this attribute is DNS.
Possible values: HOSTNAME, HOSTNAME_AND_IP, DNS

maxPostLen

maximum number of POST body bytes to consider when evaluating parameters for a content group for which you have configured hitParams and invalParams. Default value: 4096 Maximum value: 131072

prefetchMaxPending

The maximum number of outstanding prefetches in the IC.

enableBypass

The bypass parameter. When this value is set to NO, an incoming request will serve a hit if a matching object is found in cache storage, regardless of the cacheability policy configuration. If set to YES, the bound request cacheability policies are evaluated before attempting any hit selection in the cache storage. If the request matches a policy with a NOCACHE action, the request will bypass all cache processing. This flag does not affect processing of requests that match any invalidation policy. Possible values: YES, NO

undefAction

Set the default cache undef action. If an UNDEF event is triggered during policy evaluation and if the current policy’s undefAction is not specified, then this global undefAction value is used. Can be NOCACHE or RESET. NOCACHE is the default value of default cache undef action. Possible values: NOCACHE, RESET

unset cache parameter

Synopsis

Description

Use this command to remove cache parameter settings. Refer to the set cache parameter command for meanings of the arguments.

show cache parameter

Synopsis

show cache parameter
Description

Display the global configuration of the Integrated Cache.

Top
CLI Commands

This group of commands can be used to perform operations on the following entities:

- config
- whoami
- exit
- quit
- man
- history
- help
- source
- batch
- unalias
- alias
- cls
- cli attribute
- cli prompt
- cli mode
config

config

Synopsis
config

Description
Enter this command to enter contextual mode.
whoami

Synopsis

whoami

Description

Show the current user.
exit

Synopsis
   exit

Description
   Use this command to back out one level in config mode, or to terminate the CLI when not in config mode. );
quit

Synopsis

quit

Description

Use this command to terminate the CLI. Note: typing <Ctrl>+<d> will also terminate the CLI.
Synopsis

man [(commandName)]

Description

Use this command to invoke the man page for the specified command. You can specify the command in full, or partially, if it is uniquely resolvable.

Parameters

commandName

The name of the command.

Example

man add vs
Synopsis
    history

Description
    Use this command to see the history of the commands executed on CLI.

Example

    history

              1 add snmp trap SPECIFIC 10.102.130.228
              2 save config
              3 show system session
              4 swhell
              5 shell
              6 what
              7 shell
              8 help stat lbvserver

...
help

help

Synopsis

help [(commandName) | <groupName> | -all]

Description

Use this command to display help information for a CLI command, for a group of commands, or for all CLI commands.

Parameters

commandName

The name of a command for which you want full usage information.

groupName

The name of a command group for which you want basic usage information.

all

Use this option to request basic usage information for all commands.

Example

1. To view help information for adding a virtual server, enter the following CLI command:
   help add vserver
   The following information is displayed:
   Usage:  add vserver <vServerName> <serviceType> [<IPAddress> port] [-type ( CONTENT | ADDRESS )] [-cacheType <cacheType>] [-backupVServerName <string>] [-redirectURL <URL>] [-cacheable ( ON | OFF )] [-state ( ENABLED | DISABLED )]
   where:
   serviceType = ( HTTP | FTP | TCP | UDP | SSL | SSL_BRIDGE | SSL_TCP | NNTP | DNS | ANY )
   <cacheType> = ( TRANSPARENT | REVERSE | FORWARD )
   Done

2. To view help information for all DNS commands, enter the following command:
   help dns
   The following information is displayed:
   add aaaaRec <hostname> <IPv6Address> ... [-TTL <secs>]
   rm aaaaRec <hostname> [IPv6Address ...]
   show aaaaRec [hostname | -type <type>]
   add addRec <hostname> <IPAddress> ... [-TTL <secs>] [-private <ip_addr>]
   rm addRec <hostname> [<IPAddress> ...]
   show addRec [hostname | -type <type>]
add cnameRec <aliasName> <canonicalName> [-TTL <secs>]
rm cnameRec <aliasName>
show cnameRec [<-aliasName> | -type <type>]
add mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]
rm mxRec <domain> <mx>
set mxRec <domain> -mx <string> [-pref <positive_integer>] [-TTL <secs>]
show mxRec [<-domain> | -type <type>]
add nsRec <domain> [-p <string>] [-s <string>] [-TTL <secs>]
rm nsRec <domain> [-p <string> | -s <string>]
show nsRec [<-domain> | -type <type>]
set dns parameter [-timeout <secs>] [-retries <positive_integer>] [-minTTL <secs>] [-maxTTL <secs>] [-TTL ( ENABLED | DISABLED )] [-cacheRecords ( YES | NO )]
show dns parameter
add soaRec <domain> -contact <string> -serial <positive_integer> -refresh <secs> -retry <secs> -expire <secs> [-TTL <secs>]
rm soaRec <domain>
set soaRec <domain> [-contact <string>] [-serial <positive_integer>] [-refresh <secs>] [-retry <secs>] [-expire <secs>]
show soaRec [<-domain> | -type <type>]
add dns ptrRec <reverseDomain> <domain> ... [-TTL <secs>]
rm dns ptrRec <reverseDomain> [<-domain> ...]
show dns ptrRec [<-reverseDomain> | -type <type>]
add dns srvRec <domain> <target> -priority <positive_integer>
    -weight <positive_integer> -port <positive_integer>
rm dns srvRec <domain> [<-target> ...]
set dns srvRec <domain> <target> [-priority <positive_integer>]
    [-weight <positive_integer>] [-port <positive_integer>] [-TTL <secs>]
show dns srvRec [(-<domain> [<-target>]) | -type <type>]
Done
source

Synopsis
source <fileName>

Description
Use this command to read the contents of a file and execute each line as a separate CLI command. Each command in the file being read must be on a separate line. Lines starting with # are considered comments.

Parameters
fileName

The name of the file to be sourced.

Example

source cmds.txt
batch

Synopsis

    batch -fileName <input_filename> [-outfile <output_filename>] [-ntimes <positive_integer>]

Description

Use this command to read the contents of a file and execute each line as a separate CLI command. Each command in the file must be on a separate line. Lines starting with # are considered comments.

Parameters

fileName

    The name of the batch file.

outfile

    The name of the file where the executed batch file will write its output. The default is standard output.

ntimes

    The number of times the batch file will be executed. Default value: 1

Example

    batch -f cmds.txt
unalias

unalias

Synopsis
  unalias <pattern>

Description
  Remove an alias

Parameters
  pattern
    Name of the alias

Example

unalias info
alias

alias

Synopsis

alias [<pattern> [[(command)]]]

Description

Create (short) aliases for (long) commands. Aliases are saved across NSCLI sessions. If no argument is specified, the alias command will display existing aliases.

Parameters

pattern

Alias name. (Can be a regular expression.)

Example

alias info "show ns info"
Synopsis

Description
Clear the screen and reposition cursor at top right.
cli attribute

**show cli attribute**

**Synopsis**

```
show cli attribute
```

**Description**

Display attributes of the NetScaler CLI
cli prompt

[ clear | set | show ]

clear cli prompt

Synopsis
clear cli prompt

Description
Use this command to return the CLI prompt to the default (a single `>`).

set cli prompt

Synopsis
set cli prompt <promptString>

Description
Use this command to customize the CLI prompt.

Parameters
promptString

The prompt string. The following special values are allowed: %! - will be replaced by the
history event number %u - will be replaced by the NetScaler user name %h - will be
replaced by the NetScaler hostname %t - will be replaced by the current time %T - will be
replaced by the current time (24 hr format) %d - will be replaced by the current date %s -
will be replaced by the node state

Example

> set cli prompt "%h %T"
Done
lb-ns1 15:16>
show cli prompt

Synopsis
  show cli prompt

Description
  Use this command to display the current CLI prompt, with special values like '%h' unexpanded.

Example

  10.101.4.22 15:20> sh cli prompt
     CLI prompt is set to "%h %T"
     Done
cli mode

[ set | unset | show ]

set cli mode

Synopsis

set cli mode [-page ( ON | OFF )] [-total ( ON | OFF )] [-color ( ON | OFF )]
[-disabledFeatureAction <disabledFeatureAction>] [-timeout <secs>] [-regex ( ON | OFF )]

Description

Use this command to specify how the CLI should display command output.

Parameters

page

Determines whether output that spans more than one screen is "paged". Specify ON to
pause the display after each screen of output. Possible values: ON, OFF Default value: OFF

total

Determines whether CLI "show" commands display a total count of objects before
displaying the objects themselves. Possible values: ON, OFF Default value: OFF

color

Specifies whether output can be shown in color, if the terminal supports it. Possible
values: ON, OFF Default value: OFF

disabledFeatureAction

Specifies what will happen when a configuration command is issued for a disabled
feature. The following values are allowed: NONE - The action is allowed, and no warning
message is issued.; ALLOW - The action is allowed, but a warning message is issued.;
DENY - The action is not allowed.; HIDE - Commands that configure disabled features are
hidden, and the CLI behaves as if they did not exist. Possible values: NONE, ALLOW,
DENY, HIDE Default value: NS_ALLOW

timeout

CLI session inactivity timeout, in seconds. Timeout cannot have values in between 1 and
9. Default value: 300 Maximum value: 100000000
regex

If ON, regular expressions can be used as argument values. Possible values: ON, OFF
Default value: ON

unset cli mode

Synopsis

Description

Use this command to remove cli mode settings. Refer to the set cli mode command for meanings of the arguments.

show cli mode

Synopsis

show cli mode

Description

Use this command to display the current settings of parameters that can be set with the 'set cli mode' command.
Cluster Commands

This group of commands can be used to perform operations on the following entities:

- cluster
- cluster instance
- cluster node
- cluster files
- cluster sync
cluster

**join cluster**

**Synopsis**

```bash
join cluster -clip <ip_addr> {-password }
```

**Description**

Joins the appliance to the cluster. You must execute this command from the NetScaler IP (NSIP) address of the node you want to add to the cluster. This command is the second part of the two-step process of adding a cluster node. The first part is adding this node to the cluster by using the .add cluster node. command from the cluster IP address. Join is not permitted if any of the node in cluster is in sync state.

**Parameters**

- `clip`
  
  The cluster IP address to which you are trying to add the node.

- `password`
  
  The password for the nsroot account of the configuration coordinator (CCO).
cluster instance

[ add | rm | set | unset | enable | disable | show | stat ]

add cluster instance

Synopsis

add cluster instance <clId> [-deadInterval <secs>] [-helloInterval <msecs>] [-preemption (ENABLED | DISABLED )]

Description

Adds a cluster instance to the appliance. Execute this command only on the first node that you add to the cluster.

Parameters

clId

A unique number that identifies the cluster. Minimum value: 1 Maximum value: 16

deadInterval

The amount of time (in seconds) after which the nodes that do not respond to the heartbeats are assumed to be down. Default value: 3 Minimum value: 3 Maximum value: 60

helloInterval

The amount of time (in milliseconds) after which heartbeats are sent to each cluster node to check the health status. Default value: 200 Minimum value: 200 Maximum value: 1000

preemption

Enable or disable the preemption of a cluster node that is configured as SPARE by a node that is configured as ACTIVE. When preemption is enabled, ACTIVE nodes are given precedence over SPARE nodes. This means that when an ACTIVE node comes online and finds that a SPARE node is serving traffic, it preempt the SPARE node and starts serving traffic. When preemption is disabled, the SPARE node continues serving traffic even after an ACTIVE node comes back online. Possible values: ENABLED, DISABLED Default value: DISABLED

Example
**rm cluster instance**

**Synopsis**
rm cluster instance <clId>

**Description**
Removes the cluster instance from the node. Execute this command on the NetScaler IP (NSIP) address of the node that you want to remove from the cluster. After executing this command, you must execute the rm cluster node. command on the cluster IP address.

**Parameters**
clId
A unique number that identifies the cluster. Minimum value: 1 Maximum value: 16

**Example**
rm cluster instance 1

**set cluster instance**

**Synopsis**
set cluster instance <clId> [-deadInterval <secs>] [-helloInterval <msecs>] [-preemption (ENABLED | DISABLED )]

**Description**
Modifies the attributes of a cluster instance.

**Parameters**
clId
The ID of the cluster instance whose properties you want to set. Minimum value: 1 Maximum value: 16
### cluster instance

#### deadInterval

The amount of time (in seconds) after which the nodes that do not respond to the heartbeats are assumed to be down. Default value: 3 Minimum value: 3 Maximum value: 60

#### helloInterval

The amount of time (in milliseconds) after which heartbeats are sent to each cluster node to check the health status. Default value: 200 Minimum value: 200 Maximum value: 1000

#### preemption

Enable or disable the preemption of a cluster node that is configured as SPARE by a node that is configured as ACTIVE. When preemption is enabled, ACTIVE nodes are given precedence over SPARE nodes. This means that when an ACTIVE node comes online and finds that a SPARE node is serving traffic, it preempts the SPARE node and starts serving traffic. When preemption is disabled, the SPARE node continues serving traffic even after an ACTIVE node comes back online. Possible values: ENABLED, DISABLED Default value: DISABLED

Example

```
set cluster instance 1 -preemption ENABLED
```

### unset cluster instance

#### Synopsis

```
unset cluster instance <clId> [-deadInterval] [-helloInterval] [-preemption]
```

#### Description

Use this command to remove cluster instance settings. Refer to the set cluster instance command for meanings of the arguments.

### enable cluster instance

#### Synopsis

```
enable cluster instance <clId>
```
**enable cluster instance**

**Description**
Enables a cluster instance.

**Parameters**
- **clId**
  
  The ID of the cluster instance that you want to enable. Minimum value: 1 Maximum value: 16

**Example**

```
enable cluster instance 1
```

**disable cluster instance**

**Synopsis**
disable cluster instance <clId>

**Description**
Disables a cluster instance.

**Parameters**
- **clId**
  
  The ID of the cluster instance that you want to disable. Minimum value: 1 Maximum value: 16

**Example**

```
disable cluster instance 1
```

**show cluster instance**

**Synopsis**
show cluster instance [<clId>]

---

351
cluster instance

Description
Displays details of the cluster instance and the cluster nodes.

Parameters
clld
A unique number that identifies the cluster. Minimum value: 1 Maximum value: 16

Example
An example of the command's output is as follows:
1) Cluster ID: 1
   Dead Interval: 3 secs
   Hello Interval: 200 msecs
   Preemption: DISABLED
   Propagation: ENABLED
   Cluster Status: ENABLED(admin), ENABLED(operational), UP
   Member Nodes:
   Node ID         Node IP              Health     Admin State       Operational State
   -------         -------              ------     -----------       -----------------
   1)      1               1.1.1.1*             UP         ACTIVE            ACTIVE(Configuration Coordinator)
   2)      2               1.1.1.2              UP         ACTIVE            ACTIVE
   Done
   *: Local node

stat cluster instance

Synopsis

Description
Displays the statistics of the cluster instance.

Parameters
clld
The ID of the cluster instance whose statistics must be displayed. Minimum value: 1 Maximum value: 16
cluster node

[ add | set | unset | rm | show | stat ]

add cluster node

**Synopsis**

```
add cluster node <nodeId> <IPAddress> [-state <state>] [-backplane <interface_name>]
```

**Description**

Adds a NetScaler appliance to a cluster.

**Parameters**

- **nodeId**
  
  A unique number that identifies the cluster node. Maximum value: 31

- **IPAddress**

  The NetScaler IP (NSIP) address of the appliance that you want to add to the cluster. Only IPv4 addresses are supported.

- **state**

  The configured state of the cluster node. ACTIVE - The node serves traffic. SPARE - The node does not serve traffic till an ACTIVE node goes down. PASSIVE - The node does not serve traffic till explicitly made ACTIVE. This state is useful during temporary maintenance activities where it is desirable that the node takes part in the consensus protocol, but does not serve traffic. Possible values: ACTIVE, SPARE, PASSIVE Default value: NSACL_NODEST_PASSIVE

- **backplane**

  The interface to be used to communicate with the other cluster nodes. The interface must be specified in the three-tuple form, n/c/u, where n represents the node ID. Minimum value: 1

**Example**

```
add cluster node 1 1.1.1.1 -backplane 1/1/1 -state ACTIVE
```

Top
set cluster node

Synopsis

set cluster node <nodeId> [-state <state>] [-backplane <interface_name>]

Description

Modifies the attributes of a cluster node.

Parameters

nodeId

The ID of the cluster node whose properties you want to set. Maximum value: 31

state

The configured state of the cluster node. ACTIVE - The node serves traffic. SPARE - The node does not serve traffic till an ACTIVE node goes down. PASSIVE - The node does not serve traffic till explicitly made ACTIVE. This state is useful during temporary maintenance activities where it is desirable that the node takes part in the consensus protocol, but does not serve traffic. Possible values: ACTIVE, SPARE, PASSIVE Default value: NSACL_NODEST_PASSIVE

backplane

The interface to be used to communicate with the other cluster nodes. The interface must be specified in the three-tuple form, n/c/u, where n represents the node ID. Minimum value: 1

Example

set cluster node 1 -state PASSIVE

unset cluster node

Synopsis

unset cluster node <nodeId> [-state] [-backplane]

Description

Use this command to remove cluster node settings. Refer to the set cluster node command for meanings of the arguments.
rm cluster node

Synopsis

rm cluster node <nodeId>

Description

Removes a node from the cluster. You must execute this command on the cluster IP address after executing the rm cluster instance. command from the node that you want to remove from the cluster.

Parameters

nodeId

The ID of the cluster node that you want to remove from the cluster. Maximum value: 31

Example

rm cluster node 1

show cluster node

Synopsis

show cluster node [nodeId]

Description

Displays details of the cluster node.

Parameters

nodeId

The ID of the cluster node whose details must be displayed. If an ID is not provided, details of all nodes of the cluster are displayed. Default value: 255 Maximum value: 31

Example
An example of the command’s output is as follows:

1 cluster node:
1) Node ID: 1
   IP: 1.1.1.1*
   Backplane: 1/1/1
   Health: UP
   Admin State: ACTIVE
   Operational State: ACTIVE(Configuration Coordinator)
   Sync State: DISABLED
   Done
   *: Local node

**stat cluster node**

**Synopsis**

```
stat cluster node [<-nodeId>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]
```

**Description**

Displays the statistics of the cluster node.

**Parameters**

- **nodeId**
  
The ID of the cluster node whose statistics must be displayed. If an ID is not provided, statistics of all nodes of the cluster are displayed. Maximum value: 31
**cluster files**

**sync cluster files**

**Synopsis**

```
sync cluster files [<Mode> …]
```

**Description**

Synchronize SSL Certificates, SSL CRL lists, SSL VPN bookmarks, and other files from the CCO to other cluster nodes. This command must be executed only from the cluster IP address. This command will be automatically triggered from the CCO when a new node is added to a cluster and periodically during the lifetime of the cluster, to synchronize updated files between the cluster nodes. Note: Files on non-CCO nodes are not deleted if they do not exist on the CCO. The command can be configured to synchronize directories or files which are specified by the following modes: Mode Paths all /nsconfig/ssl/ /var/netscaler/ssl/ /var/vpn/bookmark/ /nsconfig/dns/ /nsconfig/htmlinjection/ /netscaler/htmlinjection/ens/ /nsconfig/monitors/ /nsconfig/nstemplates/ /nsconfig/ssh/ /nsconfig/rc.netscaler /nsconfig/resolv.conf /nsconfig/inetd.conf /nsconfig/syslog.conf /nsconfig/snmpd.conf /nsconfig/ntp.conf /nsconfig/httpd.conf /nsconfig/sshd_config /nsconfig/hosts /nsconfig/oncekey /var/nslw.bin/etc/krb5.conf /var/nslw.bin/etc/krb5.keytab /var/lib/likewise/db /var/download /var/wi/tomcat/webapps /var/web/tomcat/conf/Catalina/localhost /var/wi/java_home/lib/security/cacerts /var/wi/java_home/jre/lib/security/cacerts ssl /nsconfig/ssl/ /var/netscaler/ssl/ /var/netscaler/htmlinjection/ /nsconfig/htmlinjection/ imports /var/netscaler/htmlinjection/ bookmarks /var/netscaler/bookmarks /dns /nsconfig/dns/ htmlinjection /nsconfig/htmlinjection/ imports /var/download/ misc /nsconfig/license/ /nsconfig/rc.conf all_plus_misc Includes *all* files and /nsconfig/license/ and /nsconfig/rc.conf.

**Parameters**

**Mode**

Specifies the directories and files to be synchronized. Possible values: all, bookmarks, ssl, htmlinjection, imports, misc, dns, all_plus_misc. Default value: all

**Example**

```
sync cluster files ssl or sync cluster files all
```
**cluster sync**

**force cluster sync**

**Synopsis**

force cluster sync

**Description**

Synchronize the configurations of a cluster node from the CCO. This command must be executed from the NSIP of the node that needs to be synchronized.

**Example**

force cluster sync
Compression Commands

This group of commands can be used to perform operations on the following entities:

- `cmp`
- `cmp action`
- `cmp policy`
- `cmp policylabel`
- `cmp stats`
- `cmp global`
- `cmp parameter`
cmp

stat cmp

Synopsis

    stat cmp [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

    Display compression statistics.
**cmp action**

[ add | rm | show | rename ]

**add cmp action**

**Synopsis**

add cmp action <name> <cmpType>

**Description**

Create a compression action. The action thus created can be associated with the compression policy. The built-in compression actions NOCOMPRESS/COMPRESS/GZIP/DEFLATE are always present on the system. These actions are: NOCOMPRESS action - can be used to define a policy that disables compression for the matching policy. COMPRESS action - can be used to enable compression for a specific policy. This action will do GZIP or DEFLATE, based on the browser. GZIP action - can be used to enable GZIP compression for a specific policy. With this action, GZIP compression will be performed if the browser supports GZIP, otherwise compression is disabled. DEFLATE action - can be used to enable DEFLATE compression for a specific policy. With this action, DEFLATE compression will be performed if the browser supports DEFLATE, otherwise compression is disabled.

**Parameters**

**name**

The name of the compression action.

**cmpType**

The type of compression action. Possible values: compress, gzip, deflate, nocompress

**deltaType**

The type of delta action (if delta type compression action is defined). Possible values: PERURL, PERPOLICY Default value: NS_ACT_CMP_DELTA_TYPE_PERURL

**Example**

add cmp action nocmp NOCOMPRESS

Top
rm cmp action

Synopsis

rm cmp action <name>

Description

Remove the specified compression action.

Parameters

name

The name of the compression action.

Example

rm cmp action cmp_action_name

show cmp action

Synopsis

show cmp action [<name>]

Description

Display the compression actions defined including the built-in actions.

Parameters

name

The name of the compression action.

Example

Example 1

The following example shows output from the show cmp action command when no custom cmp actions have been defined:

> show cmp action
  3 Compression actions:
rename cmp action

Synopsis

rename cmp action <name>@ <newName>@

Description

Rename a cmp action.

Parameters

name

The name of the cmp action.

newName

The new name of the cmp action.

Example

rename cmp policy oldname newname

Top
cmp policy

[ add | rm | set | unset | show | stat | rename ]

add cmp policy

Synopsis

add cmp policy <name> -rule <expression> -resAction <string>

Description

Create a HTTP compression policy.

Parameters

name

The name of the HTTP compression policy to be created.

rule

The rule associated with the HTTP compression policy.

resAction

The compression action that needs to be performed when the rule matches. The string value can be either be a created compression action (user-defined) or one of the following built-in compression actions: NOCOMPRESS action - can be used to define a policy that disables compression for the matching policy. COMPRESS action - can be used to enable compression for a specific policy. This action will do GZIP or DEFLATE, based on the browser. GZIP action - can be used to enable GZIP compression for a specific policy. With this action, GZIP compression will be performed if the browser supports GZIP, otherwise compression is disabled. DEFLATE action - can be used to enable DEFLATE compression for a specific policy. With this action, DEFLATE compression will be performed if the browser supports DEFLATE, otherwise compression is disabled.

Example

Example 1:

add cmp policy pdf_cmp -rule "RES.HTTP.HEADER Content-Type CONTAINS application/pdf" -resAction COMPRESS

After creating the above compression policy, you must activate it by binding it globally:
bind cmp global pdf_cmp
The NetScaler system will use the configured pdf_cmp compression policy to perform compression of pdf files.

Example 2:

The following command disables compression for all the access from the specific subnet.

```
add cmp policy local_sub_nocmp -rule "SOURCEIP == 10.1.1.0 -netmask 255.255.255.0" -resAction NOCOMPRESS
bind cmp global local_sub_nocmp
```

---

**rm cmp policy**

**Synopsis**

```
rm cmp policy <name>
```

**Description**

Remove a HTTP compression policy.

**Parameters**

- **name**
  
  The name of the HTTP compression policy to be removed.

**Example**

```
rm cmp policy cmp_policy_name
```

The "show cmp policy" command shows all currently defined HTTP compression policies.

---

**set cmp policy**

**Synopsis**

```
set cmp policy <name> [-rule <expression>] [-resAction <string>]
```

**Description**

Modify a HTTP compression policy. Use the "show cmp policy" command to view all configured HTTP compression policies.
Parameters

name

The name of the HTTP compression policy to be modified.

rule

The new rule to be associated with the HTTP compression policy.

resAction

The compression action to be associated with the HTTP compression policy.

Example

Example 1:

add cmp policy pdf_cmp -rule "RES.HTTP.HEADER Content-Type CONTAINS application/pdf" -resAction COMPRESS

After creating the above compression policy, you must activate it by binding it globally:

bind cmp global pdf_cmp

The NetScaler system will use the configured pdf_cmp compression policy to perform compression for pdf files.

To disable pdf compression for Internet Explorer, you can change the above compression policy by issuing the following command:

set cmp policy pdf_cmp -rule "RES.HTTP.HEADER Content-Type CONTAINS application/pdf && RES.HTTP.HEADER User-Agent NOTCONTAINS MSIE"

To view the changed cmp policy, enter the following command:

>show cmp policy pdf_cmp
  Name: pdf_cmp   Rule: (RES.HTTP.HEADER Content-Type CONTAINS application/pdf && RES.HTTP.HEADER User-Agent NOTCONTAINS MSIE)
  Response action: COMPRESS       Hits: 2
  Bytes In:...609284      Bytes Out:... 443998
  Bandwidth saving...27.13%       Ratio 1.37:1

Done

unset cmp policy

Synopsis

unset cmp policy <name> [-rule] [-resAction]

Description

Use this command to remove cmp policy settings. Refer to the set cmp policy command for meanings of the arguments.
show cmp policy

Synopsis

show cmp policy [<name>] show cmp policy stats - alias for 'stat cmp policy'

Description

Display the configured HTTP compression policies.

Parameters

name

The name of the HTTP compression policy whose details are to be displayed.

Example

> show cmp policy
  4 Compression policies:
  1) Name: ns_cmp_content_type Rule: ns_content_type
     Response action: COMPRESS  Hits: 1
     Bytes In:...4325  Bytes Out:.... 1530
     Bandwidth saving...64.62%  Ratio 2.83:1
  2) Name: ns_cmp_msapp Rule: (ns_msie && ns_msword || (ns_msexcel || ns_msppt))
     Response action: COMPRESS  Hits: 7
     Bytes In:....796160  Bytes Out:... 197730
     Bandwidth saving...75.16%  Ratio 4.03:1
  3) Name: ns_cmp_mscss Rule: (ns_msie && ns_css)
     Response action: COMPRESS  Hits: 0
  4) Name: ns_nocmp_mozilla_47 Rule: (ns_mozilla_47 && ns_css)
     Response action: NOCOMPRESS  Hits: 0

Done

You can also view an individual cmp policy by giving the cmp policy name as an argument:
> show cmp policy ns_cmp_msapp
  Name: ns_cmp_msapp Rule: (ns_msie && ns_msword || (ns_msexcel || ns_msppt))
  Response action: COMPRESS  Hits: 7
  Bytes In:....796160  Bytes Out:... 197730
  Bandwidth saving...75.16%  Ratio 4.03:1

Done
stat cmp policy

Synopsis

stat cmp policy [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display cmp policy statistics.

Parameters

name

The name of the compress policy for which statistics will be displayed. If not given statistics are shown for all compress policies.

Example

stat cmp policy

rename cmp policy

Synopsis

rename cmp policy <name>@ <newName>@

Description

Rename a cmp policy.

Parameters

name

The name of the cmp policy.

newName

The new name of the cmp policy.

Example
rename cmp policy oldname newname

Top
cmp policylabel

[ add | rm | bind | unbind | show | stat | rename ]

add cmp policylabel

Synopsis
add cmp policylabel <labelName> -type ( REQ | RES )

Description
Create a HTTP compression policy label.

Parameters

labelName
The name of the HTTP compression policy label to be created.

type
Specifies when policies bound to this policy label will be evaluated. Possible values: REQ, RES

Example

add cmp policylabel cmp_pol_label -type REQ

Top

rm cmp policylabel

Synopsis
rm cmp policylabel <labelName>

Description
Remove a HTTP compression policy label.
Parameters

**labelName**

The name of the HTTP compression policy label to be removed.

Example

```bash
rm cmp policylabel cmp_pol_label
```

#### bind cmp policylabel

**Synopsis**

```bash
bind cmp policylabel <labelName> -policyName <string> -priority <positive_integer> [-gotoPriorityExpression <expression>] [-invoke (<labelType> <labelName>)]
```

**Description**

Bind an ADVANCED HTTP compression policy to a HTTP compression policy label.

**Parameters**

- **labelName**
  
  Name of the HTTP compression policy label.

- **policyName**
  
  The HTTP compression policy name.

Example

```bash
bind cmp policylabel cmp_pol_label -policyName cmp_pol -priority 1
```

#### unbind cmp policylabel

**Synopsis**

```bash
unbind cmp policylabel <labelName> <policyName> [-priority <positive_integer>]
```
cmp policylabel

Description
Unbind an ADVANCED HTTP compression policy from a HTTP compression policy label.

Parameters

  labelName
  
  Name of the HTTP compression policy label.

  policyName
  
  The HTTP compression policy name.

  priority
  
  Priority of the NOPOLICY to be unbound. Minimum value: 1 Maximum value: 2147483647

Example

unbind cmp policylabel cmp_pol_label cmp_pol

Top

show cmp policylabel

Synopsis

  show cmp policylabel [<labelName>]

Description

Display all HTTP compression policy labels or all policies bound to a HTTP compression policy label.

Parameters

  labelName
  
  The name of the HTTP compression policy label.

Example

i)  show cmp policylabel cmp_pol_label
    ii) show cmp policylabel

Top
**stat cmp policylabel**

**Synopsis**

stat cmp policylabel [<labelName>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

**Description**

Display statistics of cmp policylabel(s).

**Parameters**

- **labelName**
  
  The name of the compress policy label for which statistics will be displayed. If not given statistics are shown for all compress policylabels.

**rename cmp policylabel**

**Synopsis**

rename cmp policylabel <labelName>@ <newName>@

**Description**

Rename a cmp policy label.

**Parameters**

- **labelName**
  
  The name of the cmp policylabel.

- **newName**
  
  The new name of the cmp policylabel.

**Example**

rename cmp policylabel oldname newname
cmp stats

show cmp stats

Synopsis

    show cmp stats - alias for 'stat cmp'

Description

    show cmp stats is an alias for stat cmp
cmp global

[ bind | unbind | show ]

bind cmp global

Synopsis

bind cmp global <policyName> [-priority <positive_integer>] [-state ( ENABLED | DISABLED )] [-gotoPriorityExpression <expression>] [-type <type>] [-invoke (<labelType> <labelName>)]

Description

Activate the compression policy globally. Note that for compression feature to work, a compression license is required. To activate the compression feature, use the "enable ns feature cmp" command. When you enable the compression feature, all of the built-in compression policies are bound globally.

Parameters

policyName

The name of the HTTP compression policy.

Example

add cmp policy pdf_cmp -rule "RES.HTTP.HEADER Content-Type CONTAINS application/pdf" -resAction COMPRESS

After creating the above compression policy, you must activate it by binding it globally:
bind cmp global pdf_cmp

After binding pdf_cmp compression policy globally, the policy gets activated and the NetScaler system will perform compression for the pdf files.

To view the globally active compression policies, enter the following command:

> show cmp global
    5 Globally Active Compression Policies:
1) Policy Name: ns_cmp_content_type     Priority: 0
2) Policy Name: ns_nocmp_mozilla_47     Priority: 0
3) Policy Name: ns_cmp_mscss            Priority: 0
4) Policy Name: ns_cmp_msapp            Priority: 0
5) Policy Name: pdf_cmp                 Priority: 0

Done

Top
unbind cmp global

Synopsis

unbind cmp global <policyName> [-type <type> [-priority <positive_integer>]]

Description

Deactivate a globally bound HTTP compression policy.

Parameters

policyName

The name of the globally bound HTTP compression policy to be deactivated.

Example

To view the globally active compression policies, enter the following command:
> show cmp global
  5 Globally Active Compression Policies:
  1) Policy Name: ns_cmp_content_type    Priority: 0
  2) Policy Name: ns_nocmp_mozilla_47    Priority: 0
  3) Policy Name: ns_cmp_mscss       Priority: 0
  4) Policy Name: ns_cmp_msapp       Priority: 0
  5) Policy Name: pdf_cmp    Priority: 0
Done

To deactivate this globally active compression policy on the NetScaler system, enter the following command:
unbind cmp global pdf_cmp

show cmp global

Synopsis

show cmp global [-type <type>]

Description

Display the globally bound HTTP compression policies.

Parameters

type
cmp global

The bindpoint to which the policy is bound. Possible values: REQ_OVERRIDE, REQ_DEFAULT, RES_OVERRIDE, RES_DEFAULT

Example

> show cmp global
   4 Globally Active Compression Policies:
   1) Policy Name: ns_cmp_content_type Priority: 0
   2) Policy Name: ns_nocmp_mozilla_47 Priority: 0
   3) Policy Name: ns_cmp_mscss Priority: 0
   4) Policy Name: ns_cmp_msapp Priority: 0
Done

Top
cmp parameter

[ set | unset | show ]

set cmp parameter

Synopsis

set cmp parameter [-cmpLevel <cmpLevel>] [-quantumSize <positive_integer>] [-serverCmp (ON | OFF)] [-minResSize <positive_integer>] [-cmpBypassPct <positive_integer>] [-cmpOnPush (ENABLED | DISABLED)] [-policyType (CLASSIC | ADVANCED)] [-addVaryHeader (ENABLED | DISABLED)] [-externalCache (YES | NO)]

Description

Configurable parameters for compression.

Parameters

cmpLevel

Compression level. Possible values: optimal, bestspeed, bestcompression Default value: NSCMPLVL_OPTIMAL

quantumSize

Minimum amount of data to compress as one unit. Default value: 57344 Minimum value: 8 Maximum value: 63488

serverCmp

Compression at back-end server. Possible values: ON, OFF Default value: ON

heurExpiry

Heuristic basefile expiry. Possible values: ON, OFF Default value: OFF

heurExpiryThres

Threshold compression ratio for heuristic basefile expiry, multiplied by 100. For example, to set the threshold ratio to 1.25, specify 125. Default value: 100 Minimum value: 1 Maximum value: 1000

heurExpiryHistWt

For heuristic basefile expiry, weightage to be given to historical delta compression ratio, specified as percentage. For example, to give 25% weightage to historical ratio (and
therefore 75% weightage to the ratio for current delta compression transaction), specify 25. Default value: 50 Minimum value: 1 Maximum value: 100

**minResSize**

Size of the smallest HTTP response that will be compressed.

**cmpBypassPct**

CPU usage (%) at which NetScaler should start progressively bypassing compression on HTTP requests. Default value: 100 Maximum value: 100

**cmpOnPush**

Enable/disable compression on PUSH packet Possible values: ENABLED, DISABLED Default value: DISABLED

**policyType**

The type of the HTTP compression global policy bindings to be used for virtual servers that have no HTTP compression policies bound. Possible values: CLASSIC, ADVANCED Default value: NS_EXPR_TYPE_CLASSIC

**addVaryHeader**

Enable/disable vary header insertion during compression for HTTP/1.1 client. Possible values: ENABLED, DISABLED Default value: DISABLED

**externalCache**

Enable insertion of Cache-Control: private response directive to indicate response message is intended for a single user and must not be cached by a shared or proxy cache. Possible values: YES, NO Default value: NO

**Example**

set cmp param -cmpLevel bestspeed -quantumSize 20480

**unset cmp parameter**

**Synopsis**

**Description**

Use this command to remove cmp parameter settings. Refer to the set cmp parameter command for meanings of the arguments.
show cmp parameter

Synopsis

show cmp parameter

Description

Display configurable parameters for compression.
Cache Redirection Commands

This group of commands can be used to perform operations on the following entities:

- `cr policy`
- `cr vserver`
**cr policy**

[ add | rm | set | show ]

**add cr policy**

**Synopsis**

```
add cr policy <policyName> -rule <expression>
```

**Description**

Add a cache redirection policy. To associate the policy created with a cache redirection virtual server, use the `###bind cr vserver####` command.

**Parameters**

- **policyName**
  
  The name of the cache redirection policy.

- **rule**
  
  A condition defined by an expression. When the condition is valid, the request is directed to the origin server. Expression logic is: expression names, separated by the logical operators `||` and `&&`, and possibly grouped using parenthesis. Note: If the expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following are valid expressions:

  ```
  l ns_ext_cgi || ns_ext_asp 2 ns_non_get &&
  (ns_header_cookie || ns_headerPragma)
  ```

**Top**

**rm cr policy**

**Synopsis**

```
rm cr policy <policyName>
```

**Description**

Remove a Cache Redirection policy. You can delete a user-defined cache redirection policy that is not bound to a cache redirection virtual server. If the policy is bound to a virtual server, you must first unbind the policy, and then remove it from the system.
set cr policy

Synopsis

set cr policy <policyName> -rule <expression>

Description

Changes the rule for a cache redirection policy.

Parameters

policyName

The name of the cache redirection policy.

rule

The condition defined by an expression. When the condition is valid, the request is directed to the origin server. Expression logic is: expression names, separated by the logical operators || and &&, and possibly grouped using parenthesis. Note: If the expression contains blanks (for example, between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following are valid expressions: l ns_ext_cgi | ns_ext_asp 2 ns_non_get && (ns_header_cookie | ns_headerPragma)
**show cr policy**

**Synopsis**

```
show cr policy [<policyName>]
```

**Description**

Display all existing cache redirection policies.

**Parameters**

- **policyName**

  The name of the cache redirection policy.

*Top*
cr vserver

[ add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename ]

add cr vserver

Synopsis
add cr vserver <name> <serviceType> [<IPAddress> <port> [-range <positive_integer>]] [-cacheType <cacheType>] [-redirect <redirect>] [-onPolicyMatch ( CACHE | ORIGIN )] [-redirectURL <URL>] [-cltTimeout <secs>] [-precedence ( RULE | URL )] [-arp ( ON | OFF )] [-map ( ON | OFF )] [-format ( ON | OFF )] [-via ( ON | OFF )] [-dnsVserverName <string>] [-destinationVServer <string>] [-domain <string>] [-soPersistenceTimeout <positive_integer>] [-soThreshold <positive_integer>] [-reuse ( ON | OFF )] [-state ( ENABLED | DISABLED )] [-downStateFlush ( ENABLED | DISABLED )] [-backupVServer <string>] [-disablePrimaryOnDown ( ENABLED | DISABLED )] [-l2Conn ( ON | OFF )] [-Listenpolicy <expression>] [-Listenpriority <positive_integer>] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-srcIPExpr <expression>] [-originUSIP ( ON | OFF )] [-usePortRange ( ON | OFF )] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>] [-icmpVsrResponse ( PASSIVE | ACTIVE )]

Description
Add a cache redirection virtual server.

Parameters
name

Name of the cache redirection virtual server.

serviceType

The type of service handled by the virtual server. Note: Use service type HTTP to configure content switching on this virtual server. Possible values: HTTP, SSL, NNTP.

IPAddress

The IP address of the cache redirection virtual server. 1. To specify a specific virtual server address, type its numeric value. 2. To specify a wildcard virtual server address, type an asterisk (*).

cacheType

The supported cache server type. Note: For this command to work, you must select one of the cache types. Possible values: TRANSPARENT, REVERSE, FORWARD Default value: CRD_TRANSPARENT
redirect

The redirect policy. The valid redirect policies are: 1. CACHE - Directs all requests to the cache. 2. POLICY - Applies the cache redirection policy to determine whether the request should be directed to the cache or to the origin. This is the default setting. 3. ORIGIN - Directs all requests to the origin server. Possible values: CACHE, POLICY, ORIGIN Default value: CRD_POLICY

onPolicyMatch

Decide where to redirect the requests if the cache redirection policy is hit. The valid options are: 1. CACHE - Directs all the requests to the cache if cache redirection policy is hit. 2. ORIGIN - Directs all requests to the origing server if the cache redirection policy is hit. Note: For this option to work, you must select the cache redirection type as POLICY. Possible values: CACHE, ORIGIN Default value: CRD_ORIGIN

redirectURL

The URL where traffic is redirected if the virtual server in the system becomes unavailable. You can enter up to 127 characters as the URL argument. WARNING! Make sure that the domain you specify in the URL does not match the domain specified in the -d domainName argument of the add cs policy CLI command. If the same domain is specified in both arguments, the request will be continuously redirected to the same unavailable virtual server in the system - then the user may not get the requested content.

cltTimeout

The timeout value in seconds for idle client connection Maximum value: 31536000

precedence

You can use this argument only when configuring content switching on the specified virtual server. This argument applies only if the URL- and RULE-based policies have both been configured on the same virtual server. This argument specifies the type of policy (URL or RULE) that takes precedence on the content switching virtual server. The default setting is RULE. 1 URL - In this case, the incoming request is matched against the URL-based policies before it is matched against the rule-based policies. 1 RULE - In this case, the incoming request is matched against the rule-based policies before it is matched against the URL-based policies. For all URL-based policies, the precedence hierarchy is: 1. Domain and exact URL 2. Domain, prefix and suffix 3. Domain and suffix 4. Domain and prefix 5. Domain only 6. Exact URL 7. Prefix and suffix 8. Suffix only 9. Prefix only 10. Default Possible values: RULE, URL Default value: CS_PRIORITY_RULE

via

Determines whether the system will insert a Via: header in the HTTP requests. Possible values: ON, OFF Default value: ON

cacheVserver

The name of the default target cache virtual server to which requests are redirected.

dnsVserverName
The name of the DNS virtual server used to resolve domain names arriving at the forward proxy virtual server. Note: This parameter applies only to forward proxy virtual servers, not reverse and transparent.

**destinationVServer**

The destination virtual server for a transparent or forward proxy cache redirection virtual server. All requests to the transparent or forward proxy cache redirection virtual server are directed to this destination virtual server.

**domain**

The default domain for reverse proxies. Domains are configured in the system so that they direct an incoming request from a particular configured source domain to a particular configured target domain. There may be several configured pairs of source and target domains. You can select one pair to be the default. Then, if a source domain is not present in the host header or URL of an incoming request, the request will be sent to the target domain of the selected default pair.

**reuse**

Specifies whether TCP connections to cache or origin servers will be reused across client connections. Note: You should include this argument only if the service type argument is set to HTTP. The default setting is ON. If you set this argument to OFF and: -redirect is set to CACHE: TCP connections to the cache servers are not reused. -redirect is set to ORIGIN: TCP connections to the origin servers are not reused. -redirect is set to POLICY: TCP connections to the origin servers are not reused. If you set this argument to ON, connections are reused to both origin and cache servers. Possible values: ON, OFF Default value: ON

**state**

The initial state (enabled or disabled) of the cache redirection virtual server. Possible values: ENABLED, DISABLED Default value: ENABLED

**downStateFlush**

Perform delayed cleanup of connections on this vserver. Possible values: ENABLED, DISABLED Default value: ENABLED

**backupVServer**

The Backup Virtual Server.

**disablePrimaryOnDown**

When this argument is enabled, traffic will continue reaching backup vservers even after primary comes UP from DOWN state. Possible values: ENABLED, DISABLED Default value: DISABLED

**l2Conn**

Use L2 Parameters to identify a connection Possible values: ON, OFF

**Listenpolicy**
Use this parameter to specify the listen policy for CR Vserver. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters. Default value: "none"

Listenpriority

Use this parameter to specify the priority for listen policy of CR Vserver. Default value: 101 Maximum value: 100

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

comment

Comments associated with this virtual server.

srcIPExpr

Use this parameter to specify the expression used to extract the Source IP to be used from the requests coming from the Cache. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters.

originUSIP

For requests going to the Origin specify whether to use the SourceIP or not. Possible values: ON, OFF Default value: OFF

usePortRange

Select the source port for requests going to the origin. Possible values: ON, OFF Default value: OFF

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

netProfile

The name of the network profile.

icmpVsrResponse

Can be active or passive Possible values: PASSIVE, ACTIVE Default value: NS_VSR_PASSIVE
**rm cr vserver**

**Synopsis**
```
rm cr vserver <name>@ ...
```

**Description**
Remove a virtual server.

**Parameters**
- **name**: The name of the virtual server to be removed.

**Example**
```
rm vserver cr_vip
```

**set cr vserver**

**Synopsis**
```
set cr vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-redirect <redirect>] [-onPolicyMatch (CACHE | ORIGIN)] [-precedence (RULE | URL)] [-arp (ON | OFF)] [-via (ON | OFF)] [-dnsVserverName <string>] [-destinationVServer <string>] [-domain <string>] [-reuse (ON | OFF)] [-backupVServer <string>] [-disablePrimaryOnDown (ENABLED | DISABLED)] [-redirectURL <URL>] [-cltTimeout <secs>] [-downStateFlush (ENABLED | DISABLED)] [-l2Conn (ON | OFF)] [-Listenpolicy <expression>] [-Listenpriority <positive_integer>] [-tcpProfileName <string>] [-httpProfileName <string>] [-netProfile <string>] [-comment <string>] [-srcIPExpr <expression>] [-originUSIP (ON | OFF)] [-usePortRange (ON | OFF)] [-appflowLog (ENABLED | DISABLED)] [-icmpVsrResponse (PASSIVE | ACTIVE)]
```

**Description**
Change the attributes of a configured cache redirection vserver.

**Parameters**
- **name**: Name of the cache redirection virtual server.
**IPAddress**

The new IP address of the virtual server.

**redirect**

The redirect policy. Possible values: CACHE, POLICY, ORIGIN Default value: CRD_POLICY

**onPolicyMatch**

Decide where to redirect the requests if the cache redirection policy is hit. The valid options are: 1. CACHE - Directs all the requests to the cache if cache redirection policy is hit. 2. ORIGIN - Directs all requests to the origin server if the cache redirection policy is hit. Note: For this option to work, you must select the cache redirection type as POLICY. Possible values: CACHE, ORIGIN Default value: CRD_ORIGIN

**precedence**

The type of policy (URL or RULE) that takes precedence on the content redirection virtual server. Possible values: RULE, URL Default value: CS_PRIORITY_RULE

**via**

The state of the system in inserting a Via: header in the HTTP requests. Possible values: ON, OFF Default value: ON

**cacheVserver**

The name of the default target cache virtual server to which requests are to be redirected.

**dnsVserverName**

The name of the DNS virtual server to be used to resolve domain names arriving at the forward proxy virtual server.

**destinationVServer**

The destination virtual server for the transparent or forward proxy cache redirection virtual server.

**domain**

The default domain for reverse proxies.

**reuse**

The state of reuse of TCP connections to the cache or origin servers across client connections. Possible values: ON, OFF Default value: ON

**backupVServer**

The Backup Virtual Server.

**disablePrimaryOnDown**
When this argument is enabled, traffic will continue reaching backup vservers even after primary comes UP from DOWN state. Possible values: ENABLED, DISABLED Default value: DISABLED

**redirectURL**

The redirect URL.

**cltTimeout**

The client timeout value in seconds. Maximum value: 31536000

**downStateFlush**

Perform delayed cleanup of connections on this vserver. Possible values: ENABLED, DISABLED Default value: ENABLED

**l2Conn**

Use L2 Parameters to identify a connection Possible values: ON, OFF

**Listenpolicy**

Use this parameter to specify the listen policy for CR Vserver. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters. Default value: "none"

**Listenpriority**

Use this parameter to specify the priority for listen policy of CR Vserver. Default value: 101 Maximum value: 100

**tcpProfileName**

The name of the TCP profile.

**httpProfileName**

Name of the HTTP profile.

**netProfile**

The name of the network profile.

**comment**

Comments associated with this virtual server.

**srcIPExpr**

Use this parameter to specify the expression used to extract the Source IP to be used from the requests coming from the Cache. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters.

**originUSIP**

For requests going to the Origin specify whether to use the SourceIP or not. Possible values: ON, OFF Default value: OFF

**usePortRange**

Select the source port for requests going to the origin. Possible values: ON, OFF Default value: OFF

**appflowLog**

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

**icmpVsrResponse**

Can be active or passive Possible values: PASSIVE, ACTIVE Default value: NS_VSR_PASSIVE

### unset cr vserver ###

**Synopsis**

```bash
unset cr vserver <name> [-dnsVserverName] [-destinationVServer] [-domain]
[-srcIPExpr] [-tcpProfileName] [-httpProfileName] [-appflowLog] [-netProfile]
```

**Description**

Unset the attributes of the configured cache redirection virtual server. To set the cache redirection virtual server attributes, you can use either the `###add cr vserver###` or the `###set cr vserver###` command. Refer to the set cr vserver command for meanings of the arguments.

### bind cr vserver ###

**Synopsis**

```bash
bind cr vserver <name> [-lbvserver <string> | (-policyName <string> [-priority
<positive_integer>]}) | <targetVserver>]
```

**Description**

For the system's cache redirection feature, this command binds the cache redirection policy to the cache redirection virtual server.
Parameters

name

The name of the cache redirection virtual server to which the cache redirection policy will be bound.

lbvserver

The virtual server name (created with the add lb vserver command) to which content will be switched.

policyName

The name of the cache redirection policy. This policy must be of the type map or cache redirection policy (created using the ###add policy map### or ###add cr policy### commands).

unbind cr vserver

Synopsis

unbind cr vserver <name> [-policyName <string> | -lbvserver <string>]

Description

This command unbinds a cache redirection policy from a cache redirection virtual server.

Parameters

name

The name of the cache redirection virtual server from which to unbind the policy.

policyName

The name of the policy (previously created using the ###add cr policy### or ###add policy map### command).

lbvserver

The virtual server name (created with the add lb vserver command) to which content will be switched. Default value: “default_lb”
enable cr vserver

Synopsis
   enable cr vserver <name>@

Description
   Enable a virtual server. Note: Virtual servers, when added, are enabled by default.

Parameters
   name
      The name of the virtual server to be enabled.

Example
   enable vserver cr_vip

   Top

disable cr vserver

Synopsis
   disable cr vserver <name>@

Description
   Disables a virtual server (takes it out of service).

Parameters
   name
      The name of the virtual server to be disabled. Notes: 1. The system still responds to ARP
      and/or ping requests for the IP address of this virtual server. 2. Because the virtual
      server is still configured in the system, you can enable the virtual server using the
      enable vserver command.

Example
   disable vserver cr_vip

   Top
show cr vserver

Synopsis
   show cr vserver [<name>]

Description
   Display a specified cache redirection virtual server, or all configured cache redirection
to virtual servers.

Parameters
   name
       The name of the cache redirection virtual server.

stat cr vserver

Synopsis
   stat cr vserver [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile
   <input_filename>]

Description
   Display cache redirection vserver statistics.

Parameters
   name
       The name of the vserver for which statistics will be displayed. If not given statistics are
       shown for all cr vservers.

rename cr vserver

Synopsis
   rename cr vserver <name>@ <newName>@
Description
Rename a cache redirection virtual server.

Parameters

name
The name of the content switching virtual server.

newName
The new name of the virtual server.

Example

rename cr vserver vscr1 vscrnew

Top
Content Switching Commands

This group of commands can be used to perform operations on the following entities:

- `cs policy`
- `cs policylabel`
- `cs vserver`
- `cs parameter`
- `cs action`
cs policy

[ add | rm | set | unset | show ]

add cs policy

Synopsis
add cs policy <policyName> [-url <string> | -rule <expression> | -action <string>] [-domain <string>]

Description
Add a content switching policy. The policy created can be associated with a content switching virtual server using the bind cs vserver CLI command

Parameters
policyName
The name of the new content switching policy.
url
The URL, with wildcards. Specify the string value in this format: // [[prefix ] [*]] [.suffix]
rule
The condition for applying this policy. Expression logic is as follows: - Expression names separated by the logical operators || and &&. - Expression names may be grouped using parenthesis. - If the expression contains blanks (e.g., between an expression name and a logical operator), then the entire argument must be enclosed in double quotes. The following example shows valid expression logic: ns_ext_cgi || ns_ext_asp "ns_non_get & & (ns_header_cookie | ns_header pragma)"

domain
The domain name. The string value can range to 63 characters.

action
Content switching action to be used by the policy.

Example
To match the requests that have URL "/", you would enter the following command:
add cs policy <policyName> -url /
To match with all URLs that start with "/sports/", you would enter the following command:
add cs policy <policyName> -url /sports/*
To match requests with URLs that start with "/sports", you would enter the following command:
add cs policy <policyName> -url /sports*
To match requests with the URL "/sports/tennis/index.html", you would enter the following command:
add cs policy <policyName> -url /sports/tennis/index.html
To match requests that have URLs with the extension "jsp", you would enter the following command:
add cs policy <policyName> -url /*.jsp
To match requests with URLs that start with "/sports/" and the file extension "jsp", you would enter the following command:
add cs policy <policyName> -url /sports/* .jsp
To match requests with URLs that contain "sports", you would enter the following commands:
add pol expression sports_url "URL contains sports"
add cs policy <policyName> -rule sports_url
To match requests with URL queries that contain "gold" or cookie headers that contain "gold", you would enter the following commands:
add pol expression gold_query "URLQUERY contains gold"
add pol expression gold_cookie "Header COOKIE contains gold"
add cs policy <policyName> -rule "(gold_query || gold_cookie)"
To match requests with the domain name www.domainxyz.com, you enter the following command:
add cs policy <policyName> -domain "www.domainxyz.com"
To match requests with the domain name www.domainxyz.com and URLs with the extension "jsp", you would enter the following command:
add cs policy <policyName> -url /*.jsp -domain "www.domainxyz.com"
To match requests with the domain name www.domainxyz.com and URLs that contain "sports", you would enter the following command:
add cs policy <policyName> -rule sports_url -domain "www.domainxyz.com"
To match a policy with a rule and provide action:
add cs policy <policyname> -rule "http.req.method.eq(GET)" -action act1

Top

rm cs policy

Synopsis

rm cs policy <policyName>

Description

Remove the specified content switching policy. Note: The policy must be unbound from the content switching virtual server before it is removed.

Parameters

policyName

The name of the content switching policy to be removed.

Top
set cs policy

Synopsis

    set cs policy <policyName> [-url <string> | -rule <expression>] [-domain <string>] [-action <string>]

Description

    Change a previously configured content switching policy.

Parameters

    policyName

        Name of the policy.

    url

        The URL, with wildcards.

    rule

        The condition for applying this policy.

    domain

        The domain name.

    action

        The content switching action name.

unset cs policy

Synopsis

    unset cs policy <policyName> [-url] [-rule] [-domain] [-action]

Description

    Use this command to remove cs policy settings. Refer to the set cs policy command for meanings of the arguments.
show cs policy

Synopsis

    show cs policy [<policyName>]

Description

Display all of the content switching policies.

Parameters

    policyName

    The name of the policy to be displayed. If no name is given then all policies will be displayed.

Top
add cs policylabel

Synopsis
add cs policylabel <labelName> <cspolicylabeltype>

Description
Add a content switching policy label.

Parameters

- **labelName**
  
  Name of the content switching policy label.

- **cspolicylabeltype**
  
  The type of the policy label. Possible values: HTTP, TCP, RTSP, SSL, SSL_TCP, UDP, DNS, SIP_UDP, ANY, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, SSL_DIAMETER

Example

add cs policylabel trans_http_url HTTP

rm cs policylabel

Synopsis
rm cs policylabel <labelName>

Description
Remove a content switching policy label.
Parameters

labelName

Name of the content switching policy label.

Example

rm cs policylabel trans_http_url

Top

bind cs policylabel

Synopsis

bind cs policylabel <labelName> <policyName> <priority> [-targetVserver <string> | 
-gotoPriorityExpression <expression> | (-invoke (<labelType> <labelName>) ) ]

Description

Bind the content switching policy to one of the labels.

Parameters

labelName

Name of the content switching policy label.

policyName

Name of the policy to be bound to content switching policy label.

priority

Priority with which the policy is to be bound. Minimum value: 1 Maximum value:
2147483647

targetVserver

The virtual server name (created with the add lb vserver command) to which content will
be switched.

gotoPriorityExpression

Expression specifying the priority of the next policy which will get evaluated if the
current policy rule evaluates to TRUE. o If gotoPriorityExpression is not present or if it is
equal to END then the policy bank evaluation ends here o Else if the
gotoPriorityExpression is equal to NEXT then the next policy in the priority order is
evaluated. t o Else gotoPriorityExpression is evaluated. The result of
gotoPriorityExpression (which has to be a number) is processed as follows: - An UNDEF
event is triggered if . gotoPriorityExpression cannot be evaluated . gotoPriorityExpression evaluates to number which is smaller than the maximum priority in the policy bank but is not same as any policy's priority . gotoPriorityExpression evaluates to a priority that is smaller than the current policy's priority - If the gotoPriorityExpression evaluates to the priority of the current policy then the next policy in the priority order is evaluated. - If the gotoPriorityExpression evaluates to the priority of a policy further ahead in the list then that policy will be evaluated next.

invoke

Invoke flag.

Example

i)  bind cs policylabel cs_lab pol_cs 2 -targetVserver lb_vs

unbind cs policylabel

Synopsis

unbind cs policylabel <labelName> <policyName>

Description

Unbind entities from content switching label.

Parameters

labelName

Name of the content switching policy label.

policyName

The name of the policy to be unbound.

Example

unbind cs policylabel cs_lab pol_cs
**show cs policylabel**

**Synopsis**  
show cs policylabel [<labelName>]

**Description**  
Display policy label or policies bound to content switching policylabel.

**Parameters**  
**labelName**

Name of the content switching policy label.

**Example**

i) show cs policylabel cs_lab  
i) show cs policylabel

[Top](#)
cs vserver

[ add | rm | set | unset | bind | unbind | enable | disable | show | stat | rename ]

add cs vserver

Synopsis

add cs vserver <name> <serviceType> ((<IPAddress> [-range <positive_integer>]) | (-IPPattern <ippat> -IPMask <ipmask>)) <port> [-state ( ENABLED | DISABLED )] [-stateupdate ( ENABLED | DISABLED )] [-cacheable ( YES | NO )] [-redirectURL <URL>] [-cltTimeout <secs>] [-precedence ( RULE | URL )] [-caseSensitive ( ON | OFF )] [-soMethod <soMethod>] [-soPersistence ( ENABLED | DISABLED )] [-soPersistenceTimeOut <positive_integer>] [-soThreshold <positive_integer>] [ -redirectPortRewrite ( ENABLED | DISABLED )] [-downStateFlush ( ENABLED | DISABLED )] [-backupVServer <string>] [-disablePrimaryOnDown ( ENABLED | DISABLED )] [-insertVserverIPPort <insertVserverIPPort> [ -vipHeader > ] [-rtspNat ( ON | OFF )] [-AuthenticationHost <string>] [-Authentication ( ON | OFF )] [-Listenpriority <positive_integer>] [-authn401 ( ON | OFF )] [-authnVsName <string>] [-push ( ENABLED | DISABLED )] [-pushVserver <string>] [-pushLabel <expression>] [-pushMultiClients ( YES | NO )] [-tcpProfileName <string>] [-httpProfileName <string>] [-comment <string>] [-mssqlServerVersion <mssqlServerVersion>] [-l2Conn ( ON | OFF )] [-mysqlProtocolVersion <positive_integer>] [-mysqlServerVersion <string>] [-mysqlCharacterSet <positive_integer>] [-mysqlServerCapabilities <positive_integer>] [-appflowLog ( ENABLED | DISABLED )] [-netProfile <string>] [-icmpVsrResponse ( PASSIVE | ACTIVE )]

Description

Add a content switching virtual server.

Parameters

name

The content switching virtual server name.

serviceType

The service type of the virtual server. Possible values: HTTP, SSL, TCP, FTP, RTSP, SSL_TCP, UDP, DNS, SIP_UDP, ANY, RADIUS, RDP, MYSQL, MSSQL, DIAMETER, SSL_DIAMETER

IPAddress

The IP address of the virtual server.

IPPattern
The IP Pattern of the virtual server.

range

An IP address range. Default value: 1 Minimum value: 1 Maximum value: 254

port

A port number for the virtual server. Minimum value: 1

state

The initial state, enabled or disabled, of the virtual server. Possible values: ENABLED, DISABLED Default value: ENABLED

stateupdate

To enable the state update for a CSW vserver Possible values: ENABLED, DISABLED Default value: DISABLED

cacheable

Use this option to specify whether a virtual server, used for load balancing or content switching, routes requests to the cache redirection virtual server before sending it to the configured servers. Possible values: YES, NO Default value: NO

redirectURL

The URL where traffic is redirected if the virtual server in the system becomes unavailable. You can enter up to 127 characters as the URL argument. WARNING! Make sure that the domain you specify in the URL does not match the domain specified in the -d domainName argument of the add cs policy CLI command. If the same domain is specified in both arguments, the request will be continuously redirected to the same unavailable virtual server in the system - then the user may not get the requested content.

cltTimeout

The timeout value in seconds for idle client connection Default value: VAL_NOT_SET Maximum value: 31536000

precedence

This sets the precedence between RULE-based and URL-based policies on the content switching virtual server. The default precedence is RULE. With the precedence set to RULE, incoming requests are evaluated against the content switching policies created with the -rule argument (using the add cs policy CLI command). If none of the rules match, the URL in the request is evaluated against the content switching policies created with the -url argument (using the add cs policy CLI command). Possible values: RULE, URL Default value: CS_PRIORITY_RULE

caseSensitive

The URL lookup case option on the content switching vserver. If the case sensitivity of a content switching virtual server is set to 'ON', the URLs /a/1.html and /A/1.HTML are treated differently, and can be switched to different targets with appropriate content.
switching policies. If the case sensitivity is set to 'OFF', the URLs /a/1.html and /A/1.HTML are treated the same, and are switched to the same target. Possible values: ON, OFF Default value: ON

soMethod

The spillover factor based on which the traffic will be given to the backupvserver once the main virtual server reaches the spillover threshold. Possible values: CONNECTION, DYNAMICCONNECTION, BANDWIDTH, HEALTH, NONE

soPersistence

The state of the spillover persistence. Possible values: ENABLED, DISABLED Default value: DISABLED

soThreshold

If the spillover method is set to CONNECTION or DYNAMICCONNECTION, this value is treated as the maximum number of connections a lb vserver will handle before spillover takes place. If the spillover method is set to BANDWIDTH, this value is treated as the amount of incoming and outgoing traffic (in Kbps) a vserver will handle before spillover takes place. Minimum value: 1 Maximum value: 4294967287

redirectPortRewrite

Enable port rewrite while performing HTTP redirect. Possible values: ENABLED, DISABLED Default value: DISABLED

downStateFlush

Perform delayed cleanup of connections on this vserver. Possible values: ENABLED, DISABLED Default value: ENABLED

backupVServer

The backup virtual server for content switching.

disablePrimaryOnDown

When this argument is enabled, traffic will continue reaching backup vservers even after primary comes UP from DOWN state. Possible values: ENABLED, DISABLED Default value: DISABLED

insertVserverIPPort

The virtual IP and port header insertion option for the vserver. VIPADDR - Header contains the vserver's IP address and port number without any translation. OFF - The virtual IP and port header insertion option is disabled. V6TOV4MAPPING - Header contains the mapped IPv4 address corresponding to the IPv6 address of the vserver and the port number. An IPv6 address can be mapped to a user-specified IPv4 address using the set ns ip6 command. Possible values: OFF, VIPADDR, V6TOV4MAPPING

rtspNat

Use this parameter to enable natting for RTSP data connection. Possible values: ON, OFF Default value: OFF
AuthenticationHost
FQDN of authentication vserver

Authentication
This option toggles on or off the application of authentication of incoming users to the vserver. Possible values: ON, OFF Default value: OFF

Listenpolicy
Use this parameter to specify the listen policy for CS Vserver. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters. Default value: "none"

Listenpriority
Use this parameter to specify the priority for listen policy of CS Vserver. Default value: 101 Maximum value: 100

authn401
This option toggles on or off the HTTP 401 response based authentication. Possible values: ON, OFF Default value: OFF

authnVsName
Name of authentication vserver

push
Process traffic on bound Push vserver. Possible values: ENABLED, DISABLED Default value: DISABLED

pushVserver
The lb vserver of type PUSH/SSL_PUSH to which server pushes the updates received on the client facing non-push lb vserver.

pushLabel
Use this parameter to specify the expression to extract the label in response from server. The string can be either a named expression (configured using add policy expression command) or else it can be an in-line expression with a maximum of 63 characters. Default value: "none"

pushMultiClients
Specify if multiple web 2.0 connections from the same client can connect to this vserver and expect updates. Possible values: YES, NO Default value: NO

tcpProfileName
The name of the TCP profile.

httpProfileName
Name of the HTTP profile.

**comment**

Comments associated with this virtual server.

**mssqlServerVersion**

The version of the MSSQL server Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2 Default value: TDS_PROT_2008B

**l2Conn**

Use L2 Parameters to identify a connection Possible values: ON, OFF

**mysqlProtocolVersion**

The protocol version returned by the mysql vserver. Default value: 10

**mysqlServerVersion**

The server version string returned by the mysql vserver. Default value: NSA_MYSQL_SERVER_VER_DEFAULT

**mysqlCharacterSet**

The character set returned by the mysql vserver. Default value: 8

**mysqlServerCapabilities**

The server capabilities returned by the mysql vserver. Default value: 41613

**appflowLog**

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

**netProfile**

The name of the network profile.

**icmpVsrResponse**

Can be active or passive Possible values: PASSIVE, ACTIVE Default value: NS_VSR_PASSIVE

**Example**

1. You can use precedence when certain client attributes (e.g., browser type) require to be served with different content. All other clients can then be served from content distributed among the servers.

   If the precedence is configured as URL, the incoming request URL is evaluated against the content switching policies created with the -rule argument. If any of the policies match, the request is applied against the content any switching policies created with the -rule argument.

2. Precedence can also be used when certain content (such as images) is the same for all clients, but other content (such as text) should be served to specific clients based on attributes such as Accept-Language.

   Top
### cs vserver

**Synopsis**

```
rm cs vserver <name>@ ...
```

**Description**

Remove a virtual server.

**Parameters**

- **name**
  
The name of the virtual server to be removed.

**Example**

```
rm vserver cs_vip
```

### set cs vserver

**Synopsis**

```
```

**Description**

Change the parameters of a content switching virtual server.
Parameters

name

Identifies the virtual server name (created with the add cs vserver command).

IPAddress

The new IP address of the virtual server.

IPPattern

The IP Pattern of the virtual server.

IPMask

The IP Mask of the virtual server IP Pattern

stateupdate

To enable the state update for a CSW vserver Possible values: ENABLED, DISABLED
Default value: DISABLED

precedence

The precedence on the content switching virtual server between rule-based and URL-based policies. The default precedence is set to RULE. If the precedence is configured as RULE, the incoming request is applied against the content switching policies created with the -rule argument. If none of the rules match, then the URL in the request is applied against the content switching policies created with the -url option. For example, this precedence can be used if certain client attributes (such as a specific type of browser) need to be served different content and all other clients can be served from the content distributed among the servers. If the precedence is configured as URL, the incoming request URL is applied against the content switching policies created with the -url option. If none of the policies match, then the request is applied against the content switching policies created with the -rule option. Also, this precedence can be used if some content (such as images) is the same for all clients, but other content (such as text) is different for different clients. In this case, the images will be served to all clients, but the text will be served to specific clients based on specific attributes, such as Accept-Language. Possible values: RULE, URL Default value: CS_PRIORITY_RULE

caseSensitive

The URL lookup case option on the content switching vserver. If case sensitivity of a content switching virtual server is set to 'ON', the URLs /a/1.html and /A/1.HTML are treated differently and may have different targets (set by content switching policies). If case sensitivity is set to 'OFF', the URLs /a/1.html and /A/1.HTML are treated the same, and will be switched to the same target. Possible values: ON, OFF Default value: ON

backupVServer

The backup virtual server for content switching.

redirectURL

The redirect URL for content switching.
cacheable

The option to specify whether a virtual server used for content switching will route requests to the cache redirection virtual server before sending it to the configured servers. Possible values: YES, NO Default value: NO

cltTimeout

Client timeout in seconds. Default value: VAL_NOT_SET Maximum value: 31536000

soMethod

The spillover factor. When traffic on the main virtual server reaches this threshold, additional traffic is sent to the backup vserver. Possible values: CONNECTION, DYNAMICCONNECTION, BANDWIDTH, HEALTH, NONE

soPersistence

The state of the spillover persistence. Possible values: ENABLED, DISABLED Default value: DISABLED

soPersistenceTimeOut

The spillover persistency entry timeout. Default value: 2 Minimum value: 2 Maximum value: 1440

soThreshold

If the spillover method is set to CONNECTION or DYNAMICCONNECTION, this value is treated as the maximum number of connections a lb vserver will handle before spillover takes place. If the spillover method is set to BANDWIDTH, this value is treated as the amount of incoming and outgoing traffic (in Kbps) a vserver will handle before spillover takes place. Minimum value: 1 Maximum value: 4294967287

redirectPortRewrite

SSL redirect port rewrite. Possible values: ENABLED, DISABLED Default value: DISABLED

downStateFlush

Perform delayed clean up of connections on this vserver. Possible values: ENABLED, DISABLED Default value: ENABLED

disablePrimaryOnDown

When this argument is enabled, traffic will continue reaching backup vservers even after primary comes UP from DOWN state. Possible values: ENABLED, DISABLED Default value: DISABLED

insertVserverIPPort

The virtual IP and port header insertion option for the vserver. VIPADDR - Header contains the vserver's IP address and port number without any translation. OFF - The virtual IP and port header insertion option is disabled. V6TOV4MAPPING - Header contains the mapped IPv4 address that corresponds to the IPv6 address of the vserver and the port number. An IPv6 address can be mapped to a user-specified IPv4 address using the set ns
ip6 command. Possible values: OFF, VIPADDR, V6TOV4MAPPING

rtspNat

Use this parameter to enable natting for RTSP data connection. Possible values: ON, OFF Default value: OFF

Authentication

AuthenticationHost

FQDN of authentication vserver

Authentication

This option toggles on or off the application of authentication of incoming users to the vserver. Possible values: ON, OFF Default value: OFF

Listenpolicy

Use this parameter to specify the listen policy for CS Vserver. The string can be either an existing expression name (configured using add policy expression command) or else it can be an in-line expression with a maximum of 1499 characters. Default value: "none"

Listenpriority

Use this parameter to specify the priority for listen policy of CS Vserver. Default value: 101 Maximum value: 100

authn401

This option toggles on or off the HTTP 401 response based authentication. Possible values: ON, OFF Default value: OFF

authnVsName

Name of authentication vserver

push

Process traffic on bound Push vserver. Possible values: ENABLED, DISABLED Default value: DISABLED

pushVserver

The lb vserver of type PUSH/SSL_PUSH to which server pushes the updates received on the client facing non-push lb vserver.

pushLabel

Use this parameter to specify the expression to extract the label in response from server. The string can be either a named expression (configured using add policy expression command) or else it can be an in-line expression with a maximum of 63 characters. Default value: "none"

pushMultiClients
Specify if multiple web 2.0 connections from the same client can connect to this vserver and expect updates. Possible values: YES, NO Default value: NO

tcpProfileName

The name of the TCP profile.

httpProfileName

Name of the HTTP profile.

comment

Comments associated with this virtual server.

l2Conn

Use L2 Parameters to identify a connection Possible values: ON, OFF

mssqlServerVersion

The version of the MSSQL server Possible values: 70, 2000, 2000SP1, 2005, 2008, 2008R2 Default value: TDS_PROT_2008B

mysqlProtocolVersion

The protocol version returned by the mysql vserver. Default value: 10

mysqlServerVersion

The server version string returned by the mysql vserver. Default value: NSA_MYSQL_SERVER_VER_DEFAULT

mysqlCharacterSet

The character set returned by the mysql vserver. Default value: 8

mysqlServerCapabilities

The server capabilities returned by the mysql vserver. Default value: 41613

appflowLog

Enable logging appflow flow information Possible values: ENABLED, DISABLED Default value: ENABLED

netProfile

The name of the network profile.

icmpVsrResponse

Can be active or passive Possible values: PASSIVE, ACTIVE Default value: NS_VSR_PASSIVE

Top
**unset cs vserver**

**Synopsis**

unset cs vserver <name> [-caseSensitive] [-backupVServer] [-cltTimeout] [-redirectURL]
[-AuthenticationHost] [-authnVsName] [-pushVserver] [-pushLabel] [-tcpProfileName]
[-mysqlCharacterSet] [-mysqlServerCapabilities] [-appflowLog] [-netProfile]
[-soPersistenceTimeOut] [-soThreshold] [-redirectPortRewrite] [-downStateFlush]
[-mssqlServerVersion]

**Description**

Unset the parameters of a content switching virtual server. Refer to the set cs vserver
command for meanings of the arguments.

**bind cs vserver**

**Synopsis**

bind cs vserver <name> [-lbvserver <string> | (-policyName <string> [-targetLBVserver
<string>] [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE )] [-invoke (<labelType> <labelName>) ] )]

**Description**

Bind a content switching policy between a content-based virtual server and an
address-based virtual server. You can assign multiple policies to the virtual server pair. Do
not specify the optional policyName when adding a default policy on the content switching
virtual server. When binding policies to the content-based virtual server,
GotoPriorityExpression applies only to content switching policies with advance policy
expression in the rule part. It also applies to application firewall, tranformation, rewrite
and responder policies. Flowtype and invoke apply only to rewrite and responder policies.

**Parameters**

**name**

The virtual server name (created with the add cs vserver or add cr vserver command) for
which the content switching policy will be set.

**lbvserver**
cs vserver

The virtual server name (created with the add lb vserver command) to which content will be switched.

policyName

The content switch policy name (created with the add cs policy command).

targetVserver

The virtual server name (created with the add lb vserver command) to which content will be switched.

Example

i) bind cs vserver csw-vip1 -policyname csw-policy1 -priority 13
ii) bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT
iii) bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression 'HTTP.REQ.HEADER("a").COUNT' -flowtype REQUEST -invoke policylabel label1

unbind cs vserver

Synopsis

unbind cs vserver <name> [(-policyName <string> [-type ( REQUEST | RESPONSE )]) | -lbvserver <string>] [-priority <positive_integer>]

Description

Remove all content switching policies for the specified content switching virtual server. To remove the default policy, do not specify the optional policy name.

Parameters

name

The virtual server name (created with the add cs vserver or add cr vserver command) for which the content switching policy will be set.

policyName

The content switch policy name (created with the add cs policy command).

lbvserver

The virtual server name (created with the add lb vserver command) to which content will be switched. Default value: “default_lb”
**enable cs vserver**

**Synopsis**

`enable cs vserver <name>@`

**Description**

Enable a virtual cs server. Note: Virtual servers, when added, are enabled by default.

**Parameters**

`name`

The name of the virtual server to be enabled.

**Example**

```
enable vserver cs_vip
```

**disable cs vserver**

**Synopsis**

`disable cs vserver <name>@`

**Description**

Disable (makes out of service) a virtual cs server.

**Parameters**

`name`

The name of the virtual server to be disabled.

**Example**

```
disable vserver cs_vip
```
show cs vserver

Synopsis

show cs vserver [<name>] show cs vserver stats - alias for 'stat cs vserver'

Description

Display the list of content switching virtual servers configured in the system. To show the information for a particular virtual server and the content policies bound to that virtual server, enter the name of the content switching virtual server.

Parameters

name

The name of the content switching virtual server.

stat cs vserver

Synopsis

stat cs vserver [<name>] [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display content switch vserver statistics.

Parameters

name

The name of the vserver for which statistics will be displayed. If not given statistics are shown for all cs vservers.

rename cs vserver

Synopsis

rename cs vserver <name>@ <newName>@
**cs vserver**

**Description**

Rename a content virtual server.

**Parameters**

- **name**
  
  The name of the content switching virtual server.

- **newName**
  
  The new name of the virtual server.

**Example**

rename cs vserver cs1 cs2
cs parameter

[ set | unset | show ]

set cs parameter

Synopsis

set cs parameter [-stateupdate ( ENABLED | DISABLED )]

Description

Set a common CS parameter

Parameters

stateupdate

enable/disable state update Possible values: ENABLED, DISABLED Default value: DISABLED

Example

set cs parameter -stateupdate (ENABLED|DISABLED)

Top

unset cs parameter

Synopsis

unset cs parameter -stateupdate

Description

Use this command to remove cs parameter settings. Refer to the set cs parameter command for meanings of the arguments.

Top
show cs parameter

Synopsis
  show cs parameter

Description
  Show CS parameters

Example

  show cs parameter

  Top
cs action

[ add | rm | set | unset | show | rename ]

add cs action

Synopsis

    add cs action <name> (-targetLBVserver <string> | -targetVserverExpr <expression>)
    [-comment <string>]

Description

    add cs action <action name > <target lb vserver>.

Parameters

    name
        Name of the cs action to be added.

    targetLBVserver
        Name of the Target lb vserver.

    targetVserverExpr
        String builder expression which when evaluated, gives the vserver name

    comment
        Comments associated with this cs action.

Example

i) add cs action act1 -targetLBVserver lb1
    ii) add csaction act2 -targetVserverExpr "lb" + CLIENT.IP.DST.GET1'
    iii) add csaction act3 -targetVserverExpr "lb1" + client.tcp.dstport'

Top
**rm cs action**

**Synopsis**

   rm cs action <name>

**Description**

Remove a configured cs action.

**Parameters**

name  
Name of the cs action.

**Example**

rm cs action act_before

**set cs action**

**Synopsis**

   set cs action <name> (-targetLBVserver <string> | -targetVserverExpr <expression>)  
[-comment <string>]

**Description**

Modify a cs action.

**Parameters**

name  
Name of the cs action to be added.

targetLBVserver  
Name of the Target lb vserver.

targetVserverExpr  
String builder expression which when evaluated, gives the vserver name.
cs action

comment

Comments associated with this cs action.

Example

set cs action act1 -targetLBVserver lb2 -comment 'for url'

unset cs action

Synopsis

unset cs action <name> -comment

Description

Use this command to remove cs action settings. Refer to the set cs action command for meanings of the arguments.

show cs action

Synopsis

show cs action [<name>]

Description

Display configured cs action(s).

Parameters

name

Name of the CS action.

Example

show cs action
rename cs action

Synopsis

rename cs action <name>@ <newName>@

Description

Rename a cs action.

Parameters

name

The name of the Content Switching action.

newName

The new name of the Content Switching action.

Example

rename cs action oldname newname
DB Commands

[ add | rm | set | show ]

add db user

Synopsis

add db user <userName> {-password }

Description

Adds a database user. The user name and password that you specify in this command is added to the nsconfig file and used to authenticate the user.

Parameters

userName
The name of the database user. Must be the same as the user name specified in the database.

password
The password for logging on to the database. Must be the same as the password specified in the database.

Example

add db user johndoe -password secret

Top

rm db user

Synopsis

rm db user <userName>

Description

Removes a database user from the NetScaler appliance. Requests from the user are no longer authenticated or routed to the database server.
Parameters
userName
The name of the database user to be removed.

Top

set db user

Synopsis
set db user <userName>

Description
Modifies the parameters for an existing database user. Use this command on the NetScaler if you change user settings in the database.

Parameters
userName
The name of the database user.

password
The database users password. If you use the CLI, you are prompted for this password after specifying the user name.

Example
set db user johndoe
The above command sets the password for johndoe to abcd (Password to be supplied on prompt)

Top

show db user

Synopsis
show db user [<userName>] [-loggedIn]
Description

Displays information about a database user or users. To show all users, do not include a parameter. To display detailed information about one user, specify the users name. You can also show which users are currently logged on.

Parameters

userName

The name of the database user about which to display detailed information. Must be the same as the user name specified in the database.

loggedIn

Display the names of all database users that are logged on to the NetScaler appliance.

Top
DNS Commands

This group of commands can be used to perform operations on the following entities:

- dns
- dns aaaaRec
- dns addRec
- dns txtRec
- dns cnameRec
- dns mxRec
- dns nsRec
- dns ptrRec
- dns srvRec
- dns soaRec
- dns suffix
- dns nameServer
- dns view
- dns policy
- dns zone
- dns key
- dns proxyRecords
- dns records
- dns stats
- dns parameter
- dns policylabel
- dns global
- dns action
- dns nsecRec
DNS Commands
Stat Dns

Synopsis

stat dns [-detail] [-fullValues] [-ntimes <positive_integer>] [-logFile <input_filename>]

Description

Display DNS statistics.
dns aaaaRec

[ add | rm | show ]

add dns aaaaRec

Synopsis
add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]

Description
Add an AAAAA address record for the specified domain name.

Parameters
hostName
The domain name for which the address record is added.

IPv6Address
Specify one or more IP addresses for the domain name.

TTL
Specify the time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Example
add dns aaaaRec www.mynw.com 3::4:5 -ttl 10

rm dns aaaaRec

Synopsis
rm dns aaaaRec <hostName> [<IPv6Address> ...]
**Description**

This command removes the specified IPv6 address from the address record for the given domain name. If IPv6 address is not specified, the entire address record for the given domain name is removed.

**Parameters**

*hostName*

The host name for which the AAAA record is to be removed.

*IPv6Address*

Specify one or more IPv6 addresses for the AAAA record to be removed. If all IPv6 records within a domain are removed, the domain name entry is also removed.

**Example**

```
rm dns aaaarec www.mynw.com
```

**show dns aaaaRec**

**Synopsis**

```
show dns aaaaRec [<hostName> | -type <type>] [<IPv6Address>]
```

**Description**

Show the IPv6 address record for the specified host name. If a host name is not specified, all IPv6 address records are displayed.

**Parameters**

*hostName*

The domain name for which the address record is to be displayed.

*IPv6Address*

Specify one or more IP addresses for the domain name.

*type*

Specify the address record type. The record type can take 3 values: ADNS - If this is specified, all of the authoritative address records will be displayed. PROXY - If this is specified, all of the proxy address records will be displayed. ALL - If this is specified, all of the address records will be displayed. Possible values: ALL, ADNS, PROXY
dns aaaaRec

Top
dns addRec

[ add | rm | show ]

add dns addRec

Synopsis

add dns addRec <hostName> [IP Address] ... [-TTL <secs>]

Description

Add an address record for the specified domain name.

Parameters

hostName

The domain name for which the address record is being added.

IPAddress

One or more IP addresses for the domain name.

TTL

Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Example

Add dns addrec www.mynw.com 65.200.211.139 -ttl 10

Top

rm dns addRec

Synopsis

rm dns addRec <hostName> [IP Address] ...]
**Description**

Remove the specified ipaddress from the address record for the given domain name. If IP address is not specified, the entire address record for the given domain name is removed.

**Parameters**

**hostName**

The host name for which the address record is to be removed.

**IPAddress**

One or more IP addresses for the address record to be removed. If all address records within a domain are removed, the domain name entry is also removed.

**Example**

```
rm dns addrec www.mynw.com
```

**show dns addRec**

**Synopsis**

```
show dns addRec [ <hostName> | -type <type> ]
```

**Description**

Display the address record for the specified host name. If a host name is not specified, all address records are displayed.

**Parameters**

**hostName**

The domain name.

**type**

The address record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative address records will be displayed. PROXY - If this is specified, all of the proxy address records will be displayed. ALL - If this is specified, all of the address records will be displayed. Possible values: ALL, ADNS, PROXY
dns txtRec

[ add | rm | show ]

add dns txtRec

Synopsis

add dns txtRec <domain> <string> ... [-TTL <secs>]

Description

Add an TXT record for the specified domain name.

Parameters

domain

The owner domain name of the TXT record.

string

The text of the txt record. Maximum of 6 strings are allowed.

TTL

Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Example

add dns txtRec spf.m.test. "v=spf1 ip4:1.2.3.0/24 ip4:1.3.4.0/24 ?all"
add dns txtRec comments.m.test. "This is a CHARSTR" "This is another CHARSTR"

Top

rm dns txtRec

Synopsis

rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>@)
**dns txtRec**

**Description**
Remove the given TXT record for the given domain name.

**Parameters**
- **domain**
  The owner domain name of the TXT record.
- **string**
  The text of the txt record. Maximum of 6 strings are allowed.
- **recordId**
  The record identifier of the record to be removed. Minimum value: 1 Maximum value: 65535

**Example**
```
rm dns txtRec spf.m.test. "v=spf1 ip4:1.2.3.0/24 ip4:1.3.4.0/24 ?all"
rm dns txtRec comments.m.test. "This is a CHARSTR" "This is another CHARSTR"
rm dns txtRec comments.m.test. -recordId 1411
```

**show dns txtRec**

**Synopsis**
```
show dns txtRec [<domain> | -type <type>]
```

**Description**
Display the TXT record for the specified domain. If the domain name is not specified, all of the TXT records are displayed.

**Parameters**
- **domain**
  The owner domain name of the TXT record.
- **type**
  The TXT record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative TXT records will be displayed. PROXY - If this is specified, all of the proxy TXT records will be displayed. ALL - If this is specified, all of the TXT records will be displayed. Possible values: ALL, ADNS, PROXY Default value: NSDNS_AUTH_HOST
Example

show dns txtRec spf.m.test.
show dns txtRec

Top
dns cnameRec

[ add | rm | show ]

add dns cnameRec

Synopsis
   add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]

Description
   Add a canonical name record.

Parameters
   aliasName
       Alias name for the specified domain.
   canonicalName
       The domain for which cnamerec is created.
   TTL
       Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Example
   add dns cnameRec www.mynw.org www.mynw.com -ttl 20

Top

rm dns cnameRec

Synopsis
   rm dns cnameRec <aliasName>

Description
   Remove the canonical name record.
show dns cnameRec

Synopsis

show dns cnameRec [<aliasName> | -type <type>]

Description

Display the cname records. If no alias name is specified, all "cname" records are displayed.

Parameters

aliasName

The alias name. If an alias name is not specified, all "cname" records are displayed.

type

The cname record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative cname records will be displayed. PROXY - If this is specified, all of the proxy cname records will be displayed. ALL - If this is specified, all of the cname records will be displayed. Possible values: ALL, ADNS, PROXY Default value: NSDNS_AUTH_HOST

Example

show dns cnameRec www.mynw.org

Top
dns mxRec

[ add | rm | set | unset | show ]

add dns mxRec

Synopsis

add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]

Description

Add the DNS mail exchange (MX) record.

Parameters

  domain
  The domain for which the added MX record is added.

  mx
  The MX record name.

  pref
  The route priority number. Note: A domain name can have multiple mail routes, with a priority number assigned to each. The mail route with the lowest number identifies the server responsible for the domain. Other mail servers listed are used as backups.
  Maximum value: 65535

  TTL
  Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

rm dns mxRec

Synopsis

rm dns mxRec <domain> <mx>
remove the DNS mail exchange record.

**Parameters**

- **domain**
  - The domain for the mail exchange record to be removed.
- **mx**
  - The mail exchange record name.

**set dns mxRec**

**Synopsis**

```
set dns mxRec <domain> -mx <string> [-pref <positive_integer>] [-TTL <secs>]
```

**Description**

Set the DNS MX (mail exchange) record parameters.

**Parameters**

- **domain**
  - The domain to be associated with the MX record.
- **mx**
  - The name of the MX record.
- **pref**
  - The priority number of the domain's mail route. Because one domain name can have multiple mail routes, you must specify a priority number for each domain's route. The mail route with the lowest number identifies the server responsible for the domain. Other mail servers listed are used as backups. Maximum value: 65535
- **TTL**
  - The time to live, in seconds. Default value: 3600 Maximum value: 2147483647
**unset dns mxRec**

**Synopsis**

```bash
unset dns mxRec <domain> -mx <string> -TTL
```

**Description**

Use this command to remove dns mxRec settings. Refer to the set dns mxRec command for meanings of the arguments.

**show dns mxRec**

**Synopsis**

```bash
show dns mxRec [ <domain> | -type <type> ]
```

**Description**

Display the mail exchange (MX) record for the specified domain. If a domain name is not specified, all mail exchange records are displayed.

**Parameters**

- **domain**
  
  The domain name.

- **type**
  
  The MX record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative MX records will be displayed. PROXY - If this is specified, all of the proxy MX records will be displayed. ALL - If this is specified, all of the MX records will be displayed. Possible values: ALL, ADNS, PROXY Default value: NSDNS_AUTH_HOST
dns nsRec

[ add | rm | show ]

add dns nsRec

Synopsis

    add dns nsRec <domain> <nameServer> [-TTL <secs>]

Description

Add the name server record for a given domain name.

Parameters

domain

    The domain name for which a name server record is added.

nameServer

    The nameserver for the domain.

TTL

    Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Top

rm dns nsRec

Synopsis

    rm dns nsRec <domain> <nameServer>

Description

Remove the name server record for a domain.

Parameters

domain
show dns nsRec

Synopsis
show dns nsRec [<domain> | -type <type>]

Description
Display the name server record for a domain. If no domain name is specified, all of the name server records are displayed.

Parameters

domain
The domain name for the name server record.

type
The name server record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative name server records will be displayed. PROXY - If this is specified, all of the proxy name server records will be displayed. ALL - If this is specified, all of the name server records will be displayed. Possible values: ALL, ADNS, PROXY
dns ptrRec

[ add | rm | show ]

add dns ptrRec

Synopsis

add dns ptrRec <reverseDomain> <domain> ... [-TTL <secs>]

Description

Add a PTR record for the specified reverse domain name.

Parameters

reverseDomain

Reverse domain name with suffixes, e.g.: in-addr.arpa. or ip6.arpa..

domain

The domain name for which reverse mapping is being done.

TTL

Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

Example

add dns ptrrec 1.1.1.in-addr.arpa. abc.com

rm dns ptrRec

Synopsis

rm dns ptrRec <reverseDomain> [<domain> ...]

Description

Remove a PTR record corresponding to a given reverse domain name and domain name.
Parameters

reverseDomain

The reverse domain name of the PTR record being removed.

domain

The domain name whose reverse mapping is being removed.

Example

rm dns ptrrec 1.1.1.1.in-addr.arpa. ptr.com

show dns ptrRec

Synopsis

show dns ptrRec [<reverseDomain> | -type <type>]

Description

Display the PTR record for the specified reverse domain name and domain name.

Parameters

reverseDomain

The reverse domain name of the PTR record being displayed.

type

PTR record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative ptr records will be displayed. PROXY - If this is specified, all of the proxy ptr records will be displayed. ALL - If this is specified, all of the ptr records will be displayed. Possible values: ALL, ADNS, PROXY
dns srvRec

[ add | rm | set | unset | show ]

add dns srvRec

Synopsis

add dns srvRec <domain> <target> -priority <positive_integer> -weight <positive_integer> -port <positive_integer> [-TTL <secs>]

Description

Add an SRV record for the specified domain name.

Parameters

  domain

    The domain name that is offering the services. The domain name includes the service offered and transport layer protocol, e.g.: _ftp._tcp.abc.com.

  target

    The target host that is hosting the specified service.

  priority

    The target host priority. This helps in server selection by the client. Maximum value: 65535

  weight

    Weight for the target host. This helps in server selection by the client in case of same priority Maximum value: 65535

  port

    Port on which the target host is listening for client requests. Maximum value: 65535

  TTL

    The time to live, measured in seconds. Default value: 3600 Maximum value: 2147483647
**rm dns srvRec**

**Synopsis**

rm dns srvRec <domain> <target> ...

**Description**

Remove the SRV record for a given domain name and target.

**Parameters**

- **domain**
  The domain name of the SRV record to be removed.
- **target**
  The target host that is hosting the service to be removed.

**set dns srvRec**

**Synopsis**

set dns srvRec <domain> <target> [-priority <positive_integer>] [-weight <positive_integer>] [-port <positive_integer>] [-TTL <secs>]

**Description**

Set the SRV record attributes.

**Parameters**

- **domain**
  The domain name for which the service is configured.
- **target**
  The target host that is hosting the service whose attributes are to be changed
- **priority**
  Priority of the target host. This helps in server selection by the client. Maximum value: 65535
weight
Weight for the target host. This helps in server selection by the client in case of same
priority Maximum value: 65535

port
Port on which the target host is listening for client requests. Maximum value: 65535

TTL
The time to live, measured in seconds. Default value: 3600 Maximum value: 2147483647

unset dns srvRec

Synopsis
unset dns srvRec <domain> <target> -TTL

Description
Use this command to remove dns srvRec settings. Refer to the set dns srvRec command for
meanings of the arguments.

show dns srvRec

Synopsis
show dns srvRec [(<domain> [<target>]) | -type <type>]

Description
Display the SRV record for the specified domain. If the domain name is not specified, all of
the SRV records are displayed.

Parameters

domain
The domain name for which the SRV record will be displayed.

target
The target host that is hosting the service whose attributes are to be displayed
type

SRV record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative SRV records will be displayed. PROXY - If this is specified, all of the proxy SRV records will be displayed. ALL - If this is specified, all of the SRV records will be displayed. Possible values: ALL, ADNS, PROXY
dns soaRec

[ add | rm | set | unset | show ]

add dns soaRec

Synopsis

Description

Add the Start of Authority (SOA) record.

Parameters

domain

The domain name for which the SOA record is added.

originServer

The name of the origin server for the given domain.

contact

The contact person for this ADNS. Typically this is an email address for which the at sign (@) has been replaced by a period (.).

serial

The secondary server uses this parameter to determine if it requires a zone transfer from the primary server. If the secondary server's number is lower than the primary's, the secondary server knows that its records are out of date. This parameter is not used by a primary server. Default value: 100 Maximum value: 4294967294

refresh

The number of seconds between a successful serial number check on the primary server's zone, and the next attempt. It is usually 2-24 hours. This value is not used by a primary server. Default value: 3600 Maximum value: 4294967294

retry
When a refresh attempt fails, a server will retry after the specified number of seconds. This parameter is not used by a primary server. Default value: 3 Maximum value: 4294967294

expire

Measured in seconds. If the refresh and retry attempts fail after the specified number of seconds, the server will stop serving the zone. The typical value is 1 week. This parameter is not used by a primary server. Default value: 3600 Maximum value: 4294967294

minimum

The default TTL for every record in the zone. You can override this value for a particular record. Typical values range from eight hours to four days. This value is often set at ten minutes or less when changes are being made to a zone. Default value: 5 Maximum value: 2147483647

TTL

The time to live, in seconds. Default value: 3600 Maximum value: 2147483647

rm dns soaRec

Synopsis

rm dns soaRec <domain>

Description

Remove the Start of Authority (SOA) record for a given domain name.

Parameters

domain

The domain name for the SOA record to be removed.

set dns soaRec

Synopsis

**Description**
Set the DNS Start Of Authority (SOA) record attributes.

**Parameters**

**domain**
The domain name for which the SOA record attributes are set.

**originServer**
The origin server name for the given domain.

**contact**
The contact person for this ADNS. Typically it is the email address, with the at sign (@) replaced by a period (.).

**serial**
The secondary server number. This number is used by a secondary server to determine if it requires a zone transfer from the primary server. If the secondary server's number is lower than the primary's, the secondary server determines that its records are out of date. This parameter is not used by a primary server. Default value: 100 Minimum value: 1 Maximum value: 4294967294

**refresh**
The refresh time in seconds. Refresh determines the number of seconds between a successful check on the serial number on the zone of the primary, and the next attempt (usually 2-24 hours). This parameter is used by a primary server. Default value: 3600 Maximum value: 4294967294

**retry**
The retry time in seconds. If a refresh attempt fails, a server will retry after the specified number of seconds. Not used by a primary server. Default value: 3 Maximum value: 4294967294

**expire**
The expire time in seconds. If the refresh and retry attempts fail after the specified number of seconds, the server will stop serving the zone. The typical value is 1 week. Not used by a primary server. Default value: 3600 Maximum value: 4294967294

**minimum**
The default TTL for every record in the zone. You can override this value for a specific record. Typical values range from eight hours to four days. This value is often set to 10 minutes or less when changes are being made to a zone. Default value: 5 Maximum value: 2147483647

**TTL**
The time to live, measured in seconds. Default value: 3600 Maximum value: 2147483647

**unset dns soaRec**

**Synopsis**
```
```

**Description**
Use this command to remove dns soaRec settings. Refer to the set dns soaRec command for meanings of the arguments.

**show dns soaRec**

**Synopsis**
```
show dns soaRec [<domain> | -type <type>]
```

**Description**
Display the specified Start of Authority record. If the domain name is not specified, all of the SOA records are displayed.

**Parameters**

- **domain**
  The domain name.

- **type**
  The SOA record type. The type can take 3 values: ADNS - If this is specified, all of the authoritative SOA records will be displayed. PROXY - If this is specified, all the proxy SOA records will be displayed. ALL - If this is specified, all the SOA records will be displayed.
  Possible values: ALL, ADNS, PROXY
dns suffix

[ add | rm | show ]

add dns suffix

Synopsis
add dns suffix <dnsSuffix>

Description
Append suffixes while resolving the domain names.

Parameters
dnsSuffix
   Suffix to be appended while resolving the domain name.

Example

add dns suffix netscaler.com
   If the incoming domain name "engineering" is not resolved by itself, the system will append the suffix netscaler.com and attempt to resolve the name engineering.netscaler.com.

rm dns suffix

Synopsis
rm dns suffix <dnsSuffix>

Description
Remove the DNS suffixes.

Parameters
dnsSuffix
show dns suffix

Synopsis

    show dns suffix [ <dnsSuffix> ]

Description

    Display all the configured DNS suffixes.

Parameters

    dnsSuffix

    Suffix to be appended while resolving the domain name.
dns nameServer

[ add | rm | enable | disable | show ]

add dns nameServer

Synopsis

add dns nameServer ((<IP> [-local]) | <dnsVserverName>) [-state ( ENABLED | DISABLED )] [-type <type>]

Description

Add a name server. Two types of name servers can be added: 1. IP Address-based name server. In this case, the user must specify the IP address of the name server to be contacted. 2. Vserver-based name server. In this case, the user must specify the name of the DNS vserver configured in the System.

Parameters

IP

The IP address of the name server.

dnsVserverName

The name of the dns vserver

local

IP is a local recursive nameserver.

state

The administrative state of the nameserver. Possible values: ENABLED, DISABLED Default value: ENABLED

type

The protocol type of the name server. While adding a vserver-based name server UDP_TCP is not a valid type. Possible values: UDP, TCP, UDP_TCP Default value: NSA_UDP

Example
Adding an-IP based nameserver IP:
   add nameserver 10.102.4.1,
Adding a vserver-based name server:
   add nameserver dns_vsvr
where dns_vsvr is the name of a DNS vserver created in the system.

rm dns nameServer

Synopsis
   rm dns nameServer (<IP> | <dnsVserverName>)

Description
   Remove the NameServer.

Parameters
   IP
   The IP address of the name server.
   dnsVserverName
   The name of the dns vserver.

Example
   Deleting an IP-based nameserver:
      rm nameserver 10.102.4.1,
   Deleting a vserver-based nameserver:
      rm nameserver dns_vsvr

enable dns nameServer

Synopsis
   enable dns nameServer (<IP> | <dnsVserverName>)

Description
   Enable a nameserver.
**Parameters**

**IP**

The IP address of the name server.

**dnsVserverName**

The name of the dns vserver.

**Example**

```
enable dns nameserver 10.14.43.149
```

**disable dns nameServer**

**Synopsis**

```
disable dns nameServer (<IP> | <dnsVserverName>)
```

**Description**

Disable a nameserver.

**Parameters**

**IP**

The IP address of the name server.

**dnsVserverName**

The name of the dns vserver

**Example**

```
disable dns nameserver 10.14.43.149
```

**show dns nameServer**

**Synopsis**

```
show dns nameServer [<IP> | <dnsVserverName>]
```
**Description**
Display the name servers configured in the system and the state of the name servers.

**Parameters**

**IP**
The IP address of the name server.

**dnsVserverName**
The name of the dns vserver.

**Top**
dns view

[ add | rm | show ]

add dns view

Synopsis

add dns view <viewName>

Description

Adds a dns view, used for dns view-based policies and for binding a view-specific IP for a gslb service.

Parameters

viewName

Name of the view name.

Example

add dns view privateview

Top

rm dns view

Synopsis

rm dns view <viewName>

Description

Removes a dns view that is used for dns view-based policies, and for binding a view-specific IP for a gslb service.

Parameters

viewName
**show dns view**

**Synopsis**

```
show dns view [\<viewName\>]
```

**Description**

Displays the dns views configured in the system.

**Parameters**

`viewName`

The name of the view to be displayed.
dns policy

[ add | rm | set | show ]

add dns policy

Synopsis
add dns policy <name> <rule> <actionName>

Description
Add a dns policy. DNS policies that can be added are Interface, IP, VLAN expressions.

Parameters
name
Name of the dns policy.

rule
Expression to be used by the dns policy.

viewName
The view name that must be used for the given policy.

preferredLocation
The location used for the given policy. This is deprecated attribute. Please use -prefLocList

preferredLocList
The location list in priority order used for the given policy.

drop
The dns packet must be dropped. Possible values: YES, NO

cacheBypass
By pass dns cache for this. Possible values: YES, NO

actionName
Name of the dns action added using add dns action command.

Example

add dns policy pol1 "dns.req.question.type.ne(aaaa)" -actionName act1
add dns policy pol2 "CLIENT.IP.SRC.IN_SUBNET(1.1.1.1/24)" -actionName action1
add dns policy pol1 dns.res.question.domain.contains("citrix") -actionName act2

```
Top
```

**rm dns policy**

**Synopsis**

rm dns policy <name>

**Description**

Removes a dns policy.

**Parameters**

- name
  
  Name of the dns policy.

```
Top
```

**set dns policy**

**Synopsis**

set dns policy <name> [<rule>] [-actionName <string>]

**Description**

Used to change the expression or action of an already existing policy. DNS policies that can be set are Interface, IP, VLAN expressions.

**Parameters**

- name
  
  Name of the dns policy.

- rule
Expression to be used by dns policy.

**viewName**

The view name that must be used for the given policy

**preferredLocation**

The location used for the given policy. This is deprecated attribute. Please use -prefLocList

**preferredLocList**

The location list in priority order used for the given policy.

**drop**

The dns packet must be dropped. Possible values: YES, NO

**cacheBypass**

By pass dns cache for this. Possible values: YES, NO

**actionName**

Name of the dns action added using add dns action command.

**Example**

```
set dns policy pol1 -rule "dns.req.question.type.ne(aaaa)"
set dns policy pol2 -rule "CLIENT.IP.SRC.IN_SUBNET(1.1.1.1/24)"
set dns policy pol1 -rule dns.res.header.rcode.eq(nxdomain)
```

**show dns policy**

**Synopsis**

```
show dns policy [<name>]
```

**Description**

Used to display the policy-related information.

**Parameters**

**name**

Name of the dns policy.
dns policy
dns zone

[ add | set | unset | rm | sign | unsign | show ]

add dns zone

Synopsis
add dns zone <zoneName> -proxyMode ( YES | NO )

Description
Add a DNS zone on NetScaler

Parameters
zoneName
The name of the zone being added.
proxyMode
zone deployed in proxy mode. Possible values: YES, NO Default value: ENABLED

Example
add dns zone foo.bar -proxyMode NO -dnssec ENABLED

Top

set dns zone

Synopsis
set dns zone <zoneName> [-proxyMode ( YES | NO )]

Description
set a DNS zone parameters on NetScaler
Parameters

zoneName

The name of the zone being added.

proxyMode

zone deployed in proxy mode. Possible values: YES, NO Default value: ENABLED

Example

set dns zone foo.bar -proxyMode NO -dnssec ENABLED

unset dns zone

Synopsis

unset dns zone <zoneName> -proxyMode

Description

Use this command to remove dns zone settings. Refer to the set dns zone command for meanings of the arguments.

rm dns zone

Synopsis

rm dns zone <zoneName>

Description

Remove the ZONE record for a given zone name.

Parameters

zoneName

The name of the zone to be removed.
sign dns zone

Synopsis
   sign dns zone <zoneName> [-keyName <string> ...]

Description
   sign a dns zone with the given key

Parameters
   zoneName
       The name of the zone being signed.
   keyName
       The name given to a public/private key pair.

Example

unsign dns zone

Synopsis
   unsign dns zone <zoneName> [-keyName <string> ...]

Description
   Unsign a zone with the specified key

Parameters
   zoneName
       The name of the zone being signed.
   keyName
       The name given to a public/private key pair.

Example
show dns zone

Synopsis

show dns zone [<zoneName> | -type <type>]

Description

Show a DNS zone on NetScaler

Parameters

zoneName

The name of the zone whose info is to be displayed.

type

Zone type. The type can take 3 values: ADNS - If this is specified, all of the authoritative zones will be displayed. PROXY - If this is specified, all of the proxy zones will be displayed. ALL - If this is specified, all of the zones will be displayed. Possible values: ALL, ADNS, PROXY

Example

show dns zone foo.bar
**dns key**

[ add | create | set | unset | rm | show ]

**add dns key**

**Synopsis**

    add dns key <keyName> <publickey> <privatekey> [-expires <positive Integer> [<units>]]
    [-notificationPeriod <positive Integer> [<units>]] [-TTL <secs>]

**Description**

Add a DNSKEY on NetScaler

**Parameters**

    **keyName**
    The name given to a public/private key pair.

    **publickey**
    File name of the public key to be used for signing zone

    **privatekey**
    File name of the private key to be used for signing zone

    **expires**
    Number of days since signing with a key, when the key expires. Default value: 120
    Minimum value: 1 Maximum value: 32767

    **notificationPeriod**
    Number of days before the expiry of a key, when a notification should be generated.
    Default value: 7 Minimum value: 1 Maximum value: 32767

    **TTL**
    Time to live, in seconds. Default value: 3600 Maximum value: 2147483647

**Example**
add dns key secure.example.zsk -public secure.example-rsasha1-1024.key
-private /nsconfig/dns/secure.example-rsasha1-1024.private

create dns key

Synopsis

create dns key -zoneName <string> -keyType <keyType> -algorithm RSASHA1 -keySize
<positive_integer> -fileNamePrefix <string>

Description

Create a public-private key for dnssec operations.

Parameters

zoneName

The name of the zone for which the key is being added.
