Citrix SCOM Management Pack for Provisioning Services
About Provisioning Services 7.1

May 19, 2015

What's new in Provisioning Services 7.1

- The Provisioning Services Imaging utility (p2pvs.exe) changes to a block-based cloning solution with Volume Shadow Copy Service (VSS). Each local disk partition is cloned separately to the vDisk. If there is a separate "System Reserved" partition on the local disk, it must be included as a source partition. Each destination partition must be equal to or larger than the source partition, regardless of the amount of available free space in the source partition.
- A new RAM write cache option (Cache on device RAM with overflow on hard disk) is available that allows write cache to seamlessly overflow to a differencing disk should RAM cache become full.
- Provisioning Services XenDesktop Setup wizard — Multiple NIC support for XenDesktop Private VM desktops. Using the wizard, Provisioning Services allows you to select the network to associate with the Provisioning Services NIC (NIC 0). The XenDesktop Controller provides the list of associated network resources for host connections. The XenDesktop Setup wizard keeps all the other NICs the same. The only exception to this rule is VMM, where the XenDesktop Setup wizard changes both NIC 1 and NIC 2 if they use the same network.
- Datareader and Datawriter database roles are now configured automatically for the Stream and SOAP Services user account, using the Provisioning Services Configuration wizard.

Citrix recommends that you always use the latest product version. However, the documentation for version 7.1 is valid for users of version 7.0, with the exception of descriptions of any features highlighted in this What's New section. Note also that Provisioning Services 7.0 does not support Windows Server 2012 R2 or Windows 8.1.

Note: You must use the most recent version of the Citrix License server to get the latest features. When upgrading from an existing version of Provisioning Services to the newest version of Provisioning Services, the most recent version of the license server is usually available with the product software. If you do not upgrade to the latest version of the licensing server, the product license will enter the 96 hour grace period.

Known issues and limitations in Provisioning Services

Image Update Management feature
Provisioning Services does not support the use of Microsoft SCCM 2007 packages with SCCM 2012. You must re-develop the packages to be either applications or updates [#335531].

XenApp Platinum Edition upgrade
Following an upgrade to XenApp Platinum Edition to enable platinum features such as PVS, XenDesktop 7 may not be able to use the licenses as expected. This is due to an issue where Studio fails to discover XenApp Platinum licenses. To work around this issue, see http://blogs.citrix.com/?p=174198466.

Windows Defender
To improve performance, disable Windows Defender. Refer to Microsoft documentation for instruction on how to disable Windows Defender. [#423349]

Fixed issues in this release
Provisioning Services 7.x Fixed Issues

Sep 08, 2015
The following issues were fixed in Provisioning Services 7.x:

Provisioning Services 7.6
Provisioning Services 7.1
Provisioning Services 7.0
Provisioning Services 7.6

Compared to: Provisioning Services 7.1

Provisioning Services 7.6 contains all fixes that were included in Provisioning Services 7 and 7.1, plus the following, new fixes:

Console

Server

Target Device

Console Issues

- While starting up, target devices complete two DHCP discovers and requests, once prior to single IO, and once when Windows starts up. Some DHCP solutions that utilize the DHCP client identifier field can identify the two DHCP discovers and requests from a single target device as originating from different devices. As a result, two separate IP addresses are assigned to a single network interface.

With this fix, the updated BDM populates the DHCP client identifier field in the DHCP discovers and requests, allowing these DHCP solutions to correctly assign target devices with the same IP address, prior to single IO and when Windows starts up.

[#LA4837]

- The virtual machine created by using the Streamed VM Setup Wizard from the template on the VMware ESX server might not have the correct boot order. In the BIOS setting, the boot order should be CD-ROM and then Network. Instead, Network is first in the boot order.

[#LA5379]

- The Streamed Virtual Machine Setup Wizard does not honor the template boot properties when creating targets.

To fix this, create the following registry key:

HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\ProvisioningServices
Name: UseTemplateBootOrder
Type: DWORD
Creating virtual machines by using the Provisioning Services XenDesktop Setup Wizard fails on VMware vSphere when vDisk Cache type is set to “Cache on server” or “Cache on the device RAM”.

The Provisioning Services Console might exit unexpectedly when opening the “Site” property.

The Provisioning Services Console might exit unexpectedly when creating a view.

The XenDesktop Setup Wizard fails to create virtual machines by using System Center Virtual Machine Manager (SCVMM) and the template does not have a logical network set. When this occurs, the console log file shows a failure.

When running the XenDesktop Setup Wizard to create virtual machines on XenServer by using a template with an ISO file attached, the provisioned VMs do not have the ISO attached.

The Remote Desktop Services (RDS) catalog provisioned by Provisioning Services contains different properties (Allocation Type: Random, User data: Discard) when compared to the catalogs provisioned by Machine Creation Services (MCS).

In Version 7.1 of Provisioning Services, attempts to set a subnet mask of 0.0.0.0 when configuring bootstrap to use the Gateway/DHCP settings to set the subnet mask value at runtime fail and the following error message appears:

"Invalid Subnet mask."

A newly formatted drive might not be accessible through the vDisk store creation utility when adding a new drive to the Provisioning Server that is later partitioned and formatted. This drive is inaccessible in the vDisk store creator until either an object is created in the drive or the properties of the drive are opened and the Security tab is selected. The issue occurs when using the browse option in the Paths tab.

If a target device has 10 or more operating system available memory areas in the memory map, the device might exit unexpectedly while the Preboot Execution Environment (PXE) starts. The device might also fail with a RAM-cache mode error of “Not enough RAM.”
• The XenDesktop Setup Wizard might not create or start the target virtual machines on the correct home server in XenServer. The issue occurs if the templates specify the second server as the home server in the template properties. If the XenDesktop Setup Wizard is run by using this template, the target device might boot on the first server.

[#LA4756]

• The Citrix PVS Trivial File Transfer Protocol (TFTP) Service and Citrix PVS Two-Stage Boot Service might fail to start when the Provisioning Services Server restarts.

To enable the fix, you must create the following registry keys:

For Citrix PVS TFTP Service:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\BNTFTP\Parameters
Name: InitTimeoutSec
Type: DWORD
Data: 1 to 4 seconds (default is 1 second)
Name: MaxBindRetry
Type: DWORD
Data: 5 to 20 retries (default is 5)

For Citrix PVS Two-Stage Boot Service:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\PVSTSB\Parameters
Name: InitTimeoutSec
Type: DWORD
Data: 1 to 4 seconds (default is 1 second)
Name: MaxBindRetry
Type: DWORD
Data: 5 to 20 retries (default is 5)

[#LA4927]

• If the vDisk and associated files are exported and imported from a store in Farm A to a store in Farm B, the Stream Process (StreamProcess.exe) might query the UNC path of Farm A instead of Farm B while starting a target device from the vDisk in Farm B. As a result, the target device might start slowly.

[#LA4930]

• When checking the replication status of the vDisk for the entire site, servers from the different sites show that the server is not reachable.

[#LA4998]

• If there is more than one login server and the first login server contacted by a target device does not respond, the virtual machine fails to start and becomes unresponsive instead of attempting to contact another login server in the boot strap list. As a result, starting the target device by using the Boot Device Manager (BDM) fails with a “No ARP Reply” message.

[#LA5029]

• When merging vDisks, the absolute path for the virtual hard disk (VHD) and automatic virtual hard disk (AVHD) files might be used first instead of using the relative path. This can cause a merge failure or might result in a corrupted merged disk.
The issue occurs if the absolute path points to a wrong location after moving the vDisk around.

[#LA5316]

- When starting targets from a missing vDisk, the incorrect error message of "vDisk file access permission denied. error: 0x2" appears instead of a "File not found" error.

[#LA5327]

- The Soap Service might exhibit poor performance when accessing the database. The Soap Service must be restarted for the Provisioning Services Console to work. This fix improves performance.

[#LA5418]

- When a Soap Server starts, it might fail to retrieve the domain name associated with the system on which it is running. The issue occurs because the Soap Server starts before all the network interfaces on the system are initialized and the Soap Server fails to contact the domain controller.

[#LA5459]

- The replication status shows that the vDisk is not available on some Provisioning Service until you restart the stream service on the remote servers.

[#LA5514]

- This feature enhancement adds the ability to assign a Personal vDisk (PvD) to a PvD target device.

**Warning**: Unless the vDisk is of the same lineage as the PvD target, the PvD software will erase all data of that PvD target at boot time, resulting in a complete loss of all data on that PvD target. It is your responsibility to ensure that the lineage is correct before assigning the new vDisk to a PvD target.

[#LA5661]

- The Stream Process (StreamProcess.exe) might exit unexpectedly due to the socket error when sending packets.

[#LA5686]

- The Citrix Provisioning Services console shows incorrect vDisk replication status until the StreamService is restarted.

[#LA5762]

- When adding a vDisk on one of two servers in a store with distributed high availability configuration using a local path, the .pvp and .vhd files are created on the other server.

[#LA5775]

- When using the Streamed Virtual Machine Setup Wizard, Provisioning Services can fail when attempting to retrieve template information from the stores of the hosts within a cluster and the following error message appears:

  "Object reference not set to an instance of an object"

[#LA5783]

- When replicating vDisks from one store to another on all Provisioning Servers, the replication status does not appear...
correctly in the logs.

[LA5818]

- Merging vDisk versions fails with the following error message while using Network File System (NFS) storage:

  "There is not enough space on the disk. Error number 0xE0000070."

[LA5906]

- Enabling "Auto Rebalance" to rebalance the target device that has a fixed Subnet Affinity setting might fail to honor the correct Subnet Affinity setting. As a result, target devices are rebalanced to servers that are not in the same subnet.

[LA5917]

- In multi-homed PVS server environments where the management and streaming networks are configured as separate networks, sending a message or a reboot request from the PVS console fails.

[LC0074]

- Microsoft Windows is not activated on the target device after restart if the vDisk is configured to use Microsoft Multiple Activation Key (MAK) licensing.

[LC0079]

- With RAM cache enabled, target devices can fail to start and a BInitializeLibrary error appears.

[LC0179]

- Attempts to merge vDisk might result in a corrupted vDisk.

[LC0239]

- Attempts to use MAK activation for Microsoft Windows can fail and the following error message appears:

  "Confirmation ID not retrieved, check internet access."

The issue occurs in scenarios where Microsoft Office is installed on the vDisk and the record of the Office product exists in the VAMT database. During activation, the Install-VamtproductKey command attempts to install the Windows product key for both Windows and Office and returns the error above. With his fix, there is no more attempt to include Office in the MAK activation.

Note: This fix does not provide support for Microsoft Office MAK. Provisioning Services still does not support MAK for Office. The only supported way of having Office on a PVS image is to use KMS for both Windows and Office.

[LC0277]

Target Device Issues

- With this fix, when the PVS BNISTACK driver sends a heartbeat to the server and receives a socket error, it immediately reconnects.

[LA2651]

- The Provisioning Server's Printer Management feature might fail to remove network printers, while successfully removing
local printers.

When setting the write cache to *target device RAM*, the storage performance of PVS streamed target devices on XenServer can be poor.

To enable the fix, you must create the following registry key:

```plaintext
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\BNIStack\Parameters
Name: WcRamConfiguration
Type: DWORD
Value: 1
```

When launching the Provisioning Services Imaging Wizard and creating a new disk, if the values of the free space are changed without using the AutoFit button, the imaging wizard might miscalculate the capacity size.

The Provisioning Server's Printer Management feature might display all the target devices' printers instead of displaying the specified local printers.

The *Cache on device RAM with overflow on hard disk* setting might fail to obtain the Operating System's memory pool settings for used page. As a result, the cache operation might fail to work as expected.

PVS target devices might experience a fatal exception, displaying a blue screen, on CFsDep2.sys.

If a target device is running a session on a server configured for High Availability, the session might not successfully reconnect during server failover.

This is an enhancement to facilitate NIC teaming with the latest Broadcom NICs used in HP Moonshot systems.

Connection attempts from the target device to a virtual hard disk (VHD), where the icon in the notification area has a red "X" on it, might fail with the following error message: "Bnistack failed to load due to NIC Miniport is not ready."

This fix improves the robustness of the High Availability feature for XenApp 6.5 VMs.

The Provisioning Services server might fail to capture the newly assigned machine account Active Directory password if
the initial password change request to the domain server times out. As a result, targets fail to be able to log on to the domain.

[#LC0078]

- When booting a target device where Update CPVS61020 is installed, the BNDevice.exe process exits unexpectedly.

[#LC0282]

- Attempts to create a VHD by running `p2pvs disk e:\vhd c:` at the command line creates a RAW unpartitioned disk that is not bootable.

[#LC0327]

Provisioning Services 7.1

Compared to: Provisioning Services 7.0

Provisioning Services 7.1 contains all fixes that were included in Provisioning Services 7.0, plus the following, new fixes:

**Console**

**Server**

**Target Device**

Consoles Issues

- In Large Active Directory structures with numerous domains, the console can be slow and on occasion become unresponsive. Specifically, the issue can be seen:

  - When sibling Active Directory domains cannot be contacted
  - When changing the vDisk mode between Standard and Private mode without disabling the KMS licensing mode first
  - After using the XenDesktop wizard

The issue occurs because when a user logs in, the PVS SOAP Server queries all Active Directory groups to which the user belongs in order to establish what permissions the user has. The Active Directory groups are cached and updated every five minutes. The process of caching and updating the groups (updateUserGroupCacheThread) can be time consuming in extensive Active Directory forest structures with numerous domains, and/or when domains cannot be contacted intermittently.

This fix modifies the default behavior so that caching and updating the Active Directory groups is disabled by default. To enable caching and updating, you must set the following registry key:

HKEY_LOCAL_MACHINE\SOFTWARE\Citrix\ProvisioningServices
Name: AutoUpdateUserCache
Type: REG_DWORD
Data: 1 (enable AutoUpdateUserCache); 0 (disable AutoUpdateUserCache)

Note: To enable this fix, you must install both a Server and a Console hotfix that contains Fix #LA2490.

[#LA2490]

- When using the XenDesktop setup wizard, the Provisioning Services Console might fail to retrieve the template information and the following error message appears:

  "Cannot connect to the hypervisor at <hypervisor location>
  Object reference not set to an instance of an object."

  [#LA3483]

- After installing Hotfix 16 for Provisioning Services 6.1 in environments with multiple VMware ESX data centers, the Streamed VM Setup Wizard enumerates only those clusters/hosts that are located in the default data centers.

  [#LA3600]

- The Provisioning Services Console might exit unexpectedly while exporting a vDisk.

  [#LA4126]

Server Issues

- The Stream Service might fail to restart after the service exits unexpectedly due to hung threads or can experience delays while shutting down.

  [#LA2798]

- Attempts to merge vDisk versions might fail with the following error message:

  "Not enough storage is available to complete this operation. Error number 0xE000000E."

  [#LA2886]

- The StreamProcess might fail to restart properly after the service exits unexpectedly due to a defect with connections to the Provisioning Services database.

  [#LA3018]

- Newly created or imported vDisks might boot only from the PVS server they were created or imported from until the Stream Service on the remaining servers is restarted.

  [#LA3312]

- The replication status might fail to display the remote Provisioning Servers within a farm. This happens when there is a large number of vDisks and versions in a farm with two or more servers.

  [#LA3518]

- After running an automatic update for a vDisk, the Citrix PVS Soap Server service exit unexpectedly, regardless of whether or not the update was successful.

  [#LA3540]
Target devices assigned with multiple virtual hard disks (VHDs) experience a boot delay equal to the amount of time configured under "Login general timeout" rather than booting immediately. This fix enables targets to start immediately after the VHD of choice is selected. To enable this fix, you must:

- Copy the ARDBP32.BIN bootstrap file to the C:\ProgramData\Citrix\Provisioning Services\Tftpboot folder, replacing the original file by the same name.
- Reconfigure your bootstrap configuration as necessary.

**Caution:** Replacing the ARDBP32.BIN bootstrap file as described in Step 1 erases your existing bootstrap configuration. To ensure you have all necessary information available to reconfigure the bootstrap file after replacing it, make note of your existing bootstrap configuration before replacing the file.

[#LA3628]

The StreamProcess can exit unexpectedly at random.

[#LA3740]

The StreamProcess.exe and Notifier.exe processes might fail to restart when a Stream Service keep-alive failure occurs.

[#LA3878]

When using SQL Mirroring for the Provisioning Services farm database, Notifier.exe cannot access the database if the SQL database fails over to the mirror.

[#LA3978]

When using vDisk versioning, the StreamProcess might exit unexpectedly due to a NULL pointer exception.

[#LA4035]

Target devices can unexpectedly fall back to server-side caching, significantly slowing overall performance. The console fails to indicate the issue and continues to show caching to be taking place on the target device.

[#LA4440]

While starting up, target devices complete two DHCP discovers and requests, once prior to single IO, and once when Windows starts up. Some DHCP solutions that utilize the DHCP client identifier field can identify the two DHCP discovers and requests from a single target device as originating from different devices. As a result, two separate IP addresses are assigned to a single network interface.

With this fix, the updated BDM populates the DHCP client identifier field in the DHCP discovers and requests, allowing these DHCP solutions to correctly assign target devices with the same IP address, prior to single IO and when Windows starts up.

[#LA4578]

**Target Device Issues**

- Target devices can randomly become unresponsive with memory dumps indicating that the issue occurs while getting the performance timer.

[#LA2398]
Attempts to BDM boot multiple Windows NT 6 systems using static IP addresses might fail; all systems other than the first might experience a fatal exception, displaying a blue screen with a "duplicate IP address" error message.

To support static IP addresses on a PVS target device using BDM, you must perform the steps described in Knowledge Center article CTX137820.

If you require Fix #LA2479, install it using the pvs_device.exe and pvs_device_x64.exe full installers. Doing so also gives you all other fixes in this hotfix. If you do not require Fix #LA2479, there is no need to use the full installers; use the loose binaries instead.

[#LA2479]

With this fix, the target device reports errors to the Windows system event log when the usage of RAM cache exceeds a set threshold (default 90%). After that warning, every 2% increase in usage triggers the error as well. This error report will also be redirected to the server side "StreamProcess.log" as a warning message if the log is enabled.

To enable the fix, you must create the following registry key:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNIStack\Parameters
Name: WcWarningPercent
Type: DWORD
Value: <threshold of RAM cache usage - default value is 90>

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNIStack\Parameters
Name: WcWarningIncrement
Type: DWORD
Value: <interval of incremental report - default value is 2; 0 to disable the incremental report>

[#LA3382]

This fix addresses an issue with high availability failover that can prevent target devices from failing over to other servers.

[#LA3683]

When target devices use the local disk for the write cache, various errors can occur, including cache malfunctions and cache failover to the server. This logging enhancement allows you to view local disk cache related errors and configuration conditions.

With this enhancement, the detailed "disk/partition qualifying for cache usage" process is reported to the server provided that target debug logging is enabled.

To enable target debug logging, set the logging level to Debug from the logging tab of the target device properties on the PVS console.

[#LA3892]

Provisioning Services 7.0
Active Directory issues

- In large environment, it takes 1-2 hours for AD group enumeration to complete in the console when they try and add groups.
  [From CPVS61E001][#0046851]

- Delay when attempting to add a group to farm administrators group in the PVS console.
  [From CPVS61E001][#0035424]

- When an AD group begins with $ it cannot be added.
  [From CPVS61E001][#0287057]

- Unable to run XDSW as a user from a different domain.
  [From CPVS61E001][#0272660]

- Show ALL domains in domain list.
  [From CPVS61E001][#0284573]

- Mismatch Uppercase and Lowercase Domains cause the display of create AD account OU's dropdown list not consistent.
  [From CPVS61E001][#0289658]

Console Issues

- Merge of vDisk versions fails with message “There is not enough space on the disk Error number 0xE0000070” when NFS storage is used.
  [From CPVS61E002][#0304681]

- XenDeskTop Wizard is slow in obtaining the list of ESX templates.
  [From CPVS61E003][#0308003]

- A delay when attempting to add a group to farm administrators group is experienced in the PVS console.
  [From CPVS61E003][#0035424]

- PVS Console crashes when doing Copy/Paste of server or vdisk properties.
  [From CPVS61E014][#0331252]

- PVS Console does not allow you to alter the vdisk description after the vdisk is created.
  [From CPVS61E014][#0331465]

- In VMware ESX deployments, the XenDesktop Setup wizard can throw an exception, preventing users from setting up templates and machines properly.
  [From PVS610ConsoleWX86016, PVS610ConsoleWX64016][#LA2499]
Selecting the **Streamed image with Personal Vdisk** option of the XenDesktop Setup wizard results in the creation of a fixed disk rather than a dynamic disk.

[From PVS610ConsoleWX86016, PVS610ConsoleWX64016][#LA2501]

Attempts by device administrators to add a disk to a device fail and the following error message appears: "The user does not have sufficient privileges to perform the operation."

To address this issue in its entirety, you must install both a Server and a Console hotfix that contains Fix #LA2756.

[#LA2756]

The console might exit unexpectedly while performing any of the following actions:

- Adding domain groups for administration roles.
- Using the "*" wildcard character to search for domain groups in environments that contain more than 60000 groups.
- Creating or deleting a machine account, or resetting a machine account password.

[#LA3122]

Attempts to sort devices can cause the console to exit unexpectedly.

[#LA3246]

**Server Issues**

- This fix addresses a security vulnerability. For more information, see Knowledge Center article [CTX133039].

[From CPVS61E001][#0267586]

- Cannot stream more than 1000 VM's from a single PVS.

[From CPVS61E001][#0287379]

- StreamProcess randomly restarts if targets reconnect with invalid vdisk ID or as "unknown device" causing multiple "Record was not found" exceptions from DB access.

[From CPVS61E001][#0284386]

- A few VM targets randomly hang at "Write cache is being redirected to the server" message when booting many targets together.

[From CPVS61E001][#0274395]

- When issuing a Boot from the PVS server console the WoL packet is always sent out of the first interface despite what interface may be used for streaming traffic.

[From CPVS61E001][#0287523]

- When target local cache failover to server side causing the "surprise cache write," the existing large server-side cache file should not be truncated.

[From CPVS61E001][#0286780]

- Streamprocess crashes when many targets login and reconnect, causing corruption on the booting target list.
• Target randomly hangs at "No servers available for disk" message when booting many targets together and duplicate login request occurs.

• StreamProcess can't handle "surprise cache READ" from a HA failover target which had local cache failed over to server side.

• "Server did not respond to a request in time" error when attempting to create a vDisk.

• A few VM targets randomly hang at "Write cache is being redirected to the server" message when booting many targets together.

• SCVMM virtual machine deployments have been parallelized to deploy multiple VMs on each selected host concurrently, for both SCVMM 2012 and 2008.

• Streamed VM Wizard also gains the SCVMM parallelization benefits, although to a lesser effect since it can only target a single host.

• WinRM is no longer a requirement for the XenDesktop setup wizard when using SCVMM 2008 or 2012.

• Inventory.exe and Notifier.exe appear to be taking 100% CPU.

• Target rebalancing fails due to DB and Inventory reporting different server entry for a vdisk.

• Booting in a VMware environment can take more than 4 minutes to get past the bootstrap portion of the boot process. This has only been reported using ESX 4.1.

• A few VM targets randomly hang at "Write cache is being redirected to the server" message when booting many targets together.

• Bootstrap does not process ARP reply packet and uses broadcast MAC address for IO request.
When booting target to vdisk, it may randomly hang at "vdisk found", or "Insert system disk", or Windows OS file missing or corrupted error.

When a ERR_SA_EXPIRE license is detected, it's incorrectly treated as the License server is not available, this may cause the PVS Server to enter the licensing grace period. (was hotfix 9, superseded buy 10).

Streamprocess randomly crashes when handling targets login.

When a NAS controller fails or a (temporary) network interruption occurs, target devices can take up to 20 minutes to recover. During that time, the target devices remain unresponsive.

Stopping the license server causes target devices to attempt to fail over after about five minutes, rendering the Stream Service unresponsive in the process.

The Stream Process (StreamProcess.exe) can exit unexpectedly when many target devices reconnect at the same time due to HA failover or rebalancing.

Using Multiple Activation Key (MAK) activation, attempts to activate a target device from the Provisioning Services Console can fail with the following error: "Error IPC ---- Command timeout. Error 0xE0070102." The issue occurs if the local host name of the Provisioning Server contains lowercase letters.

Stopping the Stream Service on a given Provisioning Server can render some target devices connected to that server unresponsive as failover to other servers does not occur.

The StreamProcess can exit unexpectedly at random.

When a NAS controller fails or a (temporary) network interruption occurs, target devices can take up to 20 minutes to recover. During that time, the target devices remain unresponsive.

StreamProcess.exe can exit unexpectedly while handling targets' relogin or service requests.
Attempts by target devices to download the bootstrap file from the server can fail. The issue occurs if the bootstrap file is located in a folder with a four-letter name where the final character is uppercase. In that case, the PVS Configuration Wizard fails to properly pass the folder name to the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNTFTP\Parameters\GetDirectory registry key.

[#LA2967]

The StreamProcess.exe process can exit unexpectedly while it shuts down.

[#LA3136]

Target Device Issues

- Slow shutdown/reboot of target devices with multiple partitions on vDisk for Windows 2003.
  [From CPVS61E001][#0287320]
- Slow shutdown/reboot of target devices with multiple partitions on vDisk for Windows 2008.
  [From CPVS61E001][#0284511]
- Relogin by targets during rebalancing or HA failover is not load balanced across the servers.
  [From CPVS61E001][#0289427]
- Streamed VM's are failing to boot successfully and are getting stuck at a black screen after loading the OS.
  [From CPVS61E001][#0284998]
- bnistack automatically configures the dedicated dump file causing the file to be created on the local drive.
  [From CPVS61E001][#0034058]
- NIC teaming gets broken after installing PVS6.0 target device software.
  [From CPVS61E001][#0283684]
- Windows 7 and Windows 2008 targets do not boot up with the correct subnet mask when using CIDR addressing.
  [From CPVS61E004][#0313632]
- Slow shutdown of the target devices with multiple partitions on Windows 7, Windows Server 2008 or Windows Server 2008 R2 machines.
  [From CPVS61E007][#0284511]
- Targets randomly fail to download the bootstrap file in an environment with possible packet loss.
  [From CPVS61E011][#0322639]
- Target randomly experiences BSOD with socket-open failure error.
  [From CPVS61E013][#0331100]
• Target randomly hangs at getting performance timer count.

[From CPVS61E013][#0322649]

• On x64 OS target devices shut down after 30 minutes while waiting for SCCM 2012 updates.

[From CPVS61E015][#0283754]

• Application packages created for the Image Update Service target devices are not detected by PVS agent and hence not installed.

[From CPVS61E015][#0283755]

• Target devices can randomly become unresponsive during shutdown. Memory dump indicate that the issue occurs while trying to obtain performance counters.

[From PV5610TargetDeviceWX86016, PV5610TargetDeviceWX64016][#LA2463]

• Target devices can become unresponsive or experience a fatal exception, displaying a blue screen. The issue occurs when attempts to open a socket fail because a network interface is not ready or misconfigured. If the defaults provided by this fix do not fully resolve the issue, you can manually configure the number of retries and the delay time by setting the following registry keys:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNIStack\Parameters
Name: SocketOpenRetryLimit
Type: REG_DWORD
Data: <range of 5 (default) to 40>

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNIStack\Parameters
Name: SocketOpenRetryIntervalMS
Type: REG_DWORD
Data: <range of 200 (default) to 2000 (milliseconds)>

[From PV5610TargetDeviceWX86016, PV5610TargetDeviceWX64016][#LA2483]

• When the target device uses the local disk for its write cache and the disk is full, users can experience various application or system errors. The device can become unresponsive, even experience a fatal exception, displaying a blue screen.

[From PV5610TargetDeviceWX86016, PV5610TargetDeviceWX64016][#LA2546]

• When a target is set to use a gateway IP address obtained through DHCP, which is blank by default, the Provisioning Services target device driver overwrites the blank IP address obtained through DHCP with an incorrect entry of “0.0.0.0”. The same incorrect entry is also added to the routing table. As a result, various routing or connection issues for the services and applications hosted by the target device can occur.

[From PV5610TargetDeviceWX86016, PV5610TargetDeviceWX64016][#LA2669]

• Stopping the Stream Service on a given Provisioning Server can render some target devices connected to that server unresponsive as failover to other servers does not occur.

[From PV5610TargetDeviceWX86016, PV5610TargetDeviceWX64016][#LA2812]

• When streaming multiple guests to a XS 6.1 host, Provisioning Services consumes one PVS target license per virtual
machine instead of checking for available XenServer licensing options.

**Note:** To enable this fix in its entirety, you must also install XenServer Hotfix **XS61E010** or its replacement hotfix.

[From PVS610TargetDeviceWX86017, PVS610TargetDeviceWX64017][#LA3362]

- The automatic update feature of Windows Server Update Services (WSUS) might fail to work in Japanese deployments.

[#LA3046]
Provisioning Services Product Overview

Feb 20, 2013

Most enterprises struggle to keep up with the proliferation and management of computers in their environment. Each computer, whether it is a desktop PC, a server in a data center, or a kiosk-type device, must be managed as an individual entity. The benefits of distributed processing come at the cost of distributed management. It costs time and money to set up, update, support and ultimately decommission each computer. The initial cost of the machine is often dwarfed by operational costs.

Provisioning Services takes a very different approach from traditional imaging solutions by fundamentally changing the relationship between hardware and the software that runs on it. By streaming a single shared disk image (vDisk) rather than copying images to individual machines, Provisioning Services enables organizations to reduce the number of disk images that they manage, even as the number of machines continues to grow, simultaneously providing the efficiencies of a centralized management with the benefits of distributed processing.

In addition, because machines are streaming disk data dynamically and in real time from a single shared image, machine image consistency is ensured, while at the same time large pools of machines can completely change their configuration, applications, and even OS in the time it takes them to reboot.

Using Provisioning Services, any vDisk can be configured in Standard Image mode. A vDisk in Standard Image mode allows many computers to boot from it simultaneously; greatly reducing the number of images that must be maintained and the amount of storage that would be required. The vDisk is in read-only format and the image can not be changed by target devices.

Benefits for XenApp and other Server Farm Administrators

If you manage a pool of servers that work as a farm, such as XenApp servers or web servers, maintaining a uniform patch level on your servers can be difficult and time consuming. With traditional imaging solutions you start out with a pristine golden master image, but as soon as a server is built with the master image, you now must patch the individual server along with all of the others. Rolling patches out to individual servers in your farm is not only inefficient, but it can also be unreliable. Patches often fail on an individual server and you may not realize you have a problem until users start complaining or the server has an outage. Once that happens, getting the server back into sync with the rest of the farm can be challenging and sometimes it can require a full re-imaging of the machine.

With Provisioning Services, patch management for server farms is simple and reliable. You start out managing your golden image and you continue to manage that single golden image. All patching is done in one place and then streamed to your servers when they boot-up. Server build consistency is assured because all your servers are using a single shared copy of the disk image. If a server becomes corrupted, simply reboot it and it’s instantly back to the known good state of your master image. Upgrades are extremely fast. Once you have your updated image ready for production you simply assign the new image version to the servers and reboot them. In the time it takes them to reboot you can deploy the new image to any number of servers. Just as importantly, roll-backs can be done in the same manner so problems with new images will not take your servers or your users out of commission for an extended period of time.

Benefits for Desktop Administrators

As part of XenDesktop, desktop administrators have the ability to use Provisioning Services' streaming technology to simplify, consolidate, and reduce the costs of both physical and virtual desktop delivery. Many organizations are beginning to explore desktop virtualization. While virtualization addresses many of the consolidation and simplified management
needs of IT, deploying it also requires deployment of supporting infrastructure. Without Provisioning Services, storage costs can put desktop virtualization out of the budget. With Provisioning Services, IT can reduce the amount of storage required for VDI by as much as 90%. At the same time the ability to manage a single image rather than hundreds or thousands of desktops significantly reduces the cost, effort, and complexity for desktop administration.

Different types of workers across the enterprise need different types of desktops. Some require simplicity and standardization, while others require high performance and personalization. XenDesktop can meet these requirements in a single solution using FlexCast™ delivery technology. With FlexCast™, IT can deliver every type of virtual desktop - each specifically tailored to meet the performance, security and flexibility requirements of each individual user.

Not all desktops applications can be supported by virtual desktops. For these scenarios, IT can still reap the benefits of consolidation and single image management. Desktop images are stored and managed centrally in the datacenter and streamed out to physical desktops on demand. This model works particularly well for standardized desktops such as those in lab and training environments, call centers, and "thin client" devices used to access virtual desktops.

Provisioning Services Solution

Provisioning Services streaming technology allows computers to be provisioned and re-provisioned in real-time from a single shared-disk image. In doing so, administrators can completely eliminate the need to manage and patch individual systems. Instead, all image management is done on the master image. The local hard-disk drive of each system may be used for runtime data caching or, in some scenarios, removed from the system entirely, which reduces power usage, system failure rates, and security risks.

The Provisioning Services solution's infrastructure is based on software-streaming technology. After installing and configuring Provisioning Services components, a vDisk is created from a device's hard drive by taking a snapshot of the OS and application image, and then storing that image as a vDisk file on the network. A device that is used during this process is referred to as a Master target device. The devices that use those vDisks are called target devices.

vDisks can exist on a Provisioning Server, file share, or in larger deployments, on a storage system that the Provisioning Server can communicate with (iSCSI, SAN, NAS, and CIFS). vDisks can be assigned to a single target device as Private Image Mode, or to multiple target devices as Standard Image Mode.

When a target device is turned on, it is set to boot from the network and to communicate with a Provisioning Server. Unlike thin-client technology, processing takes place on the target device (refer to Step 1 in the illustration that follows).

The target device downloads the boot file from a Provisioning Server (refer to Step 2), and then the target device boots. Based on the device boot configuration settings, the appropriate vDisk is located, then mounted on the Provisioning Server (refer to step 3). The software on that vDisk is streamed to the target device as needed. To the target device, it appears like a regular hard drive to the system.

Instead of immediately pulling all the vDisk contents down to the target device (as done with traditional or imaging
deployment solutions), the data is brought across the network in real-time, as needed. This approach allows a target device to get a completely new operating system and set of software in the time it takes to reboot, without requiring a visit to a workstation. This approach dramatically decreases the amount of network bandwidth required by traditional disk imaging tools; making it possible to support a larger number of target devices on your network without impacting overall network performance.

Product Licenses

Product licenses are issued based on the product edition that you choose. For Citrix product licensing documentation, open the Citrix Knowledge Center, then select Licensing under the Knowledge Resources section. For licensing time out conditions, refer to Licensing.
Provisioning Services Product Infrastructure

May 07, 2015

The Provisioning Services infrastructure design directly relates to administrative roles within a Provisioning Services farm. The Provisioning Services administrator role determines which components that administrator can manage or view in the Console.

There are several components that make up a Provisioning Services farm. The graphic that follows provides a high-level view of a basic Provisioning Services infrastructure and illustrates how Provisioning Services components might appear within that implementation.

The sections that follow provide a brief introduction to Provisioning Services components.

License Server

The product license server is installed within the shared infrastructure or an existing Citrix licence server can be selected. Note: The license server is selected when the Configuration Wizard is run on a Provisioning Server. All Provisioning Servers within the farm must be able to communicate with the license server.

Provisioning Services Database

The database stores all system configuration settings that exist within a farm. Only one database can exist within a farm and all Provisioning Servers in that farm must be able to communicate with that database. You may choose to leverage an existing SQL Server database or install SQL Server Express, which is free and available from Microsoft. Note: The database server is selected when the Configuration Wizard is run on a Provisioning Server.

Console

The Console is a utility that is used to manage your Provisioning Services implementation. After logging on to the Console, you select the farm that you want to connect to. Your administrative role determines what you can view in the Console and manage in the farm. Note: The Console is installed as a separate component and is available from the product installation media. The Provisioning Services Console is an MMC (Microsoft Management Console) snap-in. MMC specific console features are not
described in this document. Refer to Microsoft's MMC documentation for detailed information. When the Farm node is expanded at the highest level, the Provisioning Services Console window appears. The Console includes the following:

Action Menu

The Action menu displays Provisioning Services tasks that can be performed on an object that is highlighted in the Console. The same tasks are available when you right-click on the object in the Console.

Tasks are object specific and can only be performed if the user has the appropriate role assigned (role-based administration). Your role determines what displays in the Console. For example, if you are a farm administrator, you can perform all tasks and see all objects in the farm. Device administrators can only perform device-collection management tasks on collections to which they have privileges. Administrator roles are described later in this chapter.

Console Tree and Details Pane

To view information about an object in the Details pane, click on the object or folder in the Tree pane. The Details pane provides information such as the objects name and a description of that object.

Properties Menus

To view or change an object's properties, right-click on the object, then select the Properties menu option. You can also highlight the object in the Console window, then select Properties from the Action menu options. The Properties dialog displays property settings in tabular format.

Network Services

Network services include a DHCP service, Preboot Execution Environment (PXE) service, and a TFTP service. These service options can be used during the boot process to retrieve IP addresses, and locate then download the boot program from the Provisioning Server to the target device. Alternative boot options are also available.

Note: Network services can be installed with the product installation (optional), and then configured when the Configuration Wizard is run. Existing network services within your infrastructure can also be leveraged.

Farms

A farm represents the top level of a Provisioning Services infrastructure. The farm is created when the Configuration Wizard is run on the first Provisioning Server that will be added to that farm. Farms provide a farm administrator with a method for managing all components within the farm, such as:

- Product licensing
- Farm properties
- Administrative roles
- Active Directory configurations
- Provisioning Servers
- vDisk images
- Target devices
- Target device collections
- Sites
- Stores
- Views

Note: All sites within a farm share that farm's Microsoft SQL database. The Console does not need to be directly...
associated with the farm because remote administration is supported on any Console that can communicate with that farm's network.

The Farms hierarchy in the Console consists of the following major components:

- Stores
- Sites
- Views

Stores

A farm contains one or more stores. A store is a logical name that is given to a physical or virtual vDisk storage location. The store name is the common name used by all Provisioning Servers within the farm.

**Example One**

The physical vDisk for Windows XP resides on a Provisioning Server local to a site. The logical name that is given to this physical location is the store.

Store name (logical name): bostonwinxp

Physical path to the vDisk is: C:\vDisks\

**Example Two**

The physical vDisk for Windows XP resides on a network share (FinanceVdisks) at the farm level.

Store name (logical name): financevdisks

Physical path to the vDisk for all Provisioning Servers in the farm is: \\finance\server\financevdisks\

Access or visibility to a store depends on the users administrative privileges:

- Farm administrators have full access to all stores within the farm.
- Site administrators have access to only those stores owned by the site. They can delete stores owned by the site but they can not modify store properties or add vDisks to the store.
- Device administrators and device operators have read-only access and can not view store information. Site administrators may also have read-only access if that store exists at the farm level, or if that store belongs to another site.

Examples of store tasks that a Farm administrator is able to perform includes:

- Configuring store properties
- Creating or importing new vDisks
- Adding new vDisk Versions to the store

Sites

One or more sites can exist within a Farm. The first site is created with the Configuration Wizard is run on the first Provisioning Server in the farm. A site provides both a site administrator and farm administrator, with a method of representing and managing components within a site, which includes:

- Servers
- vDisk Pools
- vDisk Update Management components
- Device Collections
- Views
Hosts

Sites are represented in the Console as follows:

Provisioning Servers

A Provisioning Server is any server that has Stream Services installed, which is used to stream software from vDisks, as needed, to target devices. In some implementations, vDisks reside directly on the Provisioning Server. In larger implementations, Provisioning Servers may get the vDisk from a shared-storage location on the network.

Provisioning Servers also retrieve and provide configuration information to and from the Provisioning Services Database. Provisioning Server configuration options are available to ensure high availability and load-balancing of target device connections.

For Provisioning Server details, refer to Managing Provisioning Servers.

vDisk Pools

vDisk pools are the collection of all vDisks available to a site. There is only one vDisk pool per site.

vDisk Update Management

In the Console, the vDisk Update Management feature is used to configure the automation of vDisk updates using virtual machines. Automated vDisk updates can occur on a scheduled basis, or at any time that the administrator invokes the update directly from the Console. This feature supports updates detected and delivered from Electronic Software Delivery (ESD) servers, Windows updates, or other pushed updates.

When the Site node is expanded in the Console tree, the vDisk Update Management feature appears. When expanded, the vDisk Update Management feature includes the following managed components:

- vDisks
- Tasks

For details on using the vDisk Update Management feature, refer to Automating vDisk Updates.

Device Collections

Device collections provide the ability to create and manage logical groups of target devices. A target device is a device, such as desktop computer or server, that boots and gets software from a vDisk on the network. A device collection could represent a physical location, a subnet range, or a logical grouping of target devices. Creating device collections simplifies device management by performing actions at the collection level rather than at the target-device level.

Note: A target device can only be a member of one device collection. Device collections are created and managed by farm administrators, site administrators that have security privileges to that site, or device administrators that have security privileges to that collection. Device administrators cannot modify the
collection itself; only the devices within it. Device operators can only perform tasks on device collections to which they are assigned.

vDisks

vDisks exist as disk image files on a Provisioning Server or on a shared storage device. A vDisk consists of a VHD base image file, any associated properties files (.pvp), and if applicable, a chain of referenced VHD differencing disks (.avhd).

vDisks are assigned to target devices. Target devices boot from and stream software from an assigned vDisk image.

vDisk Modes

vDisk images are configured to be in Private Image mode (for use by a single device, read/write) or Standard Image mode (for use by multiple devices, read-only with various caching options).

vDisk Chain

Any updates to a vDisk base image may be captured in a versioned differencing disk, leaving the original base disk image unchanged. The following illustrates the basic relationship between a base disk and versions that reference that base disk.

<table>
<thead>
<tr>
<th>VHD Filename</th>
<th>Base Image</th>
<th>win7dev.avhd</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version 1</td>
<td>win7dev.1.avhd</td>
<td></td>
</tr>
<tr>
<td>Version 2</td>
<td>win7dev.2.avhd</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td></td>
</tr>
<tr>
<td>Version N</td>
<td>win7dev.N.avhd</td>
<td></td>
</tr>
</tbody>
</table>

Each time a vDisk is to be updated, a new version of the VHD differencing disk can be created and the file name is numerically incremented, as captured in the table that follows.
Booting a vDisk

The method used to locate and boot from a vDisk on a server share is illustrated in the graphic that follows.

1. The target device begins the boot process by communicating with a Provisioning Server and acquiring a license.
2. The Provisioning Server checks the vDisk pool for vDisk information, which includes identifying the Provisioning Server(s) that can provide the vDisk to the target device and the path information that server should use to get to the vDisk. In this example, the vDisk shows that only one Provisioning Server in this site can provide the target device with the vDisk and that the vDisk physically resides on the Finance Server (shared storage at the farm level).
3. The Provisioning Server locates the vDisk on Finance Server, then streams that vDisk, on demand, to the target device.

Views

Views provide a method that allows you to quickly manage a group of target devices. Views are typically created according to business needs. For example, a view can represent a physical location, such as a building or user type. Unlike device collections, a target device can be a member of any number of views.

Views are represented in the Console as follows:

Note: Farm views can include any target device that exists in this farm. Site views can only include target devices that exist within that site.
Provisioning Services Administrator Roles

Jun 26, 2012

The ability to view and manage objects within a Provisioning Services implementation is determined by the administrative role assigned to a group of users. Provisioning Services makes use of groups that already exist within the network (Windows or Active Directory Groups).

All members within a group share the same administrative privileges within a farm. An administrator may have multiple roles if they belong to more than one group.

Groups are managed at the farm level through the Console’s Farm Properties dialog.

The following roles exist within a Provisioning Services farm:

- **Farm Administrator** – Farm administrators can view and manage all objects within a farm. Farm administrators can also create new sites and manage role memberships throughout the entire farm.

- **Site Administrator** – Site administrators have full management access to the all objects within a site. For example, a site administrator can manage Provisioning Servers, site properties, target devices, device collections, vDisks, vDisk pools, and local vDisk stores. A site administrator can also manage device administrator and device operator memberships.

- **Device Administrator** – Device administrators can perform all device-collection management tasks on collections to which they have privileges, including: view vDisk properties (read-only), assign or remove vDisks from a device, boot or shut down target devices, edit device properties, and send messages to target devices within a device collection to which they have privileges.

- **Device Operator** – Device operators can view target device properties (read-only), boot or shut down target devices, and send messages to target devices within a device collection to which they have privileges.
Product Utilities

Mar 28, 2013

Provisioning Services includes several tools for use when configuring and managing a Provisioning Services deployment. After installing Provisioning Services software, the following tools become available:

- **Installation Wizard** – Use this wizard to install Provisioning Services components to create a Provisioning Servers and Master target devices.
- **Configuration Wizard** – Use this wizard to configure Provisioning-Server components, including network services, and database permissions. This wizard is installed during the Provisioning Services installation process.
- **Imaging Wizard** – On the master target device, run the Provisioning Services Imaging Wizard to create a vDisk file in the Provisioning Services database and then image to that file without having to physically go to a Provisioning Server. This utility is installed during the target device installation process.
- **Virtual Disk Status Tray** – Use this target device utility to get target-device connection status and streaming statistical information. This utility is installed during the Provisioning Services target device installation process.
- **XenDesktop Setup Wizard** – Creates virtual machines (VMs) on a XenDesktop hosted hypervisor server from an existing machine template, creates and associates target devices to those VMs, assigns a vDisk to each target device, then adds all virtual desktops to the XenDesktop catalog.
- **Streamed VM Setup Wizard** – Creates VMs on a hosted hypervisor from an existing machine template, creates and associates target device for each machine within a Collection, then assigns a vDisk image all the VMs.
- **Virtual Host Connection Wizard** – Adds a new virtual host connections to the vDisk Update Manager.
- **Managed vDisk Setup Wizard** – Adds new managed vDisks to the vDisk Update Manager.
- **Update Task Wizard** – Configures a new update task for use with vDisk Update Manager.
- **Boot Device Manager** – Use this utility to configure a boot device, such as a USB or CD-ROM, which then receives the boot program from the Provisioning Services.
- **Upgrade Utilities** – There are several upgrade methods available. The method you select depends on your network requirements.
- **Programming Utilities** – Provisioning Services provides programmers with a management application programming utility and a command line utility. These utilities can be accessed by all users. However, users can only use those commands associated with their administrator privileges. For example, a Device Operator is able to use this utility to get a list of all target devices that they have access to.
Getting the Bootstrap File

Nov 07, 2013

A target device initiates the boot process by first loading a bootstrap program. A bootstrap program is a small program that runs before the operating system is loaded. Provisioning Services uses a special bootstrap program which initializes the streaming session between the target device and the Provisioning Server. After this session starts, the operating system begins to be streamed and loaded from the vDisk that was initiated.

There are three ways that a target device may load the bootstrap program:
- Over the network, via Preboot eXecution Environment (PXE)
- From a boot device stored on attached media
- From a BIOS Embedded bootstrap (OEM versions only)

After the target device's BIOS is configured to allow it to boot from the network, the device can boot and get a vDisk assignment from the Provisioning Server. The target device firmware gets the bootstrap file using standard network protocols.

Note: The device firmware (NIC) must support PXE 0.99j, PXE 2.1 or greater.

Network Booting a Target Device

The DHCP service delivers IP configurations to a target device. It can also deliver the bootstrap file location using options 67 and 60 or 66. Consider delivering the bootstrap file location with a DHCP service to reduce the number of services and increase reliability.

Note: The BOOTP service can deliver IP configuration to a target device according to BOOTP tab. It can also deliver the boot program location using optional fields. Use of this service is no longer typical. Use this service only if DHCP does not meet your requirements.

The PXE service can deliver the bootstrap file location to a target device according to the PXE Specification Version 2.1. Use this service if a DHCP service exists and cannot be changed, and another PXE service is not used.

The TFTP service delivers the bootstrap file to a target device on request. Use it if another TFTP service is not available.

The illustrations and steps that follow, describe the boot process both with and without the use of PXE.

Using DHCP to Retrieve IP Address and Scope Options (Without PXE)

1. When a target device boots from the network, DHCP sends a request to the Provisioning Server for an IP address and Scope Option settings (66 and 67). The Provisioning Server returns the information as requested.
2. Using TFTP, a request for the bootstrap file is sent from the target device to the Provisioning Server. The Provisioning Server downloads the boot file on the target device.
3. The target device boots the assigned vDisk image.

Using DHCP with PXE to Retrieve IP Address and Scope Options

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved. p.35
1. When a target device boots from the network, DHCP sends a request to the Provisioning Server for an IP address and Scope Option settings (option 60; PXEClient identifier). The Provisioning Server returns the information as requested.
2. The target device sends a request to the Provisioning Server for the bootstrap file name and location to the PXE service (options 66 and 67). The PXE service returns the information to the target device.
3. Using TFTP, a request for the bootstrap file is sent from the target device to the Provisioning Server. The Provisioning Server downloads the bootstrap file to the target device and the target device boots.

Booting From an Optional Boot Device

As an alternative to using PXE, the Boot Device Manager (BDM) can create a bootstrap file on a local hard drive, USB flash drive, or ISO image. The bootstrap file will then be used to boot the target device.

Note: The BIOS Embedded Bootstrap boot method also exists to allow OEMs to embed the bootstrap file on the target device.
Selecting a vDisk Access Mode

Dec 08, 2011
The vDisk access mode options include:
- Standard Image Mode
- Private Image Mode

Standard Image Mode

Standard Image mode allows multiple target devices to stream from a single vDisk image at the same time; reducing the amount of vDisk management and reducing storage requirements.

When a vDisk is configured to use Standard Image mode, it is set to read-only mode. Each target device then builds a write cache to store any writes the operating system needs to make. There are several write-cache options available. Because the vDisk is read-only, each time a target device boots, it always boots from a ‘clean’ vDisk. If a machine becomes infected with a virus or spyware, the target device only needs to reboot the image.

When updates are made to a vDisk in Standard Image mode, changes against the base vDisk image are captured in a differencing disk file (.aVHD), resulting in a new version of the base image. Each new version remains directly associated with the base image. Versioning allows for the updates captured in the differencing disk to be staged (Maintenance, Test, Production) before those changes become available to Production devices. If issues are encountered with a version, that version can simply be reverted. For details on versioning, refer to Updating vDisks.

While each target device is using the same vDisk, Provisioning Services personalizes the streamed image for each target device, providing the information needed to ensure the device is uniquely identifiable on the network. In addition, the product provides a mechanism to specify additional personality settings for each device. This feature allows you to store application specific values in the database and retrieve the target device’s unique value as the device loads. For more details, refer to Managing Target Device Personality.

Private Image Mode

A vDisk that is in Private image mode closely models how a computer uses a regular hard drive. That is, only one target device can use a Private Image vDisk at a time.

The following illustrates Private Image vDisks (read/write) that are each assigned to a single Production device, and a Standard Image vDisk (read-only) that is assigned to and shared by a collection of Production devices. For Standard Image vDisks, write cache options include cache on server disk, on a devices hard disk drive, or in the devices RAM.
Selecting the Write Cache Destination for Standard vDisk Images

May 07, 2015
Provisioning Services supports several write cache destination options. The write cache destination for a vDisk is selected on the General tab, which is available from the vDisk File Properties dialog.

Considerations and requirements:

- If selecting cache on local hard drive, ensure that the hard-disk drive is formatted with NTFS for Window devices, with a minimum of 500 MB.
- If selecting cache on the target device RAM and Standard Image mode, the max size of the RAM write cache is determined by the registry setting WcMaxRamCacheMB in the BNIStack Parameters. This is a DWORD parameter. If the registry entry does not exist, then the default value used is 3584 MB.
- Provisioning Services versions prior to 7.1 do not support Microsoft System Center Configuration Manager.
- Provisioning Services 7.x only supports the use of Microsoft System Center Configuration Manager (ConfigMgr) Client as follows:

<table>
<thead>
<tr>
<th>ConfigMgr Client</th>
<th>Cache on server</th>
<th>Cache on server persisted</th>
<th>Cache on device hard drive persisted</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConfigMgr 2007 - all</td>
<td>not supported</td>
<td>not supported</td>
<td>not supported</td>
</tr>
<tr>
<td>ConfigMgr 2012</td>
<td>not supported</td>
<td>not supported</td>
<td>not supported</td>
</tr>
<tr>
<td>ConfigMgr 2012 SP1</td>
<td>not supported</td>
<td>not supported</td>
<td>not supported</td>
</tr>
<tr>
<td>ConfigMgr 2012 R2</td>
<td>not supported</td>
<td>not supported</td>
<td>not supported</td>
</tr>
</tbody>
</table>

The following sections list then describe all valid write cache destination options:

- Cache on device hard drive
- Cache on device hard drive persisted (experimental phase only)
- Cache in device RAM
- Cache in device RAM with overflow on hard disk (only available for Windows 7 and Server 2008 R2 (NT 6.1) and later)
- Cache on a server disk
- Cache on server persisted

Cache on device hard drive

Write cache can exist as a file in NTFS format, located on the target-device's hard drive. This write cache option frees up the Provisioning Server since it does not have to process write requests and does not have the finite limitation of RAM.

The hard drive does not require any additional software to enable this feature.

Note: The write cache file is temporary unless the vDisk mode is set to Private Image mode.

Cache on device hard drive persisted (experimental phase only)

The same as Cache on device hard drive, except cache persists. At this time, this write cache method is an experimental feature only, and is only supported for NT6.1 or later (Windows 7 and Windows 2008 R2 and later). This method also requires a different bootstrap. To select the correct bootstrap from the Console, right-click on the Provisioning Server, select Configure Bootstrap. On the General tab, click on the drop-down Bootstrap file option, then choose CCTXBPB.IN. Citrix highly recommends that the local HDD (client side) drive has enough free space to store the entire vDisk.

Cache in device RAM

Write cache can exist as a temporary file in the target device's RAM. This provides the fastest method of disk access since memory access is always faster than disk access.

Cache in device RAM with overflow on hard disk

This write cache method uses VHDX differencing format and is only available for Windows 7 and Server 2008 R2 (NT 6.1) and later:

- When RAM is zero, the target device write cache is only written to the local disk.
- When RAM is not zero, the target device write cache is written to RAM first. When RAM is full, the least recently used block of data is written to the local differencing disk to accommodate newer data on RAM. The amount of RAM specified is the non-paged kernel memory that the target device will consume.

Compared to “Cache on device hard drive” cache mode, the VHDX block format has a faster file expansion rate. The local disk free space should be reconsidered to accommodate the streaming workload. To ensure target device reliability in high demand workload, Citrix recommends that local disk free space be larger than vDisk capacity size.

When the local disk is out of space, the target device vDisk IO goes in to a pause state waiting for more local disk free space to become available. This condition has a negative impact on workload continuity; thus, Citrix recommends allocating enough local disk free space.

The amount of RAM specified does not change the local disk free space requirement. The more RAM assigned, the more vDisk IOs temporarily saved in RAM cache before all data gets flushed back to the VHDX file. The RAM reduces the initial VHDX expansion rate.

Cache on a server

Write cache can exist as a temporary file on a Provisioning Server. In this configuration, all writes are handled by the
Provisioning Server, which can increase disk IO and network traffic.

For additional security, the Provisioning Server can be configured to encrypt write cache files. Since the write-cache file does exist on the hard drive between reboots, the data will be encrypted in the event a hard drive is stolen.

Cache on server persistent

This cache option allows for the saving of changes between reboots. Using this option, after rebooting, a target device is able to retrieve changes made from previous sessions that differ from the read only vDisk image. If a vDisk is set to Cache on server persistent, each target device that accesses the vDisk automatically has a device-specific, writable disk file created. Any changes made to the vDisk image are written to that file, which is not automatically deleted upon shutdown.

The file name uniquely identifies the target device by including the target device's MAC address and disk identifier. A target device can be assigned to multiple vDisks and therefore have multiple cache files associated to it.

In order to restore a vDisk that uses Cache Persistent on Server, be sure to backup all vDisk files and associated user cache files prior to making any vDisk modifications.

The benefits of using this cache option include:
- Saves target device specific changes that are made to the vDisk image.
- Same benefits as Standard Image Mode.

The drawbacks of using this cache option include:
- The cache file is available so long as the file remains valid. Any changes made to the vDisk force the cache file to be marked invalid. For example, if the vDisk is set to Private Image Mode, all associated cache files are marked invalid.
  Note: Cache files that are marked as invalid are not deleted. Periodically, these files should be manually deleted.

Invalidating changes include:
- Placing a vDisk in Maintenance
- vDisk is placed in Private Image mode
- Mapping the drive from the Console
- Changing the location of the write cache file
- Using Automatic update
Upgrading a Provisioning Services Farm

Mar 26, 2015

Note: Provisioning Services 7.0 supports upgrading from 5.1 SP1, 5.1 SP2, 5.6, 5.6 SP1, 6.x.

Before attempting to upgrade a Provisioning Services farm:

- Select a maintenance window that has the least amount of traffic.
- Backup the Provisioning Services database.
- Backup all vDisks.

Remember: Mirror if you are in a high-availability scenario; for more information, see Database Mirroring. No special action is required during the upgrade once mirroring is set up.

Upgrading from a previous Provisioning Services farm requires completing the following procedures:

1. Upgrade the first Provisioning Server, which upgrades the Provisioning Services database.
2. Upgrade Consoles. The Console is a separate executable that can be installed on upgraded servers (PVS_Console.exe or PVS_Console_64.exe). It is recommended that both Provisioning Services server and console software be upgraded at the same time for each Provisioning Server system in the farm. Remote Consoles can be upgraded at any time.
3. Upgrade the remaining Provisioning Servers within the farm.
4. Upgrade vDisks using the Hyper-V method or the Reverse Imaging method.
   
   Caution: If upgrading a Provisioning Services vDisk within a XenDesktop deployment, the Provisioning Services master target device software must be upgraded before upgrading the XenDesktop VDA software.

Upgrade Utilities

The Upgrade Wizard facilitates the automation of the upgrade process, and includes the following utilities:

- The UpgradeAgent.exe runs on the target device to upgrade previously installed product software.
- The UpgradeManager.exe runs on the Provisioning Server to control the upgrade process on the target device.
Upgrading Provisioning Servers

Nov 24, 2014

In a Provisioning Services farm, the database is upgraded at the same time that the first Provisioning Server is upgraded. After the database and the first server in the farm are upgraded, the remaining servers within the farm can be upgraded. While upgrading the first Provisioning Server, some Administrative features may not be available. Citrix recommends closing all Consoles until the upgrade is complete in order to avoid failed operations.

Note: The Upgrade Wizard must be installed and run in a folder that does not contain surrogate pair characters (Unicode code point after 0x10000).

Upgrading the First Provisioning Server

To upgrade:

1. Uninstall Provisioning Services software from a Provisioning Server in the farm (for details, refer to Uninstalling the Provisioning Services). If uninstalling software prior to 6.x, this step does not automatically uninstall the Console.

2. To upgrade the server and database, run the new version of the server software on the server, then select the "Automatically close and attempt to restart applications" option. If this option is not selected and a "File in use" screen displays, select the "Do not close applications option."

   Note: Alternatively, the database can be upgraded by running the upgrade script, which is produced by the database administrator using DbScript.exe. Running the upgrade script against the database eliminates the need to grant high-level permissions to Provisioning Services Administrators.

3. Install the Console on this server or on a server that will be used to manage the farm (for details on installing the Console, refer to Installing Provisioning Services Server Software).

4. On the Configuration Wizard (if the wizard does not start automatically after completing the product installation, start it now), select the option to join a farm that is already configured. Running the wizard starts the services (for details, refer to the instructions on how to join an existing farm in Configuration Wizard Tasks).

Upgrading Remaining Provisioning Servers in the Farm

Complete the same procedure that was performed on the first server on each of the remaining servers in the farm. Note: The database upgrade is ignored because the database was upgraded when the first server was upgraded.
Upgrading vDisks

Dec 01, 2014

Note: Backup all vDisks before attempting to upgrade to a newer product version.

Upgrading vDisks requires installing the new version of the Provisioning Services target device software on the vDisk image.

The following vDisk upgrade methods are supported:

- Upgrading vDisks using Hyper-V: if upgrading from Provisioning Services 6.x to 7.x, this inline upgrade method is recommended because it is faster than re-imaging, and uses the least amount of storage.
- Upgrading vDisks by Re-imaging: if upgrading vDisks using Hyper-V is not a viable option in your implementation, select from one of the following re-imaging upgrade methods:
  - **Versioned vDisk Upgrade** – If upgrading vDisks from Provisioning Services 6.x to 7.x, use this vDisk upgrade method. This method re-images to a maintenance version of the vDisk, allowing production devices to continue running and booting from the production version of the vDisk. After the upgraded version of the vDisk is promoted to production, target devices will boot or reboot from the upgraded vDisk version.
  - **Automated Inline Upgrade** – if upgrading vDisks from Provisioning Services 5.1.x, 5.6.x, or 6.x to 7.x, use this method if the Upgrading vDisks using Hyper-V or Versioned vDisk Upgrade methods cannot be used. This method uses the Upgrade Wizard and Upgrade Manager to automate some of the steps included in the Manual vDisk Upgrade method.
  - **Manual vDisk Upgrade** – if upgrading from 5.1.x, 5.6.x, or 6.x to 7.x, using this vDisk upgrade is not recommended unless the Upgrading vDisks using Hyper-V or Versioned vDisk Upgrade methods cannot be used, or the Automated Inline Upgrade method fails. It may also be considered if multiple partitions exist on the vDisk and the same system and machine are available for re-imaging (the hard disk drive does not need to be the same).
Upgrading vDisks using Hyper-V

Nov 14, 2014
Before upgrading using Microsoft Hyper-V, review the following requirements:

- General Hyper-V knowledge.
- Hyper-V must be installed (Hyper-V does not need to be installed on the Provisioning Server).
  
  Note: Hyper-V upgrade does not support vDisks using 16 MB block size. When creating new vDisk images, the block size should be 2 MB or greater.

This is the recommended method for upgrading vDisks. This method is faster and uses less storage than methods that require re-imaging.

The procedure that follows describes how to upgrade vDisks using Hyper-V as the mechanism to install new versions of the Provisioning Service drivers and other target device components. Using this method, neither physical media nor imaging and re-imaging is required. This method greatly simplifies the upgrade process and reduces the number of tasks you must complete.

1. On a Hyper-V, un-install previously installed Provisioning Services software.
2. Install the newer version of Provisioning Services software.
3. Copy a newly created VHD file to the Hyper-V server.
   1. Create a new version of the vDisk.
   2. Promote the new version to test mode.
   3. Perform a merge base to test mode.
   4. Copy the VHD from step c to the Hyper-V server
4. Create a new virtual machine in the Hyper-V Manager.
5. During the creation steps, attach the existing newvDisk.vhd instead of using a new VHD.
6. Go into the properties of the newly created Hyper-V virtual machine (Action panel > Settings) and remove the Network adapter. Go to Add Hardware and add the Legacy NIC.
7. Go to the Legacy NIC and attach it to the physical system's NIC.
8. Boot the virtual machine.
9. Let the system install the new drivers, then reboot if prompted.
10. Un-install Provisioning Services target device software, then reboot.
11. Optional: Install Hyper-V's Integration Services. This is only necessary when the resulting VHD must be bootable in both physical and virtual systems. While the virtual machine is on, go to Action, then choose Insert Integration Services set up disk, then install.
12. Install Provisioning Services target device software.
13. Choose to bind Provisioning Services to the inactive NIC (the physical NIC from the original target device). When installing Provisioning Services target device software on NT6.x systems within a multi-NIC environment, all available NICs can be used. Therefore bindcfg.exe is no longer required and no longer installed with target device software (Windows Vista, Windows 2008, Windows 7, Windows 2008 R2, Windows 8, and Windows Server 2012). However, if Provisioning Services detects NT5.x systems (Windows XP or Windows 2003), bindcfg.exe continues to install with the target device product software, which appears during the target device installation process. With NT5.x Windows XP or Windows 2003 systems, if the inactive NIC fails to bind to Provisioning Services, start bindcfg.exe from the Provisioning Services installation directory (default is C:\Program Files\Citrix\Provisioning Services).
14. Shutdown the virtual machine.
15. Go to the virtual machine's properties (Action panel > Settings), then set it to boot to the legacy NIC first.
16. Transfer the VHD (newvDisk.vhd) back to the Provisioning Server.
17. From the Provisioning Service's Console:
   1. Add the VHD to the Provisioning Services database using the Add existing vDisk menu option.
   2. Add the Hyper-V virtual machine to the list of the target devices.
   3. Associate the vDisk with the appropriate target devices.
   4. Set the vDisk to Standard Image Mode
18. Boot the physical target device (assuming this is set to PXE first), then the Hyper-V virtual machine.

   The original vDisk is now upgraded and a common image between the physical and virtual machines has also been created.
Upgrading vDisks by Re-imaging

May 07, 2015

Unlike traditional software packages, target device software cannot be uninstalled while running from a vDisk. It can only be uninstalled while the operating system is running on a physical hard disk so that the vDisk storage and network driver stack can be properly shut down. The re-imaging upgrade method that you choose will depend on your existing Provisioning Services implementation and network requirements.

Versioned vDisk Upgrade

This vDisk upgrade method can be selected when upgrading vDisks from 6.x to the latest version of the target device software. This method re-images to a maintenance version of the vDisk, allowing production devices to continue running and booting from the production version of the vDisk. After the upgraded version of the vDisk is promoted to production, target devices will boot, or reboot, from the upgraded vDisk version.

Upgrade prerequisites include:

- upgrading all Provisioning Servers
- upgrading Provisioning Services Consoles
- creating a backup copy of the vDisk

To upgrade, complete the procedure that follows.

1. Boot the Maintenance device from the managed vDisk while in Maintenance mode.
2. From the product installation directory, run P2PVS.exe to reverse image using volume-to-volume imaging. Select the vDisk as the source and the hard disk drive (HDD) as the destination. If your destination partition is on any partitions other than partition 1, you must edit the boot.ini or bcedit partition settings before rebooting from the HDD.
3. Reboot the Maintenance device from the HDD (do not PXE boot).
4. On the Maintenance device, uninstall 6.x target device software, and then install the latest version of the target device software.
5. Run the Provisioning Services Imaging Wizard to create a new vDisk image, create the target device (if it does not already exist), and assign the vDisk to the target device.
6. Test streaming the new vDisk image by booting a Maintenance or Test device from the upgraded vDisk.

Automated Inline Upgrade

Use the Automated vDisk Upgrade method when upgrading from 5.1.x, 5.6.x, or 6.0 to 6.1, and the Hyper-V upgrade method cannot be used. This upgrade method takes an existing vDisk and converts it to the current product version using the Upgrade Wizard and Upgrade Manager.

Note: Some of the imaging tasks performed during a manual upgrade, are automated by the Upgrade Wizard and Upgrade Manager.

Prerequisites:

- All Provisioning Services Consoles have been upgraded.
- All Provisioning Servers have been upgraded.
- A copy of the vDisk has been created prior to upgrading.

Automated Inline vDisk upgrades require that the vDisk is offline to target devices until the vDisk upgrade completes. To avoid vDisks from being offline, a clone of the vDisk can be created and used for the upgrade process. Then, after the upgrade completes, target devices can be migrated to the upgraded vDisk.

1. On the master target device or maintenance device, depending on the target device platform, run either:
PVS_UpgradeWizard.exe or PVS_UpgradeWizard_x64.exe.

2. Copy UpgradeManager61.exe from the Provisioning Services 6.1 Target Device product installation directory, into the installation directory of the Provisioning Server, which will be specified in Step 4 C. (Default product installation directory is C:\Program Files\Citrix\Provisioning Services).

3. On the Provisioning Server, run UpgradeManager61.exe.

4. On the master target device, run UpgradeConfig.exe from the Windows Start menu shortcut or from the product installation directory.

1. Specify a local account with Administrator privilege to AutoLogon. This local account cannot have an empty password.
2. Specify a local partition to which reverse imaging will clone data. The original hard drive that the vDisk was cloned from is recommended.
   Note: If this is a new hard drive, please use the manual upgrade method to initialize the hard drive.
3. Specify the Provisioning Server IP address and a user account and password to connect to UpgradeManager. This account cannot have an empty password.
4. Click OK.
5. UpgradeConfig performs a sanity check on various parameters. If everything passes, the UpgradeConfig exits, and then reboots the machine to start the upgrade script.
6. The machine will reboot several times, and then display a message to indicate that the script has successfully completed.

Note: The AutoLogon clears when the upgrade completes. If AutoLogon is wanted for vDisk deployment, setup AutoLogon as necessary.

1. Upgrading vDisks Manually

This section describes how to upgrade Provisioning Server vDisks manually.

Use the manual upgrade as a universal approach to upgrading vDisks, or if any of the following are true:

- The vDisk has gone through a number of modifications in Private Image mode
- The original hard drive is no longer available

Some of the imaging tasks performed during a manual upgrade are automated by the Upgrade script that is used in the Automated Upgrade method. The manual upgrade method includes completing the tasks defined in Image Back to Master Target Devices Hard Drive.

Image Back to Master Target Devices Hard Drive

Updated: 2015-05-07

There are two procedures that allow you to image a vDisk back to a hard drive. The procedure you select depends on the state of the disk drive you are imaging to. Select one of the following procedures:

- Image back to the original hard drive from which the vDisk was created
  Use the original hard drive from which the vDisk was created (recommended method).

- Image back using an unformatted, uninitialized hard-disk drive
  Use an unformatted, uninitialized hard-disk drive.

Image Back to the Original Hard Drive from Which the vDisk was Created
1. Boot from the vDisk in Private or Shared Image Mode.
3. In the tree, under Storage, select Disk Management.
4. Note the partition letter of the active partition of the original hard disk. If new, format the disk before continuing.
5. Run the Image Builder utility on the target device. This utility is located at \Program Files\Citrix\Provisioning Services\BNImage.exe
6. Specify the drive letter of the newly created partition (or the original boot HDD partition) as the Destination Drive. The destination drive should point to the vDisk first partition by default.
7. Proceed cloning the hard drive image to the vDisk Destination Drive.
8. To connect the vDisk to the Provisioning Server, from the Console, set the target device to boot from the hard drive, then PXE boot the target device. If this step is not completely properly, the Provisioning Server will not be able to connect with the vDisk.
9. Uninstall the product software (for details, refer to Uninstall Product Software).

Image back using an unformatted, uninitialized hard-disk drive

1. Boot from the vDisk in Private Image Mode.
3. In the tree, under Storage, select Disk Management.
4. Create a new primary partition, as the first partition, assign a drive letter to it, and then format the partition.
5. Right-click on the newly created partition, then choose Mark Partition as Active.
6. Delete the boot.ini/hdisk file from the root of the vDisk.
7. Run the Image Builder utility on the target device. This utility is located at \Program Files\Citrix\Provisioning Services\BNImage.exe.
8. Specify the drive letter of the newly created partition (or the original boot HDD partition) as the Destination Drive. The destination drive should point to the vDisk first partition by default.
9. Proceed cloning the hard drive image to the vDisk Destination Drive.
10. To connect the vDisk to the Provisioning Server, from the Console, set the target device to boot from the hard drive, then PXE boot the target device. If this step is not completely properly, the Provisioning Server will not be able to connect with the vDisk.
11. Uninstall the product software (for details, refer to Uninstall Product Software).

Install Master Target Device Software

Complete the following steps to install the latest product software on the Master Target Device.

1. Run the new Provisioning Server Target Device installer on the target device.
2. PXE boot the target device.

Imaging the Hard Drive

Complete the following steps to image the target device's hard drive on to the vDisk file:

1. Run the Image Builder utility on the target device. This utility is located at \Program Files\Citrix\Provisioning Services\BNImage.exe.
2. Specify the drive letter of the newly created partition (or the original boot HDD partition) as the Destination Drive. The destination drive should point to the vDisk first partition by default.
3. Proceed cloning the hard drive image to the vDisk Destination Drive.

Boot from the vDisk

Using the Console, set the target device on the Provisioning Server to boot from vDisk first, then reboot the target device. The new target device should now be running the new vDisk image.
Installing and Configuring Provisioning Services

May 07, 2015

We recommend that, before installing and configuring Provisioning Services, you first understand the installation wizards that are described here. Then follow the installation and configuration procedures in the rest of this section.

Note: Provisioning Services product software and components are installed from the product CD-ROM or from the product download site.

Installation Wizards and Utilities

Citrix Licensing

CTX_Licensing.msi installs the Citrix licensing software on a server that can communicate with Provisioning Servers within your implementation.

Provisioning Services Installation Wizard

Run PVS_Server.exe or PVS_Server_x64.exe to install the following Provisioning Services components within a farm:

- Provisioning Services Stream Service
- Network Boot Services (optional)
- Configuration Wizard (runs after the installation wizard to configure installed components and creates the Provisioning Services database)
- Programming Utilities
- Boot Device Manager (BDM)

Note: Installing from a UNC path is not supported.

Provisioning Services Console Wizard

Run PVS_Console.exe or PVS_Console_x64.exe to install the Console, which also includes the Boot Device Management utility. The Console can be installed on any machine that can communicate with the Provisioning Services database.

Master Target Device Installation Wizard

For Windows: PVS_Device.exe or PVS_Device_x64.exe

Installs the target device software on a Master Target Device. The Master Target Device is used to create the 'golden image,' which is then saved to a vDisk file using the Imaging Wizard.

Upgrade Wizard

The Upgrade Wizard must be installed and run in a folder that does not contain surrogate pair characters (Unicode code point after 0x10000). The Upgrade Wizard facilitates the automation of the upgrade process, and includes the following utilities:

- The UpgradeAgent.exe runs on the target device to upgrade previously installed product software.
- The UpgradeManager.exe runs on the Provisioning Server to control the upgrade process on the target device.
Requirements for Provisioning Services 7.1

May 19, 2015

The following planning procedures must be completed prior to installing and configuring Provisioning Services.

Note: The Citrix Licensing Server download for this release is included with the installation media. Refer to Citrix License Server documentation for licensing details and requirements. You should always use the most recent Citrix License server to get the latest features.

Select and configure the MS SQL Database

Only one database is associated with a farm. You can choose to install the Provisioning Services database software on:

- An existing SQL database, if that machine can communicate with all Provisioning Servers within the farm
- A new SQL Express database machine, created using the SQL Express software which is free from Microsoft

The following databases can be used for the Provisioning Services database:

Note: For a complete detailed list of supported databases, refer to http://support.citrix.com/article/CTX114501.

In a production environment, best practice is to not install the database and Provisioning Server software on the same server. Also, in some production environments, the database administrator may prefer to create the Provisioning Services database. In this case, provide the MS SQL database administrator with the file that is created using the DbScript.exe utility. This utility is installed with the Provisioning Services software.

Caution: Installing SQL Server and Provisioning Services on the same server can cause poor distribution during load balancing. Citrix recommends that they do not co-exist on the same server.

If you are using the Database Mirroring feature, SQL native client is required on the server. If this does not already exist, the option to install SQL native client x64 or x86 is presented when product software is installed.

Database clustering is supported.

Database sizing

Initial size and growth

When the database is created, its initial size is 20 MB with a growth size of 10 MB. The database log initial size is 10 MB with a growth size of 10%.

Base amount

The base amount of space required is 112 KB, which does not change. This includes the following:

- DatabaseVersion record requires approximately 32 KB
- Farm record requires approximately 8 KB
- DiskCreate record requires approximately 16 KB
- Notifications requires approximately 40 KB
- ServerMapped record requires approximately 16 KB

Variable amount based on objects (the following tables can get large if additional items are included):

- Access and groupings (each)
- A User group that has access to the system requires approximately 50 KB
- A Site record requires approximately 4 KB
- A Collection requires approximately 10 KB

FarmView (each)
- FarmView requires approximately 4 KB
- FarmView/Device relationship requires approximately 5 KB

SiteView (each)
- SiteView requires approximately 4 KB
- SiteView/Device relationship requires approximately 5 KB

Target device (each)
- A target device requires approximately 2 KB
- DeviceBootstrap requires approximately 10 KB
- Device:Disk relationship requires approximately 35 KB
- Device:Printer relationship requires approximately 1 KB
- DevicePersonality requires approximately 1 KB
- DeviceStatus when a Device boots requires approximately 1 KB
- DeviceCustomProperty requires approximately 2 KB

Disk (each)
- Unique disk requires approximately 1 KB
- DiskVersion requires approximately 3 KB
- DiskLocator requires approximately 10 KB
- DiskLocatorCustomProperty requires approximately 2 KB

Provisioning Server (each)
- A server requires approximately 5 KB
- ServerIP requires approximately 2 KB
- ServerStatus when a Server boots requires approximately 1 KB
- ServerCustomProperty requires approximately 2 KB

Store (each)
- Store requires approximately 8 KB
- Store:Server relationship requires approximately 4 KB

Disk update (each)
- VirtualHostingPool requires approximately 4 KB
- UpdateTask requires approximately 10 KB
- DiskUpdateDevice requires approximately 2 KB
- Each DiskUpdateDevice:Disk relationship requires approximately 35 KB
- Disk:UpdateTask relationship requires approximately 1 KB

Variable change size

The following changes cause the size requirements to increase:

- Each processed task (for example: vDisk versioning merge) requires approximately 2 KB
- If auditing is turned on, each change made by the administrator in the Console, MCLI, or PowerShell interface requires approximately 1 KB

Database mirroring

Considerations:
- For Provisioning Services to support MS SQL database mirroring, the database needs to be configured with **High-safety mode with a witness (synchronous)**.
- If you are using the Database Mirroring feature, the SQL native client is required on the server. If this does not already exist, the option to install SQL native client x64 or x86 is presented when product software is installed.

To use the MS SQL Server's database mirroring feature within your farm:

1. Run the Configuration wizard, then select the Create farm option.
2. Configure the mirroring database by following Microsoft's instructions.
3. Re-run the Configuration wizard, then select the Join existing farm option.
4. On the Existing Farm dialog, select the checkbox next to Specify database mirror failover partner. Enter the database server and instance name of the database mirror failover partner and, if necessary, an optional TCP port.

**Database clustering**

Provisioning Services supports database clustering. To implement database clustering, follow Microsoft's instructions then run the Provisioning Services Configuration wizard. No additional steps are required because the wizard considers the cluster as a single SQL Server.

**Configure authentication**

Provisioning Services uses Windows authentication for accessing the database. Microsoft SQL Server authentication is not supported except by the Configuration Wizard.

**Configuration wizard user permissions**

The following MS SQL permissions are required for the user that is running the Configuration wizard:
- dbcreator; for creating the database
- securityadmin; for creating the SQL logins for the Stream and SOAP services.

If the user does not have sufficient SQL privileges, a dialog prompts for an SQL Server user that has the appropriate permissions (dbcreator and securityadmin).

If using MS SQL Express in a test environment, you can choose to provide the user that is running the Configuration wizard sysadmin privileges (the highest database privilege level).

Note: Alternatively, if the database administrator has provided an empty database, the user running the Configuration wizard must be the owner of the database and have the "View any definition permission" (these settings are set by the database administrator when the empty database is created).

**Service Account permissions**

The user context for the Stream and SOAP services requires the following database permissions:
- db_datareader
- db_datawriter
- Execute permissions on stored procedures

Note: Datareader and Datawriter database roles are configured automatically for the Stream and SOAP Services user account using the Configuration wizard.

Note: The Configuration wizard assigns these permissions provided the user has securityadmin permissions.

In addition, the service user must have the following system privileges:
Determine which of the following supported user accounts the Stream and SOAP services run under:

- Network service account
  - Minimum privilege local account, which authenticates on the network as computers domain machine account
- Specified user account (required when using a Windows Share)
  - Workgroup or domain user account

Provisioning Services support for KMS licensing requires that the SOAP Server user account be a member of the local administrators group.

If using Personal vDisks with XenDesktop, the SOAP Server user account must have XenDesktop Full administrator privileges.

Because authentication is not common in workgroup environments, minimal privilege user accounts must be created on each server, and each instance must have identical credentials (that is, password).

Determine the appropriate security option to use in this farm (only one option can be selected per farm and the selection you choose impacts role-based administration).

- Use Active Directory groups for security (default); select this option if you are on a Windows Domain running Active Directory. This option enables you to leverage Active Directory for Provisioning Services administration roles.
  - Note: Windows 2000 Domains are no longer supported.
- Use Windows groups for security; select this option if you are on a single server or in a Workgroup. This option enables you to leverage the Local User/Groups on that particular server for Provisioning Services administration roles.

Console users do not directly access the database.

Minimum permissions required for additional Provisioning Services functionality include:

- Provisioning Services XenDesktop Setup wizard, Streamed VM Setup wizard, and ImageUpdate service
  - vCenter, SCVMM, and XenServer minimum permissions
  - A XenDesktop controller exists with permissions for the current user
  - A Provisioning Services Console user account is configured as a XenDesktop administrator and it has been added to a PVS SiteAdmin group or higher
  - When creating new accounts in the Console, the user needs the Active Directory Create Accounts permission. To use existing accounts, Active Directory accounts have to already exist in a known OU for selection
  - If using Personal vDisks with XenDesktop, the SOAP Server user account must have XenDesktop Full administrator privileges.
- AD account synchronization
  - Create, Reset, and Delete permissions
- vDisk
  - Privileges to perform volume maintenance tasks

Kerberos Security
By default, the Provisioning Services Console, Imaging wizard, PowerShell snap-in and MCLI use Kerberos authentication when communicating with the Provisioning Services SOAP Service in an Active Directory environment. Part of the Kerberos architecture is for a service to register (create a service principal name, SPN) with the domain controller (Kerberos Key Distribution Center). The registration is essential as it allows Active Directory to identify the account that the Provisioning Services SOAP service is running in. If the registration is not performed, the Kerberos authentication will fail and Provisioning Services will fall back to using NTLM authentication.

The Provisioning Services SOAP Service will register every time the service starts and unregister when the service stops. However, there are times when the registration will fail because the service user account does not have permission. By default, the Network Service account and domain administrators have permission while normal domain user accounts do not.

To work around this permissions issue:

- Use a different account that has permissions to create SPNs.
- Assign permissions to the service account.

<table>
<thead>
<tr>
<th>Account Type</th>
<th>Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer Account</td>
<td>Write Validated SPN</td>
</tr>
<tr>
<td>User Account</td>
<td>Write Public Information</td>
</tr>
</tbody>
</table>

- Create the SPNs manually using the SETSPN.EXE tool included with Windows 2008 or distributed with the Windows Support Tools included on the Windows 2003 operating system disk. As an administrator, run the following commands:
  - `setspn -a PVSSoap/<hostname> <username>`
  - `setspn -a PVSSoap/<fully qualified domain name> <username>`
  
  Note: If the service account is ever changed, the SPNs will need to be removed and new ones created for the new account. To remove the SPNs, run the following commands:
  - `setspn -d PVSSoap/<hostname> <username>`
  - `setspn -d PVSSoap/<fully qualified domain name> <username>`

Provisioning Server requirements

Caution: Provisioning Services is not compatible with Windows when the System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing security setting is enabled.

Operating Systems

Provisioning Services English on English, Japanese, German, French, Spanish, Simplified Chinese, Traditional Chinese, Korean, and Russian versions of operating systems are supported on all versions and editions of Windows Server 2003 through Windows Server 2012 R2.

Processors

Intel or AMD x86 or x64 compatible; 2 GHz minimum; 3 GHz preferred; 3.5 GHz Dual Core/HT or similar for loads greater than 250 target devices.

Memory
Minimum of 2 GB RAM; 4 GB preferred; 4 GB is required for a larger number of vDisks (greater than 250).

**Hard Disk and Storage**

Disk storage management is very important because a Provisioning Server can have many vDisks stored on it, and each disk can be several gigabytes in size. Your streaming performance can be improved using a RAID array, SAN, or NAS.

There must be enough space on the hard disk to store the vDisks. For example, if you have a 15 GB hard drive, you can only create a 14 GB vDisk.

Additional requirements depend on several factors such as:

- **Hard disk capacity** – requirement of the operating system and applications running on a target device. Citrix recommends that you add 20% on the base size of the final installed image.
- **Private Image Mode** – number of target devices using a vDisk in Private Image mode (vDisks in Private Image mode should be backed up daily).
- **Standard Image Mode** – number of target devices using a vDisk in Standard Image mode.
  
  Note: Best practice is to include making a copy of every vDisk created.

- **Minimum Common Storage Sizes**
  - 250 MB for the database
  - 5 GB on a clean Windows system
  - 15 GB per vDisk for Vista Class images (estimated)

Additional space per vDisk based on additional significant applications loaded.

**Network Adapter**

- Static IP
- Minimum 100 MB Ethernet, 1 GB Ethernet preferred; Dual 1 GB Ethernet for more than 250 target devices
  
  Note: Two NICs often perform better than a single dual-ported NIC.

**Required Provisioning Server software**

- The Provisioning Server install program requires Microsoft .NET 4.0 and Windows PowerShell 2.0
- If using Provisioning Services with Xen Desktop, .NET 3.5.1
- If using Provisioning Services with SCVMM 2012 SP1, PowerShell 3.0

**Network requirements**

**UDP and TCP port requirements**

- Provisioning Server to Provisioning Server Communication – Each Provisioning Server must be configured to use the same ports (UDP) in order to communicate with each other (uses the Messaging Manager). At least five ports must exist in the port range selected. The port range is configured on the Stream Services dialog when the Configuration wizard is run.
  
  Note: If configuring for a high availability (HA), all Provisioning Servers selected as failover servers must reside within the same site. HA is not intended to cross between sites.

  - The first port in the default range is UDP 6890 and the last port is 6909.

- Each Provisioning Server must be configured to use the same ports (UDP) in order to communicate with target devices (uses the StreamProcess)
The port range is configured using the Console's Network tab on the Server Properties dialog.

The default ports include: UDP 6910, 6911, 6912, 6913, 6914, 6915, 6916, 6917, 6918, 6919, 6920, 6921, 6922, 6923, 6924, 6925, 6926, 6927, 6928, 6929 and 6930. However, the first 3 ports (6910, 6911, 6912) are reserved for Provisioning Services.

Target device to Provisioning Services communication

- Target devices communicate with Provisioning Services using UDP 6901, 6902, 6905 ports.
  
  Note: Unlike Provisioning Servers to target device port numbers, target device to Provisioning Services cannot be configured.

Logon server communication

- Each Provisioning Server used as a logon server must be configured on the Stream Servers Boot List dialog when the Configuration wizard is run.
- The default port for logon servers to use is UDP 6910.

Console communication

- The SOAP Server is used when accessing the Console. The ports (TCP) are configured on the Stream Services dialog when the Configuration wizard is run. For Powershell: MCLI-Run SetupConnection. For MCLI: MCLI Run SetupConnection.
  
  Note: Refer to the Provisioning Server Programmer Guides for details.

TFTP communication

- The TFTP port value is stored in the registry:
  
  HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\BNTFTP\Parameters Port
- The TFTP port defaults to UDP 69.

TSB communication

- The TSB port value is stored in the registry:
  
  HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\PVSTSB\Parameters Port
- The TSB port defaults to UDP 6969.

Port Fast

- Port Fast must be enabled.

Network Card

- PXE 0.99j, PXE 2.1 or later.

Network addressing

- DHCP

Target device requirements

In most implementations, there is a single vDisk providing a standard image for multiple target devices. vDisk and target device maintenance is simplified by creating and maintaining fewer vDisks and assigning more target devices to each vDisk.
In order to have a single vDisk, all target devices must have certain similarities to ensure that the OS has all of the drivers it requires to run properly. The three key components that should be consistent are the motherboard, network card, or video card.

Microsoft NIC teaming driver, introduced in Windows Server 2012, or OEM NIC teaming software should be installed and configured prior to the Target Device software.

Target devices are identified by the operating system that runs on the device. The following lists the supported operating systems for target devices.

Note: Dual boot vDisk images are not supported.

Operating systems

- Provisioning Services target devices without the Virtual Desktop Agent (VDA) installed:
  - Windows 8 (32 or 64-bit) and Windows 8.1 (64 or 86-bit); all editions
  - Windows 7 SP1 (32 or 64-bit); Enterprise, Professional, Ultimate.
    Note: The Ultimate edition of Windows 7 is supported only in Private Image mode.
  - Windows XP Professional SP3 32-bit and Windows XP Professional SP2 64-bit
  - Windows Server 2012 and 2012 R2; Standard, Essential, and Datacenter editions
  - Windows Server 2008 R2 SP1: Standard, DataCenter, Enterprise editions
    Caution: Before using Windows Server 2008, view all related known issues at http://support.citrix.com/article/CTX131944. If you experience issues updating a Microsoft Root Certificate, using Internet Explorer, go to Microsoft's website to install the certificate, then reinstall the target device software.
  - Windows Server 2003 and 2003 R2; Standard, Enterprise, and Datacenter editions

- XenDesktop target devices with latest version of VDA installed:
  - Windows 8 (32 or 64-bit) and Windows 8.1 (64 or 86-bit); all editions
  - Windows 7 SP1 (32 or 64-bit); Enterprise, Professional, Ultimate
    Note: The Ultimate edition of Windows 7 is supported only in Private Image mode.
  - Windows Server 2008 R2 SP1: Standard, DataCenter, Enterprise editions
    Caution: Before using Windows Server 2008, view all related known issues at http://support.citrix.com/article/CTX131944. If you experience issues updating a Microsoft Root Certificate, using Internet Explorer, go to Microsoft's website to install the certificate, then reinstall the target device software.
  - Windows Server 2012 and 2012 R2; Standard, Essential, and Datacenter editions
  - Windows Server 2003 and 2003 R2; Standard, Enterprise, and Datacenter editions
    Note: Although the installation media includes VDA 5.6 software to support devices running Windows XP Professional (32-bit and 64-bit), Citrix recommends upgrading to an OS supported by the most current version of the VDA software.
    Note: The VDA software version must be the same for all machines within a XenDesktop catalog.
    Note: When updating the VDA on the vDisk image, you must also set the VDA functional level for the XenDesktop catalog. See XenDesktop upgrade topics for more information.

Supported languages

Provisioning Services English on English, Japanese, German, French, Spanish, Simplified Chinese, Traditional Chinese, Korean, and Russian versions of operating systems are supported.

Target device software requirements

.NET 4.0 (default). Optional: If using XenDesktop and the Image Update Management feature, Microsoft .NET 3.5.1 is also required.
Microsoft licensing key considerations

- Windows 7, Windows 8, Windows Server 2008, and Windows Server 2012 are deployed using either Key Management Server (KMS) or with Microsoft Multiple Activation Key (MAK) volume licensing keys.
- Windows Office 2010 is deployed using KMS licensing.
  Note: Both Private and Standard Image Modes support MAK and KMS.
- Volume licensing is configured within the vDisk image when the Imaging wizard is run on the Master target device.
- Volume licensing is configured for the vDisk file on the Microsoft Volume Licensing tab, which is available from the Console vDisk File Properties dialog.

Supported file system types

NTFS

Console requirements

- Processor – Minimum 1 GHz, 2 GHz preferred
- Memory – Minimum 1 GB, 2 GB preferred
- Hard Disk – Minimum 500 MB
- Supported Operating Systems:
  - Windows Server 2008 (32 or 64-bit); all editions
  - Windows Server 2008 R2; Standard, DataCenter and Enterprise editions
  - Windows Server 2012; Standard, Essential, and Datacenter editions
  - Windows Server 2012 R2; Standard, Essential, and Datacenter editions
  - Windows 7 (32 or 64-bit), Windows XP Professional (32 or 64-bit), Windows Vista (32 or 64-bit); Business, Enterprise, Ultimate (retail licensing)
  - Windows 8 (32 or 64-bit); all editions
  - Windows 8.1 (64-bit); all editions
- Software:
  - MMC 3.0, Microsoft .NET 4.0, Windows PowerShell 2.0
  - If using Provisioning Services with XenDesktop, NET 3.5.1
  - If using Provisioning Services with SCVMM, PowerShell 3.0

Note: When installing Provisioning Services target device software on NT6.x systems within a multi-NIC environment, all available NICs can be used. Therefore bindcfg.exe is no longer required and no longer installed with target device software (Windows Vista, Windows 2008, Windows 7, Windows 2008 R2, Windows 8, and Windows Server 2012). However, if Provisioning Services detects NT5.x systems (Windows XP or Windows 2003), bindcfg.exe continues to install with the target device product software and appears during the target device installation process. With NT5.x Windows XP or Windows 2003 systems, if the inactive NIC fails to bind to Provisioning Services, start bindcfg.exe from the Provisioning Services installation directory (default is: C:\Program Files\Citrix\Provisioning Services).

Store requirements

The store must be able to communicate with the Provisioning Services database.

Note: A store is the logical name for the physical location of the vDisk folder. This folder can exist on a local server or on shared storage. When vDisk files are created in the Console, they are assigned to a store. Store information is saved in the Provisioning Services database.

Disk storage management is very important because a Provisioning Server can have many vDisks stored on it, and each vDisk can be several gigabytes in size. Your streaming performance can be improved using a RAID array, SAN, or NAS.
XenDesktop Setup wizard requirements

The Provisioning Services XenDesktop Setup Wizard operates only with the equivalent version of the XenDesktop controller, that is, the version levels must be the same.

- One or more configured XenDesktop hosts with identical templates exist.
- A Device Collection has been created in the Provisioning Services Site.
- The vDisk that will be assigned to each VM must be in standard image mode.
- Permissions:
  - A XenDesktop controller exists with permissions for the current user.
  - vCenter, SCVMM, and XenServer minimum permissions.
  - A Provisioning Services Console user account is configured as a XenDesktop administrator and it has been added to a PVS SiteAdmin group or higher.
  - If using Provisioning Services with XenDesktop, the SOAP Server user account must have XenDesktop Full administrator privileges.
- When creating new accounts in the Console, the user needs the Active Directory Create Accounts permission. To use existing accounts, Active Directory accounts have to already exist in a known OU for selection.
- When creating a machine catalog in XenDesktop, the boot device file is created automatically (eliminating the need to boot using PXE) and an unformatted write cache disk is automatically attached and formatted on first boot.
- When updating the Virtual Desktop Agent (VDA) on the vDisk image, you must also set the appropriate functional level for the XenDesktop catalog using the XenDesktop Console. See the XenDesktop upgrade topics for more information.
- If importing an Active Directory .CSV file, use the following format: <name>,<type>,<description>. The CSV file must contain the column header. For example, the CSV file contents is as follows:
  
  Name,Type,Description,
  PVSPC01,Computer,,

  The trailing comma must be present to signify three values, even if there is no description. This is the same formatting used by Active Directory Users and Computers MMC when exporting the contents of an organizational unit.

- If using Personal vDisks with XenDesktop, the SOAP Server user account must have XenDesktop Full administrator privileges.
- Template virtual machine (VM) requirements:
  - A template virtual machine must be created from a working virtual machine (connected to the network and boots successfully)
  - Boot order: Network/PXE first in list (as with physical machines)
  - Network: Static MAC addresses. If using XenServer, address cannot be 00-00-00-00-00-00

  Note: If using hard disks, the wizard automatically creates and formats the disk (NTFS) with a write cache partition large enough for the cache. No hard disks are required.
- System Center Virtual Machine Management (SCVMM) requirements:
  - SCVMM servers require that PowerShell 2.0 is installed and configured for the number of connections. The number of required connections for an SCVMM server should be greater than or equal to the number of hosted hypervisors used by the setup wizard for virtual machine cloning. For example: to set connections to 25 from a Powershell prompt, run:
    
    winrm set winrm/config/wins @{MaxShellsPerUser="25"};winrm set winrm/config/wins @{MaxConcurrentUsers="25"}.
    
    SCCM 2012 SP1 requires PowerShell 3.0.
  - For Microsoft SCVMM to work with XenDesktop, the user must run the following PowerShell command; set-
ExecutionPolicy unrestricted on SCVMM.

- For Microsoft SCVMM, please verify that the MAC address for the template is not 00-00-00-00-00-00 before attempting to clone the template. If necessary, use the template properties dialog to assign a MAC address.
- If running a vCenter server on alternate ports, the following registry modifications must be made in order to connect to it from Provisioning Services:
  - Create a new key HKLM\Software\Citrix\ProvisioningServices\PlatformEsx
  - Create a new string in the PlatformEsx key named ServerConnectionString and set it to http://{0}:PORT#/sdk
    Note: If using port 300, ServerConnectionString= http://{0}:300/sdk
- If using multiple NICs, the XenDesktop wizard assumes that the first NIC is the Provisioning Services NIC, and therefore changes it in accordance with the virtual machine network in the Domain Controller. This is the first NIC listed in the virtual machines properties.
- To use the Synthetic switch-over feature, both the first legacy NIC and the synthetic NIC must be on the same network. If the Provisioning Services XenDesktop Set Up Wizard is used with SCVMM, both the first legacy and the synthetic NICs' network will change according to the network resource set by XenDesktop, or by the user if SCVMM host has multiple network resources.
- Multi-NIC support for XenDesktop private virtual machine desktops.
- Legacy XenDesktop Virtual Desktop Agents are supported on VMs. For details, refer to VDA requirements in the XenDesktop documentation.

Streamed VM Setup wizard requirements

- One or more hypervisor hosts exist with a configured template.
- A Device Collection exists in the Provisioning Services Site.
- A vDisk in Standard Image mode exists, to be associated with the selected VM template.
- Image Update Management requires the installation of Microsoft .NET 4.0 and Microsoft .NET 3.5 SP1 on the client. The client installer only provides Microsoft .NET 3.0, which is a minimum prerequisite on the client.
- Template VM requirements:
  - Boot order: Network/PXE first in list (as with physical machines).
  - Hard disks: If using local write cache, an NTFS formatted disk large enough for the cache must exist. Otherwise, no hard disks are required.
  - Network: Static MAC addresses. If using XenServer, address cannot be 00-00-00-00-00-00
  - Before attempting to create a template from a VM, ensure that the VM is fully operational.
- Permissions:
  - The Provisioning Services Console user account was added to a PVS SiteAdmin group or above.
  - If using Active Directory, when creating new accounts in the Console, the user needs the Active Directory Create Accounts permission. To use existing accounts, Active Directory accounts have to already exist in a known OU for selection.

ESD servers requirements for vDisk Update Management

- WSUS Server – 3.0 SP2
- Microsoft System Center Configuration Management (SCCM):
  - SCCM 2012
  - SCCM 2012 SP1
  - SCCM 2012 R2

Hypervisor requirements

For the most current list of supported hypervisors, refer to XenDesktop and Provisioning Services Hypervisor support.
Hypervisor considerations

**XenServer 5.6 and newer**
- The template’s MAC address cannot be 00-00-00-00-00-00.

**System Center Virtual Machine Manager (SCVMM) VMM 2012 and newer**
- VMM 2012, 2012 Sp1, and 2012 R2 are significantly different from each other.
- When creating a machine template for VMM 2012 only, ensure that it has a similar hard disk drive structure and that it can boot from a vDisk in Private Image mode. Examples:
  - To PXE boot a VM with write cache, create a VM with one hard disk drive.
  - To use Boot Device Manager (BDM) to boot a VM with write cache, create a VM with two hard disk drives.
  - To use BDM to boot a VM that uses a personal vDisk and write cache, create a VM with three hard disk drives.
- To do the Synthetic NIC Switch Over (boot using legacy NIC and then stream using synthetic NIC), both the legacy and the synthetic NICs must be in the same vlan in the template VMs. The Provisioning Services XenDesktop Set Up Wizard changes the vlan of both NICs to the vlan selected during the XenDesktop Set Up Wizard run. This uses two IP addresses.
- When running the imaging wizard, make sure you select the legacy NIC’s MAC address.
- Provisioning Services does not support multiple legacy NICs in the VMM’s VM. This is because VMM uses the last legacy NIC and XenDesktop Set Up Wizard always uses the first NIC, regardless of whether it is legacy or synthetic.
- When creating a VMM template, make sure you select None – customization not required as the Guest OS profile in Configure Operating System menu.
- Problem description – When using the XenDesktop Set Up Wizard, the targets are created but are not bootable with the error Device not found in PVS dB. This usual reason is the template has the legacy and synthetic NICs in reverse order, synthetic is NIC 1 and legacy is NIC 2. To fix this, delete the NICs in the template. Make a legacy NIC 1 and synthetic NIC 2.

**VMware vSphere ESX 4.1 and newer. Depending on the Provisioning Services version.**
- Supported Provisioning Services PXE NIC.
  - ESX 4.x – E1000
  - ESX 5.0 and newer – VMXNET3
- Template VM and the master VM.
  - Both must have the same guest operating system, configuration, and virtual machine version. Mismatches cause the process to stop unexpectedly.
- Provisioning Services and ESX virtual machine version.
  - vCenter 5.5 defaults to virtual machine version 8, which is for ESX 5.0.
  - Virtual machine version must be changed prior to OS installation.
  - Template and master VM must have the same virtual machine version.
- Windows 7 and Windows 2008 R2 with VMXNET3 NICs.
  - Windows 7 and Windows 2008 R2 without service packs — Install Microsoft iSCSI hotfix [http://support.microsoft.com/kb/2344941](http://support.microsoft.com/kb/2344941) and restart the VM before installing Provisioning Services target device software.
  - Windows 7 and Windows 2008 R2 with service pack 1 – Install Microsoft iSCSI hotfix [http://support.microsoft.com/kb/2550978](http://support.microsoft.com/kb/2550978) and restart the VM before installing Provisioning Services target device software.
- For ESX 5.0 only, the Interrupt Safe Mode must be enabled on the Provisioning Services bootstrap. Otherwise, the VM displays a partial MAC address during reboot.
- With ESX 5.5, a VM created using the Web client defaults to virtual hardware version 10 (ESX 5.5) and a VM created using
the vSphere client defaults to version 8 (ESX 5.0).

- When creating a new ESXi 5.5 template using the vSphere web client, you can only create hardware version 10 templates. Be sure to modify the templates CD/DVD drives virtual mode from SATA to IDE. Remove the SATA controller if you are planning to use the VMXNet3 driver. This will insure that the template is compatible with XenDesktop setup wizard, which requires the drives that are created for the target to be attached using the SCSI driver.

- When using multiple NICs in ESX VM, be aware that the NIC order in the VM’s properties, BIOS, and OS do not necessary line up in the same order. For example, a VM with three NICs in the VM’s properties does not guarantee that they will be in the same order in the BIOS or Windows. Keep this in mind when making your choices for the streaming NIC. This should be the first NIC in VM’s properties. You can choose the PXE NIC in the BIOS.

- Host record – Regardless of the ESX version, the host’s address for the XenDesktop host will be that of the vCenter system. Do not enter the address used by the web client.
Licensing

May 19, 2015

The Citrix License Server must be installed on a server within the farm that is able to communicate with all Provisioning Servers within the farm. You must use the most recent version of the Citrix License server to get the latest features.

Consider the following options when deciding which server to use as the license server:
- **Single System**: Same system as Provisioning Services; for evaluations, test labs, or implementations with one Citrix product.
- **Stand-alone**: Separate system that has an existing license server installed; for larger implementations or implementations using multiple Citrix products.
- **Point to an existing license server**.

For licensing information, see Licensing Your Product.

**Licensing Grace Periods**

Note: When upgrading an existing environment to the newest version of Provisioning Services, you must upgrade to the latest version of the licensing server or the product license will enter a 96-hour grace period and new product features will be unavailable.

There are three types of grace periods provided by Citrix Licensing. Provisioning Services implements these grace periods as follows:
- **Start up license from license server** is 30 days (720 hours): Initial installation of the licensing server provides start up licenses for all Citrix products. Start up licenses expire after 30 days. The 30 day countdown does not begin until the product prompts you for the start up license for the first time. Provisioning Services product licenses must be installed during this period. A start up license for a Citrix product is voided if a license for that product is installed, regardless of whether it is valid or invalid.
- **No Valid License Grace Period for target devices** for 5.6 = 3 hours, for 5.6 SP1 and newer is four days (96 hours). During this grace period, all provisioned target devices, including new, restarted, and currently running devices, receive a 96 hour license countdown and an hourly reminder from Citrix License Management. All target devices will be shut down when the countdown ends. This grace period may apply in the following scenarios:
  - No valid edition licenses for XenApp, XenDesktop, XenServer, Essentials for Hyper-V or Provisioning Services are available, and any start up license from the license server have already been used and are expired.
  - Licenses are available, but have expired (applies to Evaluation, and NFR license).
  - The Subscription Advantage expiration date of the licenses precedes the eligibility date for the version of Provisioning Services in use.
  - Incompatible license server version. The version of Citrix License Server is not compatible with the installed version of Provisioning Services. The minimum supported Citrix License Server version is 11.11.1 for Provisioning Services 7.0 and 7.1.
- **License server Connectivity Outage Grace Period** is 30 days (720 hours): If connectivity to the Citrix License Server is lost, Provisioning Services will continue to provision systems for a period of 30 days. If this grace period lapses, existing target device sessions continue to run, but new or restarted provisioning sessions will be subject to the 'No Valid License Grace Period' message on the provisioned client.

Installing the License Server

Note: If Provisioning Services is installed after the license server or if new licenses are added, the Stream Service must be restarted.
Installing Provisioning Services Server Software

Aug 18, 2012

Install any Windows service packs, drivers, and updates before installing the Provisioning Services software.

Note: When installing Provisioning Services software on a server that has previous versions of .Net installed, Citrix recommends rebooting if prompted to do so during the .Net installation.

Note: This installation task is for new Provisioning Services implementations. For upgrade tasks, refer to the Upgrading from Previous Releases section. The software can also be installed silently (refer to the Silent Install section).

Complete the steps that follow to install the services and applications required to create a Provisioning Server.

1. Click on the appropriate platform-specific install option. The Provisioning Services Welcome window appears.
2. Click Next. The Product License Agreement appears.
3. Scroll to the end to accept the terms in the license agreement, then click Next to continue. The Customer Information dialog appears.
4. Optionally, type or select your user name and organization name in the appropriate text boxes, then click Next. The Destination Folder dialog appears.
5. Click Change, then enter the folder name or navigate to the appropriate folder where the software should be installed, or click Next to install Provisioning Services to the default folder. The Setup Type dialog appears.
6. Select the radio button that best describes the installation to perform:
   - Complete - Installs all components and options on this computer (default).
   - Custom - Choose which components to install and where to install those components.
   Note: Installing the Network Boot Services does not activate them. If uncertain about the need for any of these services, choose the Complete installation option.
7. Click Next.
8. If you select Complete, the ‘Ready to Install the Program’ dialog appears. If you selected Custom, the ‘Custom Setup’ dialog appears. This dialog provides a ‘Feature Description’ text box that provides a description for the selected component as well as the space required to install that component.
   - Expand each component icon and select how that component is to be installed.
   - After making component selections, click Next. The ‘Ready to Install the Program’ dialog appears. Or, click Cancel to close the wizard without making system modifications.
9. On the ‘Ready to Install the Program’ dialog, click Install to continue with the installation process (the installation may take several minutes).
10. The ‘Installation Wizard Completed’ message displays in the dialog when the components and options are successfully installed.
    Note: The Installation Wizard can be re-run to install additional components at a later time, or re-run on a different computer to install select components on a separate computer.
11. Click Finish to exit the Installation Wizard. The Provisioning Services Configuration Wizard automatically opens.

Note: Although Provisioning Services does not require that you restart the server after installing the product software, in some instances, a Microsoft message may appear requesting a restart. If this message appears, complete Task 4: Configuring the Farm using the Configuration Wizard, before restarting the server. If this message appears and the server is not restarted, the removeable drive may not appear.

Silent Product Software Install

Target devices, Provisioning Servers, and Consoles can be silently installed to a default installation directory using the following command:

<Installer Name>.exe /s /v"/qn"
Or, use the following to set a different destination:

<Installer Name>.exe /s \n"/qn INSTALLDIR=D:\Destination"
Configuring the Farm

Aug 13, 2014

Understand all system requirements before attempting to configure a farm. Refer to Requirements for Provisioning Services 7.1.

Run the Configuration Wizard on a Provisioning Server when creating a new farm, adding new Provisioning Servers to an existing farm, or reconfiguring an existing Provisioning Server.

When configuring a Provisioning Server, consider the following:

- All Provisioning Servers within a farm must share the same database to locate vDisks for target devices on shared storage devices within the farm. If that shared storage device is a Windows network share, refer to configuration information described in the Administrator's Guide, Managing Network Components section. If that shared storage device is a SAN, no additional configuration is necessary.
- To properly configure the network services, be sure that you understand network service options and settings.

Note: If all Provisioning Servers in the farm share the same configuration settings such as site and store information, consider Running the Configuration Wizard Silently.

Configuration Wizard Settings

Before running the Configuration Wizard, be prepared to make the following selections:

Note: The Configuration Wizard can also be run silently on servers that share similar configuration settings. For details, refer to Running the Configuration Wizard Silently.

- Network Topology
- Identify the Farm
- Identify the Database
- Identify the Site
- License Server Settings
- Select Network Cards for the Stream Service
- Configure Bootstrap Server

Note: If errors occur during processing, the log is written to a ConfigWizard.log file, which is located at:

- C:\ProgramData\Citrix\Provisioning Services for 2008 and newer.
- C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services for 2003.

Starting the Configuration Wizard

The Configuration Wizard starts automatically after Provisioning Services software is installed. The wizard can also be started by selecting:

1. Start > All Programs > Citrix > Provisioning Services > Provisioning Services Configuration Wizard
2. After starting the Configuration Wizard, click Next to begin the configuration tasks that follow.

   Note: When running the Configuration Wizard, the tasks that display depend on the network service options that are selected and the purpose for running the wizard.

Network Topology

Complete the network configuration steps that follow.

1. Select the network service to provide IP addresses
Note: Use existing network services if possible. If for any reason existing network services cannot be used, choose to install the network services that are made available during the installation process. To provide IP addresses to target devices, select from the following network service options:

- If the DHCP service is on this server, select the radio button next to one of the following network services to use, then click Next:
  - Microsoft DHCP
  - Provisioning Services BOOTP service
  - Other BOOTP or DHCP service
- If the DHCP service is not on this server, select the radio button next to The service is running on another computer, then click Next.

2. Select the network service to provide PXE boot information
   Each target device needs to download a boot file from a TFTP server.

Select the network service to provide target devices with PXE boot information:

- If you choose to use this Provisioning Server to deliver PXE boot information, select The service that runs on this computer, then select from either of the following options, then click Next:
  - Microsoft DHCP (options 66 and 67)
  - Provisioning Services PXE Service
- If Provisioning Services will not deliver PXE boot information, select The information is provided by a service on another device option, then click Next.

Identify the Farm

Note: When configuring the farm, the combination of the database name and farm name cannot exceed 54 characters. Exceeding this limitation may cause the farm name to display truncated in the Existing Farms screen.

1. Select from the following farm options:
   - Farm is already configured
     Select this option to reconfigure an existing farm, then continue on to the “Configure user account settings” procedure. This option only appears if a farm already exists.
   - Create farm
     1. On the Farm Configuration dialog, select the Create Farm radio button to create a new farm, then click Next.
     2. Use the Browse button to browse for existing SQL databases and instances in the network, or type the database server name and instance. Optionally, enter a TCP port number to use to communicate with this database server.
     3. To enable database mirroring, enable the Specify database mirror failover partner option, then type or use the Browse button to identify the failover database server and instance names. Optionally, enter a TCP port number to use to communicate with this server.
        Note: Refer to — Database Mirroring in the — Provisioning Services Administrator’s Guide for more information.
     4. Click Next to continue on to the “Selecting the database location” procedure.
   - Join existing farm
     1. On the Farm Configuration dialog, select the Join Existing Farm radio button to add this Provisioning Server to an existing farm, then click Next.
     2. Use the Browse button to browse for the appropriate SQL database and instance within the network.
3. Select the farm name that displays by default, or scroll to select the farm to join.
   Note: More than one farm can exist on a single server. This configuration is common in test implementations.
4. To enable database mirroring, enable the Specify database mirror failover partner option, then type or use the
   Browse button to identify the failover database server and instance names. Optionally, enter a TCP port number to
   use to communicate with this server.
   Note: Refer to
   — Database Mirroring
   in the
   — Provisioning Services Administrator’s Guide
   for more information.
5. Click Next.
6. Select from the following site options, then click Next:
   - Existing Site: Select the site from the drop-down menu to join an existing site.
   - New Site: Create a site by typing the name of the new site and a collection.
   Continue on to Configure user account settings procedure.

Identify the Database

Only one database exists within a farm. To identify the database, complete the steps that follow.
1. Select the database location if the database server location and instance have not yet been selected, complete the
   following procedure.
   1. On the Database Server dialog, click Browse to open the SQL Servers dialog.
   2. From the list of SQL Servers, select the name of the server where this database exists and the instance to use (to use
      the default instance, SQLEXPRESS, leave the instance name blank). In a test environment, this may be a staged
      database.
      Note: When re-running the Configuration Wizard to add additional Provisioning Servers database entries, the Server
      Name and Instance Name text boxes are already populated. By default, SQL Server Express installs as an instance
      named ‘SQLEXPRESS’.
   3. Click Next. If this is a new farm, continue on to the “Defining a Farm” procedure.
2. To change the database to a new database
   1. On the old database server, perform a backup of the database to a file.
   2. On the new database server, restore the database from the backup file.
   3. Run the Configuration Wizard on each Provisioning Server.
   4. Select Join existing farm on the Farm Configuration dialog.
   5. Enter the new database server and instance on the Database Server dialog.
   6. Select the restored database on the Existing Farm dialog.
   7. Select the site that the Server was previously a member of on the Site dialog.
   8. Click Next until the Configuration Wizard finishes.
3. Define a farm. Select the security group to use:
   - Use Active Directory groups for security
     Note: When selecting the Active Directory group to act as the Farm Administrator from the drop-down list, choices
     include any group the current user belongs to. This list includes Built-in groups, which are local to the current machine.
     Avoid using these groups as administrators, except for test environments. Also, be aware that some group names may
     be misleading and appear to be Domain groups, which are actually Local Domain groups. For example:
     ForestA.local/Builtin/Administrators.
   - Use Windows groups for security
4. Click Next.
   Continue on to the “Selecting the license server” procedure.
Create a New Store for a New Farm

A new store can be created and assigned to the Provisioning Server being configured:

Note: The Configuration Wizard only allows a server to create or join an existing store if it is new to the database. If a server already exists in the database and it rejoins a farm, the Configuration Wizard may prompt the user to join a store or create a new store, but the selection is ignored.

1. On the New Store page, name the new Store.
2. Browse or enter the default path (for example: C:\PVSStore) to use to access this store, then click Next. If an invalid path is selected, an error message appears. Re-enter a valid path, then continue. The default write cache location for the store is located under the store path for example: C:\PVSStore\WriteCache.

Identify the Site

1. When joining an existing farm, identify the site where this Provisioning Server is to be a member, by either creating a new site or selecting an existing site within the farm. When a site is created, a default target device collection is automatically created for that site.
   - Create a new site
     1. On the Site page, enable the New Site radio button.
     2. In the Site Name text box, type the new site name where this Provisioning Server is to be a member.
     3. In the Collection Name, accept the default collection, Collection, or create a new default collection name to associate with this Provisioning Server, then click Next.
   - Select an existing site
     1. On the Site page, enable the Existing Site radio button. (The default site name is Site.)
     2. Select the appropriate site from the drop-down list, then click Next.
     3. Create a new store or select an existing store on the Store page, then click Next.

Select the License Server

Note: When selecting the license server, ensure that all Provisioning Server's in the farm are able to communicate with that server in order to get the appropriate product licenses.

1. Enter the name (or IP address) and port number of the license server (default is 27000). The Provisioning Server must be able to communicate with the license server to get the appropriate product licenses.
2. Optionally, select the checkbox Validate license server version and communication to verify that the license server is able to communicate with this server and that the appropriate version of the license server is being used. If the server is not able to communicate with the license server, or the wrong version of the license server is being used, an error message displays and does not allow you to proceed.
3. Click Next to continue on to the “Configure user account settings” procedure.

Configure User Account Settings

The Stream and Soap services run under a user account. To provide database access privileges to this user account, Datareader and Datawriter database roles are configured automatically using the Configuration wizard.

1. On the User Account dialog, select the user account that the Stream and Soap services will run under:
   - Network service account (minimum privilege local account that authenticates on the network as computers domain machine account).
   - Specified user account (required when using a Windows Share: workgroup or domain user account). Type the user name, domain, and password information in the appropriate text boxes.
2. Click Next, then continue on to the “Selecting network cards for the Stream Service” procedure.
Select Network Cards for the Stream Service

1. Select the checkbox next to each of the network cards that the Stream Service can use.
2. Enter the base port number that will be used for network communications in the First communications port: text box.
   Note: A minimum of 20 ports are required within the range. All Provisioning Servers within a farm must use the same port assignments.
3. Select the Soap Server port (default is 54321) to use for Console access, then click Next.

Continue on to the “Selecting the bootstrap server” procedure.

Configure Bootstrap Server

Complete the steps that follow to identify the bootstrap server and configure the bootstrap file location.

Note: Bootstrap configurations can be reconfigured by selecting the Configure Bootstrap option from the Provisioning Services Action menu in the Console.

1. Select the bootstrap server. To use the TFTP service on this Provisioning Server:
   1. Select the Use the TFTP Service option, then enter or browse for the boot file. The default location is: C:\Documents and Settings\All Users\ProgramData\Citrix\Provisioning Services\Tftpboot
      If a previous version of Provisioning Services was installed on this server, and the default location is:
      C:\Program Files\Citrix\Provisioning Services\TftpBoot
      You must run the Configuration Wizard to change the default location to:
      C:\Documents and Settings\All Users\ProgramData or ApplicationData\Citrix\Provisioning Services\Tftpboot
      If the default is not changed, the bootstrap file can not be configured from the Console and target devices will fail to boot; receiving a ‘Missing TFTP’ error message.
   2. Click Next.

2. Select Provisioning Servers to use for the boot process:
   1. Use the Add button to add additional Provisioning Servers to the list, the Edit button to edit existing information, or Remove to remove the Provisioning Server from the list. Use the Move up or Move down buttons to change the Provisioning Server boot preference order. The maximum length for the server name is 15 characters. Do not enter FQDN for the server name.
      In an HA implementation, at least two Provisioning Servers must be selected as boot servers.
   2. Optionally, highlight the IP address of the Provisioning Server that target devices will boot from, then click Advanced. The Advanced Stream Servers Boot List appears.
      The following table describes advanced settings that you can choose from. After making your selections, click OK to exit the dialog, then click Next to continue.

<table>
<thead>
<tr>
<th><strong>Table 1. Advanced Stream Servers Boot List</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Verbose Mode</strong></td>
</tr>
<tr>
<td><strong>Interrupt Safe Mode</strong></td>
</tr>
<tr>
<td>Advanced Memory Support</td>
</tr>
<tr>
<td>-------------------------</td>
</tr>
<tr>
<td>Network Recovery Method</td>
</tr>
<tr>
<td>Logon Polling Timeout</td>
</tr>
<tr>
<td>Login General Timeout</td>
</tr>
</tbody>
</table>

3. Verify that all configuration settings are correct, then click Finish.
Running the Configuration Wizard Silently

Jun 11, 2012

Run the Configuration Wizard silently to configure multiple Provisioning Servers that share several of the same configuration settings such as the farm, site, and store locations.

The Configuration Wizard must first be run on any Provisioning Server in the farm that has the configuration settings that will be used in order to create the Provisioning Services database and to configure the farm.

The basic steps involved in the silent configuration of servers within the farm include:

- Create a ConfigWizard.ans file from a configured Provisioning Server in the farm.
- Copy the ConfigWizard.ans file onto the other servers within the farm, and modify the IP address in the ConfigWizard.ans file to match each server in the farm.
- Run the ConfigWizard.exe with the /a parameter.

1. Run the ConfigWizard.exe with the /s parameter on a configured server.
2. When selecting farm settings on the Farm Configuration page, choose the Join existing farm option.
3. Continue selecting configuration settings on the remaining wizard pages, then click Finish.
4. Copy the resulting ConfigWizard.ans file from the Provisioning Services Application Data directory. The location for this directory varies depending on the Windows version. For Windows 2003, use \Documents and Settings\All Users\Application Data\Citrix\Provisioning Services. For Windows 2008 and Windows 2008 R2, use \ProgramData\Citrix\Provisioning Services.

1. For each server that needs to be configured, copy the ConfigWizard.ans file to the Provisioning Services Application Data directory.
2. Edit the StreamNetworkAdapterIP= so that it matches the IP of the server being configured. If there is more than one IP being used for Provisioning Services on the server, add a comma between each IP address.

To configure servers, run the ConfigWizard.exe with /a parameter on each server that needs to be configured.

Note: To get a list of valid ConfigWizard parameters:
1. Run ConfigWizard.exe with the /? parameter.
2. In the Provisioning Services Application Data directory, open the resulting ConfigWizard.out file.
3. Scroll down to the bottom of the file to view all valid parameters.

Note: To get the list of valid ConfigWizard commands with descriptions:
1. Run the ConfigWizard.exe with the /c parameter.
2. In the Provisioning Services Application Data directory, open the resulting ConfigWizard.out file.
3. Scroll down to the bottom of the file to view all valid parameters.
The Provisioning Services Console can be installed on any machine that can communicate with the Provisioning Services database.

Note: To view Console installation requirements, see Requirements for Provisioning Services 7.1 under the Installation and Configuration section.

Note: The Console installation includes the Boot Device Management utility.

Note: If upgrading from the most current product version, the Console software is removed when the Provisioning Server software is removed. Upgrading from earlier versions may not remove the Console software automatically.

1. Run the appropriate platform-specific install option; PVS_Console.exe or PVS_Console_x64.exe.
2. Click Next on the Welcome screen. The Product License Agreement appears.
3. Accept the terms in the license agreement, then click Next to continue. The Customer Information dialog appears.
4. Type or select your user name and organization name in the appropriate text boxes.
5. Enable the appropriate application user radio button, then click Next. The Destination Folder dialog appears.
6. Click Change, then enter the folder name or navigate to the appropriate folder where the software should be installed, or click Next to install the Console to the default folder. The Setup Type dialog appears.
7. Select the radio button that best describes the installation to perform:
   - Complete - Installs all components and options on this computer (default).
   - Custom - Choose which components to install and where to install those components.
8. Click Next.
9. If you select Complete, the ‘Ready to Install the Program’ dialog appears. If you selected Custom, the ‘Custom Setup’ dialog appears. This dialog provides a ‘Feature Description’ text box that provides a description for the selected component as well as the space required to install that component.
   - Expand each component icon and select how that component is to be installed.
   - After making component selections, click Next. The ‘Ready to Install the Program’ dialog appears. Or, click Cancel to close the wizard without making system modifications.
10. On the ‘Ready to Install the Program’ dialog, click Install to continue with the installation process (the installation may take several minutes).
11. The ‘Installation Wizard Completed’ message displays in the dialog when the components and options are successfully installed.
    Note: The Installation Wizard can be re-run to install additional components at a later time, or re-run on a different computer to install select components on a separate computer.
Adding Additional Provisioning Servers

Apr 08, 2010

To add additional Provisioning Servers, install the Provisioning Services software on each server that is to be a member of the farm. Run the Provisioning Services Installation Wizard, then the Configuration Wizard on each server.

Note: The maximum length for the server name is 15 characters. Do not enter FQDN for the server name when the Configuration Wizard prompts for the site to add the server to, choose an existing site or create a new site.

After adding Provisioning Servers to the site, start the Console and connect to the farm. Verify that all sites and servers display appropriately in the Console window.
Preparing a Master Target Device for Imaging

Preparation:

A Master Target Device refers to a target device from which a hard disk image is built and stored on a vDisk. Provisioning Services then streams the contents of the vDisk created from the Master Target Device to other target devices.

The Master Target Device is typically different from subsequent target devices because it initially contains a hard disk. This is the hard disk that will be imaged to the vDisk. If necessary, after imaging, the hard disk can be removed from the Master Target Device.

In order to support a single vDisk, that is shared by multiple target devices, those devices must have certain similarities to ensure that the operating system has all required drivers. The three key components that must be consistent include the:
- Motherboard
- Network card, which must support PXE
- Video card

However, the Provisioning Services Common Image Utility allows a single vDisk to simultaneously support different motherboards, network cards, video cards, and other hardware devices.

If target devices will be sharing a vDisk, the Master Target Device serves as a ‘template’ for all subsequent diskless target devices as they are added to the network. It is crucial that the hard disk of Master Target Device be prepared properly and all software is installed on it in the proper order.

Note: Follow the instructions below after installing and configuring the Provisioning Server and creating target devices.
Software must be installed on the Master Target Device in the order that follows:
1. Windows Operating System
2. Device Drivers
3. Service Packs Updates
4. Target Device Software

Applications can be installed before or after the target device software is installed. If target devices will be members of a domain, and will share a vDisk, additional configuration steps must be completed (refer to Managing Domain Computer Accounts, before proceeding with the installation).

Note: Dual boot vDisk images are not supported.

The following steps describe how to configure the target devices system's BIOS and the BIOS extension provided by the network adapter, to boot from the network. Different systems have different BIOS setup interfaces – if necessary, consult the documentation that came with your system for further information on configuring these options.

1. If the target device BIOS has not yet been configured, re-boot the target device and enter the system's BIOS setup. (To get to BIOS setup, press the F1, F2, F10 or Delete key during the boot process. The key varies by manufacturer).
2. Set the network adapter to On with PXE.
   Note: Depending on the system vendor, this setting may appear differently.
3. Configure the target device to boot from LAN or Network first. Optionally, select the Universal Network Driver Interface; UNDI first, if using a NIC with Managed Boot Agent (MBA) support.
   Note: On some older systems, if the BIOS setup program included an option that permitted you to enable or disable
disk-boot sector write protection, ensure that the option is disabled before continuing.

4. Save changes, then exit the BIOS setup program.

5. Boot the target device from its hard drive over the network to attach the vDisk to the target device.

Configuring Network Adapter BIOS

This procedure is only necessary for older systems.

1. Re-boot the Master Target Device.

2. Configure the network adapter's BIOS extension through setup.

   During the system boot, the network adapter's BIOS extension will present an initialization message similar to the following: Initializing Intel® Boot Agent Version 3.0.03 PXE 2.0 Build 078 (WIM 2.0) RPL v2.43

   Enter the network adapter's BIOS extension. (Consult the network adapter's documentation.) The key combination for entering the network adapter's BIOS extension varies by manufacturer. For example, to enter the Intel Boot Agent setup screen, type Ctrl+S.

   A screen similar to the following appears:

   ![Network Adapter BIOS Configuration Screen]

   3. Change the boot order to Network first, then local drives.

   4. Save any changes, and exit the setup program. In the Intel Boot Agent, typing F4 saves the changes.

Alternatively, a device can be configured to provide IP and boot information (boot file) to target devices using the Manage Boot Devices utility.

Note: It is recommended that you read the Release Notes document before installing target-device software. Before installing the product software on a Master Target Device, turn off any BIOS-based-virus protection features. To include anti-virus software on the vDisk image, be sure to turn the anti-virus software back on prior to running the Imaging Wizard. Provisioning Services target device software must be installed on a Master Target Device prior to building a vDisk image.

Install and configure Microsoft NIC teaming driver, introduced in Windows Server 2012, or OEM NIC teaming software prior to installing Target Device software.

Provisioning Services target device software components include:

- **Provisioning Services Virtual Disk**, which is the virtual media used to store the disk components of the operating system and applications.
- **Provisioning Services Network Stack**, which is a proprietary filter driver that is loaded over the NIC driver, allowing communications between the target devices and the Provisioning Server.
- **Provisioning Services SCSI Miniport Virtual Adapter**, which is the driver that allows the vDisk to be mounted to the operating system on the target device.
- **Provisioning Services Imaging Wizard**, use to create the vDisk file and image the Master Target Device.
- **Virtual Disk Status Tray Utility**, to provide general vDisk status and statistical information. This utility includes a help
system.

- **Target Device Optimizer Utility**, used to change target device setting to improve performance.

Provisioning Services target device software is available for 32-bit and 64-bit Windows operating systems.

Note: When installing Provisioning Services target device software on NT6.x systems within a multi-NIC environment, all available NICs can be used. Therefore bindcfg.exe is no longer required and no longer installed with target device software (Windows Vista, Windows 2008, Windows 7, Windows 2008 R2, Windows 8, and Windows Server 2012). However, if Provisioning Services detects NT5.x systems (Windows XP or Windows 2003), bindcfg.exe continues to install with the target device product software and appears during the target device installation process. With NT5.x Windows XP or Windows 2003 systems, if the inactive NIC fails to bind to Provisioning Services, start bindcfg.exe from the Provisioning Services installation directory (default is: C:\Program Files\Citrix\Provisioning Services).

1. Boot the Master Target Device from the local hard disk.
2. Verify that all applications on the device are closed.
3. Double-click on the appropriate installer. The product installation window appears.
4. On the Welcome dialog that displays, click Next, scroll down to the end, then accept the terms of the license agreement.
5. Click Next to continue, the Customer Information dialog appears.
6. Type your user name and organization name in the appropriate text boxes.
7. Select the appropriate install user option. The option you select depends on if this application will be shared by users on this computer, or if only the user associated with this computer should have access to it.
8. Click Next, the Destination Folder dialog appears.
9. Click Next to install the target device to the default folder (C:\Program Files\Citrix\Provisioning Services). Optionally, click Change, then either enter the folder name or navigate to the appropriate folder, and then click Next, then click Install. The installation status information displays in the dialog.
   Note: The installation process may take several minutes. While the installation process is running, you can click Cancel to cancel the installation and roll-back any system modifications. Close any Windows Logo messages that appear.
10. The 'Installation Wizard Completed' message displays in the dialog when the components and options have successfully been installed. Close the wizard window. If both .NET 3.0 SP1 or newer is installed and Windows Automount is enabled, the Imaging Wizard will start automatically by default (for details, refer to [Image Wizard]).
   Note: If a Windows reboot request message displays before the imaging process completes, ignore the request until imaging completes successfully.
11. Reboot the device after successfully installing product software and building the vDisk image.
Using the Imaging Wizard to Create a New vDisk

Jan 28, 2015

Use the Imaging Wizard to automatically create the base vDisk image from a master target device.

Note: Windows XP and Vista are not supported in Provisioning Services 7.6.

Prerequisites

Windows NT 5.x:
- Enable Windows Automount on Windows Server operating systems.
- Disable Windows Autoplay.
- Verify adequate free space exists in the vDisk store, which is approximately 101% of used space on the source volumes.
- Make note of which NIC(s) the master target device was bound to when the Provisioning Services software was installed on the target device. This information is necessary during the imaging process.

Windows NT 6.x:

For Windows 7 and later, the Provisioning Services Imaging wizard changes to a block-based cloning solution in conjunction with Volume Shadow Copy Service (VSS).

- Each local disk partition is cloned separately to the vDisk. If there is a separate "System Reserved" partition on the local disk, it must be included as a source partition.
- Each destination partition must be equal or larger than the source partition, regardless of the amount of available free space in the source partition.
  - If a larger destination partition is desired, after imaging completes, use Windows disk management "Extend Volume..."
  - If a smaller destination partition is desired, prior to imaging, the source partition can be resized using Windows disk management "Shrink Volume..."

Note: If a Windows reboot request message displays before the imaging process completes, ignore the request until imaging completes successfully.

Imaging

The Imaging Wizard prompts for information that allows for connecting to the farm as well as information necessary to set the appropriate credentials/Active Directory and licensing information to apply to this particular vDisk.

1. From the master target device's Windows Start menu, select Citrix>Provisioning Services>Imaging Wizard. The wizard's Welcome page appears.
2. Click Next. The Connect to Farm page appears.
3. Enter the name or IP address of a Provisioning Server within the farm to connect to and the port to use to make that connection.
4. Use the Windows credentials (default), or enter different credentials, then click Next. If using Active Directory, enter the appropriate password information.
5. On the Microsoft Volume Licensing page, select the volume license option to use for target devices or select None if volume licensing is not being used:
   - None
   - Key Management Service (KMS)
     Note: Additional steps are required to implement KMS licensing after the vDisk image is created. Refer to Managing Microsoft KMS Volume Licensing in the Administrator's Guide for details.
   - Multiple Activation Key (MAK)
6. Select to create a new vDisk (default), or use an existing vDisk by entering that vDisk's name, then click Next.

7. If the create new vDisk option was selected, the New vDisk dialog displays.
   1. Enter a name for the vDisk
   2. Select the Store where this vDisk will reside
   3. Select the vDisk format from the appropriate drop-down menus. If the VHD format is Dynamic, from the VHD block size drop-down, select the block size as either 2 MB or 16 MB.
   4. Click Next, then define volume sizes on the Configure Image Volumes page.

8. Click Next. The Add Target Device page appears.

9. Select the target device name, the MAC address associated with one of the NICs that was selected when the target device software was installed on the master target device, and the collection to add this device to. Click Next. If the target device is already a member of the farm, the Existing Target Devices page appears.

10. Click Next. Summary of Farm Changes appears.

11. Optional step, unless the vDisk is used to boot VMs. Select to optimize the vDisk for use with Provisioning Services.

12. Verify all changes, then click Finish. A confirmation message displays.

13. Click Yes on the confirmation message to start the imaging process.
Assigning vDisks to Target Devices

May 08, 2015

A vDisk can be assigned to a single target device or to all devices within a target device collection. If a target device has more than one vDisk assigned to it, a list of vdisks displays at boot time allowing the user to select the appropriate vDisk to boot.

If one or more versions exist for a vDisk, the version target devices use in Production is either the highest numbered production version or an override version. For details refer to ‘Accessing a vDisk Version’ in the Administrator's Guide. For Maintenance and Test devices, the State of any non-production versions are labeled.

A vDisk cannot be assigned to a target device using drag-and-drop if that target device was assigned a personal vDisks using the XenDesktop Wizard. A message dialog displays if a vDisk is dragged and dropped onto a collection that contains one or more target devices that use personal vDisks. The dialog provides the option to continue by acknowledging that the vDisk being assigned will only be assigned to those devices that are not currently assigned a personal vDisk. Also, target devices that use personal vDisks cannot inherit the properties of a target device that doesn't use a personal vDisk (copy/paste). To reassign a vDisk to a target device that uses a personal vDisk see Configure target devices that use personal vDisks.

Assigning vDisks to a target device

vDisks can be assigned to a single target device using:

- Drag-and-drop
- Target Device Properties dialog

To assign a vDisk, using drag-and-drop, to one or all target devices within a collection:

1. In the Console tree, expand the vDisk Pool within a given site or expand Stores to display the vDisk to be assigned in the right pane of the window.
2. Left-click and hold the mouse on the vDisk, then drag and drop it onto the target device or onto the collection.

To assign one or more vDisks to a single target device from the Target Device Properties dialog:

1. In the Console tree, expand the Device Collections folder, then click on the collection folder where this target device is a member. The target device displays in the details pane.
2. Right-click on the target device, then select Properties. The Target Device Properties dialog appears.
3. On the General tab, select the boot method that this target device should use from the Boot from drop-down menu options.
4. On the vDisks tab, select the Add button within the vDisk for this Device section. The Assign vDisks dialog appears.
5. To locate vDisks to assign to this target device, select a specific store or server under the Filter options, or accept the default settings, which includes All Stores and All Servers.
6. In the Select the desired vDisks list, highlight the vDisk(s) to assign, then click OK, then OK again to close the Target Device Properties dialog.
Uninstalling Provisioning Services Product Software

Mar 28, 2013
Removing the software from your system requires that you uninstall both the Provisioning Server and target device components.

1. On the Provisioning Server, open the system's Control Panel. From the Windows Start menu, select Settings, and then click Control Panel.
2. Double click on the Programs and Features icon.
3. Select Provisioning Services, then click the Uninstall menu option.

1. Set the system BIOS to boot from the original hard drive.
2. Re-boot the target device directly from the hard drive.
3. On the target device, open the system's Control Panel.
4. Double-click on the Programs and Features icon.
5. Select the Provisioning Services software, then click the Uninstall menu option.

1. On a machine in which the Console is installed, open the system's Control Panel.
2. Double click on the Programs and Features icon.
3. Select the Provisioning Services software, then click the Uninstall menu option.
Configuring the Bootstrap File From the Console

Jun 17, 2011

For the Provisioning Server to start a target device, a boot file is downloaded by the Provisioning Services's MBA or PXE-compliant boot ROM, when the device is turned on. This file must be configured so that it contains the information needed to communicate with the Provisioning Servers. The Configure Bootstrap dialog is used to define the IP addresses for up to four Provisioning Servers in the boot file.

Note: For alternative boot methods, refer to Using the Manage Boot Devices Utility.

The Configure Bootstrap dialog field descriptions are as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap File</td>
<td>The currently selected boot file displays. If you want to select a different boot file to configure, click the Add button or Read Servers from Database button.</td>
</tr>
<tr>
<td>IP Settings</td>
<td>The IP Address, Subnet Mask, Gateway, and Port for up to four Provisioning Servers, which will perform login processing.</td>
</tr>
<tr>
<td>Add</td>
<td>Click the Add button to add a new Provisioning Server to the file. Up to four Provisioning Servers may be specified for Provisioning Servers.</td>
</tr>
<tr>
<td>Edit</td>
<td>Highlight an existing Provisioning Server from the list, then click the Edit button to edit this server's IP settings.</td>
</tr>
<tr>
<td>Remove</td>
<td>Select an existing Provisioning Server from the list, then click the Remove button to remove this server from the list of available Provisioning Servers.</td>
</tr>
<tr>
<td>Move Up and Move Down</td>
<td>Select an existing Provisioning Server, and click to move up or down in the list of Provisioning Servers. The order in which the Provisioning Servers appear in the list determines the order in which the Provisioning Servers are accessed should a server fail.</td>
</tr>
<tr>
<td>Read Servers from Database</td>
<td>To populate the boot file with the Stream Service IP settings already configured in the database, click the Read Servers from Database button. This clears the list then populates the list with the first four servers found in the database.</td>
</tr>
</tbody>
</table>

Target Device IP: Configure Bootstrap

<table>
<thead>
<tr>
<th>Use DHCP to retrieve target device IP</th>
<th>Select this option to retrieve target device IP; default method.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use static target device IP</td>
<td>Selecting this method requires that a primary and secondary DNS and Domain be identified.</td>
</tr>
</tbody>
</table>

Server Lookup: Configure Bootstrap
Use DNS

Select this option to use DNS to find the server. The host name displays in the Host name textbox. If this option is selected and the Use DHCP to retrieve Device IP option is selected (under Device IP Configuration settings), your DHCP server needs to provide option 6 (DNS Server).

Note: If using HA, specify up to four Provisioning Servers for the same Host name on your DNS server.

Use Static IP

Use the static IP address of the Provisioning Server from which to boot from. If you select this option, click Add to enter the following Provisioning Server information, then click OK to exit the dialog:

- IP Address
- Subnet Mask
- Gateway
- Port (default is 6910)

Note: If using HA, enter up to four Provisioning Servers. If you are not using HA, only enter one. Use the Move Up and Move Down buttons to sort the Provisioning Servers boot order. The first Provisioning Server listed will be the server that the target device attempts to boot from.

Options Tab: Configure Bootstrap

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verbose Mode</td>
<td>Select the Verbose Mode option if you want to monitor the boot process on the target device (optional) or view system messages.</td>
</tr>
<tr>
<td>Interrupt Safe Mode</td>
<td>Select Interrupt Safe Mode if you are having trouble with your target device failing early in the boot process.</td>
</tr>
<tr>
<td>Advanced Memory Support</td>
<td>This setting enables the bootstrap to work with newer Windows OS versions and is enabled by default. Only disable this setting on older XP or Windows Server OS 32 bit versions that do not support PAE, or if your target device is hanging or behaving erratically in early boot phase.</td>
</tr>
</tbody>
</table>
| Network Recovery Method | Restore Network Connections — Selecting this option results in the target device attempting indefinitely to restore its connection to the Provisioning Server.  
Reboot to Hard Drive — (a hard drive must exist on the target device) Selecting this option instructs the target device to perform a hardware reset to force a reboot after failing to re-establish communications. The user determines the number of seconds to wait before rebooting. Assuming the network connection cannot be established, PXE will fail and the system will reboot to the local hard drive. The default number of seconds is 50, to be compatible with HA configurations. |
| Login Polling Timeout   | Enter the time, in milliseconds, between retries when polling for Provisioning Servers. Each Provisioning Server is sent a login request packet in sequence. The first Provisioning Server that responds is used. In non-HA systems, this time-out simply defines how often to retry the single available Provisioning Server with the initial login request. This time-out defines how quickly the round-robin routine will switch from one Provisioning Server to the next in trying to find an active Provisioning Server. The valid range is from 1,000 to 60,000 milliseconds. |
1. In the Console, select a Provisioning Server within the Servers folder in the tree, then select Configure bootstrap from the Actions pane or the context menu. The Configure Bootstrap dialog appears. Select the boot file that was copied to the directory you selected during the Provisioning Server setup. Because the server returns the list of bootstrap files found under Provisioning Services ProgramData, the server must be active for the Configure Bootstrap menu item to appear.

Important:
If a previous version of Provisioning services was installed on this server, you must change the default location from:

C:\Program Files\Citrix\Provisioning Services

to:

C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services\Tftpboot

If the default is not changed, the bootstrap file can not be configured from the Console and target devices will fail to boot; receiving a ‘Missing TFTP’ error message.

If you installed the Console on a separate machine, select the path of the remote Provisioning Server (which has boot services installed).

2. The Configuration Wizard writes the list of IP addresses to the database for the server. Selecting Read Servers from the Database gets the first IP and Port for the server and populates it into the list. This step should only be performed when the list is blank, or to replace the whole list with new values. These values are set in the Streaming network cards section of the Configuration Wizard’s Network Communications page. Provisioning Services uses the first network card selected.

3. Choose from the following options:
   - Select the Verbose Mode option if you want to monitor the boot process on the target device (optional). This enables system messaging on the target device.
   - Select Interrupt Safe Mode if the target device hangs early in the boot process.
   - Select Advanced Memory Support option to enable the bootstrap to work with newer Windows OS versions (enabled by default). Only disable this setting on older XP or Windows Server OS 32 bit versions that do not support PAE, or if your target device is hanging or behaving erratically in early boot phase.

4. Select from the following Network Recovery Methods:
   - Restore Network Connections - Selecting this option results in the target device attempting indefinitely to restore it’s connection to the Provisioning Server.
   - Reboot to Hard Drive - Selecting this option instructs the target device to perform a hardware reset to force a reboot after failing to re-establish communications for a defined number of seconds. The user determines the number of seconds to wait before rebooting. Assuming the network connection can not be established, PXE will fail and the system will reboot to the local hard drive. The default number of seconds is 50. Click the Browse button to search for and select the folder created in Step 1, or enter a full path or UNC name.
Note: If the partition containing the vDisks is formatted as a FAT file system, a message displays a warning that this could result in sub-optimal performance. It is recommended that NTFS be used to format the partition containing the vDisks. Do not change the address in the Port field.

Caution: All boot services (PXE, TFTP) must be on the same NIC (IP). But the Stream Service can be on a different NIC. The Stream Service allows you to bind to multiple IPs (NICs).

5. Configure the following:

   **Login Polling Timeout**

   Enter the time, in milliseconds, between retries when polling for servers. Each server is sent a login request packet in sequence. The first server that responds is used. This time-out simply defines how often to retry the single available server with the initial login request. This time-out defines how quickly the round-robin routine will switch from one server to the next, in trying to find an active server. The valid range is from 1,000 to 60,000 milliseconds.

   **Login General Timeout**

   Enter the time-out, in milliseconds, for all login associated packets, except the initial login polling time-out. The valid range is from 1,000 to 60,000 milliseconds.

6. Click OK to save your changes.
Using the Manage Boot Devices Utility

Jan 10, 2013

The Manage Boot Devices Utility provides an optional method for providing IP and boot information (boot device) to target devices; as an alternative to using the traditional DHCP, PXE, and TFTP methods. Using this method, when the target device starts, it obtains the boot information directly from the boot device. With this information, the target device is able to locate, communicate, and boot from the appropriate Provisioning Server. After the user is authenticated, the Provisioning Server provides the target device with its vDisk image.

Supported Boot Devices

The following boot devices are supported in this release:

Note: The Boot Device Management utility is not supported on operating systems older than, and including, Windows 2000. Wireless NICs are not supported.

- USB
- CD-ROM (ISO)
- Hard Disk Partition

Caution: When an entire hard drive is selected as boot device, all existing disk partitions are erased and re-created with a single active partition. The targeted partition is reserved as a boot device and cannot be used by the operating system or data.
When a hard disk partition is selected as boot device, the selected disk partition data is deleted and set as an active partition. This active partition becomes the boot device.

Boot devices are configured using the Boot Device Management utility. The Manage Boot Devices utility is structured as a wizard-like application, which enables the user to quickly program boot devices.

After installing the boot device, complete the procedures that follow.

- The vDisk must already be formatted and ready before the BDM.exe is run.
- If using the target device hard disk drive as the boot device, copy BDM.exe from the product installation directory on the server, into the product installation directory on the target device.
- The target device settings in the Console should be set to boot from the vDisk but the actual device should be set to boot from hard disk first.

1. From the Provisioning Services product installation directory, run BDM.exe. The Boot Device Management window opens and the Specify the Login Server page appears.
2. Under Server Lookup, select the radio button that describes the method to use to retrieve Provisioning Server boot information:
   - Use DNS to find the Provisioning Server from which to boot from. If this option is selected and the Use DHCP to retrieve Device IP option is selected (under Device IP Configuration settings), your DHCP server needs to provide option 6 (DNS Server).
     Note: The boot device uses Host name plus DHCP option 15 (Domain Name, which is optional) as the fully qualified domain name (FQDN) to contact the DNS server to resolve the IP address.
   If using HA, specify up to four Provisioning Servers for the same Host name on your DNS server.
Use the static IP address of the Provisioning Server from which to boot from. If you select this option, click Add to enter the following Provisioning Server information:

- IP Address
- Port (default is 6910)

If using HA, enter up to four Provisioning Servers. If you are not using HA, only enter one. Use the Move Up and Move Down buttons to sort the Provisioning Servers boot order. The first Provisioning Server listed will be the server that the target device attempts to boot from.

3. Click Next. The Set Options dialog appears.

4. Configure the following local boot options, then click Next:
   - Verbose Mode: enable/disable the displaying of extensive boot and diagnostic information that is helpful when debugging issues.
   - Interrupt Safe Mode: enable/disable for debugging issues, which is sometimes required for drivers that exhibit timing or boot behavior problems.
   - Advanced Memory Support: enables/disables the address extensions, to match your operating system settings. Select this option to enable the bootstrap to work with newer Windows OS versions (enabled by default). Only disable this setting on older XP or Windows Server OS 32 bit versions that do not support PAE, or if your target device is hanging or behaving erratically in early boot phase.
   - Network Recovery Method: select to attempt to restore the network connection or to reboot from a hard drive if the target device loses connection to the Provisioning Server, and how long (in seconds) to wait to make this connection.
   - Login Polling Timeout; in general, it is recommended that you start values of one second for each of the polling and general timeouts. You should extend these when using 3DES encryption. You should further extend the timers based upon workload. A reasonable setting for 100 target devices running triple DES in the network would be three seconds.
   - Login General Timeout; a reasonable setting for 100 target devices running triple DES in the network would be ten Seconds for the General Timeout.

5. On the Burn the Boot Device dialog, configure the target device IP. If the Use DNS to find the Server option is selected and your DHCP service does not provide option 6 (DNS Server), then enter the following required information (note that the server name must be less than 16 characters length and the domain name less than 48 characters in length):
   - Primary DNS Server Address
   - Secondary DNS Server Address
   - Domain Name

6. Configure the Boot Device properties.
   - Add an active boot partition. Check this option to add a boot partition. Note: A boot partition is required if booting from the device's hard drive (for example, when selecting a XENPVDISK boot device with small partition or partition offset).
   - Select the boot device from the list of devices.

   If a partition offset size is set, a confirmation message displays to confirm the destination size. Type Yes (case sensitive) to continue.

7. If applicable, configure Media Properties.

8. Click Burn. A message appears to acknowledge that the boot device was successfully created. If selecting ISO format, use your CD burning software to burn the ISO image.

9. Click Exit to close the utility.

10. Boot the target device and enter the BIOS Setup. Under the Boot Sequence, move the boot device to the top of the list of bootable devices. Save the change, then boot the target device.

After the boot device is programmed, a target device boot sequence can be configured using the Console’s Target Device
Disk Properties dialog. These boot behaviors are used after a target device connects to a Provisioning Server. The Console allows multiple vDisk images to be assigned to a target device. The way in which these vDisks boot depends upon the selected boot behavior.

When configuring the BIOS to work with the boot device (either USB or ISO image), it is imperative that the NIC PXE option is enabled. The PXE boot option is required in order for the NIC Option ROM to stay resident in memory during the pre-boot process. This way, UNDI will be available to the boot device to properly initialize the NIC. Otherwise, the "API not found" message would be displayed by the boot device.
Using the Provisioning Services Console

Nov 14, 2014

Use the Provisioning Services Console to manage components within a Provisioning Services farm. The Console can be installed on any machine that can access the farm.

Before starting the Console, make sure that the Stream Service is started and running on the Provisioning Server. (After the Configuration Wizard runs, the Stream Service starts automatically).

To start the Console

From the Start menu, select:

All Programs>Citrix>Provisioning Services>Citrix Provisioning Console

The Console’s main window appears.

Note: To connect to a farm refer to Farm Tasks.

On the main Console window, you can perform tasks necessary when setting up, modifying, tracking, deleting, and defining the relationships among vDisks, target devices, and Provisioning Servers within your network.

Using the Console Tree

The tree is located in the left pane of the Console window. The tree shows a hierarchical view of your network environment and managed objects within your network. What displays in the Details view depends on the object you have selected in the tree and your user role.

In the tree, click + to expand an managed object node, or click - to collapse the node.

Basic Tree Hierarchy

Farm administrators can create new sites, views, and stores within the farm. The farm-level tree is organized as follows:

- Farm
  - Sites
  - Views
  - Stores

Site administrators generally manage those objects within sites to which they have privileges. Site’s contain Provisioning Servers, a vDisk Pool, device collections and views. The site-level tree is organized as follows:

- Site
Using the Details View

The right-hand pane of the Console window contains the details view. This view provides information about the object selected in the tree, in table format. The types of objects that display in the view include Provisioning Servers, target devices, and vDisks. For more detailed information, right-click on the object, then select the Properties menu.

The tables that display in the details view can be sorted in ascending and descending order.

In the Console, the objects that display and the tasks that you can perform are dependant on the role that you are assigned.

Common Action Menu Options

The following menu options are common to most objects in the Console:

New Window From Here

To open a new Console window, right-click on an object in the tree or in the details pane, then select the New Window from Here menu option. A new Console window opens. It may be necessary to minimize the window to view and toggle between one or more windows.

Refresh

To refresh information in the Console, right-click a folder, icon, or object, then select Refresh.

Export List

1. To export table information from the details pane to a text or comma delimited file, select Export from the Action menu.
2. Select the location where this file should be saved in Save in:
3. Type or select the file name in the File name textbox.
4. Select the file type from and Save as text boxes.
5. Click Save to save the file.

Help

Select an object in the Console, then select Help from the Action menu to display information about that object.

View Options

To customize a Console view:
1. Select View, then select either Add/Remove Columns... or Customize....
2. If you selected:
   - Add/Remove Columns..., use the Add and Remove buttons to select which columns to display.
   - Customize..., select the check box next to each MMC and Snap-in view option that should display in the Console window.
3. Click OK. The Console view refreshes to display the view options selected.
Performing Tasks in the Console

Sep 15, 2010

Use the following Console menus and features to perform tasks:

Note: Use the Ctrl key to make non-continuous selections or the Shift key to make continuous selections.

Select object-related tasks from the Action menu such as; boot, restart, send message, view properties, copy or paste properties. For a complete list of tasks, refer to that object’s management chapter within this guide.

Right-click a managed object(s) to select object-related tasks. For a complete list of tasks, refer to that object’s management chapter within this guide.

Using the Drag-and-Drop feature, you can quickly perform several common Console tasks such as:

- Move target devices by dragging them from one device collection, and dropping them on another device collection within the same site.
- Assign a vDisk to all target devices within a collection by dragging the vDisk and dropping it on the collection. The vDisk and the collection must be in the same site. (The new vDisk assignment replaces any previous vDisk assignments for that collection).
- Add a target device to a view by dragging the device, then dropping it on the view in Console’s tree.
- Drag a Provisioning Server from one Site, then drop it into another site. (Any vDisks assignments that were specific to this server and any store information will be lost).

Select an object in the Console window, then use the Copy and Paste right-click menu options to quickly copy one or more properties of a vDisk, Provisioning Server, or target device, to one or more existing vDisks, Provisioning Servers, or target devices.

To copy the properties of a one object type and paste those properties to multiple objects of the same type:

1. In the tree or details pane, right-click the object which has the properties you want to copy, then select Copy. The object-specific Copy dialog appears.
2. Place a check in the checkbox next to each of the object properties you want to copy, then click OK.
3. In the Console tree, expand the directory where the object exists so that those objects display in either the tree or details pane.
4. Right-click on the object(s) in the tree or details pane that you want to paste properties to, then select Paste.

Using Views

Create views containing target devices to display only those target devices that you are currently interested in viewing or performing tasks on. Adding target devices to a view provides a quick and easy way to perform a task on members of that view, such as:

- Boot
- Restart
Views can be created at the site level or at the farm level. To perform a task on members of a view:

1. Right-click on views icon, then select the Create View... menu option. The View Properties dialog appears.
2. Type the name and a description of the new view in the appropriate text boxes, then select the Members tab.
3. To add target devices to this view, click the Add button. The Select Target Devices dialog appears.
4. If you are creating the view at the farm level, select the site where the target devices reside. If you are creating the view at the site level, the site information is already populated.
5. From the drop-down menu, select the device collection where the target devices to add are members.
6. Select from the list of target devices that display, then click OK.
7. If necessary, continue adding target devices from different device collections within a site.
8. Click the OK button to close the dialog.

For more information on views, refer to Managing Views.
Managing Views in the Console

Sep 01, 2011

1. In the Console, right-click on the Views folder where the new view will exist, then select the Create view menu option. The View Properties dialog appears.
2. On the General tab, type a name for this new view in the Name text box and a description of this view in the Description text box, then click the Members tab.
3. Click the Add button to add new target device members to this view. The Select Devices dialog appears.
4. From the drop-down menus, select the site, then the device collection that you want to add target device(s) from. All members of that device collection appear in the list of available target devices.
5. Highlight one or more target devices in this collection, then click Add to add them to the new view. To add additional target devices from other device collections, repeat steps 4 and 5.
6. Click OK to close the dialog. All selected target devices now display on the Members tab.

To copy the properties of one target device, and paste those properties to target device members within a view, complete the steps that follow.

To paste device properties to members in a view:
1. In the Console's details pane, right-click on the target device that you want to copy properties from, then select Copy device properties. The Copy Device Properties dialog appears.
2. Select the checkbox next to the properties that you want to copy, then click Copy. The properties are copied to the clipboard and the dialog closes.
3. Right-click on the view containing the target devices that will inherit the copied properties, then select the Paste device properties menu option. The Paste Device Properties dialog appears displaying the name and properties of the target device that were copied.
4. Under the Paste to... table heading, highlight the target devices that will inherit these properties, then click Paste.
5. Click Close to close the dialog.

If a view becomes obsolete, you can delete the view. Deleting a view does not delete the target device from the collection.
1. In the Console's tree, right-click on the view folder that you want to delete, then select the Delete menu option. A confirmation message appears.
2. Click OK to delete this view. The view no longer displays in the Console tree.

After making changes to a view, it may be necessary to refresh the view before those changes appear in the Console. To refresh the view, right-click on the view in the tree, then select the Refresh menu option.

1. Right-click on the view in the Console tree, then select the Boot devices menu option. The Target Device Control dialog displays with the Boot devices menu option selected in the Settings drop-down menu. By default, all devices are highlighted in the Device table.
2. Click the Boot devices button to boot target devices. The Status column displays the Boot Signal status until the target device boots. As each target device successfully boots, the status changes to Success.

1. Right-click on the view in the Console tree, then select the Restart devices menu option. The Target Device Control dialog displays with the Restart devices menu option selected in the Settings drop-down menu. By default, all devices are highlighted in the Device table.
2. Type the number of seconds to wait before restarting target devices in the Delay text box.
3. Type a message to display on target devices in the Message text box.
4. Click the Restart devices button to restart target devices. The Status column displays the Restart Signal status until the target device restarts. As each target device successfully restarts, the status changes to Success.

1. Right-click on the view in the Console tree, then select the Shutdown devices menu option. The Target Device Control dialog displays with the Shutdown devices menu option selected in the Settings drop-down menu. By default, all devices are highlighted in the Device table.
2. Type the number of seconds to wait before shutting down target devices in the Delay text box.
3. Type a message to display on target devices in the Message text box.
4. Click the Shutdown devices button to shutdown target devices. The Status column displays the Shutdown Signal status until the target device shuts down. As each target device successfully shuts down, the status changes to Success.

To send a message to target devices members within a view:
1. Right-click on the view in the Console tree, then select the Send message menu option. The Target Device Control dialog displays with the Message to devices menu option selected in the Settings drop-down menu. By default, all devices are highlighted in the Device table.
2. Type a message to display on target devices in the Message text box.
3. Click the Send message button. The Status column displays the Message Signal status until target devices receive the message. As each target device successfully receives the message, the status changes to Success.
Managing Views

Apr 08, 2010

The Console's Views feature provides a method that allows you to quickly manage a group of devices. Views are typically created according to business needs. For example, a view can represent a physical location, such as a building or user type. Unlike device collections, a target device can be a member of any number of views.

Farm administrators can create and manage views in the Console tree's Farm>Views folder. Farm views can include any target device that exists in this farm. Site administrators can create and manage views in the Console tree's Farm>Sites>YourSite>Views folder. Site views can only include target devices that exist within that site (YourSite).

To display or edit a views properties, right-click on an existing view in the Console, then select the Properties menu option. The View Properties dialog displays and allows you to view or make modifications to that view.

To perform actions on all members of a view, such as rebooting all target devices members in this view, refer to Configuring Views in the Console.
View Properties

Apr 08, 2010
To display or edit the properties of an existing view, right-click on the view in the Console, then select the Properties menu option. The View Properties dialog displays and allows you to view or make modifications to that view.

View properties are described in the tables that follow.

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name given to this view.</td>
</tr>
<tr>
<td>Description</td>
<td>Describes the purpose of this view.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Members of this view</td>
<td>Lists target device members that belong to this view.</td>
</tr>
<tr>
<td>Add button</td>
<td>Opens the Select Devices dialog, from which target devices to add to this view are selected.</td>
</tr>
<tr>
<td>Remove button</td>
<td>Removes highlighted target devices from this view.</td>
</tr>
<tr>
<td>Remove All button</td>
<td>Removes all target devices from this view.</td>
</tr>
</tbody>
</table>
Managing Farms

Apr 08, 2010

A farm represents the top level of a Provisioning Services infrastructure. Farms provide a “Farm Administrator” with a method of representing, defining, and managing logical groups of Provisioning Services components into sites.

All sites within a farm share that farm’s Microsoft SQL database. A farm also includes a Citrix License Server, local or network shared storage, and collections of target devices.

To learn more about managing farms, refer to the following documents:

- Configuring a New Farm
- Farm Tasks
- Farm Properties
### Farm Properties

Aug 18, 2011
The Farm Properties dialog contains the following tabs and properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Enter or edit the name of this farm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Enter or edit a description for this farm</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Add button</th>
<th>Click the Add button to apply farm administrator privileges to a group. Check each box next the groups to which farm administrator privileges should apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove button</td>
<td>Click the Remove button to remove groups from those groups with farm administrator privileges. Check each box next the groups to which farm administrator privileges should not apply.</td>
</tr>
</tbody>
</table>

| Add button | Click the Add button to open the Add System Groups dialog.  
To display all security groups, leave the text box set to the default ‘*’.  
To display select groups, type part of the name using wildcards ‘*’: For example, if you want to see MY_DOMAIN\Builtin\Users, type: User*, Users, or *ser*  
However, in this release, if you type MY_DOMAIN\Builtin\*, you will get all groups, not just those in the MY_DOMAIN\Builtin path.  
Select the checkboxes next to each group that should be included in this farm.  
Note: Filtering on groups was introduced in 5.0 SP2 for efficiency purposes. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove button</td>
<td>Click the Remove button to remove existing groups from this farm. Highlight the groups to which privileges should not apply.</td>
</tr>
</tbody>
</table>

Note: Changing licensing properties requires that the Provisioning Services Stream Service be restarted on each Provisioning Server for licensing changes to take effect.

<p>| License server name | Type the name of the Citrix License Server in this textbox. |</p>
<table>
<thead>
<tr>
<th><strong>License server port</strong></th>
<th>Type the port number that the license server should use or accept the default, which is 27000.</th>
</tr>
</thead>
</table>

**Auto-Add**  
Check this checkbox if using the Auto-add feature, then select the site that new target devices will be added to from the Add new devices to this site drop-down menu.

If the No default site is chosen for the default site setting, then the site of that Provisioning Server that logs in the target device is used during auto-added. Use the No default site setting if your farm has site scoped PXE/TFTP servers.

**Important!** This feature should only be enabled when expecting to add new target devices. Leaving this feature enabled could result in computers being added without the approval of a farm administrator.

**Auditing**  
Enable or disable the auditing feature for this farm.

**Offline database support**  
Enable or disable the offline database support option. This option allows Provisioning Servers within this farm, to use a snapshot of the database in the event that the connection to the database is lost.

**Alert if number of versions from base image exceeds:**  
Set an alert should the number of versions from the base image be exceeded.

**Default access mode for new merge versions**  
Select the access mode for the vDisk version after a merge completes. Options include: Maintenance, Test (default), or Production.

**Note:** If the access mode is set to Production and a test version(s) already exists, the state of the resulting auto-merged version will automatically be set to Maintenance or Test. If a Maintenance version exists, an automatic merge will not be performed.

**Merge after automated vDisk update, if over alert threshold**  
Enable automatic merge

Check to enable the automatic merge feature should the number or vDisk versions exceed the alert threshold.

**Minimum value is 3 and Maximum value is 100.**

**Current status of the farm**  
Provides database status information and information on group access rights being used.
Farm Tasks

May 07, 2015

The farm is initially configured when you run the Configuration Wizard. The wizard prompts you for the farm's name, a store, and a device collection. When you first open the Console, those objects display in the tree.

The wizard also prompts you for additional farm information such as the name of the license server, your user account information, and those servers that can serve the bootstrap file to target devices. You can always rerun the wizard to change settings. You can also choose to make farm configuration changes using the Farm Properties Dialog.

A farm administrator can view and manage all objects in any farm to which they have privileges. Only farm administrators can perform all tasks at the farm level.

1. Right-click on Provisioning Services Console in the Console tree, then select Connect to farm.
2. Under Server Information, type the name or IP address of a Streaming Server on the farm and the port configured for server access.
3. Select to log in using one of the following methods:
   • Use the Windows credentials that you are currently logged with, then optionally enable the Auto-login on application start or reconnect feature.
   • Use different Windows credentials by entering the username, password, and domain associated with those credentials, then optionally enable the Save password and Auto-login on application start or reconnect feature.
4. Click Connect. The Farm icon appears in the Console tree.

You can manage connections to farms from the Manage Connections dialog. To open the dialog, right-click on the Provisioning Services Console icon in the tree, then select the Manage Connections... menu option.
Managing Sites

May 07, 2015

A site provides both a site administrator and farm administrator, with a method of representing and managing logical groupings of Provisioning Servers, Device Collections, and local shared storage. A site administrator can perform any task that a device administrator or device operator within the same farm can perform.

A site administrator can also perform the following tasks:

Farm-level tasks

- Managing Site Properties, as described here
- Managing Stores

Some Site-level tasks include:

- Defining Device administrator and device operator roles.
- Managing Provisioning Servers
- Managing connections
- Creating a New Site in a Farm, as described here
- Rebalancing Devices on the Provisioning Server
- Importing Target Devices into Collections
- Accessing Audit Information

To create a new site

1. Right-click on the sites folder in the farm where you want to add the new site. The Site Properties dialog appears.
2. On the General tab, type the name and a description for the site in the appropriate text boxes.
3. On the Security tab, click Add to add security groups that will have the site administrator rights in this site. The Add Security Group dialog appears.
4. Check the box next to each group, then click OK. Optionally, check the Domains/group Name checkbox to select all groups in the list.
5. On the Options tab, if new target devices are to be added using the Auto-Add feature, select the collection where these target devices should reside (this feature must first be enabled in the farm's properties).

To modify an existing site's properties, right-click on the site in the Console, then select Properties. Make any necessary modifications in the Site Properties dialog. The tabs in this dialog allow you to configure a site. Site administrators can also edit the properties of a site that they administer.

The Site Properties dialog contains the following tabs.

General Tab

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type the name of this site in the textbox.</td>
</tr>
<tr>
<td>Description</td>
<td>Optional. Type the description of this site in the textbox.</td>
</tr>
</tbody>
</table>
### Security Tab

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add button</td>
<td>Click the Add button to open the Add Security Groups dialog. Check the box next to each group to which site administrator privileges should apply. To add all groups that are listed, check the Domain\Group Name checkbox.</td>
</tr>
<tr>
<td>Remove button</td>
<td>Click the Remove button to remove site administrator privileges to select groups. To remove all groups that are listed, check the Domain\Group Name checkbox.</td>
</tr>
</tbody>
</table>

### MAK Tab

Enter the administrator credentials used for Multiple Activation Key enabled Devices

MAK administrator credentials must be entered before target devices using MAK can be activated. The user must have administrator rights on all target devices that use MAK enabled vDisks and on all Provisioning Servers that will stream those target devices. After entering the following information, click OK:

- User
- Password

Note: If credentials have not been entered and an activation attempt is made from the Manage MAK Activations dialog, an error message displays and the MAK tab appears to allow credential information to be entered. After the credentials are entered, click OK and the Manage MAK Activations dialog re-appears.

### Options Tab

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto-Add</td>
<td>Select the collection that the new target device will be added to from the drop-down menu. (This feature must first be enabled in the farm properties.) Set the number of seconds to wait before Provisioning Services scans for new devices on the Seconds between inventory scans scroll box. Default is 60 seconds.</td>
</tr>
</tbody>
</table>

### vDisk Update Tab

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable automatic vDisk updates on this site</td>
<td>Select this checkbox to enable automatic vDisks to occur, then select the server that should run the updates for this site.</td>
</tr>
</tbody>
</table>
Managing Administrative Roles

Dec 10, 2012

The ability to view and manage objects within a Provisioning Server implementation is determined by the administrative role assigned to a group of users. Provisioning Services makes use of groups that already exist within the network (Windows or Active Directory Groups). All members within a group will share the same administrative privileges within a farm. An administrator may have multiple roles if they belong to more than one group.

Note: Provisioning Services extends built-in administrator roles to support XenDesktop's new Delegated administration roles.

The following administrative roles can be assigned to a group:

- Farm Administrator
- Site Administrator
- Device Administrator
- Device Operator

After a group is assigned an administrator role through the Console, if a member of that group attempts to connect to a different farm, a dialog displays requesting that a Provisioning Server within that farm be identified (the name and port number). You are also required to either use the Windows credentials you are currently logged in with (default setting), or enter your Active Directory credentials. Provisioning Services does not support using both domain and workgroups simultaneously.

When the information is sent to and received by the appropriate server farm, the role that was associated with the group that you are a member of, determines your administrative privileges within this farm. Group role assignments can vary from farm to farm.
Managing Farm Administrators

May 09, 2013

Farm administrators can view and manage all objects within a farm. Farm administrators can also create new sites and manage role memberships throughout the entire farm. In the Console, farm-level tasks can only be performed by farm administrators. For example, only a farm administrator can create a new site within the farm.

When the farm is first configured using the Configuration Wizard, the administrator that creates the farm is automatically assigned the Farm Administrator role. While configuring the farm, that administrator selects the option to use either Windows or Active Directory credentials for user authorization within the farm. After the Configuration Wizard is run, additional groups can be assigned the Farm Administrator role in the Console.

To assign additional Farm Administrators

Note: The authorization method displays to indicate if Windows or Active Directory credentials are used for user authorization in this farm.

1. In the Console, right-click on the farm to which the administrator role will be assigned, then select Properties. The Farm Properties dialog appears.
2. On the Groups tab, highlight all the groups that will be assigned administrative roles in this farm, then click Add.
3. On the Security tab, highlight all groups to which the Farm Administrator role will be assigned, then click Add.
4. Click OK to close the dialog box.
Managing Site Administrators

Apr 08, 2010

Site administrators have full management access to all objects within a site. For example, the site administrator can manage Provisioning Servers, site properties, target devices, device collections, vDisk assignments and vDisk Pools.

![Diagram of Site, Provisioning Servers, Console, Device Collections]

If a farm administrator assigns a site as the ‘owner’ of a particular store, the site administrator can also manage that store. Managing a store can include tasks such as adding and removing vDisks from shared storage or assigning Provisioning Servers to the store. The site administrator can also manage device administrator and device operator memberships.

To assign the Site Administrator role to one or more groups and its members:

1. In the Console, right-click on the site for which the administrator role will be assigned, then select Properties. The Site Properties dialog appears.
2. Click the Security tab, then click the Add button. The Add Security Group dialog appears.
3. From the drop-down menu, select each group to associate with the site administrator role, then click OK.
4. Optionally, repeat steps 2 and 3 to continue assigning additional site administrators.
5. Click OK to close the dialog.
Managing Device Administrators

Sep 02, 2011

Device administrators manage device collections to which they have privileges. Management tasks include assigning and removing vDisks from a device, editing device properties and viewing vDisk Properties (read-only). Device collections consist of a logical grouping of devices. For example, a device collection could represent a physical location, a subnet range, or a logical grouping of target devices. A target device can only be a member of one device collection.

To assign the Device Administrator role to one or more groups and its members:

1. In the Console tree, expand the site where the device collection exists, then expand the Device Collections folder.
2. Right-click on the device collection that you want to add device administrators to, then select Properties. The Device Collection Properties dialog appears.
4. To assign a group with the device administrator role, select each system group that should have device administrator privileges, then click OK.
5. Click OK to close the dialog box.
Managing Device Operators

Jun 26, 2012

A device operator has administrator privileges to perform the following tasks within a Device Collection for which they have privileges:

- Boot and reboot a target device
- Shut down a target device

To assign the Device Operator role to one or more groups:

1. In the Console tree, expand the site where the device collection exists, then expand the Device Collections folder.
2. Right-click on the device collection that you want to add device operators to, then select Properties. The Device Collection Properties dialog appears.
4. To assign a group the Device Operator role, select each system group that should have device operator privileges, then click OK.
5. Click OK to close the dialog box.
Managing Stores

Jun 17, 2011

A store is the logical name for the physical location of the vDisk folder. This folder can exist on a local server or on shared storage. When vDisks files are created in the Console, they are assigned to a store. Within a site, one or more Provisioning Servers are given permission to access that store in order to serve vDisks to target devices.

Separating the physical paths to a vDisks storage locations allows for greater flexibility within a farm configuration, particularly if the farm is configured to be highly available. In a highly available implementation, if the active Provisioning Server in a site fails, the target device can get its vDisk from another Provisioning Server that has access to the store and permissions to serve the vDisk.

If necessary, copies of vDisks can be maintained on a secondary shared-storage location in the event that connection to the primary shared-storage location is lost. In this case, the default path can be set in the store properties if all Provisioning Servers can use the same path to access the store. If a particular server cannot use the path (the default path is not valid for that server, not because of a connection loss, but because it is simply not valid) then an override path can be set in the store properties for that particular server. Provisioning Servers will always use either the default path (if the override path does not exist in the database) or the override path if it does exists in the database.

For more information on stores, refer to any of the following topics:
- Store administrative privileges
- Store properties
Store configuration and management tasks
Store Administrative Privileges

Apr 08, 2010

Stores are defined and managed at the farm level by a farm administrator. Access or visibility to a store depends on the user's administrative privileges:

- Farm Administrators have full access to all stores within the farm
- Site Administrators have access to only those stores owned by the site
- Device Administrators and Device Operators have read-only access. Site Administrators may also have read-only access if that store exists at the farm level, or if that store belongs to another site.

For details, refer to Managing Administrative Roles
Store Properties

Sep 19, 2011

A store can be created when the Configuration Wizard is run or in the Store Properties dialog. The store properties dialogs allows you to:

- Name and provide a description of the store
- Select the owner of the store (the site which will manage the store)
- Provide a default path to the store (physical path to the vDisk)
- Define default write cache paths for this store
- Select the servers that can provide this store

After a store is created, Store information is saved in the Provisioning Services database. Each site has one vDisk Pool, which is a collection of vDisk information required by Provisioning Servers that provide vDisks in that site. The vDisk information can be added to the vDisk pool using the vDisk Properties dialog or by scanning a store for new vDisks that have not yet been added to the database.

| Name | View, type the logical name for this store. For example, PVS-1  
View or type a description of this store. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>View or type a description of this store.</td>
</tr>
<tr>
<td>Site that acts as owner of this store</td>
<td>Optional. View or scroll to select the site that will act as owner of this store. This feature allows a farm administrator to give one site's administrators, special permission to manage the store. These rights are normally reserved for farm administrators.</td>
</tr>
</tbody>
</table>
| Default store path | View, type, or browse for the physical path to the vDisk folder that this store represents. The default path is used by all Provisioning Servers that do not have an override store path set.  
Note: If setting an override store path on the Server's Properties dialog, the path must be set prior to creating a new version of the vDisk. Because this path information is stored and referenced in the .VHD header information, changing the path after versioning may cause unexpected results. |
<p>| Default write cache paths | View, add, edit, remove, or move the default write cache paths for this store. Entering more than one write cache path allows for vDisk load to be distributed to physically different drives. When a target device first connects, the Stream Service picks from the list. The order of the write cache paths, for any override paths in the server store properties, must match the order of the write cache paths specified here. |
| Validate | Click to validate store path selections from the Validate Store Paths dialog. The validation results display under the Status column. |</p>
<table>
<thead>
<tr>
<th>Site</th>
<th>View or scroll to select the site where Provisioning Servers that can access this store exist (multiple sites can access the same store).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Servers that provide this store</td>
<td>All Provisioning Servers within the selected site display in this list. Check the box next to all servers that are permitted to access this store. If the store is only for a specific site, only those servers within that site are valid selections.&lt;br&gt;&lt;br&gt; If the default path is not valid for a selected Provisioning Server, you must define an override path in that server's properties dialog, on the Store tab.</td>
</tr>
<tr>
<td>Validate</td>
<td>Click to validate store path selections from the Validate Store Paths dialog. The validation results display under the Status column.</td>
</tr>
</tbody>
</table>
Store Configuration and Management Tasks

Jun 23, 2011

The following lists tasks that are specific to configuring and managing a store:

- Creating a store, as described below
- Accessing Audit Information

Creating a Store

1. In the Console tree, right-click on Stores, then select the Create store menu option. The Store Properties dialog appears.
2. On the General tab, type the store name (logical name for this storage location) and a description of this store.
3. Optional. Select the site that will act as owner of this store. Otherwise, accept the default <None> so that only farm administrators can manage this store.
4. On the Servers tab, select a site from the list. All Provisioning Servers in that site appear.
5. Check the box each to each server that is permitted to access this store. If the store is only for a specific site, only those servers within that site are valid selections. Also, if the default path is not valid for a selected server, an override path must be defined in for that server on the Server Properties dialogs Store tab. Repeat this step for each site if necessary. (If this procedure is performed by a site administrator, only those sites that they administer appear.)
6. On the Paths dialog, type or browse for the default path for this store (physical location of the vDisk folder). Optionally, a new folder can be created by clicking on the browse button, and then clicking on Create New Folder. If the user is a site administrator, only those sites that they administer will be available in the list.
7. The write cache path(s) for the selected store display under the paths list. Optionally, a new store cache folder can be created by clicking on the browse button, and then clicking on Create New Folder. Additional write cache paths can be added for use by the store by clicking Add. Entering more than one write cache paths allows for vDisk load to be distributed to physically different drives. When a target device first connects, the Stream Service picks from the list. If using HA, the order of the write-cache paths for any override paths in store properties for that server, must match the order of the write-cache paths specified here. If a write cache path is not selected and the OK button is clicked, the user is prompted to create the default write cache path. Click OK on this message to create the default write cache path (C:\pvsstore\WriteCache).
8. After configuring the store and paths this store will use, click Validate to open the Validate Store Paths dialog and validate the path settings.
9. Under the Status column, view the path validation results. Click Close to close this dialog and return to the Store Properties dialog to make any necessary changes or to continue.
10. Click OK to save Property settings.
Managing Provisioning Servers

Apr 08, 2010

A Provisioning Server is any server that has Stream Services installed. Provisioning Servers are used to stream software from vDisks, as needed, to target devices. In some implementations, vDisks reside directly on the Provisioning Server. In larger implementations, Provisioning Servers get the vDisk from a shared-storage device on the network.

Provisioning Servers also retrieve and provide configuration information to and from the Provisioning Services database. Provisioning Server configuration options are available to ensure high availability and load-balancing of target device connections.

To configure a Provisioning Server and software components for the first time, run the Configuration Wizard (the Configuration Wizard can be re-run on a Provisioning Server at a later date in order to change network configuration settings). Refer to the Installation and Configuration Guide for Configuration Wizard details.

After the Provisioning Server software components are successfully installed, and the wizard configurations have been made, servers are managed through the Provisioning Services Console.
Provisioning Servers in the Console

Apr 08, 2010

A Provisioning Server is any server that has Stream Services installed. Provisioning Servers are used to stream software from vDisks, as needed, to target devices. In some implementations, vDisks reside directly on the Provisioning Server. In larger implementations, Provisioning Servers get the vDisk from a shared-storage device on the network.

Provisioning Servers also retrieve and provide configuration information to and from the Provisioning Services database. Provisioning Server configuration options are available to ensure high availability and load-balancing of target device connections.

To configure a Provisioning Server and software components for the first time, run the Configuration Wizard (the Configuration Wizard can be re-run on a Provisioning Server at a later date in order to change network configuration settings). Refer to the — Installation and Configuration Guide for Configuration Wizard details.

After the Provisioning Server software components are successfully installed, and the wizard configurations have been made, servers are managed through the Provisioning Services Console. The Console is used to perform Provisioning Server management tasks such as editing the configuration settings or the properties of existing Provisioning Servers.

Provisioning Servers appear in the Console main window as members of a site within a farm. To manage Provisioning Servers that belong to a specific site, you must have the appropriate administrative role (Site Administrator for this site, or Farm Administrator).

Note: In the Console, the appearance of the Provisioning Server icon indicates that server's current status. In the Console, Provisioning Servers are managed by performing actions on them. The following actions can be performed. To view a list of actions that can be performed on a selected Provisioning Server, choose from the following options:

- Click the Action menu in the menu bar
- Right-click on a Provisioning Server in the Console
- Enable the Action pane from the Views menu

Note: Actions appear disabled if they do not apply to the selected Provisioning Server (refer to “Management Tasks” for task details).
Provisioning Server Properties

Aug 22, 2011

On the Console, the Provisioning Server Properties dialog allows you to modify Provisioning Server configuration settings.

To view an existing Provisioning Server's properties, choose one of the following methods:

- Highlight a Provisioning Server, then select Properties from the Action menu.
- Right-click a Provisioning Server, then select Properties.
- If the details pane is open, highlight a Provisioning Server, then select the Properties menu item from the list of actions.

Note: Provisioning Services displays a message if a change made on a Provisioning Server Properties dialog requires that the server be rebooted.

Name and Description

Displays the name of the Provisioning Server and a brief description. The maximum length for the server name is 15 characters. Do not enter FQDN for the server name.

Power Rating

A power rating is assigned to each server, which is then used when determining which server is least busy. The scale to use is defined by the administrator.

For example, an administrator may decide to rate all servers on a scale of 1 to 10, or on a scale of 100 to 1000. Using the scale of 1 to 10, a server with a rating of 2 is considered twice as powerful as a server with a rating of 1; therefore it would be assigned twice as many target devices. Likewise, when using a scale of 100 to 1000, a server with a power rating of 200 is considered twice as powerful as a server with the rating of 100; therefore it would also be assigned twice as many target devices.

Using the default setting of 1.0 for all servers results in even device loading across servers. In this case, the load balancing algorithm does not account for individual server power.

Ratings can range between 0.1-1000.0; 1.0 is the default.

Note: The load balancing method is defined in vDisk Load Balancing dialog.

Log events to the server's Window Event Log

Select this option if you want this Provisioning Server's events to be logged in the Windows Event log.

Advanced Server Properties

Server tab

Threads per port — Number of threads in the thread pool that service UDP packets received on a given UDP port. Between four and eight are reasonable settings. Larger numbers of threads allow more target device requests to be processed simultaneously, but is consumes more system resources.

Buffers per thread — Number of packet buffers allocated for every thread in a thread pool. The number of buffers per thread should be large enough to enable a single thread to read one IO transaction from a target device. So buffers per threads should ideally be set to \((\text{IOBurstSize} / \text{MaximumTransmissionUnit}) + 1\). Setting the value too large consumes extra memory, but does not hurt efficiency. Setting the value too small consumes less RAM, but detrimentally affects efficiency.

Server cache timeout — Every server writes status information periodically to the Provisioning Services database. This status information is time-stamped on every write. A server is considered 'Up' by other servers in the farm, if the status information in the database is newer than the Server cache timeout seconds. Every server in the farm will attempt to write
its status information every \( (\text{Server cache timeout}/2) \) seconds, i.e. at twice the timeout rate. A shorter server cache timeout value allows servers to detect offline servers more quickly, at the cost of extra database processing. A longer Server cache timeout period reduces database load at the cost of a longer period to detect lost servers.

Local and Remote Concurrent I/O limits — Controls the number of concurrent outstanding I/O transactions that can be sent to a given storage device. A storage device is defined as either a local drive letter (C: or D: for example) or as the base of a UNC path, for example \( \text{\textbackslash ServerName} \).

Since the PVS service is a highly multi-threaded service, it is possible for it to send hundreds of simultaneous I/O requests to a given storage device. These are usually queued up by the device and processed when time permits. Some storage devices, Windows Network Shares most notably, do not deal with this large number of concurrent requests well. They can drop connections, or take unrealistically long to process transactions in certain circumstances. By throttling the concurrent I/O transactions in the PVS Service, better performance can be achieved with these types of devices.

Local device is defined as any device starting with a drive letter. Remote is defined as any device starting with a UNC server name. This a simple way to achieve separate limits for network shares and for local drives.

If you have a slow machine providing a network share, or slow drives on the machine, then a count of 1 to 3 for the remote limit may be necessary to achieve the best performance with the share. If you are going to fast local drives, you might be able to set the local count fairly high. Only empirical testing would provide you with the optimum setting for a given hardware environment. Setting either count to 0 disables the feature and allows the PVS Service to run without limits. This might be desirable on very fast local drives.

If a network share is overloaded, you'll see a lot more device retries and reconnections during boot storms. This is caused by read/write and open file times > 60 seconds. Throttling the concurrent I/O transactions on the share reduces these types of problems considerably.

Network tab

Maximum transmission unit — Number of bytes that fit in a single UDP packet. For standard Ethernet, the default value is correct. If you are attempting to operate over a WAN, then a smaller value may be needed to prevent IP fragmentation. Provisioning Services currently does not support IP fragmentation and reassembly. Also, if you are using a device or software layer that adds bytes to every packet (for security reasons for example), a smaller value may be needed. If your entire infrastructure supports jumbo packets (Provisioning Services NIC, target device NIC and any intervening switches and/or routers) then you can set the MTU to 50 bytes less than your jumbo packet max size to achieve much higher network throughput.

I/O burst size — The number of bytes that will be transmitted in a single read/write transaction before an ACK is sent from the server or device. The larger the IO burst, the faster the throughput to an individual device, but the more stress placed on the server and network infrastructure. Also, larger IO Bursts increase the likelihood of lost packets and costly retries. Smaller IO bursts reduce single client network throughput, but also reduce server load. Smaller IO bursts also reduce the likelihood of retries. IO Burst Size / MTU size must be <= 32, i.e. only 32 packets can be in a single IO burst before a ACK is needed.

Socket communications — Enable non-blocking I/O for network communications.

Pacing tab

Boot pause seconds — The amount of time that the device will be told to pause if the Maximum devices booting limit has been reached. The device will display a message to the user and then wait Boot pause seconds before attempting to continue to boot. The device will continue to check with the server every Boot pause seconds until the server allows the

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved.  p.122
device to boot.

Maximum boot time — The amount of time a device will be considered in the booting state. Once a device starts to boot, the device will be considered booting until the Maximum boot time has elapsed for that device. After this period, it will no longer be considered booting (as far as boot pacing is concerned) even if the device has not actually finished booting. Maximum boot time can be thought of as a time limit per device for the booting state for boot pacing.

Maximum devices booting — The maximum number of devices a server allows to boot at one time before pausing new booting devices. The number of booting devices must drop below this limit before the server will allow more devices to boot.

vDisk creation pacing — Amount of pacing delay to introduce when creating a vDisk on this Provisioning Server. Larger values increase the vDisk creation time, but reduce Provisioning Server overhead to allow target devices that are running, to continue to run efficiently.

**Device tab**

License timeout — Amount of time since last hearing from a target device to hold a license before releasing it for use by another target device. If a target device shuts down abnormally (loses power for example) its license is held for this long.

**IP Address**
The IP addresses that the Stream Service should use for a target device to communicate with this Provisioning Server. When adding a new Provisioning Server, enter the valid IP address for the new server.

Add — Add an IP address for the selected Provisioning Server.

Edit — Opens the IP address dialog so that IP address for the selected Provisioning Server can be changed.

Remove — Removes the selected IP address from the list of available IP addresses for the selected Provisioning Server.

**Ports**
Enter the First and Last UDP port numbers to indicate a range of ports to be used by the Stream Service for target device communications.

Note: The minimum is five ports in a range. The default first port number is 6910 and the last port number is 6930.

**Stores**
Lists all stores (logical names representing physical paths to vDisks that are available to this Provisioning Server.

Add — Opens the Store Properties dialog so that a new store and that store's properties can be included in the list of stores, which overrides the default path.

Edit — Opens the Store Properties dialog so that the store's properties can be changed. Select an existing store, then click Edit to change that store's properties.

Remove — Removes the selected store from the list of available stores for this Provisioning Server.

**Store Properties (opens when Add or Edit is selected under Stores)**
Store — The name of the store. This displays populated when editing an existing store. If this is a new store, select the
store from the drop-down list.

Path used to access the store — The store path is only required if you need to override the ‘default path’ configured in the store properties. If the default path in the store properties is valid for this server, leave the path for the store blank in the server store properties.

Note: If setting an override store path on the Server’s Properties dialog, the path must be set prior to creating a new version of the vDisk. Because this path information is stored and referenced in the .VHD header information, changing the path after versioning may cause unexpected results.

Write cache paths — Click the Add or Edit buttons to open the Write cache path dialog, then enter the appropriate write cache path for this store.

Select an existing path from the list, then click Remove to remove the paths association with the store.

Use the Move Up and Move Down buttons to change the order of cache path priority. If configured for high availability, the order that the cache paths are listed must be the same order for each server.

**Active Directory**

Automate computer account password updates— If target devices are domain members, and require renegotiation of machine passwords between Windows Active Directory and the target devices, select the Automate computer account password updates, and use the slider to set the number of days between renegotiation.

**Enable automatic vDisk updates**

Check to enable vDisks to be updated automatically, then set the time of day to check for updates.

**Logging Level**

Select from the following logging level options:

- **TRACE**
  
  TRACE logs all valid operations.

- **DEBUG**
  
  The DEBUG level logs details related to a specific operation and is the highest level of logging. If logging is set to DEBUG, all other levels of logging information are displayed in the log file.

- **INFO**
  
  Default logging level. The INFO level logs information about workflow, which generally explains how operations occur.

- **WARN**
  
  The WARNING level logs information about an operation that completes successfully, but there are issues with the operation.

- **ERROR**
  
  The ERROR level logs information about an operation that produces an error condition.
FATAL

The FATAL level logs information about an operation that the system could not recover from.

File size maximum
Enter the maximum size that a log file can reach before a new file is created.

Backup files maximum
Enter the maximum number of backup log files to retain. When this number is reached, the oldest log file is automatically deleted.
Overview of Provisioning Server Tasks

May 07, 2015
You typically perform the following tasks when managing Provisioning Servers in your farm.

Important: After making any changes to a Provisioning Server’s properties, restart the Stream Service to implement those changes. Use caution when restarting services. If target devices are connected to the Provisioning Server, changes could prevent the device from reconnecting. The IP address field on the Network tab must reflect the real static IP address of the Provisioning Server.

- Copying and Pasting Server Properties
- Deleting a Server
- Starting, Stopping, or Restarting Provisioning Services on a Server
- Showing Server Connections
- Balancing Target Devices on a Server
- Checking for vDisk Access Updates
- Configuring Provisioning Servers Manually
- Auditing
- Configure Bootstrap
To copy the properties of one Provisioning Server to another Provisioning Server:

1. Right-click on the Provisioning Server to copy properties from, then select Copy server properties. The Copy Server Properties dialog appears.
2. Enable the checkbox next to each property to copy, or click the Select all button to enable all properties to be copied.
3. Click Copy. Right-click on the Provisioning Server that you want to copy properties to, then select Paste.
Deleting a Provisioning Server

Apr 08, 2010

Occasionally, it may be necessary to delete a Provisioning Server from the list of available Provisioning Servers in a farm.

Note: Before you can delete a Provisioning Server, you must first mark the server as down or take the server off line, otherwise the Delete menu option will not appear. The Stream Service can not be deleted.

When you delete a Provisioning Server, you do not affect vDisk image files or the contents of the server drives. However, you do lose all paths to the vDisk image files on that server.

After deleting a Provisioning Server, target devices are no longer assigned to any vDisk image files on that server. The target device records remain stored in the Virtual LAN Drive database, but the device cannot access any vDisk that was associated with the deleted Provisioning Server.

Note: If there are vDisks associated with the Provisioning Server being deleted, it is recommended that backup copies are created and stored in the vDisk directory prior to deleting.

To delete a Provisioning Server:

1. In the Console, highlight the Provisioning Server that you want to delete, then select Show connected devices from the Action menu, right-click menu, or Action pane. The Connected Target Devices dialog appears.
2. In the Target Device table, highlight all devices in the list, then click Shutdown. The Target Device Control dialog appears.
3. Type a message to notify target devices that the Provisioning Server is being shut down.
4. Scroll to select the number of seconds to delay after the message is received.
5. If the Stream Service is running on the Provisioning Server, stop the Stream Service (Starting, Restarting or Stopping the Stream Service).
6. Unassign all target devices from the Provisioning Server.
7. Highlight the Provisioning Server you want to delete, then choose Delete from the Action menu, right-click menu, or Action pane. A delete confirmation message appears.
8. Click Yes to confirm the deletion. The Provisioning Server is deleted and no longer displays in the Console.
Starting, Stopping, or Restarting Provisioning Services

Jan 17, 2014

To start or stop SOAP or Stream Services on a Provisioning Server, the user the services are running under must have Windows permissions to control those services. This limitation is due to Window's security issue.

To work around this issue, install the subinacl tool from Microsoft https://www.microsoft.com/downloads/details.aspx?FamilyID=e8ba3e56-d8fe-4a91-93cf-ed6985e3927b&displaylang=en, then use the following command line to set the permissions on the StreamService: subinacl /service streamservice /grant=NetworkService=TOP.

To start, stop, or restart Provisioning Services on a Provisioning Server:

1. Highlight the Provisioning Server in the Console, then select the Stream Services menu option from the Actions menu, right-click menu, or Actions pane. The Provisioning Server Control dialog appears.

2. Select from the following menu options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Starts the Stream Service</td>
</tr>
<tr>
<td>Stop</td>
<td>Places the Provisioning Server in off-line mode</td>
</tr>
<tr>
<td>Restart</td>
<td>After modifying Provisioning Server settings, such as adding or removing IPs, restart the Stream Service</td>
</tr>
</tbody>
</table>

3. Highlight the Provisioning Servers that you want to take action on, then click that action's button.

4. Click Close to exit the dialog.
Showing Provisioning Server Connections

Apr 08, 2010

To view and manage all target device connections to the Provisioning Server:

1. Highlight a Provisioning Server in the Console, then select Show connected devices from the Action menu, right-click menu, or Action pane. The Connected Target Devices dialog appears.

2. Select one or more target devices in the table to perform any of the following connection tasks:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shutdown</td>
<td>Shuts down target devices that are highlighted in the dialog.</td>
</tr>
<tr>
<td>Reboot</td>
<td>Reboots target devices that are highlighted in the dialog.</td>
</tr>
<tr>
<td>Message</td>
<td>Opens the Edit Message dialog to allow you to type, and then send a message to target device(s) highlighted in the dialog.</td>
</tr>
</tbody>
</table>

When selecting Shutdown or Reboot, a dialog opens providing the option to type a message that displays on the effected devices. The Shutdown or Reboot options can be delayed by entering a delay time setting.

If a message appears confirming that the target device was successfully shut down or rebooted, but the icon in the Console window does not change accordingly, select the Refresh button.
To achieve optimum server and target device performance within a highly available network configuration, enable load balancing for each vDisk.

1. Right-click on the vDisk in the Console, then select the Load Balancing... menu option. The **vDisk Load Balancing** dialog appears.

2. After enabling load balancing for the vDisk, the following additional load balancing algorithm customizations can be set:
   - Subnet Affinity – When assigning the server and NIC combination to use to provide this vDisk to target devices, select from the following subnet settings:
     - None – ignore subnets; uses least busy server. This is the default setting.
     - Best Effort – use the least busy server/NIC combination from within the same subnet. If no server/NIC combination is available within the subnet, select the least busy server from outside the subnet. If more than one server is available within the selected subnet, perform load balancing between those servers.
     - Fixed – use the least busy server/NIC combination from within the same subnet. Perform load balancing between servers within that subnet. If no server/NIC combination exists in the same subnet, do not boot target devices assigned to this vDisk.
     - Rebalance Enabled using Trigger Percent – Enable to rebalance the number of target devices on each server in the event that the trigger percent is exceeded. When enabled, Provisioning Services checks the trigger percent on each server approximately every ten minutes. For example: If the trigger percent on this vDisk is set to 25%, rebalancing occurs within ten minutes if this server has 25% more load in comparison to other servers that can provide this vDisk.

   Note: The load balance algorithm takes into account the **Server Power setting** of each server when determining load. Load balancing will not occur if:
   - less than five target devices are using a particular server
   - the average number of target devices using all qualifying servers is less than five
   - the number of target devices that are booting on a given server is more than 20% of the total number of devices connected to the server (preventing load shift thrashing during a ‘boot storm’)

   Load balancing is also considered when target devices boot. Provisioning Services determines which qualified Provisioning Server, with the least amount of load, should provide the vDisk. Whenever additional qualified servers are brought online, rebalancing will occur automatically.

**To implement load balancing in a HA network configuration**

- Assign a power rating to each Provisioning Server on the **Server Properties’ General tab**.
- For each vDisk, select the load balancing method and define any additional load balancing algorithm settings on the **vDisk Load Balancing** dialog.

   Note: Target devices that are not using a vDisk that is in HA mode will not be diverted to a different server. If a vDisk is misconfigured to have HA enabled, but they are not using a valid HA configuration (Provisioning Servers and Store), target devices that use that vDisk can lock up.

   To rebalance Provisioning Server connections manually

1. In the Console, highlight the Provisioning Servers to rebalance, right-click then select the **Rebalance devices** menu option.
   The **Rebalance Devices** dialog appears.
2. Click Rebalance. A rebalance results message displays under the Status column.
3. Click Close to exit the dialog.
Checking for Provisioning Server vDisk Access Updates

Dec 06, 2010
To check for updates to vDisks that the selected Provisioning Server has access to:
1. Right-click the Provisioning Server in the details pane, then select Check for updates.
2. Select the Automatic... menu option.
3. Click OK on the confirmation message that appears. The vDisk is automatically updated or is scheduled to be updated.
Configuring Provisioning Servers Manually

Apr 08, 2010

If you are setting up a remote Provisioning Server, or have special requirements, you will need to configure and start your Stream Services manually. The Configuration Wizard needs to be run on remote Provisioning Servers to insure that all settings are configured properly. Failure to run the Configuration Wizard may make it impossible for you to map a vDisk. Refer to the Installation and Configuration Guide if you are running the Configuration Wizard for the first time.

The Configuration Wizard can be used when updating the Stream Service if the IP address of your Provisioning Server changes. If you change your Provisioning Server's IP address for any reason, simply re-run the Configuration Wizard and choose the new IP address when prompted to do so. Completing the Configuration Wizard resets the appropriate IP addresses in the configuration and restarts the Stream Service.

After configuring the Stream Service, you must start the service for the change to take effect. It is highly recommended to set the service to start automatically each time a Provisioning Server boots.

Note: The Configuration Wizard starts and configures the necessary services to start automatically. If you need to start and configure the services manually, see the instructions below.

The Stream Service needs to be started in order for the Provisioning Server to operate. Start the following boot services if they have not yet been started:

- BOOTP Service or PXE Service
- TFTP Service

To manually start services:

1. From the Windows Start menu, select Settings, and then click Control Panel.
2. From the Control Panel, double-click the Administrative Tools icon.
3. From the Administrative Tools window double-click on the Services icon. The Services window appears.
4. From the Services window, right click on the service you want to start, then select Start.

To manually configure services to start automatically upon booting the Provisioning Server:

1. From the Windows Start menu, select Settings, then click Control Panel.
2. From the Control Panel, double-click the Administrative Tools icon.
3. From the Administrative Tools window double-click on the Services icon. The Services window appears.
4. Right-click the service you want to configure, then select Properties.
5. Change the Startup Type to Automatic to configure the service to start automatically each time the system boots.
Disabling Write Cache to Improve Performance When Using Storage Device Drives

Jun 17, 2011

Disable write caching to improve the performance when writing from a Provisioning Server to storage device drives such as an IDE or SATA drive.

In Windows, to disable write caching on the server hard drive for the storage device on which your vDisks are stored:

2. Double-click the Disk Management node in the tree.
3. Right-click the storage device for which Windows write caching will be disabled.
4. Select Properties, then click the Hardware tab.
5. Click the Properties button.
6. Click the Policies tab.
7. Clear the Enable write caching on the disk checkbox.
8. Click OK, then click OK again.
9. Close the Computer Management window, then the Administrative Tools window.
10. Right-click the Provisioning Server node in the Console, then click Restart service. Alternatively, you can also re-run the Configuration Wizard to re-start the services, or manually restart the services through the Windows Control Panel>Administrative Tools>Services window. (At the Services window, right-click on the Stream Service, then select Start from the shortcut menu.)
Providing Provisioning Servers Access to Stores

Apr 08, 2010
For each store, select the Provisioning Servers that can access that store:
1. In the Console, right-click on the Store, then select the Properties menu option. The Store Properties dialog appears.
2. On the Servers tab, select the site where Provisioning Servers that should be able to access this store exists.
3. Enable the checkbox next to each Provisioning Server that can provide vDisks in this store, then click OK.
Managing Target Devices

May 08, 2015

A device, such as desktop computer or server, that boots and gets software from a vDisk on the network, is considered a target device. A device that is used to create the vDisk image is a considered a Master Target device.

The lifecycle of a target device includes:

- Preparing
  - a Master target device used for creating a vDisk image
  - a target device that will boot from a vDisk image
- Adding target devices to a collection in the farm
  - from the Console
  - using Auto-Add
  - importing
- Assigning the target device type
- Maintaining target devices in the farm

After a target device is created, the device must be configured to boot from the network, the device itself must be configured to allow it to boot from the network, a vDisk must be assigned to the device, and a bootstrap file must be configured to provide the information necessary for that device to boot from the assigned vDisk.

There are several types of target devices within a farm. For example, while a device is being used to create a vDisk image, it is considered a Master target device. All other devices are configured as a particular device type. The device Type determines a devices current purpose, and determines if that device can access a particular vDisk version that is in Production, Test, or Maintenance.

The device Type is selected on the General tab of the Target Device Properties dialog, which includes the following options:

- Production: select this option to allow this target device to stream an assigned vDisk that is currently in production (default).
- Maintenance: select this option to use this target device as a Maintenance device. Only a Maintenance device can access and make changes to a vDisk version that is Maintenance mode (only the first Maintenance device to boot the version while in Maintenance mode, is allowed to access that version).
- Test: select this option to use this target device to access and test differencing disk versions that are currently in Test mode.

A target device becomes a member of a device collection when it is added to the farm. The use of device collections simplifies the management of all target devices within that collection. A target device can only be a member in one device collection. However, a target device can exist in any number of views. If a target device is removed from the device collection, it is automatically removed from any associated views.

When target devices are added to a collection, that devices properties are stored in the Provisioning Services database. Target Device properties include information such as the device name and description, boot method, and vDisk assignments (refer to Target Device properties for details).

Target Devices are managed and monitored using the Console and Virtual Disk Status Tray utilities.

In the Console, actions can be performed on:

- An individual target device
• All target devices within a collection
• All target devices within a view
Configuring the BIOS Embedded Bootstrap

Oct 20, 2011

This feature is OEM specific and provides end users with systems preconfigured with Provisioning Services, allowing customers to deploy an Provisioning Services-enabled environment with minimal effort. This feature becomes an alternative to the standard PXE boot method.

As part of this solution, the OEM embeds the bootstrap within the target device’s BIOS at the factory. The OEM also pre-configures the device with product license keys.

For the BIOS-Embedded Bootstrap feature to work automatically from the factory, the target network must support the following:

- A DHCP server that is capable of providing the target device’s IP, Subnet & Gateway address. Additionally, the DHCP service must provide the default DNS server for the client to use.
- A DNS server must be active on the network
- A DNS entry must be defined which points the name <IMAGESERVER1> to each Provisioning Server’s active IP address. This DNS entry is used by the target device to find an active server.

If the target device boots using the BIOS-Embedded Bootstrap, the configuration settings are obtained from the device’s BIOS. These BIOS settings may indicate using DHCP with DNS to lookup the IP and server information (dynamic), or it may list up to four server IP addresses in the BIOS (static).

The first time a target device boots, it reads the product license key and configuration information from the BIOS, locates the Stream Service, and then sends a device registration message to the server. This message contains the information, in addition to the information inherited from the device collection template, necessary to add the device to the Provisioning Services database.

The OEM configures the BIOS-embedded bootstrap settings so that the bootstrap works ‘out-of-the-box’. If the Provisioning Services administrator needs to change settings, use the Configure BIOS Bootstrap feature in the Console. Configuration changes are updated automatically the next time the target device boots. However, only those BIOS settings that differ from the new settings are updated.

Note: The target device must have enough information stored in the BIOS to make initial contact with the Provisioning Server.

1. Right-click on a Provisioning Server in the Console window, then select the Configure Bootstrap menu option. The Configure Bootstrap dialog appears.
2. To allow target device BIOS settings to be automatically updated if connected to this server, on the General tab, check the Automatically update the BIOS on the target device with these settings check box. The next time the target device boots, these settings are automatically applied.

1. Select the Target Device IP tab on the Configure BIOS Bootstrap dialog.
2. Select from the following methods to use to retrieve target device IP addresses:
Use DHCP to retrieve target device IP; default method.
Use static target device IP; selecting this method requires that a primary and secondary DNS and Domain be identified.

1. On the Server Lookup tab, select the method that the target device will use to find the Provisioning Server it will boot from:
   - Use DNS to find server
     Select this option to find the server using DNS. The host name displays in the Host name textbox.
     Note: When using DNS, the DNS server must be able to resolve the name with the IP address of the server.
   - Use specific servers
     Select this option to manually enter Provisioning Server data. If this information was not previously entered, no data appears. To quickly list all servers in the database, click Read Servers from Database button.
     To change or enter new information, click Edit, then manually enter the information in the Server Address dialog.
     Note: Selecting the Reset to Default button will display a confirmation message to indicating that automatic BIOS updates on the target devices will be disabled and to use DNS to find the server.

1. On the Options tab, select from the network options that follow:
   - Select the Verbose mode option if you want to monitor the boot process on the target device (optional). This enables system messaging on the target device.
   - Select Interrupt safe mode if the target device hangs early in the boot process.
   - Select the Advanced Memory Support option to enable the bootstrap to work with newer Windows OS versions (enabled by default). Only disable this setting on older XP or Windows Server OS 32 bit versions that do not support PAE, or if your target device is hanging or behaving erratically in the early boot phase.

2. Select from the following Network Recovery Methods:
   - Restore network connections
     Selecting this option results in the target device attempting indefinitely to restore its connection to the Provisioning Server.
   - Reboot to Hard Drive
     Selecting this option instructs the target device to perform a hardware reset to force a reboot after failing to re-establish communications for a defined number of seconds. The user determines the number of seconds to wait before rebooting. Assuming the network connection can not be established, the target device will fail to contact the server and the system will reboot to the local hard drive. The default number of seconds is 50.
     Note: If the partition containing the vDisks is formatted as a FAT file system, a message displays a warning that this could result in sub-optimal performance. It is recommended that NTFS be used to format the partition containing the vDisks. Do not change the address in the Port field.
     Caution: All boot services must be on the same NIC (IP). But the Stream Service can be on a different NIC. The Stream Service allows you to bind to multiple IPs (NICs).

3. Configure the following:
Login Polling Timeout

Enter the time, in milliseconds, between retries when polling for servers. Each server is sent a login request packet in sequence. The first server that responds is used. This time-out simply defines how often to retry the single available server with the initial login request. This time-out defines how quickly the round-robin routine will switch from one server to the next, in trying to find an active server. The valid range is from 1,000 to 60,000 milliseconds.

Login General Timeout

Enter the time-out, in milliseconds, for all login associated packets, except the initial login polling time-out. The valid range is from 1,000 to 60,000 milliseconds.

4. Click OK to save your changes.
Adding Target Devices to the Database

Dec 12, 2011
To create new target device entries in the Provisioning Services database, select one of the following methods:

- Using the Console to Manually Create Target Device Entries
- Using Auto-add to Create Target Device Entries
- Importing Target Device Entries

After the target device exists in the database, you can assign a vDisk to the device. Refer to assign a vDisk to the device for more details.

1. In the Console, right-click on the Device Collection where this target device is to become a member, then select the Create Device menu option. The Create Device dialog appears.
2. Type a name, description, and the MAC address for this target device in the appropriate text boxes.
   Note: If the target device is a domain member, use the same name as in the Windows domain. When the target device boots from the vDisk, the machine name of the device becomes the name entered. For more information about target devices and Active Directory or NT 4.0 domains, refer to “Enabling Automatic Password Management”
3. Optionally, if a collection template exists for this collection, you have the option to enable the checkbox next to Apply the collection template to this new device.
4. Click the Add device button. The target device inherits all the template properties except for the target device name and MAC address.
5. Click OK to close the dialog box. The target device is created and assigned to a vDisk

Target device entries can be imported into any device collection from a .csv file. The imported target devices can then inherit the properties of the template target device that is associated with that collection. For more details, refer to Importing Target Devices into Collections.
Using the Auto-Add Wizard

Jun 27, 2012

The Auto-Add Wizard automates the configuration of rules for automatically adding new target devices to the Provisioning Services database using the Auto-Add feature.

The Auto-Add Wizard can be started at the Farm, Site, Collection or Device level. When started at a level lower than Farm, the wizard uses that choice as the default choice. For example, if it is started on a particular target device, it will:

- Select the Site for that Device as the Default Site choice in the combo-box.
- Select the Collection for that Device as the Default Collection choice in the combo-box.
- Select that Device as the Template Device choice in the combo-box.

The wizard displays each page with choices pre-selected based on the location that the Auto-Add Wizard was started from.

A Farm Administrator has the ability to turn Auto-Add on or off and to select the default Site.

A Site Administrator only has the ability to select the default site if the current default site is a site in which that administrator is the Site Administrator. If the Site Administrator is not the Administrator of the currently selected default Site, then that administrator can only configure the sites they have access to.

To configure Auto-Add settings (the default collection of a site, template device for the default collection and target device naming rules):

1. On the Console, right-click on the farm, then select the Auto-Add wizard. The Welcome to the Auto-Add Wizard page appears.
2. Click Next. The Enable Auto-Add dialog appears.  
   Note: Only a farm administrator can change settings on this page.
3. Check the box next to Enable Auto-Add to enable this feature, then click Next. The Select Site page appears.  
   Note: Site administrators can only select sites to which they have permissions.
4. From the Site drop-down list, select the site where devices should be added, then select Next. The Select Collection page displays with the default collection selected.
5. Accept the default collection or select a different collection from the Collection drop-down list, then click Next. The Select Template Devices page appears.
6. Select the device to use as a template, so that new devices being added will inherit the existing target device's basic property settings, then click Next.
7. To view the selected device's properties, click Properties. A read-only dialog displays the selected device's properties. Close the dialog after reviewing the properties.
8. Click Next. The Device Name page displays.
9. Enter a static prefix that helps identify all devices that are being added to this collection. For example: 'Boston' to indicate devices located in Boston.  
   Note: The prefix can be used in combination with the suffix, but is not required if a suffix is provided. The entire device name can have a maximum of 15 characters (the prefix length + number length + suffix length). For example, the following device names are considered valid:
   - **Boston000Floor2** (prefix, incrementing number length, and suffix provided; the maximum of 15 characters has been reached)
   - **Boston000** (no suffix is provided)
   - **000Floor2** (no prefix is provided)
The prefix cannot end with a digit.

10. Enter the length of the incrementing number to associate with the devices being added to this collection. This number is incremented as each device is added. For example, if the number length is set to ‘3’, Provisioning Services starts naming at ‘001’ and stops naming or adding devices after the number reaches ‘999’.

    Note: Enable the Zero fill option to automatically add the necessary number of preceding zeros to a numbers length. For example, if the numbers length is set to ‘4’, than the first target device number would be assigned as ‘0001’.

    The number length must have a minimum of three digits and a maximum of 9 digits.

11. Enter a static suffix that helps to identify all devices being added to this collection. For example: Boston001Floor2 might be helpful to indicate the floor where these devices reside.

    The suffix can be used in combination with the prefix, but is not required if a prefix is provided.

    The entire device name can have a maximum of 15 characters (the prefix length + number length + suffix length).

    The suffix cannot start with a digit.

    The prefix and suffix combination must be unique in each collection.

12. Click Next. The Finish dialog appears.

13. Review all Auto-Add wizard settings, then click Finish. Auto-Add is now configured.
Set the Target Device as the Template for this Collection

Oct 26, 2011

A target device can be set as the template for new target devices that are added to a collection. A new target device inherits the properties from the template target device, which allows you to quickly add new devices to a collection.

Note: Target devices that use personal vDisks are created and added to a collection when the XenDesktop Setup Wizard is run. If a target device template exists, it is ignored when the target device that uses a personal vDisk is added to the collection.

To set a target device as the template device for a collection, in the Console, right-click on the target device, then select Set device as template.

Note: Disable the target device that serves as the template to permit all target devices using this template to be added to the database, but not permit the target device to boot. Target devices receive a message requesting that they first contact the administrator before being allowed to boot. A ‘T’ appears in light blue on the device serving as the template. New target devices automatically have a name generated and all other properties will be taken from the default template target device. No user interaction is required.
Copy and Paste Target Device Properties

Jul 11, 2012
To copy the properties of one target device, and paste those properties to other target device members:
Note: Target devices that use personal vDisks can only inherit the properties of another target device that uses a personal vDisk.

1. In the Console's details pane, right-click on the target device that you want to copy properties from, then select Copy device properties. The Copy Device Properties dialog appears.
2. Select the checkbox next to the properties that you want to copy, then click Copy. The properties are copied to the clipboard and the dialog closes.
3. Right-click on one or more target devices that will inherit the copied properties, then select the Paste menu option. The Paste Device Properties dialog appears.
4. Click Close to close the dialog.
Booting Target Devices

Apr 08, 2010

To boot target devices:

1. Right-click on a collection to boot all target devices in the collection, or highlight only those target devices that you want to boot within the collection tree, then select the Boot devices menu option. The Target Device Control dialog displays with the Boot devices menu option selected in the Settings drop-down menu.

2. Click the Boot devices button to boot target devices. The Status column displays the Boot Signal status until the target device successfully receives the signal, then status changes to Success.
Checking a Target Device's Status from the Console

The target device status indicates whether it is currently active or inactive on the network.

To check the status of a target device:

1. Double-click on the target device in the Console window, then select the Properties menu option. The Device Properties tab appears.
2. Select the Status tab and review the following status information:
   - Current status (active or inactive)
   - IP address
   - Current Provisioning Server
   - Current vDisk name
   - Provisioning Server cache file size in bytes

   Also, in the Console window, if the target device is active, the target device icon appears as a green computer screen. If the target device is inactive, the icon appears as a black computer screen.
Sending Messages to Target Devices

Apr 08, 2010

To send a message to target devices members:

1. Right-click on the collection to send a message to all members within the collection, or highlight only those target devices within the collection that should receive the message, then select the Send message menu option. The Target Device Control dialog displays with the Message to devices menu option selected in the Settings drop-down menu. Target devices are displayed in the Device table.
2. Type a message to display on target devices in the Message text box.
3. Click the Send message button. The Status column displays the Message Signal status until target devices successfully receives the message, the status changes to Success.
Disabling a Target Device

Apr 08, 2010

The Disable Target Device feature prevents a new target devices from booting. When enabled, each time a new target device boots, if the Auto-add option is enabled, a new record is automatically created in the database and the following message appears on the target device:

This target device has been disabled. Please Contact your system administrator.

Once contacted, the system administrator can validate the target device. After the administrator disables the option, the target device can boot successfully.

To disable or enable a target device, in the Console, right-click on the target device, then select the Disable or Enable menu option.

Note: Enable the Disable target device option on the template target device, to disable all target devices as they are added to a collection.
Deleting Target Devices

Apr 08, 2010
To delete a target device:

1. In the Console, right-click on the target devices you want to delete within the collection (multiple selections can be made in the Details view), then select the Delete menu option.
2. Click Yes to confirm the delete request. The target device is deleted from the collection and any associated views. However, the vDisk image file for the target device still exists.
Shutting Down Target Devices

Apr 08, 2010
To shutdown target devices:

1. Right-click on the collection to shut down all target devices within the collection, or highlight only those target devices that should be shut-down within a collection, then select the Shutdown devices menu option. The Target Device Control dialog displays with the Shutdown devices menu option selected in the Settings drop-down menu. Target devices display in the Device table.

2. Type the number of seconds to wait before shutting down target devices in the Delay text box.

3. Type a message to display on target devices in the Message text box.

4. Click the Shutdown devices button to shutdown target devices. The Status column displays the shutdown signal status until the target device shuts down. As each target device successfully shuts down, the status changes to Success.
Restarting Target Devices

Apr 08, 2010

To restart target devices:

1. Right-click on a collection in the Console tree or highlight only those target devices that should be restarted within the collection, then select the Restart devices menu option. The Target Device Control dialog displays with the Restart devices menu option selected in the Settings drop-down menu. Target devices display in the Device table.

2. Type the number of seconds to wait before restarting target devices in the Delay text box.

3. Type a message to display on target devices in the Message text box.

4. Click the Restart devices button to restart target devices. The Status column displays the Restart Signal status until the target device successfully receives the signal, then status changes to Success.
Moving Target Devices Between Collections

Apr 08, 2010

A target device can be moved from one collection to another collection within a site using drag and drop in the Console's details pane (drag the device(s) from one collection, then drop the device into another collection). Alternatively, target devices can be moved using the Move menu option.

To move a target device using the Move menu option:

1. In the Console, expand the collection, right-click on the target device in the details pane, then select the Move menu option.
2. From the drop-down menu, select the collection to move this target device into. If applicable, apply the collection's device template to the target device being moved, by enabling Apply target collection's template device properties to moved devices.
3. Click Move.
Using the Status Tray on a Target Device

May 16, 2011

The Virtual Disk Status Tray provides device and product edition information on the target device. The purpose of this tool is to aid in the management and troubleshooting of vDisks.

Note: This tool is installed automatically during the installation process.

To manually start the Virtual Disk Status tray, double-click on the Status Tray icon in the System Tray. The Virtual Disk Status Tray dialog appears.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| vDisk Information | Status: Indicates the current state of the vDisk. Values include:  
|                   | • Active (target device is accessing this vDisk)  
|                   | • Inactive (target device is currently not accessing this disk)  
|                   | Server: Indicates the IP address and port of the Provisioning Server providing access to the vDisk.  
|                   | Boot from: Indicates if this vDisk is set to boot from a local hard drive or from a vDisk.  
|                   | Virtual Disk: Is the name of the vDisk being accessed by the target device.  
|                   | Mode: The current access mode for the vDisk. Values include:  
|                   | • Read only  
|                   | • Read and write  

|         | Build Identifies the specific product build and compile date.  

| Preferences | Prompt status message in system tray: Enable this option if you want the vDisk Status Tray to automatically start when the user logs into the target device.  
|            | Show icon in system tray: To indicate connection status to the vDisk, enable this option and the icon appears in your Windows system tray when this program runs.  

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boot Statistics | Boot time: The number of seconds elapsed during the boot phases of the operating system. This value does not include the POST, BIOS, PXE, DHCP, or TFTP.  
|           | Retries: The number of packet retries that occurred during the boot phases. |
### Field Description

- **Bytes Read**: The total number of bytes read during the boot phases.
- **Bytes Written**: The total number of bytes written during the boot phases.
- **Throughput**: A value calculating the overall throughput of the software during the boot phases. Throughput = (Bytes Read + Bytes Written)/Boot Time (in seconds).

### Session Statistics

- **Uptime**: The length of time the target device has been booted (HHHH:MM:SS)
- **Retries**: The total number of retries.
- **Bytes Read**: The total number of bytes read.
- **Bytes Written**: The total number of bytes written.

### Diagnostic Statistics

- **Uptime**: The length of time the target device has been booted (HHHH:MM:SS)
- **Retries**: The total number of retries.
- **Bytes Read**: The total number of bytes read.
- **Bytes Written**: The total number of bytes written.

---

On the General tab of the Virtual Disk Status dialog, the tray can be configured to run automatically when the target device starts, or it can be manually started. You may also choose to have the Virtual Disk Status tray icon appear in your system tray.

To configure the Virtual Disk Status Tray, choose from the following methods:
- Configure the tray to appear automatically as each target device starts.
- Add the Virtual Disk Status tray icon to your system tray.

**Configuring the tray to appear automatically as each target device starts**

1. Start the Virtual Disk Status Tray, and then select the **General** tab.
2. Select the Automatically start this program checkbox under Preferences. The tray starts automatically the next time the target device boots.

**Adding the Virtual Disk Status tray icon to your system tray**

1. Start the Virtual Disk Status tray, and then select the **General** tab.
2. Select the Show icon in System Tray checkbox under Preferences. The Virtual Disk Status tray icon appears in your system tray the next time the target device boots.
Managing Target Device Personality

Aug 05, 2011

Normally, all target device’s sharing the same vDisk must have identical configurations. The Target Device Personality feature allows you to define data for specific target devices and make it available to the target device at boot time. This data can then be used by your custom applications and scripts for a variety of purposes.

For example, suppose you are using Provisioning Server to support PCs in three classrooms. Each classroom has its own printer, and you want the PCs in each classroom to default to the correct printer. By using the Target Device Personality feature, you can define a default printer field, and then enter a printer name value for each target device. You define the field and values under Target Device Properties. The information is stored in the database. When the target device boots, the device-specific printer information is retrieved from the database and written to an .INI file on the vDisk. Using a custom script or application that you develop, you can retrieve the printer value and write it to the registry. Using this method, each time a target device boots, it will be set to use the correct default printer in its classroom.

The number of fields and amount of data that you can define for each target device is limited to 64Kb or 65536 bytes per target device. Each individual field may be up to 2047 bytes.

**Target Device Personality Tasks**
- Define personality data for a single target device using the Console
- Define personality data for multiple target device using the Console
- Using Target Device Personality Data

To define personality data for a single target device:

1. In the Console, right-click on the target device that you want to define personality data for, then select the Properties menu option.
2. Select the Personality tab.
3. Click the Add button. The Add/Edit Personality String dialog appears.
   - Note: There is no fixed limit to the number of field names and associated strings you can add. However, the limits to the total amount of personality data assigned to a single string (names and data combined) is approximately 2047 bytes. Also, the total amount of data contained in names, strings, and delimiters is limited to approximately 64Kb or 65536 bytes per target device. This limit is checked by the administrator when you attempt to add a string. If you exceed the limit, a warning message displays and you are prevented from creating an invalid configuration.
   - Target device personality data is treated like all other properties. This data will be inherited when new target devices are added automatically to the database by either the Add New Target Device silently option, or with the Add New Target Device with BIOS Prompts option.
4. Enter a name and string value.
   - Note: You can use any name for the field Name, but you cannot repeat a field name in the same target device. Field names are not case sensitive. In other words, the system interprets "FieldName1" and "FieldName" as the same name. Blank spaces entered before or after the field name are automatically removed. A personality name cannot start with a $. This symbol is used for reserved values such as $DiskName and $WriteCacheType.
5. Click OK.

To add additional fields and values, repeat Steps 5 and 6 as needed. When finished adding data, click OK to exit the Target Device Properties dialog.

Define target device personality for multiple devices:

1. In the Console, right-click on the target device that has the personality settings that you want to share with other device, then select Copy. The Copy device properties dialog appears.
2. Highlight the target devices in the details pane that you want to copy personality settings to, then right-click and select the Paste device properties menu.
3. Click on the Personality strings option (you may also choose to copy other properties at this time), then click Paste.

Once the file system becomes available to the target device, the personality data is written to a standard Windows .ini text file called Personality.ini. The file is stored in the root directory of the vDisk file system for easy access by your custom scripts or applications.

The file is formatted as follows:

[StringData]
FieldName1=Field data for first field
FieldName2=Field data for second field

This file is accessible to any custom script or application. It can be queried by the standard Windows .INI API. Additionally, a command line application, called GetPersonality.exe, is provided to allow easier batch file access to the personality settings.

A target device’s vDisk name and mode can be retrieved using GetPersonality.exe. The following reserve values are included in the [StringData] section of the Personality.ini file:

$DiskName=<xx>
$WriteCacheType=<0 (Private image)

All other values are standard image; 1 (Server Disk), 2 (Server Disk Encrypted), 3 (RAM), 4 (Hard Disk), 5 (Hard Disk Encrypted), 6 (RAM Disk), or 7 (Difference Disk). Min=0, Max=7, Default=0.

The xx is the name of the disk. A vDisk name cannot start with a $. This symbol is used for reserved values such as $DiskName and $WriteCacheType. The following message displays if a name that starts with $ is entered:

A name cannot start with a $. This is used for reserve values like $DiskName and $WriteCacheType. The $DiskName and $WriteCacheType values can be retrieved on the target device using GetPersonality.exe.

The command line utility GetPersonality.exe allows users to access the Target Device Personality settings from a Windows batch file. The program queries the .INI file for the user and places the personality strings in the locations chosen by the user. GetPersonality.exe supports the following command line options:

GetPersonality FieldName = RegistryKeyPath < - Place field in registry
GetPersonality FieldName = FileName < - Place field in .ini
GetPersonality FieldName /o < - Output field to STDOUT
GetPersonality /? or /help < - Display help

**Examples**

Setting a Registry Key Value:

The example below retrieves the Target Device Personality data value from the DefaultPrinter field and writes it to the target device registry to set the default printer for the device.

The Target Device Personality String Set in Target Device Properties is:

DefaultPrinter= \CHESBAY01\SAVIN 9935DPE/2035DPE PCL 5e, winspool,Ne03:
A batch file run on the target device would include the following line:
GetPersonality DefaultPrinter /r=HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Device
Note: The actual key name should be the UNC name of the network printer, such as \dc1\Main, and the value that should be entered for the key would be similar to winspool\Ne01: where Ne01 is a unique number for each installed printer.

Setting Environment Variables:

Setting environment variables with personality data is a two-step process:

1. Use the GetPersonality command with the /f option to insert the variable into a temporary file.
2. Use the set command to set the variable. For example, to set the environment variable Path statement for the target device a personality name, define the Pathname with the string value:

   %SystemRoot%;%SystemRoot%;%System32;\Wbem;\C:\Program Files\Microsoft Office\OFFICE11\\C:\Program Files\Microsoft SQL Server\80\Tools\Bin

   The /f option creates a temporary file, allowing for a name to be assigned, in this case temp.txt. The following lines would then need to be included in the batch file:

   GetPersonality Pathname /f=temp.txt
   set /p Path= <temp.txt

   Note: if the filename specified with the /f option already exists, GetPersonality will not append the line to the file. Instead, the existing line is overwritten in the file.
Changing the Device Status to Down

Occasionally, a target device may display as active when it is actually down. This occurs when the status record is not refreshed properly in the database. To change the target device's status in the database to down, Complete the steps that follow.

1. In the Console, right-click on the target device that should be marked as down, then select the Mark Device Down... option. A confirmation dialog appears.
2. Click OK to mark the device as down.
Target Device Properties

Jan 31, 2012

Note: A reboot is required if a target device is active when modifications are made to any of the following device properties:
- Boot from
- MAC
- Port
- vDisks for this Device

The following sections define the properties associated with a target device.

Name
The name of the target device or the name of the person who uses the target device. The name can be up to 15 bytes in length. However, the target device name cannot be the same as the machine name being imaged.

Note: If the target device is a domain member, use the same name as in the Windows domain, unless that name is the same as the machine name being imaged. When the target device boots from the vDisk, the name entered here becomes the target device machine name.

Description
Provides a description to associate with this target device.

Type
Select the access type for this target device from the drop-down list, which includes the following options:
- Maintenance: select this option to use this target device as a Maintenance device which will apply updates to a new maintenance version of a vDisk. A Maintenance device has exclusive read-write access to a maintenance version.
- Test: select this option to use this target device to access versions that are in Test mode. Test devices have shared read-only access to the test versions of a vDisk in order to facilitate QA testing of a vDisk version in Standard Image mode, prior to the release of that version to production machines.
- Production: select this option to allow the target device to stream an assigned vDisk that is currently in production. Production devices have shared, read-only access to production versions of a vDisk. Production devices do not have access to maintenance or test versions, which prevents updates that have not been tested from accidentally being deployed on production machines.

The default Type for a new device is Maintenance. The default Type for an existing device is Maintenance.

Boot from
The boot method this target device should use. Options include booting from a vDisk, hard disk, or floppy disk.

MAC
Enter the media access control (MAC) address of the network interface card that is installed in the target device.

Port
Displays the UDP port value.
In most instances, you do not have to change this value. However, if target device software conflicts with any other IP/UDP software (that is, they are sharing the same port), you must change this value.

Class
Class used for matching new vDisks to target devices when using Automatic Disk Image Update in order to match new vDisks images to the appropriate target devices.

**Disable this device**

Enable this option to prevent target devices from booting. Regardless if enabled or disabled, new target devices that are added using Auto-add, have records created in the database.

**vDisks for this Device**

Displays the list of vDisk assigned to this target device.

Click Add to open the Assign vDisks dialog. To filter the vDisks that display, select a specific store name and Provisioning Server or select All Stores and All Servers to list all vDisks available to this target device. Highlight the vDisks to assign, then click OK.

Click Remove to remove vDisks from this device.

Click Printers to open the Target Devices vDisk Printers dialog. This dialog allows you to choose the default printer and any network and local printers to enable or disable for this target device.

**Options**

Provides secondary boot options:

- Include the local hard drive as a boot device.
- Include one or more custom bootstraps as boot options.

If enabling a custom bootstrap, click Add, to enter the bootstrap file name and the menu text to appear (optional), then click OK.

If more than one vdisk is listed in the table or if either (or both) secondary boot options are enabled, the user is prompted with a disk menu at the target devices when it is booted. Enter a menu option name to display to the target device. The target device can select which boot options to use.

Click Edit to edit an existing custom bootstrap's file name or menu text.

Click Remove to remove a custom bootstrap file from those available to this target device.

**Name and String**

There is no fixed limit to the number of names you can add. However, the maximum name length is 250 characters and the maximum value length is 1000 characters.

Use any name for the field Name, but do not repeat a field name in the same target device. Field names are not case sensitive. In other words, the system interprets "FIELDNAME" and "fieldname" as the same name. Blank spaces entered before or after the field name are automatically removed.

A personality name cannot start with a $. This symbol is used for reserved values such as SDiskName and SWriteCacheType.

Password information entered in this dialog is for initial target device login only. It does not affect Windows account login.

**Authentication**

https://docs.citrix.com  © 1999-2017 Citrix Systems, Inc. All rights reserved.
If authenticating with a user name and password, enter the user name for the account. Follow your organization's user name conventions.

Note: Requires user names be at least two characters and no more than 40 characters in length. User names are NOT case sensitive.

Authentication methods include:

- None
- Username and password
- External verification (user supplied method)

**Username**

If the account already exists, you cannot change the user name.

**Password**

If authenticating with a user name and password:

Click the Change button to open the Change Password dialog. To create a new password for a user account, type the old password, then type the new password in both the New password and Confirm new password text boxes. Click OK to change the password.

Note: Follow your organization's password conventions. Requires passwords be at least three characters and no more than 20 characters in length. Passwords ARE case sensitive. Re-enter the new password exactly as you entered it in the previous field to confirm it.

**Target Device Status**

The following target device status information appears:

- Status: current status of this device (active or inactive).
- IP Address: provides the IP Address or 'unknown'.
- Server: the Provisioning Server that is communicating with this device.
- Retries: the number of retries to permit when connecting to this device.
- vDisk: provides the name of the vDisk or displays as 'unknown'.
- vDisk version: version of this vDisk currently being accessed.
- vDisk full name: the full file name for the version currently being accessed.
- vDisk access: identifies if the version is in Production, Maintenance, or Test.
- License information: depending on the device vendor, displays product licensing information (including: n/a, Desktop License, Datacenter License, XenApp License, or XenDesktop License).

**Logging level**

Select the logging level or select Off to disable logging:

- Off – Logging is disabled for this Provisioning Server.
- Fatal– logs information about an operation that the system could not recover from.
- Error logs information about an operation that produces an error condition.
- Warning– logs information about an operation that completes successfully, but there are issues with the operation.
- Info – Default logging level. Logs information about workflow, which generally explains how operations occur.
- Debug – logs details related to a specific operation and is the highest level of logging. If logging is set to DEBUG, all other levels of logging information are displayed in the log file.
- Trace – logs all valid operations.
Configure target devices that use personal vDisks

May 14, 2015

Citrix XenDesktop with personal vDisk technology is a high-performance enterprise desktop virtualization solution that makes VDI accessible to workers who require personalized desktops using pooled-static virtual machines.

Target devices that use personal vDisks are created using the Citrix XenDesktop Setup Wizard. Within a Provisioning Services farm, the wizard creates and adds target devices with personal vDisks to an existing site's collection and assigns an existing shared-mode vDisk to that device.

The wizard also creates virtual machines to associate with each device. A type of catalog in Citrix Desktop Studio allows you to preserve the assignment of users to desktops (static assignment); the same users are assigned the same desktop for later sessions. In addition, the wizard creates a dedicated storage disk (before logon) for each user so they can store all personalizations to their desktop. Personalizations include any changes to the vDisk image or desktop that are not made as a result of an image update, such as application settings, adds, deletes, modifications, and documents.

Target devices that use personal vDisks can inherit properties only from another device that uses personal vDisks.

Use the Device with Personal vDisk Properties dialog on the Provisioning Services console to configure, view, or modify the properties of a target device that uses a personal vDisk.

To update read-only fields, the device needs to be deleted and re-created with the XenDesktop Setup Wizard.

Name
The name of the target device or the name of the person who uses the target device. The name can be up to 15 bytes in length. However, the target device name cannot be the same as the machine name being imaged. This field is read-only.

If the target device is a domain member, it should use the same name as in the Windows domain, unless that name is the same as the machine name being imaged. When the target device boots from the vDisk, the name displayed here becomes the target device machine name.

Description
Provides a description to associate with this target device.

MAC
The media access control (MAC) address of the network interface card that is installed in the target device. This field is read-only.

Port
Displays the UDP port value.
In most instances, you do not have to change this value. However, if target device software conflicts with any other IP/UDP software (that is, they are sharing the same port), you must change this value.

vDisk
The name of the vDisk that this device uses. This field is read-only.

Change
Use to change the vDisk assignment for this device. The Assign vDisk dialog displays with the currently assigned vDisk's Store information. The vDisk you select must be from the same vDisk base image as the previous image.
Personal vDisk Drive

The drive letter from which the personal vDisk is accessed. The default is P: (the range allowed is between E: to U: and W: to Z:). This field is read-only.

Name and String

There is no fixed limit to the number of names you can add. However, the maximum name length is 250 characters and the maximum value length is 1000 characters.

Use any name for the field Name, but do not repeat a field name in the same target device. Field names are not case-sensitive. In other words, the system interprets “FIELDNAME” and “fieldname” as the same name. Blank spaces entered before or after the field name are automatically removed.

A personality name cannot start with a $. This symbol is used for reserved values such as SDiskName and SWriteCacheType.

Target Device Status

The following target device status information appears:
- Status: current status of this device (active or inactive).
- IP Address: provides the IP Address or unknown.
- Server: the Provisioning Server that is communicating with this device.
- Retries: the number of retries to permit when connecting to this device.
- vDisk: provides the name of the vDisk or displays as unknown.
- vDisk version: the version of this vDisk currently being accessed.
- vDisk full name: the full file name for the version currently being accessed.
- vDisk access: identifies that the version is in Production (it cannot be in Maintenance or Test).
- License information: depending on the device vendor, displays product licensing information (including: n/a, Desktop License, Datacenter License, XenApp License, or XenDesktop License).

Logging level

Select the logging level or select Off to disable logging:
- Off — Logging is disabled for this Provisioning Server.
- Fatal— Logs information about an operation that the system could not recover from.
- Error— Logs information about an operation that produces an error condition.
- Warning— Logs information about an operation that completes successfully, but there are issues with the operation.
- Info— Default logging level. Logs information about workflow, which generally explains how operations occur.
- Debug— Logs details related to a specific operation and is the highest level of logging. If logging is set to DEBUG, all other levels of logging information are displayed in the log file.
- Trace— Logs all valid operations.

You can assign a different vDisk to a target device that uses a personal vDisk if that vDisk is from the same base (.vhd) vDisk lineage. For example, to update an existing vDisk you can make a copy of the target device’s currently assigned vDisk, update the new vDisk, then assign the updated vDisk to the device.
To assign or reassign a vDisk:

1. On the Device with Personal vDisk Properties dialog's General tab, click Change... By default, the Assign vDisk dialog displays with the current vDisks Store location and lists all vDisks available from that Store, with the exception of the currently assigned vDisk.

2. In the Filter section, you have the option to:
   1. Change the Store location from which to select vDisks from.
   2. Filter vDisks that display in the list based on the servers that can deliver them.

3. Select the vDisk to assign to this target device.
Managing vDisks

May 18, 2015

vDisks are managed throughout the vDisk lifecycle. Provisioning Services provides support for a full image lifecycle that takes a vDisk from initial creation, through deployment and subsequent updates, and finally to retirement. The lifecycle of a vDisk consists of four stages:

1. Creating
2. Deploying
3. Updating
4. Retiring

Creating a vDisk

Creation of a vDisk requires preparing the master target device for imaging, creating and configuring a vDisk file where the vDisk will reside, and then imaging the master target device to that file; resulting in a new base vDisk image. This process can be performed automatically, using the Imaging Wizard, or manually. Provisioning Services also provides the option to create a common image for use with a single target platform or for use with multiple target platforms. For details, refer to Creating vDisks.

Deploying a vDisk

After a vDisk base image is created, it is deployed by assigning it to one or more devices. A device can have multiple vDisk assignments. When the device starts, it boots from an assigned vDisk. There are three boot mode options; Private Image mode (single device access, read/write), Standard Image mode (multiple device access, write cache options). For more details, refer to Deploying vDisks.

Updating a vDisk

It is often necessary to update an existing vDisk so that the image contains the most current software and patches. Updates can be made manually, or the update process can be automated using vDisk Update Management features. Each time a vDisk is updated a new version is created. Different devices can access different versions based on the type of target device and version classification. A maintenance device can have exclusive read/write access to the newest maintenance version; test devices can have shared read-only access to versions classified as test versions, and production devices can have shared read-only access to production versions. Versions are created and managed from the vDisk Versioning Dialog. An update can also be the result of merging versions. For more details on updating vDisks, refer to Updating vDisks.

Retiring a vDisk

Retiring a vDisk is the same as deleting. The entire VHD chain including differencing and base image files, properties files, and lock files are deleted. For details, refer to Retiring a vDisk.

Note: In addition to those vDisk tasks performed within a vDisk’s lifecycle, there are also other vDisk maintenance tasks that can be performed, such as importing or exporting the vDisk, backing-up vDisks, replicating, and load balancing.
Creating vDisks

Oct 15, 2013
This section provides the information and tasks necessary to create a new base vDisk image.

vDisks act as a hard disk for a target device and exist as disk image files on a Provisioning Server or on a shared storage device. A vDisk consists of a VHD base image file, any associated properties files (.pvp), and if applicable, a chain of referenced VHD differencing disks (.avhd).

When creating a vDisk image file, keep the following facts in mind:
- You can create as many vDisk image files as needed, as long as you have enough space available on the Provisioning Server, or on the storage device containing the vDisk image files.
- vDisk files use FAT or NTFS file systems for Microsoft operating systems.
- Depending upon the file system used to store the vDisk, the maximum size of a VHD file (vDisk) is 2 terabytes (NTFS) or 4096MB (FAT).
- A vDisk may be shared (Standard Image) by one or more target devices, or it can exist for only one target device to access (Private Image).

Creating a new vDisk is the first stage in the lifecycle of a vDisk. To create a vDisk basically requires preparing the master target device for imaging, creating and configuring a vDisk file where the vDisk will reside, and then imaging the master target device to that file; resulting in a new base vDisk image. This process can be performed automatically, using the Imaging Wizard, or manually. Provisioning Services also provides the option to create a common image for use with a single target platform or for use with multiple target platforms.

Note: Your administrator role determines what displays and which tasks you can perform in the Console. For example, you can view and manage vDisks in sites in which you are a site administrator. However, unless the farm administrator sets a site as the owner of a store, the site administrator can not perform store management tasks. The following provides an overview of the steps necessary to create a vDisk automatically and manually.

Automatically creating a vDisk image using the Imaging Wizard

This is the recommended method for creating new vDisk images.
Note: The master target device, physical or virtual, is prepared by installing and configuring the operating system of choice, as well as any applications that should be included in the base vDisk image. For details, refer to Preparing the Master Target Device.
To image the master target device, run the Imaging Wizard to automatically create a new vDisk file on a Provisioning Server or shared storage, and then image the master target device to that file.

**Manually creating a vDisk file then creating the image using Provisioning Services imaging**

This is the optional method used to create new vDisk images.

1. The master target device, physical or virtual, is prepared by installing and configuring the operating system of choice, as well as any applications that should be included in the base vDisk image. A vDisk file is then created on a Provisioning Server or shared storage, which can be accessed by any Provisioning Server that will provide the vDisk. The file must be mounted, formatted, then unmounted manually. This can be accomplished from the Console or from the target device. Note: In the Console, a new vDisk file can be created by right-clicking on the vDisk Pool or the Store, and then selecting the Create new vDisk menu option. Once created, vDisks display in the details pane when a site's vDisk pool is selected, or when a store in the farm is selected.

2. The master target device is imaged to the new vDisk file using the Provisioning Services imaging utility. Note: As a physical to virtual conversion tool, the imaging utility can convert a server or desktop workload from an online physical machine running Windows to a XenServer virtual machine or Provisioning Services vDisk. As a virtual-to-virtual tool, the imaging utility can convert a server or desktop workload from an offline virtual machine or disk, containing any guest operating system, to a XenServer VM.
Creating vDisk Files Manually

Oct 16, 2013
Creating a New vDisk File

1. In the Console tree, right-click on the vDisk Pool in the site where you want to add those vDisks, then select the Create vDisk menu option. The Create vDisk dialog appears.

2. If you accessed this dialog from the site’s vDisk pool, in the drop-down menu, select the store where this vDisk should reside. If you accessed this dialog from the store, from the drop-down menu, select the site where this vDisk will be added.

3. In the Server used to create the vDisk drop-down menu, select the Provisioning Server that will create the vDisk.

4. Type a filename for the vDisk. Optionally, type a description for this new vDisk in the description textbox.

5. In the Size text box, scroll to select the appropriate size to allocate for this vDisk file. If the disk storing the vDisk images is formatted with NTFS, the limit is approximately 2 terabytes. On FAT file systems, the limit is 4096 MB.

6. In the VHD Format text box, select the format as either Fixed or Dynamic (2040 GB for VHD emulating SCSI; 127 GB for VHD emulating IDE). If the VHD format is Dynamic, from the VHD block size drop-down, select the block size as either 2 MB or 16 MB.

7. Click Create vDisk, a progress dialog opens. Depending on the disk size and other factors, it may take several minutes or more to create the vDisk. After the vDisk is successfully created, it displays in the Console’s details pane and is ready to be formatted.

8. Right-click on the vDisk in the Console, then select Mount vDisk. The vDisk icon displays with an orange arrow if mounted properly.

A vDisk image can not be assigned to, or boot from a target device until that target device exists in the Provisioning Services database. After creating the target device, in the Console, select the Hard Disk boot option.
About the Common vDisk Image feature

May 08, 2015

The Common Image feature allows a single vDisk to simultaneously be supported by multiple target device platforms, greatly reducing the number of vDisks an administrator must maintain. The procedure for creating a common image depends on the target device platform.

Supported target device platforms include:

- A combination of XenServer VMs and physical devices (virtual-to-virtual and virtual-to-physical). For details, refer to Create Common Images for use with XenServer VMs and Physical Devices, or Blade Servers
- Multiple types of physical devices (different motherboards, network cards, video cards and other hardware devices). For details, refer to Creating a Common Image for use with Multiple Physical Device Types
- Blade servers Create Common Images for use with XenServer VMs and Physical Devices, or Blade Servers
Create Common Images for use with XenServer VMs and Physical Devices, or Blade Servers

May 12, 2015
XenServer Platinum Edition enables the provisioning of physical and virtual servers from the same workload image.

Prerequisites:

- Appropriate XenServer Platinum Licensing.
- Support for PXE on the local network.
- DHCP must be installed and configured on the local network.

Select from the following target device platforms:

- Create a common image that boots from a physical or virtual server.
- Create a common image that boots from a blade server.

Create a common image that boots from a physical or virtual server

To create a common image that boots from a physical or virtual machine, complete the procedures as follows.

**Prepare the Master Target Device**

Install a supported Windows Operating System with the latest patches and device drivers on a physical machine. This physical machine will serve as the master target device.

Note: For a list of supported Windows Operations Systems, refer to Target Device requirements.

**Install the Provisioning Services Target Device Software**

1. Log onto the master target device as a domain administrator, or a domain user (with local install privileges).
2. Install the Provisioning Server Target Device software on the physical machine.
3. Follow the onscreen prompts by selecting installation default settings.
4. When prompted, reboot the master target device from the hard disk drive.

**Install XenConvert Software**

XenConvert software and installation instructions can be downloaded from either the Provisioning Services product download site or the XenServer product download site.

After successfully installing XenConvert on the target device:

1. Run XenConvert on the target device to convert the physical machine into a XenServer VM.
2. Set the VM's vCPU setting to be the same as the physical system's vCPU setting.
   Note: This very step is important for NT5 OS.
3. Change the XenServer VM MAC (it is using the Physical system's MAC address of the NIC), or remove the NIC and add a new NIC.
4. Boot the XenServer VM.

**Install XenServer Tools**

1. Log onto the master target device as a domain administrator, or a domain user (with local install privileges).
2. Run `windows-pvdrivers-xensetup.exe`, which can be downloaded from the XenServer Product installation CD or product download site. The Citrix XenServer Windows Tools Setup warning dialog appears.

3. Click Yes to continue the install.

4. Follow the onscreen prompts and select the default settings. At the Choose Install Location dialog box, click Install.

5. When prompted by Windows Plug and Play dialogs, select the option to find drivers automatically.

6. When prompted select Yes for any unsigned driver dialog.

7. When prompted, Reboot master target device.

8. Verify that Provisioning Services successfully binded to the XenServer NIC and the physical systems NIC.

**Image the Provisioning Server Master Target Device**

Use either the Provisioning Services Imaging Wizard or XenConvert to create the XenServer vDisk image. When creating the vDisk image, you must select to optimize target device settings. Otherwise the VM may fail to boot.

After successfully creating the XenServer vDisk image, boot both the physical and virtual machines in Standard Image mode.

For details on using the Provisioning Services Imaging Wizard, refer to Using the Imaging Wizard. For details on using XenConvert to create the XenServer vDisk image, refer to XenConvert product documentation on the Provisioning Services or XenServer product download site.

Create a common image that boots from a Blade Server

To create a common image using the common hard drive method that boots from heterogeneous Blade servers, complete the steps that follow.

1. Use the Console to create a new vDisk file.
2. Log onto the blade server to create a new system:
   1. Install the OS on the new machine.
   2. Install HP System Pack (installs all drivers).
   3. Install all necessary Windows updates.
   4. Install Provisioning Services target device software.
3. PXE boot from the new system’s hard disk drive, then verify that the system can recognize the vDisk. The vDisk is shown from “My Computer” as a partition.
4. Physically move the HDD or HDDs in a RAID system to the other system (usually the older system).
5. Boot from the new systems hard disk drive.
6. After Windows installs the driver’s, reboot when prompted.
7. Verify that NIC drivers installed correctly.
8. PXE boot from the hard disk drive on the second system.
9. Use either the Provisioning Services Imaging Wizard or XenConvert to create the vDisk image.
10. After imaging completes, shut down the system.
11. Set both systems to boot from the vDisk.
12. On the Console, change the vDisk mode to standard cache on local hard disk drive.
Creating a Common Image for use with Multiple Physical Device Types

Feb 07, 2011

Using the common NIC method, a single vDisk can simultaneously support different motherboards, network cards, video cards and other hardware devices. The result is a vDisk capable of being used by heterogeneous target devices, greatly reducing the number of vDisks an administrator must maintain.

Prerequisites

- Make sure all target devices that will use the common image have the a consistent HAL -- that is, they must have the same number of logical processors.
  Note: A single processor hyper-threading capable system is considered to have two logical processors when the hyper-threading is enabled in the BIOS.
- The BIOS structure, which is presented to the OS during the boot process, must be of the same format for all target devices that share a Standard Image. The BIOS Structure contains a list of all the components connected to the motherboard so that the appropriate drivers are loaded to allow the components to function properly.
- Have either a 3Com Managed PC Boot Agent (MBA) or a PXE-compliant NIC available. This card is the common NIC that is inserted into each target device during the Common Image build process.
- Install all the latest device drivers on each target device.
- Device drivers are missing if devices do not respond after you configure the common image. For example, if a target device’s USB mouse and keyboard do not respond after you assign the common image to the target device, it is likely that you have not installed drivers for that target device’s chipset. Go to device manager and check to insure no yellow exclamation mark display on any devices, especially USB Root HUBs and controllers.
- Determine which target device contains the latest motherboard chipset. This target device is used as the first target device in the common image build process. The latest Intel chipset driver always contains all the drivers for the previous chipset, therefore it is not necessary to install as many drivers when you build the common image.
- Except on the first target device, disable built-in NICs on all target devices that will use the common image (leave the built-in NIC on the first target device enabled). This prevents confusion about which NIC to use during the common image building process.
- Install Provisioning Services components.

Building the Common Image

The steps for building a common image are as follows:

- Configure the Master Target Device
- Export Specific Data Files
- Boot the Master Target Device
- Add Additional Target Devices to the Common Image

Note: Important! When building the common image, create a vDisk that has enough space to accommodate additional information that is added by the common image build process.

Configuring the Master Target Device

1. Insert the common NIC into the Master Target Device.
2. Install the target device software on the Master Target Device. Select both the common NIC and built-in NICs during the installation process.
3. Create a vDisk, then mount, format, and unmount it. You must create a vDisk that has enough space to accommodate additional information added by the common image build process.
4. Run the Imaging Wizard on the target device to build the vDisk.
5. (Recommended) Make a copy of the original vDisk created in Step 3 and save it in the vDisk directory on the Provisioning Server.
6. On the first target device, copy CIM.exe from `C:\Program Files\Citrix\Provisioning Services` to a removable storage device, such as a USB flash drive. This utility is used to include disparate target devices in the common image.
7. Shut down the Master Target Device and remove the common NIC.

Exporting Specific Data Files

1. Insert the common NIC into a target device that will be added to the common image, then boot the target device from its local hard drive.
   Note: Although the Windows OS must be installed on this target device, the target device software does not have to be installed.
2. Copy CIM.exe from the removable storage device to this target device.
3. At a command prompt, navigate to the directory in where CIM.exe is located, then run the following command to extract the information from the target device into the .dat file:
   ```
   CIM.exe e targetdeviceName.dat
   ```
   where `targetdeviceName` identifies the first target device that will use the common image. For example, `TargetDevice1.dat`.
   Copy the .dat file created in Step 3 to the removable storage device.
4. Shut down the target device and remove the common NIC.
   Note: To include additional target devices with disparate hardware in the common image, repeat this procedure for each device, giving each .dat file a unique name.

Booting the Master Target Device

1. Reinsert the common NIC into the Master Target Device. Insert the NIC into the same slot from which it was removed during the Configuring the Master Target Device procedure. Before booting the Master Target Device, enter the BIOS setup and verify that the common NIC is the NIC used in the boot process.
2. Using the common NIC, boot the Master Target Device from the vDisk, in Private Image mode.
3. Copy CIM.exe and the .dat file associated with the first target device from the removable storage device to the Master Target Device.
4. At a command prompt, navigate to the directory where the CIM.exe and the .dat file are located.
5. Run the following command to merge the information from the .dat file into the common image:
   ```
   CIM.exe m targetdeviceName.dat
   ```
6. Shut down the Master Target Device.

Adding Additional Target Devices to the Common Image

1. Insert the common NIC into additional target devices that will be included in the Common Image. Insert the NIC into the same slot from which it was removed in the Exporting Specific Data Files procedure.
2. Using the common NIC, boot the target device off the vDisk in Private Image mode.
3. Allow Windows time to discover and configure all the device drivers on the target device (this will take some time). If prompted by the “Found New Hardware Wizard” to install new hardware, Cancel out of the wizard and proceed to Step 4.
Note: If Windows can't install drivers for the built-in NIC on a target device, and the drivers can not be installed manually, the common NIC and the target device's built-NIC are very similar to each other and the driver installation program tries to update the driver for both NICs. For example, this happens if the common NIC is an Intel Pro 100/s and the target device's built-in NIC is an Intel Pro 100+. To resolve this conflict, open System Properties. On the Hardware tab, click the Device Manager button. In the Device Manager list, right-click the built-in NIC and click Update Driver to start the Hardware Update Wizard. Choose Install from a list or specific location and specify the location of the NIC's driver files.

4. Open Network Connections, right-click the connection for the built-in NIC and click Properties in the menu that appears. (The icon for the built-in NIC is marked with a red X.)

5. Under This connection uses the following items, select Network Stack and click OK.

6. From a command prompt, run the following command:
   
   C:\Program Files\Citrix\Provisioning Server\regmodify.exe
   
   Note: After completing Steps 4-6, reboot the target device and allow Windows to discover and configure any remaining devices. If prompted by the "Found New Hardware Wizard" to install new hardware, proceed through the Wizard to complete the hardware installation.

7. Using the original vDisk, repeat Step1 through Step 6 for each of the additional target devices to be included in the Common Image.

8. Once target devices have been included in the Common Image, on the Console, set the disk access mode for the Common Image vDisk to Standard Image mode, then boot the devices.
Prerequisites Before Deploying vDisks

May 08, 2015

vDisks are configured prior to being deployed. Configuration tasks include:

- Selecting the vDisk Access Mode (for details, refer to the Provisioning Services Overview section) and if applicable, the Write Cache Mode for that vDisk.
- Configuring the vDisk for Microsoft Volume Licensing (for details, refer to Configuring a vDisk for Microsoft Volume Licensing).
- Enabling Active Directory machine account password management, if applicable (for details, refer to Enabling Domain Management.)
- Enabling printer management (for details, refer to Managing Printers).
- Additional Settings
  - Enabling or disabling the streaming of this vDisk to assigned target devices (for details, refer to vDisk Properties dialog).
  - Providing vDisk identification information (for details, refer to Identification information in the vDisk Properties dialog).
Configuring the vDisk Access Mode

Jun 27, 2012

Use the Console to select from the following vDisk access modes:

- Private Image – Select this mode if a vDisk is only used by a single target device (read/write access is enabled).
- Standard Image – Select this mode if a vDisk is shared by multiple target devices (write-cache options enabled).

To configure the vDisk mode and any applicable write cache destination:

Note: Only those write cache destinations that are supported for Standard access mode appear enabled.

1. On the Console, right-click on the vDisk for which you want to configure the vDisk access mode, then select vDisk Properties. The vDisk Properties dialog appears.
2. Click on the General tab, then select the image mode (Standard or Private) that applies to this vDisk from the Access Mode drop-down list.
3. If Standard image was selected, from the cache destination drop-down list, select the appropriate write cache destination. (Refer to the section that follows for write-cache destination descriptions.)
4. Click OK to exit the vDisk Properties dialog.
A vDisk can be configured for Microsoft Key Management Service (KMS) or Multiple Activation Key (MAK) volume licensing when the Imaging Wizard is run. If it was not configured when the Imaging Wizard was run, it can still be configure from the Console:

Note: The MCLI and SoapServer command-line interfaces can also be used to configure Microsoft volume licensing.

1. Select the vDisk in the Console, then right-click and select File Properties. The vDisk File Properties dialog appears.
2. Click the Microsoft Volume Licensing tab, then select the MAK or KMS licensing method.
3. Click OK. After a vDisk has been configured for Microsoft volume licensing, additional steps may be necessary to activate or maintain that vDisk. For additional information, refer to Managing Microsoft MAK Licensing on Target Devices, and Configuring Microsoft KMS Volume Licensing.
Configuring Microsoft KMS Volume Licensing

Nov 12, 2013

Microsoft provides two mechanisms for administering volume licenses. This section describes use of the Key Management Server (KMS) license keys with Provisioning Services to apply volume licenses for Microsoft Server 2008, Windows 7 and Vista, as well as Office 2010.

Note: Provisioning Services support for KMS licensing requires that the SOAP Server user account be a member of the local administrators group.

KMS volume licensing utilizes a centralized activation server that runs in the datacenter, and serves as a local activation point (opposed to having each system activate with Microsoft over the internet).

Note: When preparing or updating a KMS configured vDisk that will be copied or cloned, it is important to complete the final KMS configuration task, which is to change the vDisk mode from Private Image Mode to Shared Image Mode, before copying or cloning the vDisk to other Provisioning Servers. Also, both the .pvp and .vhd file must be copied to retain the properties and KMS configuration of the original vDisk.

The tasks involved in configuring a vDisk image to use KMS volume licensing and managing that vDisk in a Provisioning Services farm include:

1. Enabling KMS licensing on the vDisk being created. This is accomplished by selecting the KMS menu option on the Microsoft Volume Licensing tab when running the Imaging Wizard (refer to Imaging Wizard for details).
2. Preparing the new base vDisk image, as described below
3. Maintaining or upgrading the vDisk image, as described below

Note: If KMS licensing was not configured on the vDisk when the Imaging Wizard was run, it can alternatively be configured using the Console user interface (refer to the Microsoft Volume Licensing tab, or the MCLI and PowerShell command-line interfaces (refer to the MCLI or PowerShell Programmers Guide for details).

Preparing the New Base vDisk Image for KMS Volume Licensing

After a vDisk is created using the Imaging Wizard, it must be reset to a non-activated state using the rearm command.

It is important to perform this operation on a system booted from the vDisk in Private Image Mode so that the master target device hard disk's rearm count is not reduced.

Note: Microsoft limits the number of times you can run rearm on an installed OS image. The operating system will need to be reinstalled if the number of allowed rearm attempts is exceeded.

1. Boot the target device from the vDisk in Private Image Mode to rearm.
   Note: OSPPPREARM.EXE must be run from an elevated command prompt.
   - For Windows Vista, 7, 2008, and 2008R2 run: cscript.exe slmgr.vbs -rearm
   - For Office 2010 (for 64bit client): Program Files\Common Files\microsoft shared\OfficeSoftwareProtectionPlatform\OSPPREARM.EXE
   - For Office 2010 (for 32bit client): Program Files(x86)\Common Files\microsoft shared\OfficeSoftwareProtectionPlatform\OSPPREARM.EXE
2. A message will prompted you to reboot the system, DO NOT REBOOT. Instead shut down the Target device.
3. If the KMS option was not selected when the vDisk image was created, click on the Microsoft Volume Licensing tab and set the licensing option to KMS.
   Note: For additional information on using KMS with Provisioning Services, refer to CTX128276 (http://support.citrix.com).
4. Set the vDisk mode to Standard Image mode.
5. Stream the vDisk to one or more target devices.

Maintaining or Upgrading a vDisk Image that Uses KMS Volume Licensing

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved. p.180
To maintain or upgrade a vDisk image that is configured to use KMS volume licensing:

1. Set the vDisk mode to Private Image mode.
2. Stream the vDisk to a target device.
3. Apply the OS/application service pack/update, then shutdown the target device.
4. Set the vDisk mode back to Shared Image mode.
5. Stream the vDisk to the target device in Shared Image mode.

   Note: If Office 2010 is installed as vDisk update, or after vDisk has gone through base disk preparation once, then the base disk preparation needs to be repeated as follows:
   1. In the Console, right-click on the vDisk, then select the File Properties menu option. The vDisk File Properties dialog appears.
   2. Click on the Microsoft Volume Licensing tab, then change the licensing option from KMS to None.
   3. On the Mode tab, set the vDisk access mode to Private Image mode.

4. PXE boot to the vDisk in Private Image mode to rearm:
   
   Note: OSPPREARM.EXE must be run from an elevated command prompt.
   
   - For Windows Vista, 7, 2008, and 2008R2 run: cscript.exe slmgr.vbs -rearm
   - For Office 2010 (for 64bit client): Program Files\Common Files\microsoft shared\OfficeSoftwareProtectionPlatform\OSPPREARM.EXE
   - For Office 2010 (for 32bit client): Program Files(x86)\Common Files\microsoft shared\OfficeSoftwareProtectionPlatform\OSPPREARM.EXE

5. A message will prompted you to reboot the system, DO NOT REBOOT. Instead shut down the Target device.
6. In the Console, right-click on the vDisk, then select the File Properties menu option. The vDisk Properties dialog appears.
7. Click on the Microsoft Volume Licensing tab, then change the license option from None to KMS.
8. On the Mode tab, set the vDisk access mode to Shared Image mode.
9. Stream the vDisk to the target devices.
Configuring Microsoft MAK Volume Licensing

May 14, 2015
This document describes how to use Multiple Activation Keys (MAK) to administer volume licenses. A MAK corresponds to a certain number of purchased OS licenses. The MAK is entered during the installation of the OS on each system, which activates the OS and decrements the count of purchased licenses centrally with Microsoft.

Setting the vDisk's licensing mode
A vDisk can be configured to use Microsoft Multiple Activation Key (MAK) licensing when the Imaging Wizard is run (refer to Imaging Wizard). If MAK licensing was not configured when the Imaging Wizard was run, the vDisk's licensing mode property can be set using the Console, MCLI, or PowerShell user interface. The licensing mode should be set before attempting to activate target devices.

Note: For information on using the command-line interfaces, refer to the MCLI or PowerShell Programmers Guide.

Entering MAK User Credentials
Before target devices that use MAK-enabled vDisks can be activated, MAK user credentials must be entered for a site. Note: The user must have administrator rights on all target devices that use MAK-enabled vDisks, and on all Provisioning Servers that will stream the vDisks to target devices.
To enter credentials:
1. Right-click on the site where the target devices exist, then select the Properties menu option.
2. On the MAK tab, enter the user and password information in the appropriate text boxes, then click OK.

Activating target devices that use MAK-enabled vDisks
After a vDisk is configured for MAK volume licensing and user credentials have been entered, each booted target device that is assigned to the vDisk needs to be activated with a MAK.

Note: After all licenses for a given MAK have been used, a new key will be required in order to allow additional target devices that share this vDisk image to be activated.
To activate target devices that use MAK volume licensing from the Console:
1. Boot all target devices that are to be activated.
2. In the Console, right-click on the collection or view of the individual device that includes those target devices that require MAK license activation, then select the Manage MAK Activations... menu option. The Manage MAK Activations dialog appears.
3. In the Multiple activation key text box, enter the MAK to be used to activate the target devices.
4. The number of booted target devices that require activation, display on the dialog. From the list of booted devices, check the box next to each target device that should be activated.
5. Click OK to activate licensing for all selected target devices (do not close the dialog until the activation process is completed. The process can be stopped by clicking the Cancel button. Closing the dialog before the activation process completes stops the process and may result in some target devices not being activated). The Status column indicates if a target device is currently being activated (Activating) or the activation failed (Failed). If all target devices were activated successfully, click OK to close the dialog. After the activation process completes, if one or more target devices were not selected to be activated, or if devices were not activated successfully, the dialog displays listing any un-activated devices. After resolving any issues, repeat this step to activate the remaining target devices.

Note: The Manage MAK Activations... option does not display after all currently booted target devices have been successfully activated.

Maintaining MAK Activations
Typically, devices and their assigned vDisk activations are preserved automatically. When a different target device is assigned a MAK activated vDisk, it removes any saved existing MAK reactivation information. If the vDisk is reassigned in the future, the target device will not reactivate. To prevent the loss of MAK activation, do not unassign the activated disk from the target device.

To change a target device's vDisk, without losing the MAK activation, select one of the following methods:
1. Assign additional vDisks to the target device, without removing any, then set the default booting vDisk accordingly.
2. Assign additional vDisks to the target device and temporarily disable the MAK activated vDisk.

To update a MAK activated vDisk, the AutoUpdate feature must be used so that the MAK activation information, required for shared device reactivation, is maintained.

Additional MAK considerations:
- Use of manual vDisk updates (unassigning one vDisk and reassigning another vDisk) will result in the loss of the required MAK activation information and will require a new activation, which would consume another license.
- Use of AutoUpdate to deploy a new vDisk from an OS install different from the one on the previous vDisk will result in mismatched MAK activation information. In this case, a new activation must be performed from the command line interface, because only unactivated target devices can be activated from the Provisioning Services console.
Managing Load Balancing Across Servers

Aug 01, 2012

A vDisk can be configured so that a single server provides that vDisk, or configured so that multiple servers can provide the vDisk using a load balancing algorithm.

To configure load balancing on a vDisk:
1. Right-click on the vDisk in the Console, then select the Load Balancing... menu option.
2. Select to enable load balancing or to assign a single Provisioning Server to provide this vDisk, then click OK. Refer to the table below for dialog details.

Note: For details on configuring for high availability, refer to Managing for Highly Available Implementations.

The following table describes the vDisk Load Balancing dialog.

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
</table>
| Use the load balancing algorithm | Provides the option to enable or disable the load balancing algorithm, which selects the server that is least busy to provide this vDisk to target devices. Subnet Affinity: When assigning the server and NIC combination to use to provide this vDisk to target devices, select from the following subnet settings:  
  - None – ignore subnets; uses least busy server. None is the default setting.  
  - Best Effort – use the least busy server/NIC combination from within the same subnet. If no server/NIC combination is available within the subnet, select the least busy server from outside the subnet. If more than one server is available within the selected subnet, perform load balancing between those servers.  
  - Fixed – use the least busy server/NIC combination from within the same subnet. Perform load balancing between servers within that subnet. If no server/NIC combination exists in the same subnet, do not boot target devices assigned to this vDisk.  
Rebalance Enabled: Enable to rebalance the number of target devices on each server in the event that the trigger percent is exceeded. When enabled, Provisioning Services checks the trigger percent on each server every ten minutes.  
Note: Rebalancing will not occur if there are less than five target devices on each server, or if more than 20% of the target devices are currently booting. A target device that is currently booting will not be moved to a different server.  
Trigger Percent: The percent of overload that is required to trigger the rebalancing of target devices. For example: If the trigger percent is equal to 25%, rebalancing occurs if this server has 25% more load in comparison to other servers that can provide this vDisk. Values between 5 - 5000; default is 25. |
| Use this server to provide the vDisk | To assign a specific server to provide this vDisk, enable the Use this server to provide the vDisk radio button. |
Support for Replicated vDisk Storage

Provisioning Services supports the replication of vDisks on stores that are local (local/attached storage on Provisioning Servers) within a site.

Replication considerations include:
- All Provisioning Servers must have network connectivity with all other servers in the farm.
- Replication must be properly configured to work with Provisioning Services and meet all requirements.
- Provisioning Services files to be replicated include: *.vhd, *.avhd, and *.pvp. If importing existing vDisks, the *.xml (manifest files) may also be replicated. The *.lok files should not be replicated.
- It is not necessary to shut down a server during the replication process.
- Store path must be set for each Provisioning Server.
  Note: If setting an override store path on the Server's Properties dialog, the path must be set prior to creating a new version of the vDisk. Because this path information is stored and referenced in the .VHD header information, changing the path after versioning may cause unexpected results.
- Necessary storage must be available and have read/write access.

Note: While DFS Replication can be used with Provisioning Services, DFS Namespaces are not supported as store paths. The illustration that follows shows a replication scenario where a version is not available to all servers from local storage.

Troubleshooting and Viewing Replication Status for a Particular vDisk

Provisioning Services allows users to view the availability of replicated vDisks to Provisioning Servers within a farm.
1. Right-click on a vDisk in the Console, then select the Versions... menu option. The vDisk Versions dialog appears.
2. Highlight a version in the dialog, then click the Replication button. The vDisk Version Replication Status dialog displays showing the replication status availability for each server that can provide this version of the vDisk.
- If a version is in Maintenance (hammer icon), Test (magnifying glass), or Pending (hour glass) states, that state displays in the first row.
Blue checkmark indicates that the server has access to this version.
Orange warning indicates that a server currently does not have access to one or more versions of this vDisk. The version that is missing, or has an issue, has a orange warnings under that version column.

Troubleshooting and Viewing Replication Status for all Versions of a vDisk

1. Right-click on a vDisk in the Console, then select the Replication Status... menu option. The vDisk Version Replication Status dialog appears.
2. The Server column lists all servers that can provide this vDisk and the general replication status of that server. The version columns lists each version of the vDisk and that versions individual replication status.
   - If a version is in Maintenance (hammer icon), Test (magnifying glass), or Pending (hour glass) states, that state displays in the first row.
   - Blue checkmark indicates that the server has access to this version.
   - Orange warning indicates that a server currently does not have access to one or more versions of this vDisk. The version that is missing, or has an issue, has a orange warnings under that version column.
Exporting and Importing vDisks

Jan 10, 2012

Provisioning Services allows for the exporting and importing of both versioned and unversioned vDisks, from an existing store to a store in a different farm.

Note: If importing VHDs that were not exported using Provisioning Services, all differencing disks must first be merged to a base disk using third party tools, then the new VHD base disk can be imported.

Exporting vDisks

To export a vDisk:

Note: When deleting a vDisk that will be exported, be sure to export the vDisk first, then copy the resulting XML file to the new location before deleting it from the original location.

1. Right-click on the vDisk in the Console, then select the Export menu option. The Export dialog appears.
2. Select the version to export from the drop-down menu, then click OK. The manifest file is created in the Store.

Importing vDisks

A vDisk or vDisk chain of differencing VHD files can be imported into a store if:

- The VHD being imported does not already exist in the store and both the highest version number of the VHD and associated manifest files match, and if the VHD chain includes a base image, and that base image version number matches the base image version in the manifest file.
- The VHD does exist in the store but the imported version number in the associated manifest file is greater than the existing VHD version number.

To add or import an existing vDisk to a site:

1. Copy the vDisk and any associated properties files to shared storage, if they do not already exist there.
2. In the Console tree pane, right-click on the Store or a vDisk Pool, then select the Add or Import Existing vDisk... menu option. The Add or Import Existing vDisks dialog appears.
3. Select the store to search for vDisks from the Store to search drop-down menu.
4. Select the server to use to search for vDisks from the Server to use for searching drop-down menu, then click Search. All vDisks in the store display in the Add checked vDisks to the vDisk Pool.
5. Check those vDisks that should be added to the vDisk pool.
6. Optionally, check Enable load balancing for these vDisks to enable load balancing on Provisioning Servers that provide this vDisk to target devices.
7. Click Add to add the vDisk(s) to the vDisk pool.

Adding vDisk Versions

To add a vDisk version to a site:

1. Copy the vDisk and any associated properties files to shared storage, if they do not already exist there.
2. In the Console tree pane, right-click on the Store or a vDisk Pool, then select the Add vDisk Versions menu option. The Add vDisk Versions dialog appears.
3. Select the store to search for vDisks from the Store to search drop-down menu.
4. Select the server to use to search for vDisks from the Server to use for searching drop-down menu, then click Search. All vDisks in the store display in the Add checked vDisks new versions.
5. Check those vDisk versions that should be added to the vDisk pool.
6. Click Add to add the vDisk(s) to the vDisk pool.
Releasing vDisk Locks

Apr 08, 2010

Since multiple target devices and Provisioning Servers can gain access to a single vDisk image file, it is necessary to control access to prevent corruption of the image. Should a user accidentally assign a private image to multiple target devices, and then try to boot those target devices, a corrupt image would result. Therefore, the image becomes locked appropriately for a given configuration. The locked vDisk icon appears with a small ‘lock’ on it.

Be aware that under certain circumstances these locks may not be released properly. A lock on a vDisk image may not be released properly when a target device machine is booted from a vDisk, and then fails (or power is lost). If the same target device boots again, the same lock is used and no problem occurs. However, if an administrator tries to mount the drive on the Provisioning Server after the target device has failed, the Provisioning Server will not be able to mount that vDisk because a lock is still held by the failed target device. The Administrator has the capability to release these locks.

Note: Ensure that the vDisk is not in use before removing a lock. Removing a lock for a vDisk, which is in use, may corrupt the image.

To release select vDisk locks:

1. In the Console, right-click on the vDisk for which you want to release locks, and then select the Manage Locks... option. The Manage VDisk Locks dialog appears.
2. If a vDisk has a target device lock on it, that target device name appears in the dialog’s list. Select one or more target device from the list, then click Remove lock. You can also choose Select All to remove all target device locks on the this vDisk.
3. Click Close to close the dialog.
Copying and Pasting vDisk Properties

Apr 09, 2010
Use the Copy and Paste options to copy properties of one vDisk to one or more vDisks in your network.

To copy vDisk properties to one or more vDisks:

1. In the Console, right-click on the vDisk that has the properties settings that you want to share with other vDisks, then select Copy vDisk Properties. The Copy vDisk Properties dialog appears.
2. Select the checkboxes next to the properties that you want to copy to other vDisks, then click Copy.
3. In the details panel, highlight the vDisks that you want to paste properties settings to, then click Paste from the right-click menu.
Adding Existing vDisks to a vDisk Pool or Store

Mar 28, 2011
If vDisks exist in a store, and those vDisks will be used by target devices in your site, you can easily add them to the site's vDisk Pool by selecting the Console's Add existing vDisks right-click menu option. This option is available from the vDisk Pool folder and from a store folder.

To add existing vDisks to a site:

1. Verify the following:
   - Other servers have access to the shared folder where the store is located.
   - The new server is associated with that store.
2. In the Console tree, right-click on the vDisk Pool in the site where you want to add those vDisks, or right-click on the store where those vDisks exist, then select the Add existing vDisk menu option. The Add Existing vDisks dialog appears.
3. If you accessed this dialog from the site's vDisk pool, select the store to search from the drop-down menu. If you accessed this dialog from the store, select the site where vDisks will be added from the drop-down menu.
4. In the Select the server to use when searching for new vDisks drop-down menu, select the Provisioning Server that will perform the search. Click Search. Any new vDisks that do not exist in the database display in the text box below.
5. Check the box next to each vDisk that you want to add, or click Select All to add all vDisks in the list, then click Add.
Back up a vDisk

Apr 08, 2010

The Provisioning Server treats a vDisk image file like a regular file, but the target device treats it as a hard drive. The procedure for backing up a vDisk image file is the same as backing up any other file on your server. If a vDisk image file becomes corrupt, to restore it requires simply replacing the corrupted file with a previous, functional version.

Do not back up a vDisk while it is in use or while it is locked. It is recommended to integrate the backing up of vDisks into your normal Provisioning Server backup routine.
Viewing vDisk Usage

Apr 08, 2010
To view target devices that are connected to a specific vDisk:

1. Right-click a vDisk in the Console, then select the Show usage menu option. The Show vDisk Usage dialog appears.
2. Select one or more target devices in the list to perform any of the following target device connection tasks:
   - Shut Down – shuts down the target device
   - Reboot – reboots the target device
   - Send Message – opens the Edit Message dialog to allow you to type, and then send a message to target devices.

To view all target devices currently being served by a Provisioning Server:

1. Right-click on a Provisioning Server in the Console, then select the Show Connected devices menu option. The Connected Target Devices dialog appears.
2. Select one or more target devices in the list to perform any of the following target device connection tasks:
   - Shut Down – shuts down the target device
   - Reboot – reboots the target device
   - Send Message – opens the Edit Message dialog to allow you to type, and then send a message to target devices.
Deleting Cache on a Difference Disk

Dec 08, 2011

The Delete Cache from Selected Device(s)... context menu option allows you to manually delete cache on a difference disk. The option is only available if the vDisk cache mode is set to Server Persistent Cache.

Note: Write cache on a Difference Disk is not automatically deleted if that file becomes invalid. Files marked as invalid should periodically be deleted manually.

To delete a cache on a Difference Disk:

1. In the Console, right-click on the vDisk that is associated with difference disk files to delete. Select the Delete Cache from Selected Device(s) menu option. The Delete Cache for Devices dialog appears.
2. Check each target device box for which the cache should be deleted, or click Select all to delete all cache files associated with this vDisk.
3. Click Delete to delete the cache files from the server.
vDisk Properties

May 29, 2014

In the Console, the vDisk Properties dialogs allows you to modify vDisk configuration settings. To view an existing vDisk's properties, choose one of the following methods:

- Highlight a vDisk in the Console, then select Properties from the Action menu.
- Right-click on the vDisk in the Console, then select Properties.
- Double-click on the vDisk in the Console’s details pane.

General Tab

Site
The name of the site where this vDisk is a member of its vDisk Pool. This property can not be modified in this dialog.

Store
The name of the store where the vDisk resides. This property can not be modified in this dialog.

Filename
The filename that was given to this vDisk when it was created. This property can not be modified in this dialog.

Size
The file size of this vDisk.

Access mode

Select the vDisk access mode

- Standard Image (multi-device, read only access with write cache options)
- Private Image for use with a single target device, which has read and write access.

Local Hard Disk Drive (read/write)

Select the Cache type

For Standard Image only, select the write cache type:

- Cache on device’s hard drive (NTFS file format)
- Cache on device hard drive persisted (experimental stage only)
- Cache in device RAM
- Cache on device RAM with overflow on hard disk (only available for Windows 7 and Server 2008 R2 (NT 6.1) or later. Not supported with SCCM)
- Cache on server
- Cache on server persisted

Select the Cache Size (MBs)

If you select Standard Image and Cache in target device RAM, select the cache size in megabytes. Default is 4096.

For 32-bit systems, the max size of the RAM write cache is determined by the registry setting WcMaxRamCacheMB in the BNISocket Parameters. This is a DWORD parameter. The default value used is 3584 MB.

BIOS menu text
This field is optional and allows you to enter a menu text that will display on the target device when that device starts. The user can then select which vDisk to boot from.

Note: Important. If vDisks with the same name from different Stores are assigned to the same target device, they display as duplicate names in the menu unless different menu text or descriptions are provided.

**Enable Active Directory machine account password management**

Enables the Active Directory password management features. If your target devices belong to a domain and share a vDisk, also refer to the Active Directory section on the Options tab of the Provisioning Server Properties dialog.

**Enable printer management**

Enables the printer management option if you are not using a different printer system that installs valid printers on each target device. To view printer details for an individual target device, refer to the Target Device Properties' vDisk tab, then click the Printers button.

**Enable streaming of this vDisk**

Enables this vDisk to be streamed to target devices.

**Identification Tab**

**Description**

Provides a description for this vDisk.

**Date**

For user's informational use only. Initially set to a string representing the creation date of the image file.

**Author**

For user's informational use only. Set as appropriate for your installation.

**Title**

For user's informational use only. Set as appropriate for your installation.

**Company**

For user's informational use only. Set as appropriate for your installation.

**Internal Name**

For user's informational use only. Set as appropriate for your installation.

**Original File**

For user's informational use only. Set as appropriate for your installation.

**Hardware Target**

For user's informational use only. Set as appropriate for your installation.

**Microsoft Volume Licensing Tab for vDisk file**

**Microsoft Volume Licensing**

If using Microsoft KMS or MAK volume licenses for target devices using this vDisk image, select that licensing option from those listed below. Otherwise, select None.

Note: The vDisk license mode must be set before target devices can be activated.

- None
- Key Management Service (KMS)
- Multiple Activation Key (MAK)

Note: In order for MAK licensing to work, the Volume Activation Management Tool (VAMT) must be installed on all login servers within the farm. This tool is available from Microsoft.
Auto Update Tab

Note: This vDisk update method can only be used on a base disk that has no VHD versions associated with it.

**Enable automatic updates for this vDisk**

Enables the Automatic Disk Update process on this vDisk file.

**Class**

Enter a class to associate to the vDisk file. This field is used with Automatic Disk Update and the Managed Disk Feature in order to match new vDisk file to the appropriate target devices. Up to 40 characters can be entered.

**Type**

Enter a type to associate with the vDisk file. This field is used in Automatic Disk Update, in order to match the new vDisk file to the old file. Up to 40 characters can be entered.

**Major #, Minor #, Build #**

If the new vDisk version is greater than the old image version, the vDisk image is replaced for matching Class and Type images. Precedence is: Major, then Minor, then Build.

Note: During the update process, if several vDisks exist with the same version number because the version number was not incremented, Provisioning Services uses the first updated vDisk presented in the list.

**Serial #**

Initially set to a random Globally Unique Identifier (GUID). The user can set the serial number as needed. The serial number is used to ensure that a delta file is applied to the correct vDisk image file.
Accessing a vDisk Version

Sep 30, 2014

Numerous differencing disk versions can exist for a vDisk. Device access to a particular version, or the ability to make updates to that version, depends on that version's Access mode setting and the device Type. The sections that follow describe the different version Access modes and device Types as well as their relationship to each other.

A version's Access mode is managed on the vDisk Versioning Dialog. New versions of a vDisk are generally promoted from Maintenance to Test and then into Production. Access mode options include:

**Maintenance** – new read/write difference disk version that is only available to the first Maintenance device that selects to boot from it in order to make updates.

**Test** – read-only version used for test purposes and only available to Test or Maintenance devices.

**Pending** – read-only version and not yet available for use by Production devices because the scheduled release date and time has not been reached and/or the version is not yet available to all servers in the site. If the Boot production devices from version drop-down list is set to Newest released, after the release date and time is reached and all servers are able to access this version, access changes to Default. If access displays as blank, this version is considered released to production, however it is not the version currently selected as the version from which Production devices should boot.

**Default** – read-only version that is bootable by all device types. If the Boot production devices from version is set to Newest released, then the latest released production version is marked with a green checkmark and the status is set to Default.

**Override** – read-only version that is bootable by all device types. If a specific version is selected from the Boot production devices from version drop-down list, then that version is marked with a green checkmark and the access changes to Override.

**Newest released** – read-only version that is bootable by all devices. If a specific version is selected from the Boot production devices from version drop-down list, then that version is marked with a green checkmark and the access changes to Override.

**Merging** – a merge is occurring to this new version. This version is unavailable to all device types until the merge completes. After the merge completes, the status of the new version depends on the Access mode selected on the Mode to set the vDisk to after automatic merge drop-down list (Production, Maintenance, or Test). This Farm Properties setting is available on the vDisk Versions tab.

The device Type is selected on the Target Device Properties General tab, unless it is an Update device, which is created automatically when the managed vDisk is created. Device types include:

**Maintenance Devices**

Maintenance devices can access any available version of a vDisk. A Maintenance device's primary role is update a vDisk manually. To do this, a new version is requested from the vDisk Versions Dialog, which creates a new read/write differencing disk and places that newly created version in Maintenance Access mode. While in Maintenance mode, this version of the
vDisk can only be accessed by a single maintenance device (the first maintenance device that accesses it). Using that device, the vDisk is booted and any updates that are made are captured in the new differencing disk version. After updates are complete, the maintenance version can be promoted to Test mode or directly to Production mode.

Note: In Maintenance Mode, a new version can also be created by merging existing versions into a new version or new base disk image. For additional information on merging vDisks, refer to Merging VHD Differencing Disks.

**Test Devices**

While in Test mode, this version of the vDisk can only be streamed to Test or Maintenance devices to which it is assigned. This allows the new version to be tested before being released into the production environment, and permits Production devices to continue to stream from the previous version without interruption. If issues are found, this version can be reverted back into Maintenance mode.

If you are testing a device that uses a personal vDisk, use the assigned PvD Test device to test vDisk updates.

**Production Devices**

After successfully testing the new version, that version can be promoted to Production mode and made available to Product, Test, and Maintenance devices to which it is assigned. If issues are found, this version can be reverted back into either Test or Maintenance mode after any booted devices accessing this version are shut down.

If a device is assigned a personal vDisk, after the updated vDisk is tested using a PvD Test device, you can change the device to be a PvD production device, which allows you to continue testing for compatibility within your production environment.

**Update Devices**

Update devices are used to update a Managed vDisk. Update Devices are created automatically when the Managed vDisk Setup Wizard is run. Only one Update device exists for each managed vDisk, and that vDisk and Update device are given the same name. For more information on Managed vDisks, refer to vDisk Update Management.
Unassigning vDisks from Target Devices

Jan 31, 2012
To unassign a vDisk from one or more target devices:
Note: The Unassign from All site Devices option only unassigns vDisks that are not personal vDisks. When a personal vDisk is deleted, the vDisks' Update Device is also deleted.
1. Select the vDisk in the Console, then right-click and select the Unassign from Selected Device(s) or Unassign from All Site Devices menu option.
2. If unassigning from select devices, in the Unassign from Devices dialog, select the devices to unassign to this vDisk, then click Unassign. If unassigning from all devices in a site, click Yes on the confirmation dialog that appears.
3. After the target devices are successfully unassigned, close any open dialogs.
vDisk Versioning Dialog

Jun 27, 2012

vDisk versioning is managed from the vDisk Versions dialog. To open the dialog, right-click on a vDisk in the Console, then select the Versions... menu option. The table that follows provides a general description of the vDisk Versions dialog.

**Boot production devices from version**

From the drop-down box, select the version to use when booting target devices in production. The default is the newest version.

**Version and status**

This column lists versions and the current status of each version:

- Wrench icon indicates that this version's access mode is set to Maintenance (read/write) mode, from which only a single maintenance device can boot.
- Magnifying glass icon indicates that this version's access mode is set to Test, from which only a test device can boot.
- Clock icon indicates that this version's access mode is set to Pending. A version that is Pending has been promoted to production but the release date and time have not yet been reached.
- Green checkmark icon indicates that this version is the current production version based on settings selected on the Boot production devices from version drop-down menu. All device types can boot from vDisk version that is in production.
- Red X icon indicates that this version is obsolete, no devices are currently booted from it, and that this version can be deleted because a merged base was created, which is more current.

**Created**

Provides the date and the time that this version was created. Date format is **YYYY/MM/DD** and time format is **HH:MM**

**Released**

Provides the date and time that this version is scheduled to be released to production. Date format is **YYYY/MM/DD** and time format is **HH:MM**

**Devices**

The number of target devices streaming sessions for a given version.

**Access**

Indicates target device access availability for a given version.

- Maintenance read/write version that is available to the first maintenance device that selects to boots from it.
- Test read-only version used for test purposes and only available to test or maintenance devices.
- Pending read-only and not yet available for use because the scheduled release date and time has not been reached.
- Default read-only version that is bootable by all devices. If the Boot production devices from version is set to Newest released, then the latest released production version is marked with a green checkmark and the access is set the Default.
- Override read-only version that is bootable by all devices. If a specific version is selected from the Boot production devices from version drop-down list, the access changes to Override.

Merging a merge is occurring to this new version. This version is unavailable until the merge completes. After the merge completes, the status of the new version depends on the access mode selected on the Mode to set the vDisk to after automatic merge drop-down list (Production, Maintenance, or Test). The default Farm Properties setting is available on the
vDisk Versions tab. A wrench icon is shown for merging version.

Blank this version was released to production.

**Type**
Identifies how the vDisk was created. The options include:
- Manual created using Maintenance mode.
- Automatic created automatically using an automated update.
- Merge created by a partial merge operation.
- Merge Base created by a base merge operation (no parent needed).
- Base The original base image.

**New**
Creates a new maintenance version.

**Promote**
Opens a dialog that prompts to promote this version to Test or Production. If Production is selected, a release date and time can be set or the default (now) can be accepted.

**Revert**
Reverting from Test version: if no maintenance access version exists, revert moves latest test version into Maintenance.
Reverting from Production: any booted device will be shut down prior to reverting. Clicking Revert opens a dialog that allows the user to select to revert to Test or Maintenance.

**Delete**
Clicking Delete opens a delete confirmation dialog. Click OK to delete the selected version. Delete is only available if the latest version or obsolete version doesn't have target devices currently booted from it.

**Replication**
Selecting a version, then clicking Replication opens the Disk Versioning Replication Status dialog. This dialog displays the replication status of this version on each server:
- Blue check next to the server name indicates that the version has been replicated on the server.
- Orange triangle next to the server name indicates that the version has not yet been replicated or there is an issue. Placing the cursor over the triangle will display the related error message.

To view the replication status of all versions of this vDisk on each server, right-click on the vDisk in the Console, then select Replication Status from the context menu.

**Properties**
Clicking on the Properties button opens the vDisk Version Properties dialog, which allows you to enter a description related to this version. It also displays availability of a selected version if that version is set for release to production in the future, or if no device has booted from that version yet.

**Text**
The text box provides a description of the currently selected version.
Updating vDisks

Sep 30, 2014

It is often necessary to update an existing vDisk so that the image contains the most current software and patches. Each time the vDisk is to be updated, a new version of that vDisk is created (VHD file) to capture the changes without changing the base vDisk image.

Updating a vDisk involves the following:
- Create a new version of the vDisk, manually or automatically.
- Boot the newly created version from a device (Maintenance device or Update device), make and save any changes to the vDisk, then shut-down the device.
- Promote the new version to Production.

The following illustrates the general promotion of a vDisk update:

![Diagram illustrating vDisk promotion](image)

The availability of the updated version depends on the current promotion of that version (Maintenance, Test, or Production), and the type of device attempting to access it (Maintenance Device, Update Device, Test Device, or Production Device).

If updating a device that uses a personal vDisk image, ensure compatibility in your production environment using this procedure:

Note: Updating images for devices that use a personal vDisk, must be done on a virtual machine that does not have a personal vDisk attached. Otherwise, updates are saved to the personal vDisk image rather than the virtual machine image.
1. Create a new maintenance version of the vDisk.
2. Make any necessary updates to the maintenance version.
3. Promote the new maintenance version to test.
4. Boot the PVD test device, and then verify updates were made.
5. Promote the test version to production.

**Update Scenarios**
The following vDisk update scenarios are supported:
Manual Update – An administrator may choose to update a vDisk manually by creating a new version of that vDisk, and then using a Maintenance device to capture updates to that version. Manual updates are initiated by selecting the New button on the vDisk Versions dialog. The Access column on the vDisk Versioning dialog displays that the newly created version is currently under maintenance. While under maintenance, this version can only be accessed and updated by a single Maintenance device. Multiple Maintenance devices can be assigned to a vDisk. However, only one device can boot and access that version of the vDisk at any given time. During that time that Maintenance device will have exclusive read/write access. For details, refer to Manually Updating a vDisk Image.

Automated Update – Creating automated updates saves administration time and physical resources. Updates are initiated on-demand or from a schedule and are configured using vDisk Update Management. If updating automatically, the Access column on the vDisk Versioning dialog displays that the newly created version is currently under maintenance. While under maintenance, this version can only be accessed and updated by the one Update device to which it is assigned (only one Update Device exists per vDisk). For details, refer to Automating vDisk Updates. Note: vDisk Update Management is intended for use with Standard Image Mode vDisks only. Private Image Mode vDisks can be updated using normal software distribution tool procedures. Attempting to register a Private Image Mode vDisk for vDisk Update Management, or switching a vDisk that is already registered, will cause errors to occur.

Merge – Merging VHD differencing disk files can save disk space and increase performance, depending on the merge option selected. A merge update is initiated manually by selecting the Merge button on the vDisk Versions dialog, or automatically when the maximum vDisk versions count is reached.
VHD Chain of Differencing Disks

May 08, 2015

Versioning simplifies vDisk update and management tasks, providing a more flexible and robust approach to managing vDisks.

A vDisk consists of a VHD base image file, any associated side-car files, and if applicable, a chain of referenced VHD differencing disks. Differencing disks are created to capture the changes made to the base disk image, leaving the original base disk unchanged. Each differencing disk that is associated with a base disk represents a different version.

The following illustrates the file naming convention used and the relationship between a base disk and all versions referencing that base disk.

Note: vDisk versions are created and managed using the vDisk Versions dialog and by performing common vDisk versioning tasks.

Each time a vDisk is put into Maintenance Mode a new version of the VHD differencing disk is created and the file name is numerically incremented, as captured in the table that follows.

<table>
<thead>
<tr>
<th>VHD Filename</th>
<th>Properties Filename</th>
<th>Lock File Filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base Image</td>
<td>win7dev.vhd</td>
<td>win7dev.pvp</td>
</tr>

For information on merging VHD files, refer to [merging VHD files](https://docs.citrix.com).
Manually Updating a vDisk Image

The vDisk Versions dialog allows you to manually create a new version of the vDisk's base image. Note: To automate an update process, configure for vDisk Update Management (refer to Automating vDisk Updates).

This procedure requires that:

- a Maintenance device has been assigned to the vDisk being updated.
- no version of this vDisk is currently under maintenance.

Note: Updating images for devices that use a personal vDisk, must be done on a virtual machine that does not have a personal vDisk attached. Otherwise, updates are saved to the personal vDisk image rather than the virtual machine image.

To create a new version:

1. In the Console, right-click on a vDisk to version within a device collection or vDisk pool, then select Versions... from the context menu. The vDisk Versions dialog appears.
   Note: Verify that the vDisk is currently not in Private Image mode.
3. Boot the vDisk from a Maintenance device, install or remove applications, add patches, and complete any other necessary updates, then shutdown the Maintenance device. Optionally, test that changes were made successfully.
   Note: If booting a Test or Maintenance device, a boot menu displays that allows the user to select from which vDisk, or version of that vDisk, to boot from unless the device is a PvD Test device.
4. Right-click on the vDisk, then select the Promote... menu option from the context menu that appears (for more details on promoting versions refer to Promoting Updated Versions).
5. Select to promote this maintenance version into test or directly into production. If Production is selected, set the availability of this version in production to be either immediate or scheduled.
6. Click OK to promote this version and end maintenance.
Note: vDisk Update Management is intended for use with Standard Image Mode vDisks only. Private Image Mode vDisks can be updated using normal software distribution tool procedures. Attempting to register a Private Image Mode vDisk for vDisk Update Management, or switching a vdisk that is already registered, will cause errors to occur.

In the Console, the vDisk Update Management feature is used to configure the automation of vDisk updates using virtual machines (VMs). Automated vDisk updates can occur on a scheduled basis, or at any time that the administrator invokes the update directly from the Console. This feature supports updates detected and delivered from WSUS and SCCM Electronic Software Delivery (ESD) servers.

When the Site node is expanded in the Console tree, the vDisk Update Management feature appears. When expanded, the vDisk Update Management feature includes the following managed components:

- Hosts
- vDisks
- Tasks

To configure a site for vDisk Update Management requires completing the following high-level tasks:

1. Designate a Provisioning Server within the site to process updates. Refer to Enabling Automatic vDisk Updates.
2. Configuring a Virtual Host Pool for Automated vDisk updates. Refer to Using the Virtual Host Connection Wizard.
   Note: Supported hypervisor types include; Citrix XenServer, Microsoft SCVMM/Hyper-V, and VMWare vSphere/ESX.
3. Create and configure a ESD VM that will be used to update the vDisk. Refer to Creating and Configuring ESD Update VMs.
   Note: The user that will configure vDisk Update Management tasks must have permissions to create, modify and delete Active Directory accounts.
6. Run the update task by right-clicking on the task object in the Console, and then selecting the Run update now menu option. The Update VM will boot, install updates and reboot as necessary. After the update task successfully completes, the virtual machine is automatically shutdown. The update status can be checked from the Console tree under vDisk Update Management>vDisks>(vDisk name)> Completed Update Status. The status can also be checked using the event viewer or in WSUS.

After the site is configured to use vDisk Update Management, managed vDisks can be updated using the following methods:

- **Scheduled** – the Image Update Service automatically updates a vDisk, on a scheduled basis as defined in the Update Task. For more details, refer to Using the Update Task Wizard or Update Task Properties.
- **User Envoked** – an administrator selects a managed vDisk to be updated from the Consoles Run update now menu option (requires that the administrator also manually start, then stop the Update Device after the update is complete).

The following illustrates the basic update process for both scheduled or user envoked update methods:
1. The vDisk update process starts either automatically (scheduled), or when an administrator right-clicks on a managed vDisk, then selects the Run update now menu option.

2. Provisioning Services creates a new version (VHD) and places that version in Maintenance mode (read/write).

3. The virtual machine boots the assigned vDisk. If this is a:
   - Scheduled update – vDisk Update Management performs the boot automatically.
   - User envoked update – the administrator invokes the update.

4. All updates are automatically made and captured in the new version of the VHD file.

5. After updating the vDisk, the virtual machine is shut down automatically.

6. The vDisk is promoted from Maintenance to either Test or Production. The availability of the new vDisk version depends on the Access mode that was selected when the Update Task Wizard was run, or the mode that is currently selected on the Update Task Properties' Finish tab (Maintenance, Test, or Production). After this version is made available in production, target devices will be able to access it the next time they boot that vDisk.
Enabling Automatic vDisk Updates

Aug 04, 2011
To allow Managed vDisks to be updated automatically:
1. Right-click on the Site in the Console, then select the Properties menu option. The Site Properties dialog appears.
2. On the vDisk Update tab, check the box next to Enable automatic vDisk updates on this site.
3. Scroll to select the server to run vDisk updates for this site, then click OK.

Managed vDisks can now be automatically updated on this site. Next, virtual host connections must be configured to allow for automatic updates to be made. Refer to Configuring Virtual Host Connections for Automated vDisk Updates.
Configuring Virtual Host Connections for Automated vDisk Updates

May 08, 2015

To use vDisk Update Management, a designated hypervisor server is selected from within a virtual pool that is then used to communicate with Provisioning Services. This is accomplished by running the Virtual Host Connection Wizard.

Note: If running a vCenter server on alternate ports, the following registry modifications must be made in order to connect to it from Provisioning Services:
- Create a new registry key named PlatformEsx under HKLM\Software\Citrix\ProvisioningServices
- Create a new string value in the PlatformEsx key named ServerConnectionString and set it to http://{0}:PORT#/sdk (if using port 300, ServerConnectionString= http://{0}:300/sdk)

To configure virtual host connections:
1. Under the vDisk Update Management node in the Console tree, right-click on Hosts, then select the Add host... option. The Virtual Host Connection Wizard appears.
2. Click Next to begin. The Hypervisor page appears.
3. Select the radio button next to the type of hypervisor used by this pool, then click Next:
   - Citrix XenServer
   - Microsoft SCVMM/Hyper-V
   - VMWare vSphere/ESX
   The Name/Description page appears.
4. Enter the name, and optionally a description, for the Virtual Host Connection then click Next.
5. Enter the hostname or the IP address of the server to contact. If an ESX hypervisor was selected, you have the option to specify the datacenter to use when connecting to the host.
   Note: It can take several minutes before a hostname/IP address can be re-entered, if that hostname/IP was previously entered and then deleted.
6. Click Next. The Credentials page appears.
7. Enter the appropriate credentials required to connect to this host, then click Next:
   - Username – the account name with appropriate permissions to access the virtual host pool server.
   - Password – password used with this account name.
   The Confirmation page appears.
8. Review all settings are accurate, then click Finish.

Virtual Host Pool properties can be viewed or modified on the Virtual Host Connection Properties dialog.

After a virtual host connection is created using the Virtual Host Connection Wizard, it can be viewed or modified on the Virtual Host Pool Properties tabs:
- General
- Credentials
- Advanced

General Tab
<table>
<thead>
<tr>
<th>Field/button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>The type of virtual host connection that was selected when the Virtual Host Connection Wizard was run. This field cannot be modified.</td>
</tr>
<tr>
<td>Name</td>
<td>The name to use when referencing this virtual host connection by Provisioning Services.</td>
</tr>
<tr>
<td>Description</td>
<td>A brief description of this virtual host connection.</td>
</tr>
<tr>
<td>Host</td>
<td>The hostname or IP address of the virtual host connection server for Provisioning Services to contact. To use a different port for the ESX server connection, in the server address field, enter the full connection string and include the correct port number. The format for the connection string is <code>http://server_name:port/sdk</code>.&lt;br&gt;Note: If running a vCenter server on alternate ports, the following registry modifications must be made in order to connect to it from Provisioning Services:&lt;br&gt;• Create a new key <code>HKLM\Software\Citrix\ProvisioningServices\PlatformEsx</code>&lt;br&gt;• Create a new string in the <code>PlatformEsx</code> key named 'ServerConnectionString' and set it to <code>http://{0}:PORT#/sdk</code> (If using use port 300, ServerConnectionString= http://{0}:300/sdk)</td>
</tr>
<tr>
<td>Datacenter</td>
<td>Optional. If an ESX hypervisor was selected, you have the option to specify the datacenter to use when connecting to the host.</td>
</tr>
</tbody>

Port
Sets the IP port number. This field is not available with VMWare vSphere/ESX.
Creating and Configuring ESD Update VMs

Oct 22, 2015

Virtual machines (VMs) that are used to update a Managed vDisk must first be created on the hypervisor prior to configuring for vDisk Update Management in Provisioning Services. Supported hypervisors include: Citrix XenServer, Microsoft SCVMM/Hyper-V, and VMware vSphere/ESX.

The type of ESD determines the specific steps involved in creating and configuring the VM on the hypervisor. However, the following general prerequisites apply to Update VMs regardless of the ESD system selected:

- Download, install, and configure the appropriate ESD Server software on the server.
- A VM must be uniquely named on the hypervisor and follow naming conventions equivalent to a Provisioning Services target device name. The name can be up to 15 bytes in length.
- Only one VM should exist for a Managed vDisk because only one update task can occur on that vDisk at any given time.
- Citrix recommends allocating at least 2GBs of memory for each VM.
- Appropriate ESD licenses must be made available and the ESD client software must be properly installed and enabled on the vDisk.
- Using Microsoft HyperV Server without SCVMM is not supported.
- Configuring the Update VM, that is used to build the Update vDisk, with multiple nics when streaming to SCVMM server fails to PXE boot. Citrix suggests using a single NIC or use only one Legacy NIC.
- Because the image update client requires .NET 3.5 or higher, it must be installed on the vDisk that serves the Update VM.
- Citrix recommends to only apply updates that can be downloaded and installed in 30 minutes or less.

Creating and configuring a WSUS update VM

1. Under the server hypervisor, create and boot up a client. For the purpose of providing an example, the client VM **NameA** (client VMs must be unique on the hypervisor).
2. Add the client VM (**NameA**) to the domain and make any other settings specific to your environment.
3. Install the Provisioning Services Target Device software on the client VM (**NameA**).
4. Build a vDisk image from the client VM (**NameA**), and when prompted, you must enter a target device name. For the purpose of this example, the target device name will be **NameB**.
5. After successfully building the vDisk image, shutdown the target device.
6. Optional. If using Active Directory, enable Active Directory on the vDisk and then create a machine account for the target device (**NameB**) using the Provisioning Services Console.
7. In the Console, set the target device to boot from the vDisk image in Private Image mode.
8. Boot the target device, then complete the following:
   1. Verify that the Windows firewall setting is set to Off.
   2. Run Gpedit.msc navigate to: Computer Configurations>Administrative templates>Windows Components>Windows Update>Specify the Intranet Microsoft update service location and set to be Enabled.
   3. Enter the name of the WSUS server (from step one) under the Set the intranet update service for detecting updates and Set the intranet statistics server name (http://WSUS-SERVER-NAME).
   4. Install the Windows Update Agent specific to the platform from [http://support.microsoft.com/kb/949104](http://support.microsoft.com/kb/949104).
   5. Restart the target device to configure the Windows Update Agent.
9. Shutdown the target device.
10. On the hypervisor, create a diskless VM to serve as the Update VM (**NameC**), then set the Update VM to boot from the network (do not boot).
11. From the WSUS server, approve the updates for your client VM
12. From the Console,
   1. Set the Access Mode for the vDisk to Standard Image mode, on the vDisk Properties General tab.
   2. Configure the host connection, refer to Configure virtual host connections for automated vDisk updates.
   3. Configure a managed vDisk for automated updates. Refer to Configure Managed vDisks for automated updates.
   4. Create an update task. Refer to Create an update task.

Creating and configuring a SCCM update VM

1. Create a VM and give it a name that meets DNS requirements for computer object names.
2. Install the operating system.
3. Install the Provisioning Services target device software.
4. Run the imaging wizard. For the same device name, use the VM name in step 1.
5. Reboot to image the device.
7. Add the device to the OU that SCCM is scanning. You are advised to dedicate an OU for this rather than giving SCCM free rein of the entire Active Directory.
8. Boot the client in private image mode.
9. Open the firewall ports for SCCM on both the target device and the Provisioning Server.
10. Make the SCCM administrator and the SCCM server a local administrator.

1. On the SCCM server, select Administration > Discovery methods. Right-click on Active Directory System Discovery and choose the option Run Full Discovery Now. By default, SCCM only scans for new clients every 8 hours.
2. Wait for the client to appear. Typically, this takes about 10 minutes.
3. Right-click on the SCCM client and push it to the device. Wait until the SCCM client is installed and appears as active in SCCM.
4. Assign the client to a device collection in SCCM.
5. In SCCM Administration > Client Settings give the client a new setting and select the custom setting Computer Agent. Select the option Additional software manages the deployment of applications and software updates. Push this out to the device collection in step 4 as soon as possible.

1. Go to the site's Property > vDisk Update tab and enable the automatic vDisk update option for the site.
2. After the SCCM client is installed and appears as active, shut down the device.
3. Change the vDisk to standard image mode.
4. Right-click on the device and choose Active Directory > Delete Machine Account.
5. Delete the Provisioning Services device record.
6. Create a host record of where the image VM is located.
7. Create a managed vDisk record. Note: The device name is case-sensitive.
8. Create a task.

Note: When pushing updates and software, always push to the SCCM device collection.
Configuring Managed vDisks for Automated Updates

May 08, 2015

vDisk Update Management uses virtual machines to process updates to managed vDisk(s). vDisks are first created in the Console, then added to vDisk Update Manager as managed vDisks by running the Managed vDisk Setup Wizard.

Note: If using ESD Servers to deliver updates, the ESD client software must be installed and enabled on the vDisk, and appropriate ESD licensing must also be available.

1. Under the vDisk Update Management node in the Console tree, right-click on vDisks, then select the Add vDisks... option.
   The Managed vDisk Setup Wizard Welcome page appears.
2. Click Next to begin. The vDisk page appears.
3. Select the default search options (All stores, All servers) or use the filtering options to select specific stores and/or servers to display the vDisk(s) to select to be managed. vDisks that are not already managed will display in the vDisk selection box.
4. Select one or more vDisks to be managed, then click Next. The Host/VM page appears.
5. Select the type of connection to use when hosting the VM, from the appropriate drop-down list.
6. Enter the name of the Update VM used to process the vDisk update. The VM name field is case sensitive and must match exactly to the existing VM name on the desired hypervisor.
7. Click Next. The Active Directory page appears.
8. If using Active Directory, enter a Domain and Organizational Unit to create an Active Directory machine account that will be used by the Update Device that is created exclusively for updating this vDisk, then click Next. The Confirmation page appears.
   Note: The Update VM should not already pre-exist in the Provisioning Services database or Active Directory. If it does exist, the wizard will not run successfully.
9. Review all settings, then click Finish.

The Managed vDisk Setup Wizard can also be run from the Managed vDisk dialog, which displays all Managed vDisks currently in the store. The Managed vDisk Setup Wizard can be run from the Managed vDisk Dialog by clicking on the Add Managed vDisks button.
Creating and Managing Tasks

Sep 15, 2011

Note: The user that will configure vDisk Update Management tasks must have permissions to create, modify and delete Active Directory accounts.

Use the Update Task Wizard to schedule vDisk updates to run automatically:

1. **Under the vDisk Update Management node in the Console tree, right-click on Task, then select the Add task... menu option. The Update Task Wizard welcome page appears.**
2. **Click Next to begin configuring a task. The Name/Description page appears.**
3. **Enter a name (required) to identify this task, and a description (optional) in the appropriate text boxes, then click Next. The Schedule page appears.**
4. **Select one of the radio buttons to determine how often this task will run; None, Daily, Weekly, or Monthly. Depending on which recurrence option was selected, the page displays options specific to that selection:**
   - **None – no additional options appear**
   - **Daily**
     - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
     - Everyday – select to run this daily update everyday of the week: Monday through Sunday.
     - Weekdays only – select to run this daily update on weekdays only: Monday through Friday.
   - **Weekly**
     - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
     - Select specific days of the week to run the update.
     - Note: At least one day must be selected to proceed.
   - **Monthly**
     - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
     - Select to run the update task on specific days of the month using one of the following methods: On Date – enter which days of the month to run the update.
     - Note: Only numbers and commas are accepted in this text box. For example: 1,15 runs this update task on the first and fifteenth of every month. If either 29 or 31 are entered, this task will not run every month.
     - Or, select On, to select the week and day of the week from the drop-down menus. For example: Selecting First and Monday would run the task on the first Monday of every month.

5. **Click Next. The vDisks page appears.**
6. **Highlight existing Managed vDisks that will be updated using this new task, then click OK. Optionally, click on the Add Managed vDisks button run the Managed vDisk Setup Wizard in order to add new managed vDisks to the list; after the wizard completes, the new managed vDisks display in the list and can be selected.**
7. **Click Next. The ESD Client page appears.**
8. **Select the type of Electronic Software Delivery (ESD) client that is running on the vDisk, from the drop-down list, then click Next.**
   - **Note: The ESD client software must already be installed in the vDisk image.**
   - **Note: When the option is set to None, client-side scripts can be run if the scripts are stored on the vDisk prior to the update. These scripts need to be stored under the installation directory of the client. Update.bat is a mandatory script. Optional scripts include Preupdate.bat and Postupdate.bat, which are dependant on the users configuration.**
9. **Optionally, select from the following scripting options, then click Next:**
- Pre-update script – executes prior to the start of any update task process.
- Pre-startup script – executes just before startup of the virtual machine.
- Post-shutdown script – executes just after the virtual machine shuts down.
- Post update script – executes after the update task process completes.

Note: On the server, a sub-folder name Scripts must be created under the product installation directory. This folder is used to store server-side scripts.

10. On the vDisk Access page, select the post-update access mode to assign to the vDisk version, then click Next:
- Leave the vDisk in Maintenance mode (only available to Maintenance Devices)
- Place the vDisk in Test mode (only available to Test and Maintenance Devices)
- Make the vDisk ready for use (Production, available to all target devices)

11. Confirm that all vDisk Update Task settings are correct, then click Finish to create the new task.

vDisk Update Tasks can be viewed and modified on the Update Task Properties dialog.
Using Windows Task Scheduler to Create vDisk Update Task Scripts

Sep 01, 2011

Windows Task Scheduler can be used to create vDisk Update task scripts. These scripts are associated with a task when the Update Task Wizard is run and can later be modified on the Scripts tab of the vDisk Update Task Properties dialog. Note: Features of the Task Scheduler are used to run the batch file/script as the desired user. The following types of task scripts can be created:

- **Pre-update script** - executes prior to the start of any update task process.
- **Pre-startup script** - executes just before starting the virtual machine.
- **Post-shutdown script** - executes just after the virtual machine shuts down.
- **Post update script** - executes after the update task process completes.

Scripts are stored in a Scripts folder, which is a sub-folder of the product installation folder.

A sample batch file to boot target devices:

```plaintext
Mcli SetupConnection /p server=192.168.1.1
Mcli Run Boot /p deviceMac=00-00-00-00-00-11
Mcli SetupConnection /p server=192.168.1.1
Mcli Run Boot /p deviceMac=00-00-00-00-00-11
Mcli Run Boot /p deviceMac=00-00-00-00-00-22
Mcli Run Boot /p deviceMac=00-00-00-00-00-33
Mcli Run Boot /p deviceMac=00-00-00-00-00-44
Mcli Run Boot /p siteName=Boston collectionName=Sales
```

A sample batch file to check for vDisk updates:

```plaintext
Mcli SetupConnection /p server=192.168.1.1
Mcli Run ApplyAutoUpdate /p siteName=Boston
```

Note: When configuring the server connection using the Mcli-Run SetupConnection command, do not specify the user, password, or domain as these values will not be protected in the batch file/script.

To create a script, complete either the Windows 2008 R2 Task Scheduler procedure or the Windows 2003 R2 Task Scheduler procedure.

1. Start the Task Scheduler from the Start Menu (Start>All Programs>Accessories>System Tools>Task Scheduler). The Task Scheduler dialog appears.
2. From the Action menu, select the Create Task... menu option. The Create Task dialog appears.
3. On the General tab, type a name and a description to associate with this task.
4. If necessary, click Change User or Group... to select a different user to run the batch file/script.
5. Select the Run whether user is loggon on or not radio button.
6. On the Triggers tab, click New... to begin creating a schedule for this task.
7. Select how this task should begin from the Begin the task: drop-down list.
8. Select how often to perform this task by enabling the radio button next to the appropriate option.
9. Enter or scroll to set the start date and the time of day this task should run.
10. Optionally, enable or disable any advanced settings.
11. Click OK to close the dialog.
12. On the Actions tab, click New... The New Action dialog appears.
13. From the Action drop-down menu, select the action that this task will perform.
14. In the Program/script: text box, type or browse for the name of the batch file/script, then click OK.
15. Optionally, configure additional task configuration settings on the Conditions and Settings tabs.
16. Click OK to close the dialog.
17. If prompted, enter the password for the user running the file/script, then click OK to close the dialog.
18. In the Task Scheduler window, select the Task Scheduler Library node in the left pane tree. The new task should appear in the center pane of the window.

1. Start the Task Scheduler for the Start Menu (Start>All Programs>Accessories[System Tools]>Scheduled Tasks). The Scheduled Tasks dialog appears.
2. Click Add Scheduled Task. The Scheduled Task Wizard appears.
3. Click Next to continue.
4. Click Browse... then select the program to use to run the batch file/script.
5. Click Next, then enter a name for the task.
   Note: This name can be the same name as the program previously chosen to run the batch file/script.
6. Select when to perform this task by enabling the radio button next to the appropriate option, then click Next.
7. Under Start time:, enter or scroll to set the time of day this task should run.
8. Under Perform this task:, select the radio button next to the appropriate day criteria.
9. Under Start date:, select the starting date for this task. then click Next.
10. Enter the credentials for the user that will execute the task, then click Next.
11. The confirmation page displays with a task configuration summary. After reviewing configuration settings, click Finish to complete the creation of this task.
vDisk Update Task Properties

Sep 29, 2011
After a task is created using the Update Task Wizard, it can be modified from the following Update Task Properties tabs:

- General
- Schedule
- vDisks
- ESD
- Scripts
- Access

Name and Description
Enter a name (required) to identify this task, and a description (optional) in the appropriate text boxes.

Disable this task
If enabled, temporarily disables the update task.

Recurrence
Select one of the radio buttons to determine how often this task will run:

- None
- Daily
- Weekly
- Monthly

Depending on which recurrence option is selected, the page displays options specific to that selection.

- None – no additional options appear
- Daily
  - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
  - Everyday – select to run this daily update everyday of the week: Monday through Sunday.
  - Weekdays only – select to run this daily update on weekdays only; Monday through Friday.
- Weekly
  - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
  - Select specific days of the week to run the update.
    Note: At least one day must be selected to proceed.
- Monthly
  - Run the update at – select the time of day to run the daily update from the drop-down menu or enter a specific time.
  - Select to run the update task on specific days of the month using on of the following methods: On Date – enter which days of the month to run the update.
    Note: Only numbers and commas are accepted in this text box. For example: 1,15 runs this update task on the first and fifteenth of every month. If either 29 or 31 are entered, this task will not run every month.
    Or, select On to select the week and day from the drop-down menus. For example: Selecting First and Monday would run the task on the first Monday of every month.
vDisk
Lists Managed vDisks.

Virtual Host Pool
Lists the Virtual Host Pool (host) that communicates with Provisioning Services in order to be updates.

VM
Lists Managed devices used to update the vDisk.

Add
Opens the Managed vDisk dialog, from which additional Managed vDisks can be selected (refer to Configuring Managed vDisks for Automated Updates)

Remove
Removes Managed vDisks from the list of vDisks to update with this task.

Select ESD client to use
Select from the supported Electronic Software Device (ESD) types.
Note: When the option is set to None, client-side scripts can be run if the scripts are stored on the vDisk prior to the update. These scripts need to be stored under the installation directory of the client. Update.bat is a mandatory script. Optional scripts include Preupdate.bat and Postupdate.bat, which are dependant on the users configuration.

Scripts that should execute with the vDisk update task process
Optional:
- Pre-update script – executes prior to the start of any update task process.
- Pre-startup script – executes just before starting the virtual machine.
- Post-shutdown script – executes just after the virtual machine shuts down.
- Post update script – executes after the update task process completes.

Upon successful completion of the update, select the access to assign to the vDisk
Leave the vDisk in Maintenance mode (only available to Maintenance Devices)
Place the vDisk in Test mode (only available to Test and Maintenance Devices)
Make the vDisk ready for use in Production (available to all target devices)
Aug 16, 2011

To make an unscheduled update to a Managed vDisk:

Under the vDisk Update Management node in the Console tree, right-click on a Managed vDisk, then select Run update now menu option. If the vDisk is included in more than one task, a dialog displays the tasks from which you can choose. Updating on demand requires that the administrator manually start the Update Device, and then wait until it completes the update successfully.
Update Device Properties

Sep 29, 2011

To view or modify Update Device properties, right-click on the device in the Console, then select the Properties menu option.

**vDisk**
Displays the vDisk that is assigned to this Update device. This field cannot be modified. Each Managed Device has a one-to-one relationship with a single vDisk of the same name.

**Virtual Host Connection**
Displays the name of the virtual host server assigned to this device. This field cannot be modified.

**VM Name**
The name of the virtual machine on the virtual host provider. This field cannot be modified.

**VM MAC**
The media access control (MAC) address of the network interface card that is installed in the Update device. This field cannot be modified.

**VM Port**
Provides the UDP port value. In most instances, the port number does not have to be modified. However, if Update device software conflicts with any other IP/UDP software (that is, they are sharing the same port), this value must be changed.

**Name and String**
There is no fixed limit to the number of names you can add. However, the maximum name length is 250 characters and the maximum value length is 1000 characters.

Use any name for the field Name, but do not repeat a field name in the same device. Field names are not case sensitive. In other words, the system interprets “FIELDNAME” and “fieldname” as the same name. Blank spaces entered before or after the field name are automatically removed.

A personality name cannot start with a $. This symbol is used for reserved values such as $DiskName and $WriteCacheType.

On this tab, a new personality string can be created, or an existing string modified or removed.

**Status**
The following device status information appears:

- Update Status: displays the status of the update as either inactive or active (update in progress).
- Status: current status of the device (active or inactive).
- IP Address: provides the IP Address or 'unknown'.
- Server: the Provisioning Server that is communicating with this device.
- Retries: the number of retries to permit when connecting to this device.
- vDisk: provides the name of the vDisk or displays as 'unknown'.
- License information: depending on the device vendor, displays product licensing information (including; n/a, Desktop...
License, Datacenter License, XenApp License, or XenDesktop License).

Logging level
Select the logging level or select Off to disable logging:

- Off – Logging is disabled for this Provisioning Server.
- Fatal – logs information about an operation that the system could not recover from.
- Error – logs information about an operation that produces an error condition.
- Warning – logs information about an operation that completes successfully, but there are issues with the operation.
- Info – Default logging level. Logs information about workflow, which generally explains how operations occur.
- Debug – logs details related to a specific operation and is the highest level of logging. If logging is set to DEBUG, all other levels of logging information are displayed in the log file.
- Trace – logs all valid operations.
Merging VHD Differencing Disks

Mar 14, 2014

Merging VHD differencing disk files can save disk space and increase performance, depending on the merge method selected.

Citrix recommends merging vDisk versions to either a new base image or to a consolidated differencing disk. Each time the vDisk is versioned five times.

Note: A merge can only occur when no Maintenance version exists for this vDisk or when the vDisk is in Private Image mode. A merge starts from the top of the chain down to a base disk. A starting disk cannot be specified for the merge.

A full merge to a new base image combines a chain of differencing disks and base image disks into a new single base disk. This new disk is the next version in the chain, which is given the file extension of .VHD. This method allows for the fastest disk access to the base image and is recommended when performance is more important than disk space (a new base disk is created for every merge performed).

A partial merge combines a chain of VHD differencing disks up to, but not including, the base disk into a new differencing disk. The new differencing disk has the same parent base disk image and is given the extension .aVHD. This method consumes less disk space than the full merge and the merge process is quicker than performing a full merge.

An automatic consolidation of differencing disks can be configured from the Farm Properties dialog's vDisk Version tab. On this tab, a maximum vDisk number is selected. When that number is reached, a merge is automatically performed and the availability of that vDisk depends on the mode selected on the tab (Production, Maintenance, or Test).

Note: A consolidated differencing disk merge is recommended when disk storage is limited or when the bandwidth between remote locations is limited, which makes copying large images impractical.
1. Right-click on a vDisk in the Console, then select the Versions menu option. The vDisk Versions dialog appears.
2. Click the Merge button. The Merge dialog appears.
3. Select to perform a Merged Updates or Merged Base merge.
   - To merge all differencing disks to a single differencing disk (not to the base disk image), select the Merged Updates option.
   - To fully merge all differencing disks into a new base disk, select the Merged Base option.
4. Select the access mode (Production, Maintenance, or Test) for this version after the merge completes. If no access type is selected, the vDisk mode setting selected for automatic merge, on the Farm Properties' vDisk Version tab, is selected by default.
5. Click OK to begin the merge process.

The time it takes to complete the merge process varies based on the merge method selected and the number of differencing disks to merge. After the merge successfully completes, the new version displays in the vDisk Versions dialog. The Type column displays either Merge Base if a full merge was selected, or Merge if a partial merge was selected.
Promoting Updated Versions

Jun 06, 2014

An updated version of the vDisk is not available to Production devices until it is promoted to Production. The update promotion stages include:

- Maintenance
- Test
- Production

Each time a new version is created, the Access setting is automatically set to Maintenance to allow maintenance devices to make updates (read/write). After updates are complete, this version can be promoted from Maintenance to Test (read-only) to allow for testing by test devices, or directly to Production, for use by all target devices.

After completing an update using the manual method, the new version can be promoted to Test or Production from the vDisk Version dialog's Promote button. If Production is selected, a release date and time can be set, or the default (Immediate) can be accepted.

After completing an update using the automated update method, vDisk Update Management, the new version is promoted according to the Post Update setting selected when the Update Task Wizard is run. After the automatic update completes, promotion can also be set using the vDisk Version dialog's Promote button.

If issues exist, the new version can be reverted back from Test to Maintenance (if no active sessions exist), or from Production to either Test or Maintenance (any booted device must be shut down prior to reverting).

In order for Production devices to access the new version after it is promoted to Production, the following also applies:

- Access setting must be either Default or Override.
- If the update was scheduled for release, the date and time must be reached.
- The updated version must be available to all servers in the site.
- Boot production devices from version is set to Newest released (status is Default) on the vDisk Versions dialog.

Note: If Access displays as blank, this version is considered released to production but is not the version currently selected from which devices should boot.
Retiring or Deleting vDisks

Jan 31, 2012

When a vDisk is no longer needed, it can be retired. Retire a vDisk by deleting it. When a vDisk is deleted, all VHD differencing disk files, properties files, lock files, and difference cache are also deleted.

Note: You cannot delete a vDisk if one or more target devices are currently assigned to it. Unassign all target devices from the vDisk, before attempting to delete it. If deleting a personal vDisk, a confirmation dialog appears to warn you that you will be deleting the vDisk reference files as well as the device it is assigned to.

To delete a vDisk:
1. In the Console, expand vDisk Pool in the tree, then highlight the vDisk that you want to delete in the details pane.
2. Right-click on the vDisk, then select Delete. The Delete vDisks dialog appears.
3. To permanently delete the vDisk from the hard drive, select the checkbox for deleting the vDisk from the hard drive option. Or, do not select the checkbox to delete the vDisk from the store and database. Unless a backup copy is made before deleting a vDisk image file from the store, the vDisk image file is permanently deleted.
4. Click Yes. The vDisk is deleted.
Managing Device Collections

May 08, 2015

Device collections provide the ability to create and manage logical groups of target devices. Creating device collections simplifies device management by performing actions at the collection level rather than at the target-device level.

Note: A target device can only be a member of one device collection.

A device collection could represent a physical location, a subnet range, or a logical grouping of target devices. For example, a collection could consist of all target devices that use a particular vDisk image, and that target device collection might consist of maintenance, test, and production devices. Alternatively, three device collections could exist for a particular vDisk; one consisting of production devices, one consisting of test machines, and another consisting of maintenance machines. In the proceeding examples, all of the devices in a given collection are assigned to the same vDisk.

Depending on a site's preference, another collection use case might include the consolidation of test and/or maintenance devices into a single device collection, and then managing vDisk assignments on a per device basis rather than a per collection basis. For example, create a device collection labeled Development consisting of five target devices, each one assigned to a particular vDisk.

Device collections are created and managed by farm administrators, site administrators that have security privileges to that site, or device administrators that have security privileges to that collection. For more information on administrator roles, refer to Managing Administrative Roles.

Expanding a Device Collections folder in the Console's tree allows you to view members of a device collection. To display or edit a device collection's properties, right-click on an existing device collection in the Console, then select the Properties menu option. The Device Collection Properties dialog displays allowing you to view or make modifications to that collection.

You can perform actions on members of a device collection, such as rebooting all target devices members in this collection.
Device Collection Properties

Jul 11, 2012
Device collection properties are located on the following tabs.

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>The name of this device collection.</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Describes this device collection.</td>
</tr>
<tr>
<td><strong>Template target device</strong></td>
<td>To use the settings of an existing target device as the template to apply to all target devices that are added to this collection, select that device from the drop-down menu, then click OK.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Groups with Device</strong></td>
<td>Assign or unassign device administrators to this collection using Add or Remove. Device administrators can perform tasks on all device collections to which they have privileges.</td>
</tr>
<tr>
<td>Administrator access</td>
<td>Assign or unassign device operators to this collection using Add or Remove. Device operators have the following privileges:</td>
</tr>
<tr>
<td></td>
<td>• Boot and reboot a target device</td>
</tr>
<tr>
<td></td>
<td>• Shut down a target device</td>
</tr>
<tr>
<td></td>
<td>• View target device properties</td>
</tr>
<tr>
<td></td>
<td>• View vDisk properties for assigned target devices</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field/Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Template target device</strong></td>
<td>Displays the name of the target device, if a device was previously selected, or &lt;No template device&gt;, if a device was not selected. Use the drop-down menu to select a device to use as the template for adding new devices to this collection.</td>
</tr>
<tr>
<td></td>
<td>To view a selected device's properties, click Properties (read-only dialog appears).</td>
</tr>
<tr>
<td><strong>Prefix</strong></td>
<td>Enter a static prefix that helps identify all devices that are being added to this collection. For example: 'Boston' to indicate devices located in Boston. The prefix can be used in combination with the suffix, but is not required if a suffix is provided. The entire device name can have a maximum of 15 characters (the prefix length + number length + suffix length). For example, the following device names are considered valid:</td>
</tr>
</tbody>
</table>

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved.
### Field/Button Description

#### Number Length
Enter the length of the incrementing number to associate with the devices being added to this collection. This number is incremented as each device is added. For example, if the number length is set to '3', Provisioning Services starts naming at '001' and stops naming or adding devices after the number reaches '999'.

Enable the Zero fill option to automatically add the necessary number of preceding zeros to a numbers length. For example, if the numbers length is equal to 3, than the first target device number would be assigned as '001'.

Enable the Zero fill option to automatically add the necessary number of preceding zeros to a numbers length. For example, if the numbers length is set to '4', than the first target device number would be assigned as '0001'.

The number length must have a minimum of three digits and a maximum of 9 digits.

#### Suffix
Enter a static suffix that helps to identify all devices being added to this collection. For example: Boston000Floor2 might be helpful to indicate the floor where these devices reside.

The suffix can be used in combination with the prefix, but is not required if a prefix is provided.

The entire device name can have a maximum of 15 characters (the prefix length + number length + suffix length).

The suffix cannot start with a digit.

The prefix and suffix combination must be unique in each collection.

#### Last incremental number
Indicates the last incremental number that was assigned to a device name in this collection.

This number can be reset to '0' but cannot be lower than the highest number for the same Prefix/Suffix combination.
Creating a Device Collection

Apr 08, 2010

To create a new device collection:

1. In the Console, right-click on the Device Collections folder where the new collection will exist, then select the Create device collection menu option. The Device Collection Properties dialog appears.
2. On the General tab, type a name for this new device collection in the Name text box, and a description of this collection in the Description text box, then click the Security tab.
4. To assign a group with the Device Administrator role, type or select the appropriate domain and group name in the text box, then click OK.
5. Optionally, repeat steps 2 and 3 to continue assigning groups as device administrators.
7. To assign a group with the Device Operator role, type or select the appropriate domain and group name in the text box, then click OK.
8. Optionally, repeat steps 2 and 3 to continue assigning groups as device operators.
9. Click OK to close the dialog box.
Importing Target Devices into a Collection

Oct 12, 2015
The Import Target Devices Wizard allows you to import target device information from a file. The target device information must first be saved as a .csv file, it can then be imported into a device collection.

Note: The .csv text file can be created with a .txt file, NotePad.exe or Excel. It contains one line per target device, which is formatted as follows:
DeviceName,MAC-Address,SiteName,CollectionName,Description,Type
where:
DeviceName = Name of new target device
MAC-Address = MAC address of new device; such as 001122334455, 00-11-22-33-44-55, or 00:11:22:33:44:55
Type = 0 for production, 1 for test, 2 for maintenance

The wizard can be accessed from the farm, site, and device collection right-click menus. If accessed from the site or collection, only those target devices in the import file that match the site and collection by name, will be included in the import list.

The wizard also provides the option to automatically create the site or collection using the information in the file, if either does not already exist. There is also the option to use the default collection's device template, if it exists for that collection.

A log file is generated with an audit trail of the import actions. The file is located in:
C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services\log

To Import target devices into a Collection:

1. In the Console, right-click on the device collection that the target devices should be imported to, then click Target Device>Import devices. The Import Target Devices Wizard displays.
2. Type or browse for the file to import. The target device information is read from the file and displays in the table below. Information can include the target device name, MAC address, and optionally description.
3. Highlight one or more target devices to import. If applying the collection template to the imported target devices, select the Apply collection template device when creating devices checkbox.
4. Click Import to import the .csv text file containing target device information, into the selected collection. The status column indicates if the import was successful.
Deleting a Collection

Apr 08, 2010
Deleting a collection deletes any target device member records within the collection. The records can be recreated by manually adding them or using the Auto-add feature.

Note: Deleting a target device also deletes that device from any views that it was associated with.

If target devices are members of collections within the same site, the members of one collection can be dragged and dropped to other collections, then the original collection can be deleted. If a device collection needs to be moved to a different site or that site becomes obsolete, you can use the export and import features to add the devices to a collection in another site, then the original collection can be deleted.

To delete a collection:

1. In the Console tree, right-click on the collection folder that you want to delete, then select the Delete menu option. A confirmation message appears.
2. Click OK to delete this collection. The collection no longer displays in the Console tree.
Refreshing a Collection in the Console

Apr 08, 2010

After making changes to a collection, it may be necessary to refresh the collection before those changes appear in the Console. To refresh, right-click on the collection in the tree, then select the Refresh menu option.
Booting Target Devices within a Collection

Apr 08, 2010
To boot target devices within a collection:
1. Right-click on the collection in the Console tree, then select the Target Device>Boot menu option. The Target Device Control dialog displays with the Boot devices menu option selected in the Settings drop-down menu. Target devices display in the Device table.
2. Click the Boot devices button to boot target devices. The Status column displays the Boot Signal status until the target device successfully receives the signal, then status changes to success.
Restarting Target Devices within a Collection

Apr 08, 2010

To restart target devices within a collection:

1. Right-click on the collection in the Console tree, then select the Target Device>Restart devices menu option. The Target Device Control dialog displays with the Restart devices menu option selected in the Settings drop-down menu. Devices display in the Device table.

2. Type the number of seconds to wait before restarting target devices in the Delay text box.

3. Type a message to display on target devices in the Message text box.

4. Click the Restart devices button to restart target devices. The Status column displays the restart signal status until the target device successfully receives the signal, then status changes to Success.
To shutdown target devices members within a collection

1. Right-click on the collection in the Console tree, then select the Target Device>Shutdown devices menu option. The Target Device Control dialog displays with the Shutdown devices menu option selected in the Settings drop-down menu. Target devices display in the Device table.
2. Type the number of seconds to wait before shutting down target devices in the Delay text box. Type a message to display on target devices in the Message text box.
3. Click the Shutdown devices button to shutdown target devices. The Status column displays the shutdown signal status until the target device shuts down. As each target device successfully shuts down, the status changes to Success.
Sending Messages to Target Devices within a Collection

Apr 08, 2010
To send a message to target device members within a collection
1. Right-click on the collection in the Console tree, then select the Target Device>Send message menu option. The Target Device Control dialog displays with the Message to devices menu option selected in the Settings drop-down menu. Target devices display in the Device table.
2. Type a message to display on target devices in the Message text box.
3. Click the Send message button. The Status column displays the message signal status until the target device successfully receives the message, then the status changes to Success.
Moving Collections within a Site

Apr 08, 2010
Target devices can be moved from one collection to another collection within the same site.
To move a collection:

1. In the Console, expand the collection, right-click on the target device, then select the Move menu option.
2. From the drop-down menu, select the collection to move this target device into, then click OK to close the dialog.
Managing for Highly Available Implementations

Nov 14, 2014

The key to establishing any highly available network is to identify the critical components, create redundancy for these components, and ensure automatic failover to the secondary component in the event that the active component fails. Critical components include:

- Database
- Provisioning Servers
- vDisks and storage

Provisioning Services provides several options to consider when configuring for a highly available implementation, including:

- Database
  - Offline Database Support, allows Provisioning Servers to use a snapshot of the database if the connection to the database is lost.
  - Database Mirroring, support for database mirroring.
- Provisioning Servers
  - Provisioning Server Failover, should a server become unavailable for any reason, another server within the site can provide active target devices with the vDisk.
  - Managing Load Balancing Across Servers, provides load balancing between Provisioning Servers to prevent overload, while allowing for server capacity to be used more effective and efficiently.
- vDisks and Storage
  - Configuring Highly Available Shared Storage, supports various shared-storage configurations.
The Offline Database Support option allows Provisioning Servers to use a snapshot of the Provisioning Services database in the event that the connection to the database is lost.

Note: This option is disabled by default and is only recommended for use with a stable farm running in production. It is not recommended when running an evaluation environment or when reconfiguring farm components 'on the fly'. Only a farm administrator can set this option.

When offline database support is enabled on the farm, a snapshot of the database is created and initialized at server startup. It is then continually updated by the Stream Process. If the database becomes unavailable, the Stream Process uses the snapshot to get information about the Provisioning Server and the target devices available to the server; this allows Provisioning Servers and target devices to remain operational. However, when the database is offline, Provisioning Services management functions and the Console become unavailable.

When the database connection becomes available, the Stream Process synchronizes any Provisioning Server or target device status changes made to the snapshot, back to the database.

The following features, options, and processes remain unavailable when the database connection is lost, regardless if the Offline Database Support option is enabled:

- AutoAdd target devices
- vDisk updates
- vDisk creation
- Active Directory password changes
- Stream Process startup
- Image Update service
- Management functions; PowerShell, MCLI, SoapServer and the Console
To enable the Offline Database Support option
1. In the Console tree, right-click on the Farm, then select Properties. The Farm Properties dialog appears.
2. On the Options tab, check the checkbox next to Offline Database Support.
3. Restart Stream services.
Database Mirroring

Aug 07, 2012

In order to provide a highly available configuration, if you mirror a MS SQL database and the primary version becomes unavailable, Provisioning Services supports the mirrored version. This results in improved overall availability of Provisioning Services.

Database mirroring can be implemented in a new or existing farm and requires the following high-level tasks:

- Creating the Provisioning Services MS SQL primary database (created when the Installation Wizard is run on the server)
  
  Note: For database mirroring to function, the recovery model must be set to Full.

- Identifying the primary database server and instance (identified when the Configuration Wizard is run)

- Identifying an existing MS SQL failover database server (identified, not created, when the Configuration Wizard is run)

- Configuring mirroring between the primary and failover database servers (configured using MS SQL database server tools)

Note: Citrix recommends that the failover server be up and running before enabling database mirroring in the farm. For helpful information on configuring the MS SQL failover server, refer to http://technet.microsoft.com/en-us/library/ms188712.aspx.

Note: The procedures that follow are only intended to call out the steps that are applicable to database mirroring when running the Configuration Wizard.

Note: Run the Configuration Wizard to specify the new failover server so that the status of the Provisioning Service's farm correctly reports the new settings. After re-running the wizard, some services, including the stream service, restart so that the farm has the new failover server settings specified with the wizard was run.

To enable mirroring:

1. Start the Configuration Wizard on a server that will be in the new farm.
2. While running the wizard, when the Farm Configuration page displays, select the Create Farm radio button to create a new farm, then click Next.
3. Type or use the Browse button to identify the primary database server and instance names. Optionally, enter a TCP port number to use to communicate with this database server.
4. Enable the Specify database mirror failover partner option.
5. Type or use the Browse button to identify the failover database server and instance names. Optionally, enter a TCP port number to use to communicate with this server.
6. Click Next. If the failover database has already been configured and it is up and running, Provisioning Services should be able to connect to it. If the failover database server has not yet been created or is not running, an error message may display indicating a failure to connect. In this case, when prompted, click Yes to continue (the failover database can be created and configured after the new farm is created).
7. On the New Farm page, enter a name for the new database on the primary database server, then complete any additional requested information.
8. Click Next.
9. Complete the remaining wizard pages.

To enable mirroring within an existing farm:

1. Confirm that the primary and failover database servers are up and running.
2. Using MS SQL server tools, mirror the Provisioning Services database to a database on the failover database server.
3. Run the Configuration Wizard on each server.
4. Identify the farm by choosing either the Farm is already configured or the Join existing farm option on the Farm Configuration page.
5. On the Database Server page, select the primary and failover database servers and instance names, then enable the database mirror failover feature.
6. Complete the remaining wizard pages.
Provisioning Server Failover

May 08, 2015

By default, all Provisioning Servers within a site that can access a vDisk can provide that vDisk to target devices. Multiple Provisioning Servers can access the same physical files located on shared storage, which allows a target device to establish a connection on an alternate Provisioning Server if the connection to the active Provisioning Server is interrupted for any reason. A target device does not experience any disruption in service or loss of data when failover occurs.

Note: For implementations that use vDisk replication, if a server failover occurs, only those servers with access to an identical replicated vDisk can provide that vDisk to target devices. For example; if vDisk is replicated across three servers hard drives and then one of the vDisks is updated, that vDisk is no longer identical and will not be considered if a server failover occurs. Even if the same exact update is made to two of the vDisks, the timestamps on each will differ, therefore the vDisks are no longer identical.

Note: Provisioning Services does not support the high availability of vDisks on local storage that are in Private Image mode or that are currently in maintenance (read/write enabled).

If load balancing is enabled for the vDisk and a server providing that vDisk should fail, Provisioning Services automatically balances the target device load between the remaining servers. If the load balancing option is not enabled, a single server is assigned to provide the vDisk to target devices, therefore failover will not occur.

Note: For information on configuring Provisioning Services to automatically balance the target device load between servers, refer to Balancing the Target Device Load on Provisioning Servers.

The Provisioning Server that a target device accesses to login does not necessarily become the Provisioning Server that accesses the vDisk on behalf of the target device. In addition, once connected, if one or more Provisioning Servers can access the vDisk for this target device, the server that is least busy is selected.

To purposely force all target devices to connect to a different Provisioning Server, while avoiding having targets timeout and attempt to reconnect to the current server, stop the Stream Service on that server. Upon shutdown, the Stream Service will notify each target device to re-login to another server.

To ensure that devices can failover successfully, complete the following:
1. Double-click the vDisk status icon on the target device and then note the IP address of the connected Provisioning Server.
2. Right-click the connected Provisioning Server in the Console. Select Stream Services, then select Stop.
3. Confirm that the IP address of the connected Provisioning Server changes to that of an alternate Provisioning Server in the vDisk status dialog on the target device.
Configuring for High Availability with Shared Storage

Sep 06, 2011

Provisioning Servers are configured to access your shared-storage location. Provisioning Services supports various shared-storage configurations. The steps for configuring for highly available storage in the network varies depending on shared-storage configurations.

Note: Installing Provisioning Services affects the following registry key: HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\MRXSmb\Parameters\OplocksDisabled. Changing this registry key disables Windows Opportunity Locking, providing the fastest possible failover time when contact with the active Provisioning Server is lost. Without this change, failover times can take up to one minute. During this time, Windows does not allow access to the vDisk file that was in use by the failed Provisioning Server. By disabling Windows Opportunity Locking on Provisioning Servers, the Stream Service can have immediate access to vDisk files. However, this reduces caching of remote vDisk data for the entire Provisioning Server.

Note: The instructions below provide the procedures on a Windows XP operating system. If you are using another operating system, the dialogs may appear slightly different, and slightly different steps may be required. The concepts are the same regardless of operating system. See your operating system's online help for more information.

Stream Services run under a user account; Service account credentials. If you are using a Windows shared-storage location, the Service account credentials (user account name and password) must be a domain account that is configured on each Provisioning Server, in order to access the Stream Service and the shared storage system.

An administrator creates service account credentials in Active Directory and assigns the credentials to the Stream Service on all Provisioning Servers that will participate in HA. Alternatively, an existing domain user account can be given full control rights to the network share and be assigned to the Stream Service.

Note: Your Microsoft Windows online help contains detailed instructions for creating both local and domain accounts. Consider the following when creating service account credentials:

- You must be logged on as an administrator or a member of the Administrator group to create a domain account.
- Clear the ‘User must change password at next logon’ checkbox.

When running the Configuration Wizard on a Provisioning Server, you are prompted to enter an account name and password for the Stream Service to use. This account must have access permissions for any stores it is given access to, as well as permissions in SQL Server for database access. If necessary, credentials can be assigned manually.

To assign the Service account credentials to the Stream Service:
1. Open the Windows Control Panel
2. Go to Administrative Tools > Services.
3. Double-click on the first PVS Stream Service name in the Services list.
4. On the Log On tab, select This Account, then click Browse.
5. Click Locations, select the domain node, then click OK.
6. Type the name of the Stream Service user account, then click Check Names.
7. Click OK to close the Select User dialog.
8. On the Log On tab, enter and confirm the Stream Service account password, then click OK.

The stores that contain the vDisks need to be shared, and the Service account credentials (user account and password) needs to have access to remote storage for vDisks, with the appropriate permissions.

To share your vDisk's stores folders, and grant access permissions to your Service account credentials:
1. In Windows Explorer, right-click on the folder that contains the database and vDisk folders. For example, if the database and vDisk files are stored in the default C:\Program Files\Citrix\Provisioning Services folder, right-click on that folder.
2. Select Sharing and Security from the shortcut menu.
3. Enable the Share this folder radio button, then optionally enter a share name, and comment.
4. Click Permissions.
5. If the Service account credentials user name does not appear in the Group or user names list, click the Add button. Enter the name of the Service account credentials, and click Check Names to verify.
6. Click OK.
7. Select the service account credentials user name.
8. Enable the Full Control checkbox (the Full Control checkbox and all checkboxes below it should be checked).
9. Click Apply.
10. Click the Security tab.

Note: In Windows XP it may be necessary to turn off simple sharing, so that you can display the Security tab of the Folder Properties dialog to give permissions to the proper user (the user defined in “Creating Streaming-Service Account Credentials", or 'Everyone'). To turn off simple sharing, select Start > Control Panel. Double-click Folder Options. On the View tab, under Advanced settings, clear the ‘Use simple file sharing (Recommended) checkbox.
11. If the Service account credentials user name does not appear in the Group or user names list, click the Add button. Enter the username of the Service account credentials, then click Check Names to verify.
12. Click OK.
13. Select the Service account credentials as user name.
14. Enable the Full Control checkbox, then click Apply.
15. Click OK.

If storing the database and vDisks on a SAN, use local system accounts for the Stream Service. Unlike a Windows network share, creating special Service Account Credentials to guarantee access to your data, may not be necessary to guarantee access to your data.

In most cases, a SAN configuration allows setting up as if the database and vDisks were stored locally on the Provisioning Server.
Configuring the Boot File for High Availability

May 09, 2011

When a Provisioning Server is configured by the Configuration Wizard, that server can be selected as one of the servers used to connect target devices during the boot process. To be highly available, at least two login Provisioning Servers must be listed in the boot file (maximum of four servers).

The target device's boot file contains the IP addresses of up to four login Provisioning Servers, as well as other configuration information. The boot file lists the Provisioning Servers that a target device can contact to get access to the Provisioning Services farm. The server that is contacted may hand the target device off to a different Provisioning Server that is able to provide the target device with its vDisk.

Note: A shared storage system ensures the availability of the Provisioning Server vDisks. Depending on the type of shared storage, the vDisks use either the Universal Naming Convention (UNC) or the usual DOS naming convention.

An administrator must add Provisioning Servers to the boot file in order to provide a target device with the information necessary to make contact with the Stream Service.

When first configuring a Provisioning Server, the Configuration Wizard allows you to select to use the server, which is currently being configured, to provide TFTP services. If all target devices are on one network segment, there will typically be one TFTP server per farm. If target devices are on multiple network segments, and each segment is configured as an independent site, then one TFTP server per site (network segment) may be used.

Provisioning Servers can also be configured as login servers in the Console using the Configure Bootstrap dialog.

Select from either method to add Provisioning Servers to the boot file.

To add and configure the first Provisioning Server as the TFTP and login server using the Configuration Wizard:
1. Run the Configuration Wizard and when presented with the TFTP option and bootstrap location dialog, select the Use the Provisioning Server TFTP Service option.
2. Enter or browse for the bootstrap file location, then click Next. The default location is: C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services\Tftpboot
   Note: If a previous version of Provisioning Server was installed on this server, you may need to change the default location from C:\Program Files\Citrix\Provisioning Server\TFTPBoot or C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Server\TFTPBoot to: C:\Documents and Settings\All Users\Application Data\Citrix\Provisioning Services\Tftpboot. If the default is not changed, the bootstrap file can not be configured from the Console and target devices will fail to boot; receiving a 'Missing TFTP' error message.
3. In the Provisioning Servers boot list, click the Add button to add additional login Provisioning Servers to the list. Use the Move up or Move down buttons to change the Provisioning Server boot preference order.
   Note: In an HA implementation, at least two Provisioning Server must be selected as boot servers.
4. To set advanced configuration settings, highlight the IP address of the Provisioning Server, click Advanced, then configure the bootstrap file.
   Note: For field definitions, refer to Provisioning Server Properties.
5. Click OK, then click Next.
6. Review configuration settings, then click Finish to confirm configuration settings and restart network services on this
7. To exit the Configuration Wizard, click Done.

To add and configure additional Provisioning Servers as a login servers:
1. In the Console, right-click on a Provisioning Server that will be used as a login server, then select the Configure Bootstrap menu option. The Configure Bootstrap dialog appears.

   Note: Clicking Read DB populates the table with login servers that already exist. When the Stream Service starts, it creates a record in the database with its own IP address. There is only one Stream Service option record per database. If the service is bound to multiple IP addresses, multiple records appear in the database. The Read DB function chooses only one IP address from each Provisioning Server. This function can also be used to populate the boot file with the Stream Service IP settings already configured in the database.

2. Click Add to add a new login Provisioning Server to the bootstrap file. The Streaming Server dialog appears.
3. Type the IP address and port number of this Provisioning Server in the appropriate text boxes.
4. Select to either use subnet mask and gateway settings using DHCP/BOOTP, or type in the settings to use, then click OK. The Provisioning Server information displays in the list of available login servers.
5. To configure advanced bootstrap settings, on the Options tab, choose from the following settings:
   - Select Verbose Mode if you want to monitor the boot process on the target device (optional). This enables system messaging on the target device.
   - Select Interrupt Safe Mode if the target device hangs early in the boot process.
   - Select Advanced Memory Support checkbox unless using older versions without PAE enabled.
6. Select from the following Network Recovery Methods:
   - Restore Network Connections - Selecting this option results in the target device attempting indefinitely to restore its connection to the Provisioning Server.
     Note: Because the Seconds field does not apply, it becomes inactive when the Restore Network Connections option is selected.
   - Reboot to Hard Drive - Selecting this option instructs the target device to perform a hardware reset to force a reboot after failing to re-establish communications for a defined number of seconds. The user determines the number of seconds to wait before rebooting. Assuming the network connection can not be established, PXE will fail and the system will reboot to the local hard drive. The default number of seconds is 50.
7. Under Timeouts, scroll for the Login Polling Timeout, in milliseconds, between retries when polling for Provisioning Servers.
8. Under Timeouts, scroll for the Login General Timeout, in milliseconds, for all login associated packets, except the initial login polling time-out.
9. Click OK to save your changes.
Integrating Provisioning Services and Active Directory allows administrators to:

- Select the Active Directory Organizational Unit (OU) in which Provisioning Services should create a target device computer account.
- Take advantage of Active Directory management features, such as delegation of control and group policies.
- Configure the Provisioning Server to automatically manage the computer account passwords of target devices.

Note: For more information about using Active Directory organizational units and delegation of control, refer to Microsoft Active Directory documentation.

The following major tasks are used to manage Active Directory in a Provisioning Services environment:

- Managing Domain Passwords
- Enabling Domain Management
- Managing Domain Computer Accounts
Active Directory Integration Prerequisites

Oct 13, 2012

Before integrating Active Directory within the farm, verify that the following prerequisites are met:

- The Master Target Device was added to the domain before building the vDisk.
- The Disable Machine Account Password Changes option was selected when the image optimization wizard was run during imaging.

After all prerequisites have been verified, new target devices can be added and assigned to the vDisk. A machine account must then be created for each target device.
Managing Domain Passwords

Feb 15, 2011

When target devices access their own vDisk in Private Image mode, there are no special requirements for managing domain passwords. However, when a target device accesses a vDisk in Standard Image mode, the Provisioning Server assigns the target device its name. If the target device is a domain member, the name and password assigned by Provisioning Server must match the information in the corresponding computer account within the domain. Otherwise, the target device is not able to log on successfully. For this reason, the Provisioning Server must manage the domain passwords for target devices that share a vDisk.

To enable domain password management you must disable the Active Directory-(or NT 4.0 Domain) controlled automatic re-negotiation of machine passwords. This is done by enabling the Disable machine account password changes security policy at either the domain or target-device level. Provisioning Server provides equivalent functionality through its own Automatic Password Renegotiate feature.

While target devices booting from vDisks no longer require Active Directory password renegotiation, configuring a policy to disable password changes at the domain level applies to any domain members booting from local hard drives. This may not be desirable. A better option is to disable machine account password changes at the local level. This can be accomplished by selecting the Optimize option when building a vDisk image. The setting will then be applied to any target devices that boot from the shared vDisk image.

Note: The Provisioning Server DOES NOT in any way change or extend the Active Directory schema. Provisioning Server's function is to create or modify computer accounts in Active Directory, and reset passwords. When domain password management is enabled, it:

- Sets a unique password for a target device.
- Stores that password in the respective domain computer account.
- Gives the information necessary to reset the password at the target device before it logs on to the domain.

The illustration that follows shows how password management validates Active Directory passwords on the domain.
With password management enabled, the domain password validation process includes:

- Creating a machine account in the database for a target device, then assign a password to the account.
- Providing an account name to a target device using the Streaming Service.
- Having the domain controller validate the password provided by the target device.
Enabling Domain Management

Apr 08, 2010

Each target device that logs on to a domain requires a computer account on the domain controller. This computer account has a password that is maintained by the Windows desktop OS and is transparent to the user. The password for the account is stored both on the domain controller and on the target device. If the passwords stored on the target device and on the domain controller do not match, the user cannot log on to the domain from the target device.

Domain management is activated by completing the following tasks:

- Enabling Machine Account Password Management
- Enabling Automatic Password Management

To enable machine account password management, complete the following:

1. Right-click on a vDisk in the Console, then select the File Properties menu option.
2. On the Options tab, select Active Directory machine account password management.
3. Click OK, then close the properties dialogs, then restart the Streaming Service.

If your target devices both belong to an Active Directory domain and are sharing a vDisk, the following additional steps must be completed:

To enable automatic password support, complete the following:

1. Right-click on a Provisioning Server in the Console, then select the Properties menu option.
2. Select the Enable automatic password support option on the Options tab.
3. Set the number of days between password changes.
4. Click OK to close the Server Properties dialog.
5. Restart the Streaming Service.
Managing Domain Computer Accounts

The following tasks are normally performed in the Active Directory Users and Computers Management Console. However, these actions must now be performed using the Provisioning Server in order to take full advantage of product features.

- Supporting Cross-Forest Scenarios
- Giving Access to Users from Another Domain Provisioning Services Administrator Privileges
- Adding Target Devices to a Domain
- Removing Target Devices From a Domain
- Reset Computer Accounts

Supporting Cross-Forest Scenarios

To support cross-forest scenarios:

- Ensure that DNS is properly set up. (Refer to Microsoft's web site for information on how to prepare DNS for a Forest Trust.)
- Raise the forest functional level of both forests to Windows Server 2003.
- Create the forest trust. In order for Provisioning Services and the user from the Provisioning Services domain to create an account in a domain from another forest, create an Inbound Trust from the external forest to the forest Provisioning Services is in.

Parent-child domain scenario

A common cross-domain configuration includes the Provisioning Server in a parent domain and users, from one or more child domains, want to administer Provisioning Services and manage Active Directory accounts within their own domains.

To implement this configuration:

1. Create a Security Group in the child domain. (It can be a Universal, Global, or Local Domain Group). Make a user from the child domain a member of this group.
2. From the Provisioning Server Console, in the parent domain, make the child domain security group a Provisioning Services Administrator.
3. If the child domain user does not have Active Directory privileges, use the Delegation Wizard in the Active Directory Users & Computers Management Console to assign, create, and delete a user's computer account rights for the specified OU.
4. Install the Provisioning Services Console in the child domain. No configuration is necessary. Log into the Provisioning Server as the child domain user.

Cross-forest configuration

This configuration is similar to the cross-domain scenario, except that the Provisioning Services Console, user, and Provisioning Services administrator group are in a domain that is in a separate forest. The steps are the same as for the parent-child scenario, except that a forest trust must first be established.

Note: Microsoft recommends that administrators do not delegate rights to the default Computers container. The best practice is to create new accounts in the OUs.

Giving Access to Users from Another Domain Provisioning Services Administrator Privileges

There are several methods for giving Provisioning Services Administrator privileges to users that belong to a different domain. However, the following method is recommended:
1. Add the user to a Universal Group in their own domain (not the Provisioning Services Domain).
2. Add that Universal Group to a Local Domain Group in the PVS domain.
3. Make that Local Domain Group the PVS Admin group.

Adding Target Devices to a Domain

To add target devices to a domain:

Note: The machine name used for the vDisk image is to never be used within your environment again.

1. Right-click on one or more target devices in the Console window (alternatively, right-click on the device collection itself to add all target devices in this collection to a domain). Select Active Directory, then select Create machine account. The Active Directory Management dialog appears.
2. From the Domain scroll list, select the domain that the target device(s) belongs to, or in the Domain Controller text box, type the name of the domain controller that the target devices should be added to (if you leave the text box blank, the first Domain Controller found is used).
3. From the Organization unit (OU) scroll list, select or type the organization unit to which the target device belongs (the syntax is 'parent/child,' lists are comma separated; if nested, the parent goes first).
4. Click the Add devices button to add the selected target devices to the domain and domain controller. A status message displays to indicate if each target device was added successfully. Click Close to exit the dialog.

Removing Target Devices From a Domain

To remove target devices from a domain:

1. Right-click on one or more target devices in the Console window (alternatively, right-click on the device collection itself to add all target devices in this collection to a domain). Select Active Directory Management, then select Delete machine account. The Active Directory Management dialog appears.
2. In the Target Device table, highlight those target devices that should be removed from the domain, then click the Delete Devices button. Click Close to exit the dialog.

Reset Computer Accounts

Note: An Active Directory machine account can only be reset when the target device is inactive.

To reset computer accounts for target devices in an Active Directory domain:

1. Right-click on one or more target devices in the Console window (alternatively, right-click on the device collection itself to add all target devices in this collection to a domain), then select Active Directory Management, then select Reset machine account. The Active Directory Management dialog appears.
2. In the Target Device table, highlight those target devices that should be reset, then click the Reset devices button. Note: This target device should have been added to your domain while preparing the first target device.
3. Click Close to exit the dialog.
4. Disable Windows Active Directory automatic password re-negotiation. To do this, on your domain controller, enable the following group policy: Domain member: Disable machine account password changes.

Note: To make this security policy change, you must be logged on with sufficient permissions to add and change computer accounts in Active Directory. You have the option of disabling machine account password changes at the domain level or local level. If you disable machine account password changes at the domain level, the change applies to all members of the domain. If you change it at the local level (by changing the local security policy on a target device connected to the vDisk in Private Image mode), the change applies only to the target devices using that vDisk.
5. Boot each target device.
Network components

May 18, 2015

The documents in this section describe the tasks you need to carry out to maintain and manage the network components within your streaming implementation.
Preparing Network Switches

Network switches provide more bandwidth to each target device and are very common in networks with large groups of users. The use of Provisioning Services in the network may require changes to switch configurations. When planning an implementation, give special consideration to managed switches.

Note: For Provisioning Services networks, you must specify all network switch ports to which target devices are connected as edge-ports.

Managed switches usually offer loop detection software. This software turns off a port until the switch is certain the new connection does not create a loop in the network. While important and useful, the delay this causes prevents your target devices from successfully performing a PXE boot.

This problem manifests itself in one of the following ways:
- Target device (not Windows) login fails.
- Target device appears to hang during the boot process.
- Target device appears to hang during the shutdown process.

To avoid this problem, you must disable the loop detection function on the ports to which your target devices are connected. To do this, specify all ports to which target devices are connected as edge-ports. This has the same effect as enabling the fast link feature in older switches (disables loop detection).

Note: A network speed of at least 100MB is highly recommended. If using a 10MB hub, check whether your network card allows you to turn off auto-negotiation. This can resolve potential connection problems.

Switch Manufacturers

This feature is given different names by different switch manufacturers. For example:
- Cisco; PortFast or STP Fast Link
- Dell; Spanning Tree Fastlink
- Foundry; Fast Port
- 3COM; Fast Start
Using UNC Names

Apr 08, 2010

A Universal Naming Convention (UNC) format name defines the location of files and other resources that exist on a network. UNC provides a format so that each shared resource can be identified with a unique address. UNC is supported by Windows and many network operating systems (NOSs).

With Provisioning Services, UNC format names can be used to specify the location of the OS Streaming database for all Provisioning Servers, and to specify the location of a particular vDisk.

Syntax

UNC names must conform to the \\SERVERNAME\SHARENAME syntax, where SERVERNAME is the name of the Provisioning Server and SHARENAME is the name of the shared resource.

UNC names of directories or files can also include the directory path under the share name, with the following syntax:

\\SERVERNAME\SHARENAME\DIRECTORY\FILENAME

For example, to define the folder that contains your configuration database file in the following directory:

C:\Program Files\Citrix\Provisioning Services

On the shared Provisioning Server (server1), enter:

\server1\Provisioning Services

Note: UNC names do not require that a resource be a network share. UNC can also be used to specify a local storage for use by only a local machine.

Accessing a Remote Network Share

To access a remote network share using a UNC format name, the Stream Service must have a user account name and password on the remote system.

To use a UNC name to access a remote network share:

1. On the Provisioning Server, create a user account under which the Stream Service will run. This account MUST have a password assigned, otherwise the Stream Service will not be able to log in correctly. Your Stream Service can share the same user account and password, or separate user accounts and passwords can be set up for each service.

2. Share the vDisk and configuration database folders. In Windows Explorer, right-click on the folder, then select Properties. Click the Sharing tab, then select the Share this folder radio button. Enter or select a Share name.

3. Make sure permissions are set to allow full control of all files in the vDisk folder and database folder. Click the Permissions button on the Sharing tab, or click the Security tab, then set the correct permissions.

Note: In XP it may be necessary to turn off simple sharing, so that you can display the Security tab of the Folder Properties dialog to give permissions to the proper user (the user defined in Step 1 above, or everyone). To turn off simple sharing, select Start>All Programs>Control Panel. Double-click Folder Options. On the View tab, under Advanced settings, clear the Use simple file sharing (Recommended) checkbox.

4. For the Stream Service, complete Steps 4-A and 4-B:
   - Go to Control Panel>Computer Management>Component Services, right click on the Stream Service, and select Properties.
   - Click the Log On tab. Change the Log on as: setting to This Account, and set up the service to login to the user and
password configured in Step 1.

5. Verify that all Stream Services are restarted. The Configuration Wizard does this automatically. Stream Services can also be started from the Console or from the Control Panel.

Note: The Stream Service cannot access folders using a mapped drive letter for the directory, since the mapped drives do not yet exist when the services start at boot time. Do not use a mapped drive letter to represent the vDisk or database-location directories when configuring Stream Services.
Reducing Network Utilization

Sep 15, 2010

Windows provides several features that presume the use of a large, fast hard-disk.

- Recycle Bin
- Offline Folders
- Event Logs
- System Restore
- Logical Prefetch
- Automatic Disk Defragmentation

While many of these features can also be useful on a diskless system where the disk is actually on the network, using them decreases cache effectiveness and thereby increases network utilization. In an environment that is sensitive to network utilization, consider reducing the effect of these features by disabling them or adjusting their properties.

In particular, System Restore and Offline Folders are not useful on a diskless system and can be detrimental to the performance of Windows on a diskless system. Provisioning Services provides a clearer, more reliable, and simpler restore point than System Restore by simply rebooting the target device. Offline Folders cache network files — a feature that is not applicable to a system where all files are on the network.

All of these features are configurable through the target device itself. The following features are configurable in the Windows Group Policy.

- Offline Folders
- Event Logs

Configuring Windows features on a Standard vDisk

1. Prepare a Standard Image vDisk for configuration.
   - Shutdown all target devices that use the Standard Image vDisk.
   - From the Console, change the Disk Access Mode to Private Image.
   - Boot one target device.
2. Configure one or more features.
3. Prepare the Standard Image vDisk for use
   - Shutdown the target device previously used to configure the vDisk.
   - From the Console, change the Disk Access Mode to Standard Image.
   - Boot one or more target devices.

Configuring the Recycle Bin

Disabling the Recycle Bin deletes files immediately. Consequently, the file system reuses respective disk sectors and cache entries sooner.

To configure the Recycle Bin:
1. From the target device, or Windows Explorer, right click on the Recycle Bin.
2. Select Properties.
4. Select from the following settings:
   - Use one setting for all drives.
Do not move files to the Recycle Bin. Remove files immediately when deleted.

Configuring Offline Folders

The disabling of Offline Folders is strongly recommended to prevent Windows from caching network files on its local disk – a feature with no benefit to a diskless system. Configure this feature from the target device or Windows Group Policy.

To configure from the target device:
1. Open Windows Explorer.
2. Select Tools > Folder Options.
3. Select Offline Folders.
4. Uncheck Enable Offline Folders.

To configure using the Windows Group Policy:

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in, to configure the domain policies for the following:

<table>
<thead>
<tr>
<th>Object</th>
<th>User Configuration\Administrative Templates\Network\Offline Files</th>
</tr>
</thead>
</table>
| Policy Setting | Disable user configuration of offline files  
|                  | Enabled  |
| Policy Setting | Synchronize all offline files before logging off  
|                  | Disabled  |
| Policy Setting | Prevent use of the Offline Files folder  
|                  | Enabled  |

Configuring Event Logs

Reduce the maximum size of the Application, Security, and System logs. Configure this feature using the target device or Windows Group Policy.

To configure event logs, on the target device:
1. Select Start > Settings > Control Panel.
2. Open Administrative Tools > Event Viewer.
3. Open the properties for each log.
4. Set the Maximum log size to a relatively low value. Consider 512 kilobytes.

To configure using the Windows Group Policy:

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in to configure the domain policies for the following object:

<table>
<thead>
<tr>
<th>Object</th>
<th>Computer Configuration\Windows Settings\Event Log\Settings for Event Logs</th>
</tr>
</thead>
</table>
| Policy Setting | Policy Maximum Application Log Size  
|                  | Relatively low value. Consider 512 kilobytes.  |
### Configuring System Restore

The disabling of System Restore is strongly recommended to prevent Windows XP from storing any restore points that result in large disk files. Provisioning Services provides an inherent restore feature whenever the target device reboots.

**On Windows XP,** disable System Restore:
1. Select Start, then Control Panel.
2. Open System.
3. Select System Restore.
4. Check Turn off System Restore.

### Configuring Logical Prefetch

Disabling Logical Prefetcher prevents Windows XP from caching additional files.

To disable logical prefetcher, set the following registry value to 0 (zero):

```
HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management\PrefetchParameters\EnablePrefetcher
```

### Configuring Automatic Disk Defragmentation

Disabling Automatic Disk Defragmentation prevents Windows XP from filling the vDisk write cache by automatically defragmenting the vDisk during boot time.

To disable automatic disk defragmentation, set the following registry key value data:

```
Key HKEY_LOCAL_MACHINE\Microsoft\Dfrg\BootOptimizeFunction
```

**Value Name**: Enable

**Value Type**: REG_SZ

**Value Data**: N

### Disabling Windows Automatic Updates

If you have the Windows Automatic Updates service running on your target device, Windows periodically checks a Microsoft Web site and looks for security patches and system updates. If it finds updates that have not been installed, it attempts to download them and install them automatically. Normally, this is a useful feature for keeping your system up-to-date. However, in a Provisioning Services implementation using Standard Image mode, this feature can decrease performance, or even cause more severe problems. This is because the Windows Automatic Updates service downloads programs that fill the write cache. When using the target device’s RAM cache, filling the write cache can cause your target

---

<table>
<thead>
<tr>
<th>Object Policy Setting</th>
<th>Computer Configuration\Windows Settings\Event Log\Settings for Event Logs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum System Log Size</td>
<td>Relatively low value. Consider 512 kilobytes.</td>
</tr>
</tbody>
</table>
devices to stop responding.

Re-booting the target device clears both the target device and Provisioning Services write cache. Doing this after an auto-update means that the Automatic Updates changes are lost, which defeats the purpose of running Automatic Updates. (To make Windows updates permanent, you must apply them to a vDisk while it is in Private Image mode).

To prevent filling your write cache, make sure to disable the Windows Automatic Updates service for the target device used to build the vDisk.

To disable the Windows Automatic Updates feature:
2. Select System.
3. Click the Automatic Updates tab.
4. Select the Turn Off Automatic Updates radio button.
5. Click Apply.
6. Click OK.
7. Select Services.
8. Double-click the Automatic Updates service.
9. Change the Startup Type by selecting Disabled from the drop-down list.
10. If the Automatic Updates service is running, click the Stop button to stop the service.
11. Click OK to save your changes.

To make Windows updates permanent:
1. Shutdown all target devices that share the vDisk.
2. Change the vDisk mode to Private image.
3. Boot one target device from that vDisk.
4. Apply Windows updates.
5. Shutdown the target device.
7. Boot all target devices that share this vDisk.
Managing Roaming User Profiles

Apr 08, 2010

A Roaming User Profile is a user profile that resides on a network share. It consists of files and folders containing the user's personal settings and documents. When a user logs on to a target device system in the domain, Windows copies the respective profile from a network share to the target device’s disk. When the user logs off, Windows synchronizes the user profile on the target device’s hard disk with the user profile on the network share.

For a diskless target device, its disk is actually a vDisk residing in shared storage. Consequently, the profile returns back to the shared storage containing the vDisk. Since the persistent user data always resides on shared storage, Windows does not need to download the profile. This saves time, network bandwidth, and file cache. Since some of the files included in the profile can grow very large, the savings can be significant.

Using Roaming User Profiles with diskless systems effectively involves configuring relevant policies and using Folder Redirection.

Although unrelated to Roaming User Profiles, the Offline Folders feature affects diskless systems similarly. Disabling this feature avoids the same effects.

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in to configure the domain policies for the following objects.

### Configuring Roaming User Profiles

Configuring Roaming User Profiles for diskless systems enables roaming without having to download potentially large files in the profile.

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in to configure the domain policies for the following objects.

To prevent the accumulation of Roaming User Profiles on a vDisk:

<table>
<thead>
<tr>
<th>Object</th>
<th>Computer Configuration\Administrative Templates\System\Logon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy</td>
<td>Delete cached copies of roaming profiles.</td>
</tr>
<tr>
<td>Setting</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

To exclude directories with potentially large files from download:

<table>
<thead>
<tr>
<th>Object</th>
<th>User Configuration\Administrative Templates\System\Logon/Logoff</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy</td>
<td>Exclude directories in roaming profile</td>
</tr>
<tr>
<td>Setting</td>
<td>Enabled</td>
</tr>
<tr>
<td>Properties</td>
<td>Prevent the following directories from roaming with the profile: Application Data;</td>
</tr>
</tbody>
</table>
Using Folder Redirection with Roaming User Profiles and diskless systems retains the availability of user documents.

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in to configure the domain policies for the objects that follow.

To configure folder redirection:
1. Create a network share (\ServerName\ShareName) to contain the redirected user folders.
2. Give Full Control permission to everyone for the network share.
3. Enable Folder Redirection.

<table>
<thead>
<tr>
<th>Object</th>
<th>Computer Configuration\Administrative Templates\System\Group Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy</td>
<td>Folder Redirection policy processing</td>
</tr>
<tr>
<td>Setting</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

4. Redirect the Application Data folder.

<table>
<thead>
<tr>

Disabling Offline Folders

Disabling Offline Folders avoids the unnecessary caching of files on diskless systems with network shares.

On the domain controller, use the Microsoft Management Console with the Group Policy snap-in to configure the domain policies for the object that follows.

To disable offline folders:

<table>
<thead>
<tr>
<th>Object</th>
<th>User Configuration\Administrative Templates\Network\Offline Files</th>
</tr>
</thead>
<tbody>
<tr>

<td>Synchronize all Offline Files before logging off.</td>
</tr>
<tr>
<td></td>
<td>Disabled</td>
</tr>
<tr>
<td>Policy Setting</td>
<td>Prevent user of Offline Files folder.</td>
</tr>
<tr>
<td></td>
<td>Enabled</td>
</tr>
</tbody>
</table>
Booting Through a Router

May 09, 2013

The following documents a basic configuration for booting target devices through a network router. This configuration allows the Provisioning Server to exist on a different subnet from the target device. Since conditions vary from customer to customer, adjustments may be needed for different network configurations.

The configuration shown in the diagram below separates the Provisioning Server from the target device by using a Windows 2000 Server platform acting as a router.

![Diagram of network setup](image)

Configuring for DHCP

In this configuration, a DHCP server must be active on the local subnet (197.100.x.x) of the target device. In the configuration example above, the DHCP service is running on the same machine acting as a router between the two subnets, though it is not mandatory that the DHCP service actually runs on the router itself. This DHCP server provides the IP address and the PXE boot information to the target device.

Configure the DHCP service to provide valid IP addresses to any target device booting on the local subnet (197.100.x.x).

In order to provide the PXE boot information to the target device, configure the following options in your DHCP server:

1. **DISABLE Option 60 (Class ID)**
2. **Enable Option 66 (Boot Server Host Name)** – Enter the IP address of the TFTP Server. In this configuration, the value is 10.64.0.10.
3. **Enable option 67 (Boot file name)** – Enter the name of the boot file. For a standard configuration, the filename is ARDBP32.bin.

Configuring the Provisioning Services for PXE

Using the Console, configure the bootstrap settings to use the Gateway and Subnet mask fields. These fields should reflect the gateway and subnet to be used by the target device. In this case, they are 197.100.x.x for the gateway, and 255.255.255.0 for the netmask.

Verify the TFTP service is running on the Provisioning Server.

The PXE Service on the Provisioning Server in the above configuration is not necessary since options 66 & 67 in the router's DHCP service provide the same information to the target device. You can stop the PXE Service on the Provisioning Server if you have no target devices on the Provisioning Server subnet needing its functionality. The same is true for any DHCP service running on the Provisioning Server itself.
Running PXE and DHCP on the Same Computer

If PXE and DHCP are running on the same Provisioning Server, an option tag must be added to the DHCP configuration. This tag indicates to the target devices (using PXE) that the DHCP server is also the PXE boot server. Verify that option tag 60 is added to your DHCP scope. Provisioning Services setup automatically adds this tag to your scope provided that the Microsoft DHCP server is installed and configured before installing Provisioning Services. The Configuration Wizard sets-up the Tellurian DHCP Server configuration file if you use the wizard to configure Provisioning Services.

The following is an example Tellurian DHCP Server configuration file which contains the option 60 tag.

```
max-lease-time 120;
default-lease-time 120;
option dhcp-class-identifier "PXEClient";
subnet 192.168.4.0 netmask 255.255.255.0 {
    option routers 192.168.123.1;
    range 192.168.4.100 192.168.4.120;
}
```
Managing Multiple Network Interface Cards

Sep 26, 2014

Provisioning Services provides the ability to run redundant networks between the servers and the target devices. This requires that both the servers and the target devices be equipped with multiple NICs.

Multiple NICs on the target device may be configured into a virtual team by using Manufacturer’s NIC teaming drivers, or into a failover group using the Provisioning Services NIC failover feature.

NIC Teaming and NIC Failover features provide resilience to NIC failures that occur after the system is up and running. It is only after the OS has loaded that the actual NIC Team or NIC Failover group is established. If NIC failure occurs after being established:

- the NIC Teaming feature allows the system to continue to function because the virtual MAC address is the same as the physical MAC address of the primary boot NIC.
- the NIC Failover feature allows the system to continue to function because it automatically fails over to another NIC that was previously configured for this system.

For more details, refer to Requirements and considerations for manufacturer’s NIC teaming.

When using a template with multiple NICs, Provisioning Services overwrites the network configuration of the first NIC. All the other NICs’ configurations are not changed. For a host with multiple network resources, Provisioning Services Xendesktop Setup wizard displays the network resources available to the host and allows you to select the network resource to associate with the first NIC.

Note: When a machine powers up, the BIOS goes through the list of available boot devices and the boot order of those devices. Boot devices can include multiple PXE-enabled NICs. Provisioning Services uses the first NIC in the list as the primary boot NIC. The primary boot NIC’s MAC address is used as the lookup key for the target device record in the database. If the primary boot NIC is not available at boot time, Provisioning Services will not be able to locate the target device record in the database (a non-primary NIC may be able to just process the PXE boot phase). Although a workaround would be to add a separate target device entry for each NIC on each system, and then maintain synchronization for all entries, it is not recommended (unless the successful startup of a system is considered as critical as the continued operation of the system that is already running).
Requirements and considerations for manufacturer's NIC teaming

Dec 02, 2013

When configuring NIC teaming, consider the following requirements:

- Provisioning Services supports Broadcom and Intel NIC teaming drivers. A vDisk that is built after configuring NIC teaming can run Standard or Private Image Mode. Broadcom NIC Teaming Drivers v9.52 and 10.24b are not compatible with Provisioning Services target device drivers.
- Teaming of multi-port network interfaces is not supported with Provisioning Services.
- Multi-NIC is supported for XenDesktop Private virtual machine desktops. Using the wizard, Provisioning Services allows you to select the network to associate with the Provisioning Services NIC (NIC 0). The Delivery Controller provides the list of associated network resources for host connections.
- The target device operating system must be a server-class operating system, such as Microsoft Windows 2008.
- The new virtual team NIC MAC address has to match the physical NIC that performs the PXE boot.
- Microsoft Windows Server 2012 built-in NIC teaming or OEM NIC teaming software should be installed and configured prior to the Target Device software.
- Configure NIC teaming and verify that the selected teaming mode is expected by the application and the network topology. It should expose at least one virtual team NIC to the operating system.
- When provisioning machines to a SCVMM server, the XenDesktop Setup wizard automatically changes the network configuration of both the first legacy NIC and the second synthetic NIC.
- During the Master target device installation process, Provisioning Services target device client drivers need to bind to the new virtual team NIC MAC address. If all physical NICs have been teamed up to a single virtual NIC, the Provisioning Services installer automatically chooses the virtual NIC silently, without prompting.
- If changes are required, Provisioning Services Target Device software must be uninstalled before making changes to the teaming configuration, then reinstalled after changes are complete. Changes to teaming configurations on a Master target device that has target device software installed, may result in unpredictable behavior.
- When installing Provisioning Services target device software on NT6.x systems within a multi-NIC environment, all available NICs can be used. Therefore bindcfg.exe is no longer required and no longer installed with target device software (Windows Vista, Windows 2008, Windows 7, Windows 2008 R2, Windows 8, and Windows Server 2012). However, if Provisioning Services detects NT5.x systems (Windows XP or Windows 2003), bindcfg.exe continues to install with the target device product software and appears during the target device installation process. With NT5.x Windows XP or Windows 2003 systems, if the inactive NIC fails to bind to Provisioning Services, start bindcfg.exe from the Provisioning Services installation directory (default is: C:\Program Files\Citrix\Provisioning Services).
Requirements and considerations for Provisioning Services NIC failover

Dec 02, 2013

A Provisioning Services target device or Provisioning Server can be configured to support failover between multiple NICs. This feature works with any NIC brand or mixture of brands. Provisioning Services supports NIC failover for vDisks in either Standard and Private Image Mode.

- The PXE boot NIC is considered the primary target device MAC address, which is stored in the Provisioning Services database.
- You define the failover group of NICs when you run the Provisioning Services target device installer on the Master Target Device. If the machine has more than one NIC, the user is prompted to select the NICs in which to bind. Select all the NICs that participate in NIC failover. Alternatively, in Provisioning Services 5.1 or later, run bindcfg.exe, to selectively bind NICs post installation. bindcfg.exe is located in the product installation directory.
- A target device will only failover to NICs that are in the same subnet as the PXE boot NIC.
- Teaming of multi-port network interfaces is not supported with Provisioning Services.
- In the event that the physical layer fails, such as when a network cable is disconnected, the target device fails over to the next available NIC. The failover timing is essentially instantaneous.
- The NIC failover feature and Provisioning Services HA feature compliment each other providing network layer failover support. If a failure occurs in the higher network layer, the target device fails over to the next Provisioning Server subject to HA rules.
- The next available NIC from the failover group is used should the NIC fail and the target device reboots. NICs must be PXE capable and PXE enabled.
- If a virtual NIC (teamed NICs) is inserted into the failover group, the vDisk becomes limited to Private Image Mode. This is a limitation imposed by NIC teaming drivers.
- By default, Provisioning Services automatically switches from legacy Hyper-V NICs to synthetic NICs if both exist in the same subnet. To disable the default behavior (allowing for the use of legacy HyperV NICS even if synthetic NICs exist), edit the target device's registry settings:
  [HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\BNIStack\Parameters]
  DisableHyperVLegacyNic"=dword:00000000
- Load balancing is not supported in the NIC failover implementation.
Updating NIC Drivers

Apr 08, 2010
From time to time, you may need to upgrade the drivers for your network interface cards (NICs). Follow the guidelines below for upgrading NIC drivers.

Upgrading NIC Drivers on Target Devices

Note: Do not attempt to upgrade a NIC driver on a vDisk. Do not attempt to upgrade a NIC driver on a hard disk on which the Provisioning Server is currently installed. Improperly upgrading a NIC may make the hard drive unable to boot.

To upgrade NIC drivers for target devices:

1. Go to the target device with the original hard drive from which you made the vDisk image.
2. Set the system BIOS to boot from the hard drive.
3. Re-boot the target device directly from the hard drive.
4. Un-install the target device software from this hard drive.
5. Upgrade NIC driver as directed by the manufacturer's instructions.
6. Re-install the target device software on the hard drive.
7. Re-image the hard drive to make a new vDisk image.

Upgrading NIC Drivers on a Provisioning Server

To upgrade NIC drivers on any Provisioning Server, simply follow the manufacturer instructions for upgrading NIC drivers.
Managing and Accessing a LUN Without Using a Network Share

Jul 05, 2012

Normally, using a SAN for vDisk storage with Provisioning Services requires that a shared file system be placed in front of the SAN to coordinate multiple server access to the NTFS formatted LUN(s). However, under certain instances, it is possible to allow Provisioning Services to use a SAN without a shared file system. Provisioning Services can do this and still allow multiple servers access to the same LUN(s) without volume corruption.

Provisioning Services only allows read-only shared access to the SAN LUN(s). Therefore the desired boot modes for Provisioning Services target devices are important when using this feature.

The following table describes the boot mode and its restrictions when using read-only vDisk storage.

<table>
<thead>
<tr>
<th>Boot Mode</th>
<th>Write Cache Limitations</th>
<th>Restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private Image</td>
<td>Not supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>Standard Image with cache on server disk</td>
<td>Separate shared read-write write cache location is required for the store.</td>
<td>vDisk properties cannot be modified while the LUN is read-only. vDisks cannot be mapped on the Provisioning Server.</td>
</tr>
<tr>
<td>Standard Image with cache in target device RAM</td>
<td>No limitation.</td>
<td>vDisk properties cannot be modified while the LUN is read-only. vDisks cannot be mapped on the Provisioning Server.</td>
</tr>
<tr>
<td>Standard Image with cache on the target device’s hard drive</td>
<td>Fall back to cache on server disk does not function if the target device hard drive is not found or fails.</td>
<td>vDisk properties cannot be modified while the LUN is read-only. vDisks cannot be mapped on the Provisioning Server.</td>
</tr>
</tbody>
</table>

Basically, the main limitations to placing vDisks on read-only storage include:

- Private image boot from read-only storage is not allowed
- If cache on the Provisioning Server disk is desired, a separate shared storage location that has read-write access is needed for the write cache files.
- Modifying the vDisk properties is not allowed when the vDisk storage location is read-only.
- Mounting the vDisk on the server is not allowed when the vDisk storage location is read-only.

Prerequisites
The following are prerequisites to using this new feature:

- Provisioning Servers that will have access to the read-only shared LUN(s) are server class machines (Windows 2003 Server or 2008 Server).
- The Microsoft iSCSI initiator software is installed on all Provisioning Servers that will have access to the SAN.
- The vDisk files that will be placed on the read-only shared LUN(s) have already been created and reside on a normal read-write storage location. Creating vDisk files in place on the LUN is more difficult than pre-making the VHD files in a normal read-write store and subsequently copying them to the shared LUN. Therefore, this document will describe the procedure assuming the vDisk files have been pre-made and reside in a normal read-write storage location.
- The SAN being used has the ability to set a LUN up for shared read-write access or shared read-only access without requiring a shared file system front end. Normally, using a LUN in shared read-write access mode without a shared file system front end will result in a corrupt NTFS volume. Limiting the LUN access to read-only circumvents this problem.

Implementation

**On the SAN**

1. Create a volume on the EquaLogic SAN using the EqualLogic Group Manager (or other relevant SAN interface front end). Make the volume large enough to hold all VHD and VHD associated PVP files that will be shared between the Provisioning Servers.
2. Set the access type for the volume to read/write - shared. Note that the volume will be made read-only through the NTFS attributes not through the SAN access rights. While using the volume in read-only shared mode is possible, it requires extra steps to implement the solution. Therefore this procedure describes the process when the volume is set for read-write – shared access.

**On Provisioning Servers**

1. Use the iSCSI Initiator to login to the SAN volume on only one of the Provisioning Servers.  
   **Note:** Do NOT login to the SAN Volume from more than one server simultaneously until the volume has been marked read-only. If you allow more than one server to simultaneously login to the volume through the iSCSI interface while the volume is read-write, you will corrupt the volume and will need to re-format it. All data on the volume will be lost.
2. Format the volume through the Windows Disk Manager with an NTFS file system and assign a drive letter or mount point path. A mount point path is desirable if you will have many LUN/Volumes exposed on a server as there will be no drive letter limitations. Make sure you use a drive letter/Mount point that will be identical on all servers using the volume. If you cannot make them identical, you will need to use the Provisioning Services/store override paths to point a specific server to a different drive letter/mount point for the volume.
3. After the volume is formatted and assigned a drive letter/Mount point, the volume should be accessible on this single Provisioning Server as a read/write volume. Make sure all properties for the VHD and PVP files that will reside on the volume are set correctly (including enabling HA) and then copy all VHD files and their associated PVP files to the volume. Lock files do not need to be copied. The PVP file MUST be copied along with the VHD file. The system will not be able to create a PVP file ‘on the fly’ once the volume is read-only.
4. After all files are copied to the volume, you must make the volume read-only. Close all Explorer windows that have access to the volume, then open a command prompt on the server that has access to the volume.
5. Run diskpart.exe. This will start an interactive session with diskpart.exe.
6. Find the volume number by typing the following command: list volume.
7. Note the volume number of your volume and select it by typing the following command: select volume volumeNumber where volumeNumber is the number of the volume identified with the list volume command.
8. After the volume is selected, set the read-only attribute of the volume by typing the following command: attributes volume set readonly.
9. Check that the readonly attribute was set correctly by typing the following command: detail volume.
10. Exit diskpart.exe by typing the command: exit.

11. Using the iSCSI initiator interface, logoff the volume on this server and then re-login to the volume again. Make sure to make the volume a persistent target. You must logoff and then login to the volume to get NTFS on the server to re-read the volume attributes so that it will recognize the volume as read-only. Making the volume a persistent target will ensure the volume is accessible when the server reboots.

12. It is now safe to mount the iSCSI volume on all Provisioning Servers. Using the iSCSI Initiator applet and Microsoft Disk Manager, mount the volume on all Provisioning Servers that need access to the volume. Make the target persistent in the iSCSI interface and try to make all servers mount using the same drive letter or mount point, which makes setting up the Provisioning Services Store easier.

   Note: It may be necessary to make the Provisioning Services’ Stream Service on all servers dependent on the iSCSI Service. This ensures that the volumes are available at the proper time should the server reboot and target devices are booted during the server reboot. To do this, edit the registry for the Stream Service, then add the DependsOnService value pointing to the iscsi.exe.exe service (MSiSCSI).

13. Run the Console on one of the Provisioning Servers to create a store that points to the drive letter/mount point for the volume.

14. Select which Provisioning Servers have access to the volume for this store.

   Note: If you are using Cache on server or Difference disk mode for any VHDs on the volume, you MUST enter a Default write cache path for the store that does NOT point to the SAN read-only volume. This path must be in a shared location for all Provisioning Servers. You can use a Windows Network Share or any other read-write shared storage device, but the write cache path cannot point to the read-only volume. The read-only volume can only contain the VHD and PVP files. If you are using one of the target device cache modes (local HD or RAM) then you do not need to set up a shared read-write write cache location for the store.

15. On the Console, right-click on the store then select the Add Existing Disk… menu option, which scans the store and adds the VHD files to the database.

16. Assign the VHD files that are on this store to target devices, then boot those target devices normally. The VHD files on the read-only volume will always display in the Console as locked with the lock type: Read only media: Shared. You cannot remove this lock type. You cannot create a new vDisk on a store once it has been marked as read-only with diskPart.exe. You cannot edit the properties of the VHD once the store has been marked read-only.

Modifying vDisk Properties

vDisk properties cannot be modified while the SAN LUN location is marked read-only. To edit the vDisk properties or modify the vDisk files on the LUN, complete the following procedure:

1. Shutdown all target devices that use the VHDs that are on the store.

2. Use the iSCSI initiator on all Provisioning Servers (except one) to logoff the volume. Alternately, use the diskpart.exe utility on some server OS types and mark the volume as offline on all Provisioning Servers (this feature is not available on all OS types. If necessary, use the iSCSI initiator to logoff the volumes).

3. In order to use the diskpart.exe utility to mark the volume as read/write, Open a command prompt on the server that has access to the volume, then run diskpart.exe. This starts an interactive session with diskpart.exe.

4. Find the volume number by typing the following command: list volume.

5. Note the volume number of your volume and select it by typing the following command: select volume volumeNumber where volumeNumber is the number of the volume identified with the list volume command.

6. After the volume is selected, to clear the readonly attribute, type the following command: attributes volume clear readonly.

7. Check that the readonly attribute was set correctly by typing the following command: detail volume.

8. Exit diskpart.exe by typing the command: exit.

9. Logoff/login the volume (or mark it offline/online in diskpart) on the single server that still has access to the volume.
10. Edit the VHD file attributes through the Console, then copy the new files to the volume.
11. After all edits are complete, use the diskpart.exe utility to mark the volume read-only by selecting the volume, then setting the read-only attribute: attributes volume set readonly.
12. Check that the readonly attribute was set correctly by typing the following command: detail volume
13. Exit diskpart.exe by typing the command: exit.
14. Use the iSCSI Initiator to logoff, then relogin to the volume to re-read the read-only attributes.
15. Use the iSCSI Initiator on all Provisioning Servers to re-login to the volume.

Note: **IMPORTANT! Do NOT login to the SAN Volume from more than one server simultaneously until the volume has been marked read-only. If you allow more than one server to simultaneously login to the volume through the iSCSI interface while the volume is read-write, you will corrupt the volume and will need to re-format it. All data on the volume will be lost.**
Managing Printers

Provisioning Server provides a Printer Management feature that allows you to manage which printers target devices have access to on a vDisk. Printers are managed from the Target Device Properties dialog.

This feature should not be enabled if you use Active Directory to manage printers. If you use an existing printer management tool, this feature should be disabled to avoid printer setting conflicts.

Printers can only be added to the top-level differencing disk version while it is under Maintenance or if it is a Private Image. If a device boots from a previous version, the printer configuration may not match.

There are two types of printers that can appear in the Console window:
- Network Printers
- Local Printers

Before a target device can access a printer, the following tasks must be completed in the order that follows:
- Installing Printers on the vDisk
- Enabling Printers on the vDisk
- Enabling the Printer Management Feature
Installing Printers on a vDisk

Mar 18, 2011

Printers must be installed on the vDisk image before the printers are available to target devices booting from that disk. Printers can only be added to the top-level differencing disk version while it is under Maintenance or if it is a Private Image. If a device boots from a previous version, the printer configuration may not match.

To install printers on the vDisk:

1. Change the vDisk image mode to Private Image mode.
2. Install the required printers on the target device that is using the vDisk.
3. Perform a clean shut-down of the target device that is using the vDisk.
4. If this vDisk is shared by users, change the vDisk image mode back to Shared Image mode.
5. Verify that the printers display in the Console:
   1. Right-click on the target device, select the Properties menu option.
   2. Select the vDisks tab, then click on the Printers button. Printers associated with that vDisk should appear in the list of available printers.

After successfully installing printers, the next step is to enable printers for target devices that access this vDisk (for details, refer to enable printers for target devices).
Enabling or Disabling Printers on a vDisk

Apr 08, 2010

Note: The Printer Management feature is only recommended if you are not using Active Directory to manage printer groups.

By default, printers are not enabled on the vDisk. Enable or disable printers from the Target Device Properties vDisk tab. On the Printers dialog, enable the checkbox next to each printer to enable or disable it. After enabling (assigning) printers to target devices, the Printer Management feature must then be enabled on the vDisk.

Until Printer Management is enabled, all printers that are installed on the target device are available to that target device. By enabling Printer Management, you can select printers or remove printers from individual target devices.

After a target device boots, printer information, which is included in a vDisk image, becomes available to target devices. Printer Management is initially disabled until all printer-to-target device assignments are completed for the vDisk. Disabling individual printers prohibits target devices from accessing those printers. Note: Disabling printers does not remove the printer information from the vDisk. Changes to the target devices printer assignments do not occur until the target device reboots.

Examples of reasons you may want to disable Printer Management include:
- You may be using a different printer system that installs the valid printers on each target device and software may delete them or cause conflicting settings.
- Printers that are included on the vDisk should be accessible to all users.
- The system needs to be configured before being deployed. Until the Printer Management feature is enabled, changes can be made for different target devices as needed.

All printers installed on a vDisk appear in the Details panel when the Printers group folder is expanded for that vDisk.

If a disk is a HA vDisk (has a duplicate with same vDisk name), changes to that printer (if it is enabled or disabled for a target device) are automatically made to the duplicate vDisk.

Enablement Methods

Using the Console, you can manage which target devices use which printers. There are several methods for managing target device printer assignments. Choose from the following methods:
- Enabling printers for target devices using the Printer settings option. Use this method to enable or disable a single printer to multiple target devices accessing a vDisk.
- Enabling printers for target devices using the Printers group folder. Use this method to select printer settings (enable/disable; default) for a single target device.
- Enabling printers using Copy and Paste. Use this method to copy printer settings of one target device (enabled/disabled; default printer), to one or more target devices selected in the Details panel.
- Enabling printers using an existing target device as a template. Use this method to automatically set printer settings when a target device is added to the network.

Note: The Administrator may choose to limit the number of printers for particular target devices or select different default printers for particular target devices. The settings that are selected are saved to the target device's personality information (if the limit for this field, 65K, is reached, a message appears indicating that some of the settings will not be saved and offers suggestions for decreasing the size).
Methods for Enabling Printers on a vDisk

Apr 08, 2010
Enabling printers for target devices using the Printer Settings option

Use this method to assign a single printer to multiple target devices. This method is very useful when managing the printer-to-all target devices relationship.

1. In the Console tree, under Provisioning Servers, click the Printers group folder. All printers associated with that group appear in the Details panel.
2. Right-click on a printer in the Details panel, then select the Client Printer Settings... menu option. The printer settings dialog for that printer appears.
3. Enable or disable this printer for one or more target devices using any of the following options:
   - In the Enable column, select the checkbox next to each target device to enable or disable use of this printer.
   - Select the checkbox under the dialogs Enable heading to enable or disable this printer for all target devices assigned to the vDisk.
4. To select this printer as the default printer for target devices accessing this vDisk, select from the following methods:
   - Select the Default checkbox in the dialogs Default heading to set this printer as the default for all target devices assigned to this vDisk.
   - Highlight one or more target devices, then right-click to open the context menu. Select from the following menu options; Default, NotDefault All Default All Not Default
   - In the Default column, select the checkbox next to each target device that should use this printer as the default printer. If there is only one printer, that printer is automatically set as the default printer.
5. Click OK to save settings for this printer and exit the dialog.

Enabling printers for target devices using the Printers group folder

Use this method to select printer settings (enable/disable; default) for a single target device.

Note: After selecting printer settings for a single target device, you may choose to duplicate this target devices printer settings using the Copy and Paste features.
1. Under the target device’s vDisk, click the Printers group folder in the tree. Printers that are associated with that group appear in the Details panel. By default, printers are not enabled for a target device and the first printer listed is set as the default printer.
2. Select or deselect the Enable checkbox next to each printer to enable or disable the printer for this target device. You can also choose from one of the additional selection methods that follow.
   - In the Details panel:
     - Select or unselect the Enable checkbox within the table heading to enable or disable all printers.
     - Highlight a printer, then use the space bar to enable or disable printers.

Enabling printers using Copy and Paste

Use this method to set the same printer settings (enabled/disabled; default printer) that exist for one target device, to one or more target devices that use the same vDisks. This method is particularly useful when adding new target devices and those target devices use the same vDisks, and therefore the same printers, as an existing target device.
1. In the Console, right-click on the target device that you want to copy printer settings from.
2. Select the Copy menu option. The Copy target device properties dialog appears.
3. Under Options, select Printers, then click OK to exit the dialog.
4. In the Tree, highlight the Target Devices directory so that all target devices appear in the Details panel.
5. Highlight one or more target devices that you want to paste the printer settings to (enable/disable; default).
6. Right-click on the highlighted target devices, then select the Paste menu option.

Enabling printers using an existing target device as a template

Use this method if you want all new target devices, that are being added to your network, to automatically share printer settings (enable/disable; default).
1. In the Console, double-click the target device that you want to select as the template. The Target Device Properties dialog appears.
2. On the General tab, select the Set as default target device option.
3. Click OK to exit the dialog.
Enabling the Printer Management Feature

Apr 08, 2010

Note: The Printer Management feature is only recommended if you are not using Active Directory.

After assigning printers to target devices, the Printer Management feature must be enabled before any printers on the target device can be removed. Until Printer Management is enabled, all printers installed on the target device are available to the target device. Once the feature is enabled, any changes to target devices printer settings (enable/disable; default) become available the next time the target device boots from the vDisk.

If the Printer Management feature is disabled and a target device boots from a vDisk that has printers installed on it, that target device has access to all printers on that vDisk. If the Printer Management feature is enabled and the target device boots from that same vDisk, that target device can only access those printers that are enabled for that target device.

To enable or disable printers on a selected vDisk:

1. In the Console, expand the Provisioning Server node in the tree panel, then select the vDisk that you want printers enabled or disabled on.
2. Select File Properties from the right-click menu, then select the Options tab.
3. Under Printer Settings, select the Enable the Printer Settings checkbox option to enable settings, or leave the checkbox blank to disable printer settings.
4. If the Enable the Printer Management checkbox is selected, the Enable Printer Management menu options appear checked when the Printers group is highlighted.
5. If the Enable the Printer Management checkbox appears disabled, all printers exist on the selected vDisk.

You can also choose from the following methods to enable or disable the Printer Management feature using right-click menus:

Printers Group

In the Tree, under Provisioning Servers, expand a Provisioning Server, then expand the vDisk for which you want to disable Printer Management. Right-click on the Printers folder for that vDisk, then select the Disable Printer Management option.

Virtual Disk

In the Tree, under Provisioning Servers, right-click on the vDisk for which you want to disable Printer Management, then select the Disable Printer Management option.
Updating vDisks on Target Devices

Aug 13, 2012

This document describes how to change a vDisk on multiple target devices without having to manually reconfigure them. It provides some general information about the process, then sets out a step-by-step procedure.

Setting vDisk Class and Type Properties

For an automatic update to take place, the Class of the target device and vDisk must match. For a newer vDisk to replace an older vDisk within a target device, the vDisk Class and Type of both vDisks must match. Because multiple, duplicate vDisk instances can exist within your implementation, and those vDisks can be assigned to one or more target devices (in the case of Provisioning Server Least Busy and First Available boot behaviors), you must further qualify the old vDisk that will be replaced by the new vDisk. This is the reason for using the Type property of the vDisk. If you want to use the Automatic Disk Image Update feature, you should never assign more than one vDisk with the same Type from the same Provisioning Server to the same target device.

Scheduling vDisk updates

To schedule when automatic updates can be applied, use the Apply vDisk updates as soon as they are detected by the server or Schedule the next vDisk update to occur on radio buttons on the Auto Update tab of the vDisk. If you select Schedule the next vDisk update to occur on, you must specify the current date or a later date, otherwise the vDisk will not be updated.

Timed update of vDisks

You can set a timer to update vDisks. This means that the vDisk will be assigned to all the devices with a matching Class at a specified time, for example when devices are less active.

To do this, on one of the servers from each site create a Windows timer that calls the PowerShell Mcii-Run ApplyAutoUpdate command or the Mci Run ApplyAutoUpdate command (see the PowerShell Administrator's Guide or the MCLI Programmer's Guide for details). The command scans the site and updates all eligible vDisks that are configured to be updated. Because the command updates only those vDisks that need to be updated, the timer can execute every day and the updates are automatically made whenever new versions of vDisks are added.

Automatically adding a replacement vDisk

To automatically add a replacement vDisk to a site, place it in the store directory of the vDisk it replaces. When the update process is done, each site for the vDisk is scanned for vDisks that are not defined in the site. If a vDisk is found that has the same Class and Type as an existing vDisk in the store directory, and its major, minor and build number is higher than the existing vDisk, it is automatically added to the site and assigned to target devices with matching Class.

The replacement vDisk must include all versions since and including the last merged base, or if no merged base exists, the base. All the VHD or VHDX, AVHD or AVHDX, and the PVP files for the versions included need to be placed into the store directory.

If the replacement vDisk has multiple versions, the manifest (XML) file needs to be included with the vDisk. To create the manifest file, perform a vDisk Export. To reduce the number of files that need to be delivered, delete obsolete versions in the vDisk Versions dialog before performing the vDisk Export.

To automatically update a vDisk
1. For the original vDisk, select the Auto Update tab, then set the following vDisk properties:
   a. Enable automatic updates.
   b. Select whether the update will be applied immediately or on a scheduled date when the check for updates is done or the Run ApplyAutoUpdate command is run.
   c. Enter a Class and Type for the vDisk.
   d. Enter a Major, Minor and Build number for the vDisk.

   Note: The Serial Number field is set to a random Globally Unique Identifier (GUID) when the vDisk is created. It is for information only and you can edit it. It is not used for processing the Automatic Update.

2. For target devices that use the vDisk to be updated, select the General tab, then in the Target Devices Properties set the Class equal to the Class value of the original vDisk.

3. Ensure that the replacement vDisk is in the same store as the original vDisk.

4. For the replacement disk, select the Auto Update tab, then set the following vDisk properties:
   a. Only enable automatic updates if this vDisk may later be replaced with another vDisk.
   b. If automatic updates are enabled, select whether the update will be applied immediately or on a scheduled date when the check for updates is done or the Run ApplyAutoUpdate command is run.
   c. Enter the same Class and Type that you entered for the original vDisk.
   d. Enter a Major, Minor and Build number for the vDisk that is higher than the original vDisk.

5. If the vDisk update needs to be done in other farm sites, you can deliver and place the replacement vDisk setup described in step 4 in the same store as the original vDisk of the other farm site. This is described earlier in this document in ‘Automatically adding a replacement vDisk’.

6. Configure the update check. This will update any vDisks found with a higher Major, Minor, and Build number that are eligible to be updated. You can do this in either of the following ways:
   - Right-click on the vDisk Pool, select the Check for Automatic Updates menu option, then click OK on the confirmation dialog.
   - Set a timer as described earlier in this document.
Using the Streamed VM Setup Wizard

Mar 14, 2014

Using the Wizard

The Provisioning Services Streamed VM Setup Wizard assists in deploying a Provisioning Services streamed vDisk to a number of cloned virtual machines (VMs).

Use the wizard to:
- Create VMs on a supported hosted hypervisor from an existing template:
  - XenServer
  - Hyper-V via SCVMM
  - ESX via V-Center
- Create Provisioning Services target devices within a Collection
- Assign a vDisk image that is in Standard Image mode to the VMs

Before running the wizard, be sure that the following prerequisites are met:
- One or more hypervisor hosts exist with a configured template.
- A Device Collection exists in the Provisioning Services Site.
- A vDisk in Standard Image mode exists, to be associated with selected VM template.
- Template VM Requirements:
  - Boot order: Network/PXE first in list (as with physical machines).
  - Hard disks: If using local write cache, an NTFS formatted disk large enough for the cache must exist. Otherwise, no hard disks are required.
  - Network: Static MAC addresses. If using XenServer, address cannot be 00-00-00-00-00-00

The Provisioning Services Console user account was added to a PVS SiteAdmin group or above.

When creating new accounts in the Console, the user needs the Active Directory Create Accounts permission. To use existing accounts, Active Directory accounts have to already exist in a known OU for selection.

If importing an Active Directory .CSV file, use the following format: <name>,<type>,<description>. The .CSV file must contain the column header. For example, the .CSV file contents is as follows:

Name,Type,Description,
PVSPC01,Computer,,

The trailing comma must be present to signify three values, even if there is no description. This is the same formatting used by Active Directory Users and Computers MMC when exporting the contents of an organizational unit.

If running a vCenter server on alternate ports, the following registry modifications must be made in order to connect to it from Provisioning Services:
- Create a new key HKLM\Software\Citrix\ProvisioningServices\PlatformEsx
- Create a new string in the PlatformEsx key named 'ServerConnectionString' and set it to 'http://{0}:PORT#/sdk'
  Note: If using use port 300, ServerConnectionString= http://{0}:300/sdk

This wizard creates VMs, associates Provisioning Services target devices to those VMs, and assigns a shared vDisk to them.

The wizard is run directly from a Provisioning Services Console.
1. Right-click on the Site icon in the Console tree panel, then select the Streamed VM Setup Wizard... menu option. The Welcome to the Streamed VM Setup Wizard appears.
2. Click Next to begin the setup.
3. Select the type of hypervisor to connect to, then enter the required connection credentials.
4. Click Next to verify the connection.
   Note: For convenient reuse, the most recently used hypervisor and username will be cached in the registry of the local machine running this instance of the Console.
   Note: XenServer 5.5 Update 2 hypervisors are not supported in the 5.6.1 Streamed VM Setup Wizard. System Center Virtual Machine Management (SCVMM) servers require PowerShell 2.0 to be installed.
5. Optional. On the Hypervisor cluster screen, select the hypervisor host or cluster to host the VMs, then click Next.
6. Select one VM template from the specified host, then click Next.
7. On the Collection and vDisk page, select the collection in which to add VMs.
8. Select a single shared vDisk within to assign to VMs within that collection, then click Next.
9. Set the number of VMs to create, the number of vCPUs, and the amount of Memory each new virtual machine will use.
10. Enable the radio button next to one of the following methods used for adding Active Directory computer accounts, then click Next:
    - Create new accounts
    - Import existing accounts
    Note: An Active Directory administrator will need to delegate rights to the Provisioning Services Console user to allow Active Directory account creation.
    Note: The domain and OU default to those of the current user.
    Note: New computer names to be created are first validated that they do not already exist as computers in Active Directory. VMs, or target devices.
11. If the Create new accounts method is selected:
    - Click Next. The Active Directory accounts and location screen appears.
    - Select the appropriate domain from the Domain drop-down box, then select from the OUs listed for that Domain.
    - In the Account naming scheme drop-down box, select a valid naming scheme consisting of at least one hash symbol (#) that is 15 characters or less. Additionally, select a number/character fill option that will dynamically replace the hash symbols in the specified naming scheme, incrementing by one for each VM as they are created.
    If the Import existing accounts is selected:
    - Click Next. The Active Directory accounts and location page appears.
    - Click Browse to browse for an Active Directory Organizational Unit to import Active Directory account names, or click Import to import account names from a CSV file.
    Note: The Required count displays the number of virtual machines previously specified to be created. The Added count displays the number of validated entries added to appear in the list.
12. Review all configuration settings, and then click Next to confirm and finish configurations.
    Note: Clicking Cancel cancels the configuration of any additional machines, and the quantity of successfully configured machines displays under the Progress bar. If the wizard fails or is cancelled in the middle of an operation, any progress made is retained. If cleanup of existing progress is required, it must be done manually, which includes removing the following:
    - Provisioning Services target devices created in the selected Collection.
    - VMs created in any of the selected hosts hypervisors.
    - Active Directory computer accounts that were created.
Deploy virtual desktops to VMs using the XenDesktop Setup Wizard

Feb 28, 2014

Provisioning Services 7.x only supports XenDesktop 7.x.

Using a Provisioning Services streamed vDisk, the XenDesktop Setup Wizard assists in deploying virtual desktops to virtual machines (VMs) as well as to devices that use personal vDisks. The Provisioning Services XenDesktop Setup Wizard is only compatible with other XenDesktop components included in this release.

Attention: You must select the Target Device Optimizer when creating the vDisk image, otherwise the VM may fail to boot.

The wizard:

- Creates VMs on a XenDesktop hosted hypervisor server using an existing XenDesktop machine template:
  - XenServer
  - Hyper-V via SCVMM (when provisioning to a SCVMM server, the wizard automatically changes the network configuration of both the first legacy NIC and the second synthetic NIC.)
  - ESX via V-Center

Note: When creating a machine template for SCVMM 2012, ensure that it has a similar hard disk drive structure and that it can boot from a vDisk in Private Image mode. Examples:

- to PXE boot a VM with write cache, create a VM with 1 hard disk drive.
- to use Boot Device Manager (BDM) to boot a VM with write cache, create a VM with 2 hard disk drives.
- to use BDM to boot a VM that uses a personal vDisk and write cache, create a VM with 3 hard disk drives.

- Creates Provisioning Services target devices for each new VM within a new or existing Provisioning Services Device Collection matching the XenDesktop catalog name.
- Assigns a Standard Image vDisk to VMs within the Device Collection.
- Adds virtual desktops to a XenDesktop catalog.

ESX permissions

For ESX 5.5, the minimum permissions include the following:

Note: Other previously supported versions of ESX may require the same permissions to work with Provisioning Services 7.x.

- Datastore Permissions
  - Allocate space
  - Browse datastore
  - Low level file operations
- Network Permissions
  - Assign network
- Resource Permissions
  - Assign virtual machine to resource pool
- System Permissions - These permissions are automatically added when you create a role in vCenter.
  - Anonymous
  - Read
  - View
  - Task Permissions
To minimize the time it takes to provision, in Provisioning Services 7.x and later, the XenDesktop Set Up Wizard discards any hard disks that are attached to a template.

The wizard provisions diskless VMs if the vDisk is in Standard Image mode and cache is set as cache on the server. If the cache is on server side, Provisioning Services does not automatically boot the provisioned VMs.

The wizard provisions VMs with write cache drives (default size is 6 GB and default type is dynamic), if the vDisk is in Standard Image mode and cache is set as cache on the local hard disk. To format the write cache drive, the wizard automatically boots the VMs in Standard Image mode with cache on server. After formatting completes, VMs are automatically shut down, then XenDesktop can boot the VMs as necessary.

Virtual disk types

XenDesktop Setup Wizard provisioned virtual machines have new disks created and attached for local Provisioning Services write cache use. The default virtual disk types created are:

- “fixed” or “dynamic” depending upon the storage repository used in XenServer
There is a reg key to override the default types of write cache disks created by provisioning deployments on SCVMM and ESX. This does not apply to XenServer. To force "fixed" (or "eager-zeroed thick" for ESX):

[HKEY_CURRENT_USER\Software\Citrix\ProvisioningServices\VdiWizard]
"OVERRIDE_VM_WRITE_CACHE_DISK_TO_FIXED"="true"

Setting this same key to "false" will override to dynamic. Remove the key to return to default behavior.

Run the wizard

The wizard is run directly from the Provisioning Services Console or from a remote console.

Before running the wizard, be sure that all prerequisites are met. See the installation requirements content Requirements for Provisioning Services 7.1.

1. Right-click on any Site icon in the Console tree panel, then select the XenDesktop Setup Wizard... menu option. The XenDesktop Setup Wizard appears.
2. Click Next to begin setup.
3. On the XenDesktop Host page, enter the location of the XenDesktop Host address to connect to and to configure. The most recently used XenDesktop Controller (name or IP) is cached in the registry of the local machine running this instance of the Console.
4. Select a XenDesktop host. If you choose a cluster, machines are evenly distributed across the hosts cluster. Note: XenServer 5.5 Update 2 virtualization settings do not display. These setting are added in XenDesktop as host connections using the Manually create VMs option. As a result, you cannot specify a network or storage location for them; therefore it is not listed in the XenDesktop Setup Wizard.
5. Supply the host credentials (Username and Password).
6. From the list of available templates, select the template to use for the host you chose. If using a previous version of the VDA or if the template is built using Windows XP or Windows Vista, select the checkbox. Valid templates must have a dynamic MAC address or a static address with a value (00:00:00:00:00:00 is not a valid MAC address).
7. If there is more than one network available for the Virtualizations Settings, a page displays so you can select the appropriate network.
8. Select a single, Standard Image mode vDisk to assign to the collection of VMs.
9. Create a new catalog or use an existing catalog from a previous release (XP, Vista or Windows 7 with VDA 5.6 this must also be specified using XenDesk Studio when the delivery group is created). VDA's can be of either functional level. The options that display enabled depends on which catalog option you select.
   ● If you chose to create a new catalog, provide a name and description for that catalog. Appropriate machine types include:
     ● Windows Client Operating System – best for delivering personalized desktops to users, or delivering applications to users from desktop operating systems. Provides the option to save a user's changes to a Personal vDisk.
     ● Windows Server Operating System – best for delivering hosted shared desktops for a large-scale deployment of standardized machines or applications, or both.
     ● If you select an existing catalog using the drop-down menu, that catalog's, description, machine type, assignment type, and user data (if applicable) display.
10. Select VM preferences. Preferences vary depending on the machine OS type and if assigned user changes are discarded.
after their session ends.

1. For Windows Client or Windows Server machines that are randomly assigned to users and those users do not require a personal vDisk:
   - Number of VMs to create (default is 1)
   - vCPUs (default is based on the previously selected template)
   - If the template has dynamic memory configured, two additional configuration settings are required: minimum memory (default is 0 MB) and maximum memory (default is 1000)
   - Local write cache disk (default is 6 GB)
   - Boot mode; PXE boot (requires a running PXE service). BDM disk (creates a partition for the Boot Device Manager file).

2. For Windows Client machines that are either randomly assigned or statically assigned to users and those users can save their changes to their personal vDisk, in addition to the preferences listed in option "a." above, the following preferences display:
   - Personal vDisk size (default is 10 GB). When booting a target device from a personal vDisk, the vDisk's OS partition, C\, by default, only shows the amount of space allocated to the personal vDisk, not the true size of the personal vDisk.
   - Personal vDisk drive letter (default is P). The drive letter the target device uses for the personal vDisk. The range allowed is between E: to U: and W: to Z:

11. Choose the appropriate method for adding Active Directory computer accounts:
   - Create new accounts
   - Import existing accounts

   The page that displays depends on which Active Directory method you select.

12. To Create new accounts: An Active Directory administrator needs to delegate rights to the Provisioning Services Console user to allow Active Directory account creation or modification to manage computer account passwords.
   - Select the appropriate domain from the Domain drop-down box, then select from the OUs listed for that domain. The domain and OU default to those of the current user.
   - Select the machine naming option from the Account naming scheme drop-down text box. Enter a valid naming scheme consisting of at least one hash symbol (#) that is 15 characters or less. Additionally, select a number/character fill option that will dynamically replace the hash symbols in the specified naming scheme, incrementing by one for each VM as they are created.

13. To Import existing accounts:
   - Click Browse to browse for the appropriate OU to import, or click Import to import an existing .CSV file in the following format:
     Name,Type,Description,
     PVSPC01,Computer,\

     The Required count displays the number of VMs previously specified. The Added count displays the number of entries in the list. If you import machine account names that already exist in any of the following locations, they are not valid and do not display in the list: XenDesktop (as a machine), PVS (as a device), on the hypervisor (as a VM). If the AD structure contains a large number of objects or containers, or you are importing a large amount of machine accounts, the import may take awhile as it must validate that each imported account does not already exist in Provisioning Services, XenDesktop, and the destination hypervisor. If this is the case, you should receive feedback in the form of an hour glass cursor while the import completes.

14. Review all configuration settings. After confirming, the following actions take place one action at a time across all hosts until configurations are complete:
• If applicable, create XenDesktop Broker Catalog.
• Create VMs on a host’s hypervisor using the machine template.
• Create BDM partitions, if specified.
• If using a Streamed with personal vDisk Catalog, create a personal vDisk, then attach the personal vDisk to the VM.
• Create a write cache disk of the specified size.
• Create Provisioning Services target devices then assign the selected vDisk to those devices.
• Add the target devices to the selected Provisioning Services Collection.
• Add the VMs to the XenDesktop Catalog.
• Boot each VM to format the newly created write cache disk.

If you cancel during the configuration, you must manually remove the following:

• XenDesktop machines from the assigned catalog
• Active Directory computer accounts that were created.
• Newly created XenDesktop catalogs
• Provisioning Services target devices created in the selected device collection.
• VMs created on any of the selected host hypervisors.

vDisks can be updated and reassigned to a target device that uses personal vDisks. However, the base disk must be of the same operating system and must have the machine SID. To accomplish this, copy the target device’s currently assigned base vDisk image, update the image to include new Provisioning Services software and drivers, then reassigning the updated vDisk to the target device. To reassign the vDisk, use the vDisk Properties “Assign vDisk” dialog on the Console.
Configure Personal vDisks

Apr 11, 2013

Citrix XenDesktop with personal vDisk technology is a high-performance enterprise desktop virtualization solution that makes VDI accessible to workers who require personalized desktops, by using pooled-static virtual machines.

Provisioning Services target devices that use personal vDisks are created using the Citrix XenDesktop Setup Wizard. Within a Provisioning Services farm, the wizard creates target devices, adds target devices to an existing site's collection, and then assigns an existing vDisk, which is in standard image mode, to that device.

The wizard also creates XenDesktop virtual machines to associate with each Provisioning Services target device. A catalog exists in Citrix Desktop Studio that allows you to preserve the assignment of users to desktops; the same users are assigned the same desktop for later sessions. In addition, a dedicated storage disk is created (before logon) for each user so they can store all personalization's to that desktop (personal vDisk). Personalizations include any changes to the vDisk image or desktop that are not made as a result of an image update, such as application settings, adds, deletes, modifications, or documents. Target devices using personal vDisks can also be reassigned a different vDisk if that vDisk is from the same base vDisk lineage. For additional information on using personal vDisks with XenDesktop, refer to XenDesktop's About Personal vDisks topic.

Inventory is run when a Provisioning Services vDisk is configured or updated. The method selected to configure or update a vDisk image for use as a personal vDisk image may determine when vDisk inventory runs in your deployment. The content that follows identifies the different methods from which you can choose, provides the high-level tasks associated with each method, and indicates at which point inventory runs for each method.

After configuring and adding a new personal vDisk image, do not use your golden VM as the machine template because it creates an unnecessary large disk as your write cache disk (the size of your original HDD).

Configure and deploy a new personal vDisk image

Configuration methods include:

- Configure in the following order: Provisioning Services, then capture the image, then XenDesktop
- Configure in the following order: Provisioning Services, then XenDesktop, then capture the image
- Configure in the following order: XenDesktop, then Provisioning Services, then capture the image
- Configure using Machine Creation Services (MCS)

Provisioning Services, then capture image, then XenDesktop

1. Install and configure the OS on a VM.
2. Install the Provisioning Services target device software on the VM.
3. Run the Provisioning Services Imaging Wizard to configure the vDisk.
4. Reboot.
5. The Provisioning Services Image Wizard's second stage runs to capture the personal vDisk image.
6. From the Console, set the target device to boot from the vDisk.
7. Configure the VM to boot from the network, then reboot.
8. Install XenDesktop software on the VM, then configure with advanced options for personal vDisk.
9. Manually run inventory, then shut the VM down.
10. From the Console, place the vDisk in Standard Image Mode. Image is ready for deployment.

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved. p.295
Provisioning Services, then XenDesktop, then capture image

1. Install and configure the OS in a VM.
2. Install the Provisioning Services target device software on the VM.
3. Install XenDesktop software and configure with advanced options for personal vDisks enabled.
4. Reboot.
5. Log on to the VM.
6. Run the Provisioning Services Imaging Wizard on the VM to configure the vDisk. (Inventory automatically runs after the VM successfully shuts down and reboots.)
7. The Imaging Wizard's second stage runs to capture the personal vDisk image.
8. Shut the VM down.
9. From the Console, place the personal vDisk image in Standard Image Mode. The personal vDisk is ready for deployment.
10. Before using a VM template to provisioning multiple VMs to a XenDesktop site, verify the new vDisk can successfully boot from the VM created to serve as the machine template (not the golden VM), and verify the write cache disk is recognized successfully:
   1. Place the vDisk image in Private Image mode.
   2. Boot the new vDisk image from the VM.
   3. Format the new write cache partition manually.
   4. Shut down the VM. During the shut down process, when prompted run personal vDisk inventory.
   5. Turn this VM into a template.

XenDesktop, then Provisioning Services, then capture image

1. Install and configure the OS in a VM.
2. Install XenDesktop software on the VM, then configure with advanced options for personal vDisks enabled.
3. Reboot.
4. Log on to, then shutdown the VM. Inventory automatically runs at shutdown.
5. Log on to, then install the Provisioning Service's target device software.
6. Run the Provisioning Services Imaging Wizard on the VM to configure the vDisk.
7. Reboot. (Inventory automatically runs after the VM successfully shuts down and reboots.)
8. The Imaging Wizard's second stage runs to capture the personal vDisk image.
9. Shut the VM down.
10. Place the vDisk in Standard Image Mode. The personal vDisk is ready for deployment.
11. Before using a VM template to provisioning multiple VMs to a XenDesktop site, verify the new vDisk can successfully boot from the VM created to serve as the machine template (not the golden VM), and verify the write cache disk is recognized successfully:
   1. Place the vDisk image in Private Image mode.
   2. Boot the new vDisk image from the VM.
   3. Format the new write cache partition manually.
   4. Shut down the VM. During the shut down process, when prompted run personal vDisk inventory.
   5. Turn this VM into a template.

MCS

1. Install and configure the OS in a MCS VM.
2. Install XenDesktop software and configure with advanced options for personal vDisks.
3. Reboot the VM.
4. Log onto the VM, and then shut the VM down. Inventory automatically runs at shutdown.
5. The personal vDisk image is ready for deployment.

Update an existing personal vDisk image

Updating existing personal vDisk methods include using:

- Provisioning Services
- MCS

Updates for both Provisioning Services and MCS must be done on VMs that do not have a personal vDisk.

Provisioning Services

1. Create a new version of the vDisk image.
2. Boot the VM from the vDisk image in Maintenance Mode.
3. Install updates on the new vDisk version.
4. Shut the VM down. Inventory runs automatically when the VM shuts down.
5. Promote the new version to either Test or Production. Other VMs will have access to the updated vDisk version the next time they reboot.

MCS

1. Boot the 'golden' VM.
2. Install updates on the VM.
3. Shut the VM down. Inventory automatically runs when the VM is shutdown.

For additional information on how to create a Provisioning Services target device that uses a personal vDisk, refer to Deploy virtual desktops to VMs using the XenDesktop Setup Wizard. To view the properties of a Provisioning Services target device configured to use a personal vDisk, refer to Configure target devices that use personal vDisks.
Logging

Nov 12, 2013
Provisioning Services uses Citrix Diagnostic Facility (CDF) tracing for troubleshooting and managing a Provisioning Services farm.

Use the PVSDataCollector v2.0.0 tool to collect all Provisioning Services data, including the ETL log. For details, refer to http://support.citrix.com/article/CTX136079.

To generate a Provisioning Services ETL log, the CDF monitor must be installed. For details on installing the monitor, refer to: http://support.citrix.com/article/CTX138698.

To review ETL logs using CDF, refer to http://support.citrix.com/article/CTX111961.
Auditing

May 08, 2015

Provisioning Services provides an auditing tool that records configuration actions on components within the Provisioning Services farm, to the Provisioning Services database. This provides administrators with a way to troubleshoot and monitor recent changes that might impact system performance and behavior.

The Provisioning Services administrator privileges determines the audit information that can be viewed and the menu options that are visible. For example; a Farm Administrator can view all audit information within the farm, unlike a Device Administrator whom can only view audit information for those device collections they have privileges to.

Auditing tasks include:
- Accessing Auditing
- Archiving Audit Trail Information

Auditing is off by default. To enable it:

1. In the Console tree, right-click on the farm, then select the farm Properties menu option.
2. On the Options tab, under Auditing, check the Enable auditing checkbox.

Note: If the Provisioning Services database becomes unavailable, no actions are recorded.

The managed objects within a Provisioning Services implementation that are audited include:
- Farm
- Site
- Provisioning Servers
- Collection
- Device
- Store
- vDisks

Only those tasks that are performed from one of the following Provisioning Services utilities are recorded:
- Console
- MCLI
- SOAP Server
- PowerShell

Note: Tasks that are not performed using these utilities, such as booting target devices or Provisioning Servers by other methods, are not recorded. If the Provisioning Services database becomes unavailable, no actions are recorded.
Accessing Auditing Information

Nov 07, 2012

Auditing information is accessed using the Console. You can also access auditing information using programmer utilities included with the product installation software:

- MCLI programmer utility
- PowerShell programmer utility
- SOAP Server programmer utility

Note: For details on programmer utilities, see Provisioning Services documentation available from the Citrix Knowledge Center (http://support.citrix.com/product/prosvr/).

In the Console, a farm administrator can right-click on a parent or child node in the Console tree to access audit information. The audit information that other administrators can access depends on the role they were assigned.

The tree allows for a drill-down approach when accessing the level of audit information needed.

Right-click on a:

- **Farm**, to view audit information for all managed objects within this farm or to archive audit information.
- **Site**, to view audit information for all managed objects within a site.
- **Provisioning Server**, to view audit information for all servers within a site, or right-click on a single server to view audit information for that server.
- **Collection**, to view audit information on all managed objects that are members of this collection.
- **Store**, to view audit information for all stores within a site or farm, or right-click on a single store to view audit information for that store.
- **Target device**, to view audit information for all target devices within a site, or right-click on a single target device to view audit information for that device.
- **vDisk**, to view audit information for all vDisks within a site or farm, or right-click on a single vDisk to view audit information for that vDisk.

To access auditing information from the Console

1. In the Console, right-click on a managed object, then select the Audit Trail... menu option. The Audit Trail dialog displays or a message appears indicating that no audit information is available for the selected object.
2. Under Filter Results, select from the following filter options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>To narrow the resulting audit information that displays by user, select a user to filter on from the User drop-down menu. The default is All users.</td>
</tr>
<tr>
<td>Domain</td>
<td>To narrow the resulting audit information that displays by domains, select a domain to filter on from the Domain drop-down menu. The default is All domains.</td>
</tr>
<tr>
<td>Start date</td>
<td>To narrow the resulting audit information that displays by date, select a start date for which the audit information should display from the Start date drop-down menu. The default is one week prior to the current date. For example, if today is the 23rd, the start date would default to the 16th.</td>
</tr>
<tr>
<td>End</td>
<td>To narrow the resulting audit information that displays by date, select an end date for which the audit information should display from the End date drop-down menu. The default is the current date.</td>
</tr>
</tbody>
</table>

https://docs.citrix.com © 1999-2017 Citrix Systems, Inc. All rights reserved.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time</td>
<td>Lists all audit actions that occurred within the Start date and End date filter criteria.</td>
</tr>
<tr>
<td>Action</td>
<td>Identifies the name of the Provisioning Services action taken.</td>
</tr>
<tr>
<td>Type</td>
<td>Identifies the type of action taken, which is based on the type of managed object for which the action was taken.</td>
</tr>
<tr>
<td>Name</td>
<td>Identifies the name of the object within that object's type, for which the action was taken.</td>
</tr>
<tr>
<td>User</td>
<td>Identifies the user's name that performed the action.</td>
</tr>
<tr>
<td>Domain</td>
<td>Identifies the domain in which this user is a member.</td>
</tr>
<tr>
<td>Path</td>
<td>Identifies the parent(s) or the managed object. For example, a Device will have a Site and Collection as parents.</td>
</tr>
</tbody>
</table>

3. Click Search. The resulting audit information displays in the audit table, which displays the following information:
   Note: Columns in the audit table can be sorted in ascending and descending order by clicking on the column heading.
   - **Action list number**
     Based on the filter criteria selected, the order the actions took place.
   - **Date/Time**
     Lists all audit actions that occurred within the Start date and End date filter criteria.
   - **Action**
     Identifies the name of the Provisioning Services action taken.
   - **Type**
     Identifies the type of action taken, which is based on the type of managed object for which the action was taken.
   - **Name**
     Identifies the name of the object within that object's type, for which the action was taken.
   - **User**
     Identifies the user's name that performed the action.
   - **Domain**
     Identifies the domain in which this user is a member.
   - **Path**
     Identifies the parent(s) or the managed object. For example, a Device will have a Site and Collection as parents.

4. To view additional details for a particular action, highlight that action's row within the results table, then click one of the option buttons that follow:
   - **Secondary**
     Click to view information on any secondary objects that this action affected. This opens the Secondary dialog, which includes the Type, Name, and Path information. This dialog allows you to drill down to view secondary object actions such as Parameters, Sub Actions, and Changes as described below.
   - **Parameters**
     Click to view any other information used to process the action. This opens the Parameters dialog.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sub Actions</td>
<td>Click it to view additional actions that were performed to complete this action. This opens the Sub Actions dialog, which includes Action, Type, Name, and Path information.</td>
</tr>
<tr>
<td>Changes</td>
<td>Click to view any new or changed values (such as ‘Description’) associated with the object (such as a target device). This opens the Changes dialog, which includes Name, Old, and New information.</td>
</tr>
</tbody>
</table>

Note: If an option displays disabled, that option is not valid for the currently selected action.
Archiving Audit Trail Information

Apr 08, 2010
The Farm Administrator determines how long to make audit trail information accessible before it is archived.

To set audit trail archiving
1. In the Console tree, right-click on the farm, then select Archive Audit Trail.... The Archive Audit Trail dialog appears.
2. Browse for the location where audit trail information will be save (XML file). The Select File to Archive Audit Trail To dialog opens.
3. Select the location, then type the name of the new file in the File name textbox.
4. Open the calendar from the End date drop-down menu, then select the date that the audit trail information should be archived. The default is automatically set to the current date.
5. Check the Remove information archived from the Audit Trail checkbox to remove all audit information. Once the information is removed, it can no longer be accessed directly from Provisioning Services. It will only exist in the XML file.
6. Click OK.
